September 2010

THIS PAGE INTENTIONALLY LEFT BLANK

SUMMARY

The U.S. Department of Energy (DOE) proposes to fund the Facility for Rare Isotope Beams (FRIB) at Michigan State University (MSU). *The Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan, DOE/EA-1684 (FRIB EA)* estimates environmental impacts from the action. It is prepared in compliance with the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321 et seq.), regulations of the President's Council on Environmental Quality (40 CFR 1500–1508), and DOE's NEPA implementing regulations (10 CFR 1021). Given that the impacts of operation of the proposed FRIB accelerator are similar in nature to other linear accelerators and the impacts from construction would be similar in nature to conventional excavation and construction projects, DOE believes an EA is an appropriate level of review at this time. It will assist in DOE's determination to either prepare an Environmental Impact Statement, if there are significant environmental impacts, or to issue a Finding of No Significant Impact (FONSI), if there are no significant environmental impacts.

DESCRIPTION OF THE PROPOSED ACTION: DOE published a “funding opportunity announcement” (FOA) on May 20, 2008, seeking applications for the conceptual design and establishment of a particle acceleration facility—the FRIB—that met the criteria described in the FOA for less than or equal to \$550 million over the next decade. Subsequent to construction, funding for operations would be allocated annually based on Congressional appropriations. In its review of the applications, DOE considered the results of an independent merit review process, as well as an environmental critique. On December 11, 2008, MSU was selected to design and establish the FRIB. DOE's proposed action under NEPA is the design, construction, and operation of the FRIB. Under the Proposed Action, MSU would design, construct, operate, and ultimately decommission the FRIB. DOE would maintain substantial involvement throughout the process.

DOE and MSU propose to construct and operate the FRIB on approximately 15 acres (6.07 hectares) on MSU's East Lansing, Michigan, campus. Its design is composed of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities such as a larger liquid helium production building, and offices. Construction and operations would occur on campus, adjacent to the existing National Superconducting Cyclotron Laboratory (NSCL), which would ultimately be subsumed into the FRIB. The function and scope of operations of the FRIB would be similar to those of the NSCL, but the FRIB would have substantially more power. The existing NSCL research program relies on a coupled cyclotron driver accelerator with an energy level of 200 megaelectron volt per atomic mass unit (MeV/u) and 1 to 2 kilowatts of beam power. The FRIB would be capable of a minimum energy of 200 MeV/u for all ions and up to 400 kilowatts of beam power. A reaccelerator, with energy up to 12 MeV/u for uranium and 20 MeV/u for lighter ions, is also proposed for the facility. The linear accelerator tunnel would be situated in an excavation up to 75 feet below grade. The ground where the FRIB would be located has been previously disturbed. The U.S. Nuclear Regulatory Commission (NRC) and the State of Michigan would both have regulatory jurisdiction over nuclear activities at the FRIB, and the State of Michigan would regulate other aspects of construction and operation. MSU's broad-scope NRC license would be modified to cover oversight of all accelerator-related activities.

The FRIB would provide research opportunities for an international community of approximately 1,000 university and laboratory scientists, postdoctoral associates, and graduate students. The research conducted at the FRIB would involve experimentation with intense beams of rare isotopes—short-lived nuclei not normally found on Earth—that would enable researchers to address forefront scientific questions in nuclear structure and nuclear astrophysics. Operation would result in low levels of activation of air and groundwater, which MSU intends to manage according to NRC license requirements. Doses to workers and members of the public are anticipated to be less than one-tenth of the NRC radiation protection standards.

ALTERNATIVES: As required by Council on Environmental Quality regulations, the *FRIB EA* evaluates a No Action Alternative to serve as a basis for comparison with the action alternatives. Under the No Action Alternative, the FRIB would not be constructed and operated at MSU and the enhanced opportunities for scientific research would not be pursued. Other alternatives, including construction of the FRIB at another site, were considered and eliminated.

PURPOSE AND NEED: The purpose of the Proposed Action—the design, construction, and operation of the FRIB—is to support DOE’s mission to advance our basic understanding of science. The purpose of the Proposed Action is consistent with the outcome of DOE’s procurement process for the design, construction, and operation of an accelerator that produces rare isotope beams. DOE determined that the establishment of the FRIB is a high priority for the future of U.S. nuclear science research. The FRIB would establish a highly sophisticated research laboratory that would produce intense beams of rare isotopes. These beams enable scientists to study the nuclear reactions that power stars and generate the elements found on Earth; explore the structure of atomic nuclei, which form the core of all matter, and the forces that bind them together; test current theories about the fundamental nature of matter; and play a role in developing new nuclear medicines and other societal applications of rare isotopes.

AFFECTED ENVIRONMENT: The proposed FRIB would be constructed and operated adjacent to, and would eventually incorporate, the existing NSCL, which is located in the northeastern section of the MSU campus. The areas that would be utilized during construction are previously disturbed areas currently used for parking lots and support areas around the NSCL. During construction, an existing soil disposal area located south of the railroad tracks, east of Farm Lane, and north of East Mount Hope Road would be used for construction staging and soil disposal. This area is an open field within an area of undeveloped fields and has historically been used for these purposes. Both the FRIB construction site and the soil disposal site are highly disturbed and contain no water bodies or streams, historic resources, wetlands, floodplains, and no threatened or endangered species.

ENVIRONMENTAL IMPACTS: The *FRIB EA* evaluates the potential environmental effects that could result from implementing the Proposed Action or the No Action Alternative. As it is still early in the design phase of the FRIB, the *FRIB EA* considers a range of potential designs or configuration options for the FRIB that would provide a reasonable “bound” of the environmental impacts of construction, operation, and decommissioning of the FRIB. The configuration options under consideration by the conceptual and preliminary design teams would not be expected to substantially change the projected environmental impacts of construction, operation, or decommissioning of the FRIB. Therefore, the options discussed in more detail in the *FRIB EA* are those that might have somewhat different, but still small, environmental

impacts. These options may not precisely reflect the final design, but impacts of the final design would be bounded by the configurations considered in the *FRIB EA*.

Potential impacts identified for the resources evaluated in the *FRIB EA* include the following:

- Land Use and Visual Resources – MSU would construct the proposed project on a previously disturbed site directly adjacent to the existing NSCL and use an existing nearby soil disposal area for storage and disposal of soils. Both activities are consistent with current MSU planning. During construction, use of Bogue Street, Wilson Road, and Shaw Lane would be disrupted. In addition, the Wharton Center surface parking area would be closed and demolished and used as a laydown area during the construction period. Shaw Lane between Bogue Street and Hagadorn Road would be closed to through-traffic for approximately 2 months if the linear option is selected. Traffic would be rerouted to accommodate the road closures.

No land use impacts from the operation of the FRIB are anticipated. No adverse visual impacts were identified. During decommissioning, underground structures would be decontaminated and buried in place or otherwise managed per NRC requirements and any aboveground structures would be removed or redeployed.

With the No Action Alternative, these impacts would not occur.

- Geology and Soils – The FRIB would be constructed using cut-and-fill construction techniques. Approximately 325,000 cubic yards (248,000 cubic meters) of soil would be excavated during the construction of the tunnel associated with the FRIB. Construction is not expected to otherwise adversely impact the geology or soils of the area. Affected soils are stable and acceptable for standard construction requirements. Erosion prevention and sedimentation control measures would minimize the potential for adverse impacts. No impacts on geology and soils from the operation of the FRIB are anticipated. With decommissioning, underground structures would be buried in place or otherwise managed per NRC requirements that would be established at that time. Fill material would be required to bury underground structures. The source and quantity of fill material would be determined at the time of demolition.

With the No Action Alternative, these impacts would not occur.

- Water Resources – Erosion and sedimentation controls during construction would limit potential impacts on surface water. During construction, moderate to heavy volumes of groundwater would likely be encountered where excavations extend below the water table. A dewatering system could be used during construction to temporarily lower the water table below the level of the tunnels. The resulting groundwater would be filtered and discharged into the existing stormwater drainage system. After construction, the groundwater levels would be expected to return to normal with no long-term impacts or changes in groundwater flow or levels.

No impacts on wetlands or floodplains would occur from construction, operation, or decommissioning because none exist at the project site or soil disposal area.

Normal facility operations would not have adverse impacts on any surface water. During FRIB operation, neutrons produced from scattered beam particles that penetrate the thick concrete walls of the linear accelerator (linac) tunnels and that could activate groundwater would result in low levels of activation of any soil and groundwater adjacent to the FRIB tunnels, which MSU would manage according to NRC license requirements. These NRC license requirements require that the concentrations of radionuclides in the groundwater be below NRC water effluent limits. Consistent with the MSU as low as reasonably achievable (ALARA) program, the FRIB project design team has established a design and operations goal, which is more than a factor of 10 times better than the NRC requirements. Moreover, the FRIB project design goal is to keep the average groundwater radionuclide concentrations in the region around the linac tunnel walls below drinking water limits established by the U.S. Environmental Protection Agency (EPA). Ensuring that the water adjacent to the FRIB tunnels would meet drinking water standards, which would normally be applied to water provided by a drinking water supplier after pumping and filtering, would provide a very high degree of protection for both the environment and the public.

With the No Action Alternative, these impacts of construction would not occur.

- Air Quality – Construction emissions would be short-term, sporadic, and localized. Fugitive dust would be controlled to minimize emissions. No adverse impacts would occur from construction emissions. No continuous emissions of criteria air pollutants are expected to result from the Proposed Action during operations.

With the No Action Alternative, the construction impacts would not occur.

- Biological Resources – As the project site has been previously disturbed and has a high degree of development, impacts on protected flora and fauna are not expected. The existing soil disposal site has also been previously disturbed by soil disposal activities similar to those that would be required for the Proposed Action, so impacts on protected flora and fauna are not expected. No threatened or endangered species or critical habitats exist at the project site or soil disposal area.

With the No Action Alternative, there would be no impacts on biological resources.

- Noise Impacts – Temporary and short-term noise would be generated during construction and would have the potential, without mitigation, to adversely affect any sensitive nearby receptors. The nearest noise-sensitive receptors include dormitories to the north of Shaw Lane that are within about 140 feet (43 meters) of the proposed tunnel excavation location and within 50 feet (15 meters) of the proposed front-end building location. Other noise-sensitive facilities within 150 feet (46 meters) of the excavation include the Wharton Center for Performing Arts, the plant biology laboratories, and the Biochemistry Building. The Biochemistry Building, which includes laboratories that contain vibration-sensitive experiments, is within about 50 feet (15 meters) of the tunnel excavation and the connector high bay and south high bay extensions. Pedestrians in the area near the construction site would be impacted by construction noise. Construction noise could be mitigated by employing standard construction noise mitigation, including use of quieted

equipment, shielding of noisy equipment and activities, careful location of noisy equipment, proper maintenance of equipment, and administrative controls such as scheduling to avoid interfering with noise-sensitive activities. MSU would control the impact of construction activity on normal operation of the campus, especially on noise- and vibration-sensitive activities.

Workers would be expected to wear appropriate hearing protection during construction.

During operations, noise sources would be relatively minor and similar to ongoing NSCL activities.

During decommissioning, noise sources would be similar to those during construction, although the amount of earthmoving activity would be much less. Therefore, noise impacts from decommissioning are expected to be less.

With the No Action Alternative, operational noise impacts of the NSCL would remain and would be minor.

- Utilities – Existing nonpower utilities supporting the NSCL have adequate capacity to support construction and operation of the FRIB. Estimated power requirements for FRIB operations are about 18 megawatts, which would be supplied by offsite commercial power. The FRIB would use the existing 21-megawatt substation at the MSU Power Plant and require a new duct bank to deliver power to the FRIB.

With the No Action Alternative, these impacts would not occur.

- Cultural and Historical Resources – No intact cultural or historical resources are known to exist in potentially affected areas. All surface areas of the project site have been previously disturbed. Based on archaeological and architectural surveys previously conducted on the MSU campus in the vicinity of the NSCL, no impacts are expected on cultural or historical resources during FRIB construction, operations, or decommissioning, including excavation or equipment storage and rock/soils stockpiling in the proposed construction staging area.

With the No Action Alternative, no impacts would be expected.

- Health and Safety – Construction workers would be subject to typical hazards and occupational exposures faced at other industrial construction sites. Contractors would be expected to comply with existing health and safety requirements. MSU would apply its existing occupational health and safety program to the new operations, and impacts on workers or the public would be low.

The FRIB would be designed and operated to ensure that no adverse impacts on the public would occur during operations from exposure to direct radiation in the vicinity of the FRIB tunnels, controlled airborne radiological releases from the FRIB stacks, ingestion of contaminated groundwater, or accidents. Existing radiation safety practices and experience at the NSCL and other particle accelerators are adequate to ensure that the radiological impacts of operation of the accelerator, including potential accidents, would

be kept small and well within applicable NRC and EPA standards. MSU has committed to ensuring that the FRIB would be designed, constructed, and operated in a manner that maintains the NSCL's excellent environmental and safety record by continuing the MSU ALARA program. The FRIB would be designed and operated following the same strategy of radiation safety management that has been successfully used at the NSCL. That strategy is to: 1) abide by all limits and license commitments, 2) maintain, as a goal, individual and collective doses at or below as low as is reasonably achievable, and 3) manage the facility consistent with MSU and FRIB safety management practices (currently certified International Organization for Standardization [ISO] and Occupational Health and Safety Assessment Series [OHSAS] programs). The strategy has been effective for the NSCL and would also be effective for the FRIB. For the NSCL, incidents and near-misses since the institution of the current NSCL certified ISO 9001 (Quality Management Systems), ISO 14001 (Environmental Management Systems), and OHSAS 18001 (Occupational Health and Safety Management Systems) programs have been localized and were not considered to pose significant hazards to personnel, the public, or the environment.

As part of the design process, a range of potential accident scenarios is being considered to ensure that the FRIB would have adequate protections to minimize potential impacts. Accident conditions (including radiological conditions) are being analyzed as part of the development of a conceptual design, which is ongoing for the FRIB. These analyses continually evolve as the design effort progresses to ensure all credible hazards are evaluated and appropriate controls are included in the design to safeguard the public, FRIB personnel, environment, and the FRIB mission. For the FRIB, hazards that have been identified include electrical and chemical, non-ionizing radiation (lasers), and waste handling, as well as ionizing radiation, oxygen-deficient atmosphere, and cryogenic hazards for the accelerator, target building, and support systems. The design and operational controls included in the FRIB design are intended to provide a robust level of protection against these postulated events and provide protection for the public, FRIB workers, and the environment. Based on the experience of other accelerator facilities, the evaluations conducted and MSU's commitment to certain design features and safety controls for the FRIB, it is expected that the health and safety impacts (risk) of foreseeable accidents can be managed at acceptably low levels through the facility design process and control of operations.

With the No Action Alternative, the health and safety impacts of NSCL operations would continue to be managed and would be low.

- Waste Management – Construction activities and operation of the FRIB would generate waste, possibly including hazardous waste. Waste would be characterized, stored, and disposed of in accordance with applicable regulations. Disposal would occur in existing facilities.

During operations, hazardous and radioactive waste streams would be similar to existing NSCL wastes and would be handled and disposed of using the existing MSU waste management program; no adverse impacts would occur. With the increased size and

scope of operations, waste generation would increase but would be well within the existing capability and capacity of the MSU waste system.

With the No Action Alternative, the incremental waste generation associated with FRIB operation would not occur, and waste levels associated with the NSCL would remain the same.

- Transportation – No adverse impacts associated with the transport of construction materials are expected. Construction activities would cause an increase of approximately 400 vehicles per day due to the shipment of construction materials and wastes and the commuting of construction workers. The construction traffic would cause an increase of less than 4 percent in total traffic on the surrounding roads. Based on the estimated traffic volumes during construction, it is estimated that there would be fewer than 2 construction-related accidents involving a motor vehicle, with no fatalities or injuries. Construction workers commuting to the site would experience approximately 17 accidents, no fatalities, and 4 injuries over the duration of the construction period.

Road closures during FRIB construction would disrupt and divert traffic for periods of up to 2 years. Temporary closures of Bogue Street, Shaw Lane, and Wilson Road would also impact pedestrian and bicycle traffic. Temporary walkways would be established, with sufficient safety features such as fencing to direct pedestrian and bicycle traffic around the construction site.

With the No Action Alternative, the traffic disruptions associated with FRIB construction and incremental impacts associated with FRIB operation would not occur.

- Socioeconomics and Environmental Justice – Construction of the FRIB is expected to last from 2012 through 2016 and annual construction employment is expected to peak at 175 employees. Total peak year earnings from both direct and indirect employment are estimated to be \$20.2 million. Total spending to build the facility is estimated to be approximately \$550 million, of which \$348 million is assumed to be spent locally. Indirect economic output generated by that spending is estimated to be \$279 million, for a total economic impact of \$627 million during the construction phase. When the FRIB is fully operational, MSU estimates that it could require up to approximately 500 operations and support staff. When compared to employment at the existing NSCL, MSU estimates the FRIB could add up to approximately 160 new professional and technical service jobs. No high adverse human health or environmental impacts are anticipated as a result of the construction or operation of the FRIB; consequently, there would be no disproportionately high adverse effects on minority or low-income populations.

With the No Action Alternative, these impacts would not occur.

- Cumulative Impacts of the Proposed Action – No substantial cumulative impacts on the environment would be anticipated from implementing the Proposed Action. The cumulative impacts of construction of the FRIB and other construction projects at MSU during the FRIB construction timeframe would still be small. Operational impacts of the

FRIB would be small and those impacts, collectively with other MSU operational impacts, are also expected to be small.

Common Metric/British System Equivalents

Length

1 centimeter = 0.3937 inch

1 inch = 2.54 centimeters

1 centimeter = 0.0328 foot

1 foot = 30.48 centimeters

1 meter = 3.2808 feet

1 foot = 0.3048 meter

1 kilometer = 0.6214 mile

1 mile = 1.6093 kilometers

Area

1 square centimeter = 0.1550 square inch

1 square inch = 6.4516 square centimeters

1 square meter = 10.7639 square feet

1 square foot = 0.09290 square meter

1 square kilometer = 0.3861 square mile

1 square mile = 2.5900 square kilometers

1 hectare = 2.4710 acres

1 acre = 43,560 square feet = 0.4047 hectare

1 hectare = 10,000 square meters

1 square meter = .0001 hectare

Volume

1 cubic centimeter = 0.0610 cubic inch

1 cubic inch = 16.3871 cubic centimeters

1 cubic meter = 35.3147 cubic feet

1 cubic foot = 0.0283 cubic meter

1 cubic meter = 1.308 cubic yards

1 cubic yard = 0.76455 cubic meter

1 liter = 1.0567 quarts

1 quart = 0.9463264 liter

1 liter = 0.2642 gallon

1 gallon = 3.7845 liters

Weight

1 gram = 0.0353 ounce

1 ounce = 28.3495 grams

1 kilogram = 2.2046 pounds

1 pound = 0.4536 kilogram

1 metric ton = 1.1023 tons

1 ton = 0.9072 metric ton

Energy

1 joule = 0.00094845 British thermal unit (BTU) 1 BTU = 1054.18 joules

1 joule = 6.24×10^{12} million electron volts (MeV) 1 MeV = 1.602×10^{-13} joule

1 megawatt-year = 8.76×10^6 kilowatt-hours

1 kilowatt-hour = 1.14×10^{-7} megawatt-year

Power

1 watt = 3.414 BTU/hr

1 BTU/hr = 0.2929 watt

Pressure

1 newton/square meter = 0.0208 pound/square foot

1 pound/square foot = 48 newtons per square meter

Force

1 newton = 0.2248 pound-force

1 pound-force = 4.4478 newtons

Radiation

1 becquerel = 2.703×10^{-11} curies

1 curie = 3.70×10^{10} becquerels

1 sievert = 100 rem

1 rem = 0.01 sievert

Scientific Notation Conversion Chart

Name	Symbol	Value Multiplied by:			
pico	p		0.000000000001	or 1×10^{-12}	or 1E-12
nano	n		0.000000001	or 1×10^{-9}	or 1E-09
micro	μ		0.000001	or 1×10^{-6}	or 1E-06
milli	m		0.001	or 1×10^{-3}	or 1E-03
cento	c		0.01	or 1×10^{-2}	or 1E-02
deci	d		0.1	or 1×10^{-1}	or 1E-01
---		1		or 1×10^0	or 1E+00
deka	da	10		or 1×10^1	or 1E+01
hecto	h	100		or 1×10^2	or 1E+02
kilo	K	1,000		or 1×10^3	or 1E+03
mega	M	1,000,000		or 1×10^6	or 1E+06
giga	G	1,000,000,000		or 1×10^9	or 1E+09
tera	T	1,000,000,000,000		or 1×10^{12}	or 1E+12

The following symbols are occasionally used in conjunction with numerical expressions.

Symbol	Indicates the preceding value is:
<	less than
\leq	less than or equal to
>	greater than
\geq	greater than or equal to

In some cases, numerical values in this document have been rounded to an appropriate number of significant digits to reflect the accuracy of data being presented. For example, the numbers 0.021, 21, 2100, and 2,100,000 all contain two significant digits. In some cases, where several values are summed to obtain a total, the rounded total may not exactly equal the sum of its rounded component values. Conversions from English to metric are rounded to maintain the number of significant digits.

Glossary

accelerator: Device used to increase the energy of particles, which then collide with other particles. Major types are linear accelerators and circular accelerators. The name refers to the path taken by the accelerated particle.

affected environment: A description of the existing environment that could be affected by the Proposed Action or its alternatives.

As low as reasonably achievable (ALARA) Program: NRC licensed facilities must have a formal ALARA program that sets ALARA value below the regulatory requirements, expressed as a percentage of limits. It may be defined as a radiation safety program goal or action level, and is practiced by keeping doses, releases, contamination, and other risks as low as reasonably achievable. MSU has committed to developing and managing programs to achieve ≤ 10 percent of applicable legal limits, such as air and water release, exposure and contamination limits. It is not a violation of the law to exceed an ALARA guideline; however, these ALARA action levels alert radiation safety staff and radioactive materials users to situations that need to be reviewed to determine whether the practices may be modified to better reflect ALARA management practices. The ALARA limits are also used to plan and design facilities and work practices.

ambient air: The surrounding atmosphere, usually the outside air, as it exists around people, plants, and structures. (It is not the air in the immediate proximity of an emission source.)

atom: A particle of matter indivisible by chemical means. It is the fundamental building block of molecules. It consists of a positively charged nucleus and orbiting electrons. The number of electrons is the same as the number of protons in the nucleus.

atomic number: Z, the total number of protons found in a nucleus.

attainment: An area is designated as being in attainment by the U.S. Environmental Protection Agency if it meets the National Ambient Air Quality Standards (NAAQS) for a given criteria pollutant. Nonattainment areas are areas in which any one of the NAAQS have been exceeded, maintenance areas are areas previously designated as nonattainment and subsequently re-designated as attainment, and unclassifiable areas are areas that cannot be classified on the basis of available information as meeting or not meeting the NAAQS for any one criteria pollutant.

background radiation: Ionizing radiation present in the environment from cosmic rays and natural sources in the Earth; background radiation varies considerably with location.

beta particle (beta radiation, beta ray): An electron of either positive charge (e^+ or β^+) or negative charge (e^- , e^- or β^-) emitted by an atomic nucleus or neutron in the process of a transformation. Beta particles are more penetrating than alpha particles but less than gamma rays or x-rays. Electron capture is a form of beta decay.

criteria pollutants: The Clean Air Act requires the U.S. Environmental Protection Agency to set air quality standards for common and widespread pollutants after preparing criteria documents summarizing scientific knowledge on their health effects. Currently, there are standards in effect for six criteria pollutants: sulfur dioxide (SO₂), carbon monoxide (CO), particulate matter equal to or less than 10 microns in diameter (PM₁₀), nitrogen dioxide (NO₂), ozone (O₃), and lead (Pb).

cryogenic: The branches of physics and engineering that involve the study of very low temperatures, how to produce them, and how materials behave at those temperatures. Cryogenic cooling of devices and material is usually achieved via the use of liquid nitrogen, liquid helium, or a cryocooler, which uses high-pressure helium lines.

cyclotron: Circular accelerator in which the particle is bent in traveling through a magnetic field, and an oscillating potential difference causes the particles to gain energy.

cultural resources: The prehistoric and historic districts, sites, buildings, objects, or any other physical activity considered important to a culture, subculture, or a community for any scientific, traditional, religious, or other reasons.

cumulative impact: The impact on the environment that results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time.

curie: A measure of the radioactivity level of a substance (that is, the number of unstable nuclei that are undergoing transformation in the process of radioactivity decay); one curie equals the disintegration of 3.7×10^{10} (37 billion) nuclei per second and is equal to the radioactivity of one gram of radium-226.

decay (radioactive): The change of one radioactive nuclide into a different nuclide by the spontaneous emission of radiation such as alpha, beta, or gamma rays, or by electron capture. The end product is a less energetic, more stable nucleus. Each decay process has a definite half-life.

decibel (dB): A logarithmic measurement unit that describes a particular sound pressure level compared to a standard reference value. The threshold of human hearing is approximately 0 dB, and the threshold of discomfort or pain is around 120 dB. A-weighted decibels (dBA) refer to measured decibels whose frequencies have been adjusted to correspond to the highest sensitivity of human hearing, which is typically in the frequency range of 1,000 to 4,000 hertz.

dose: The amount of energy deposited in the body by ionizing radiation per unit body mass.

electron volt: A unit of energy equal to the kinetic energy (or energy of motion) an electron gains when being accelerated through a potential difference of 1 volt. Another unit of energy is the joule and 1 joule equals 6.2415×10^{18} electron volts. One joule is roughly the energy needed to lift 1 kilogram (2.2 pounds) on the surface of the earth 0.1 meter (4 inches) high. Kiloelectron volt: One thousand electron volts. Megaelectron volt: One million electron volts.

exposure to radiation: The incidence of radiation from either external or internal sources on living or inanimate material by accident or intent.

gamma ray: A highly penetrating type of nuclear radiation, similar to x-rays, except that it comes from within the nucleus of an atom and, in general, has a shorter wavelength.

General Conformity Rule: The General Conformity Rule is applicable to nonattainment or maintenance areas (see attainment) as designated by the U.S. Environmental Protection Agency (EPA), and ensures that Federal actions conform to each State Implementation Plan for air quality. These plans, approved by EPA, are each state's individual plan to achieve the NAAQS as required by the Clean Air Act. The EPA is required to promulgate a Federal Implementation Plan if a state defaults on its implementation plan. A conformity requirement determination for the action is made from influencing factors, including, but not limited to, nonattainment or maintenance status of the area, types of emissions and emission levels resulting from the action, and local impacts on air quality.

greenhouse gases: Gases that trap heat in the atmosphere are often called greenhouse gases. Their presence leads to global warming. Some greenhouse gases are emitted to the atmosphere through natural processes. Other greenhouse gases are created and emitted solely through human activities. The principal greenhouse gases are carbon dioxide, methane, nitrous oxide, water vapor, ozone, and fluorinated gases.

half-life: The time during which half the (large number of) atoms of a particular radioactive nuclide disintegrate. The half-life is a characteristic property of each radioactive isotope.

hazardous air pollutants: Air pollutants that are known to cause or may reasonably be anticipated to cause adverse effects on human health or adverse environmental effects. 188 specific pollutants and chemical groups were initially identified as hazardous air pollutants, and the list has been modified over time.

health effects: Within the context of this environmental assessment, health effects are defined as the number of additional latent cancer fatalities due to a radioactive release (that is, the number of cancer fatalities resulting from this release that are in excess of those cancer fatalities that the general population would normally experience from other causes).

heavy ion: An ionized (i.e., positively or negatively charged) atom, usually heavier than helium.

isotope: Any of two or more species of atom of a chemical element with the same atomic number and nearly identical chemical behavior, but with different atomic mass (number of neutrons) or mass number and different physical properties.

latent cancer fatalities: Estimation of latent cancer fatalities assumes that 1) exposures to the radioactive material released to the environment occur over a 50-year period, and 2) the internal dose resulting from such exposure are 50-year committed doses, meaning that following inhalation or ingestion of the radioactive material, the resulting internal doses are based on tracking the material in the body for a 50-year period. The time period over which latent cancer fatalities occur is undefined, and could occur well after 50 years following the release.

linear accelerator: Particle accelerator laid out in a straight line. The Facility for Rare Isotope Beams would have a linear accelerator. An alternative considered is a folded linear accelerator.

National Ambient Air Quality Standards (NAAQS): Section 109 of the Clean Air Act requires the U.S. Environmental Protection Agency to set nationwide standards, the NAAQS, for widespread air pollutants. Currently, six pollutants are regulated by primary and secondary NAAQS (see criteria pollutants).

nuclide: Any species of atom that exists for a measurable length of time. A nuclide can be distinguished by its atomic mass, atomic number, and energy state.

oxides of nitrogen (NO_x): Gases formed primarily by fuel combustion that contribute to the formation of acid rain. Hydrocarbons and oxides of nitrogen combine in the presence of sunlight to form ozone, a major constituent of smog.

proton: One of the basic particles that make up an atom. The proton is found in the nucleus and has a positive electrical charge equal to the negative charge of an electron and a mass similar to that of a neutron: a hydrogen nucleus.

radiation: The emitted particles (alpha, beta, neutrons) or photons (X-rays, gamma rays) from the nuclei of unstable (radioactive) atoms as a result of radioactive decay. Some elements are naturally radioactive; others are induced to become radioactive by bombardment in a nuclear reactor or other particle accelerator. The characteristics of naturally occurring radiation are indistinguishable from those of induced radiation.

radiation dose: The amount of energy from ionizing radiation deposited within tissues of the body; it is a time-integrated measure of potential damage to tissues from exposure to radiation and as such is related to health-based consequences.

radioactive half-life: The time required for one half of the atoms in a radioactive isotope to decay.

radioactive waste: Materials that are radioactive and for which there is no further use.

radioactivity: The spontaneous decay or disintegration of an unstable atomic nucleus accompanied by the emission of radiation.

rem: The unit dose representing the amount of ionizing radiation needed to produce the same biological effects as one roentgen of high-penetration x-rays (about 200,000 electron volts). The biological effects of 1 rem are presumed to be independent of the type of radiation.

shielding: A protective barrier, usually a dense material, that reduces the passage of radiation from radioactive materials to the surroundings by absorbing it.

source: A radioactive material that produces radiation for experimental or industrial use.

source term: The quantity of a material released during an accident to air or water pathways and the characteristics of the release (for example, particle size distribution); used for determining accident consequences.

stable: Strictly speaking, a nuclide that is not radioactive. The definition is often relaxed to include very long-lived nuclides that are naturally occurring.

superconductivity: A property that occurs in certain materials at very low temperatures. When superconductive, a material has an electrical resistance of exactly zero and no interior magnetic field.

target nuclide: The initial nucleus in a nuclear reaction on which a projectile is incident. It is used in the context of a nuclear reaction where the projectile interacts with a target nucleus, producing a product nucleus and a projectile.

x-ray: Electromagnetic radiation with wavelengths between ultraviolet and gamma rays.

Chapter 1

INTRODUCTION

The U.S. Department of Energy (DOE) has prepared this *Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan (FRIB EA)* to evaluate the potential environmental impacts associated with the construction and operation of the Facility for Rare Isotope Beams (FRIB) on approximately 15 acres (6 hectares) on the campus of Michigan State University (MSU) in East Lansing, Michigan. The FRIB's design would be composed of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities such as a larger liquid helium production building, and offices. Construction would occur on campus, adjacent to the existing National Superconducting Cyclotron Laboratory (NSCL), which would ultimately be subsumed into the FRIB.

1.1 Background

The FRIB concept has undergone numerous studies and assessments within DOE and by independent parties such as the National Research Council of the National Academy of Sciences. These studies—in addition to the joint DOE and National Science Foundation 2007 Nuclear Science Advisory Committee Long Range Plan—concluded that such a facility is a vital part of the U.S. nuclear science portfolio, complements existing and planned international efforts, and would provide capabilities unmatched elsewhere. The FRIB concept was developed to meet the goals of the studies, analyses, and recommendations conducted since the 1996 Nuclear Science Advisory Committee Long Range Plan first recommended the development of a next-generation nuclear structure and astrophysics facility as a high priority.

1.1.1 Solicitation Process

DOE published a “funding opportunity announcement” (FOA) on May 20, 2008, seeking applications for the conceptual design and establishment of a particle acceleration facility—the FRIB—as a National User Facility (DOE 2008a). The applications received were subject to a merit review process conducted by a panel of world-renowned experts from universities, national laboratories, and Federal agencies. The appraisal included rigorous evaluation of the proposals based on the merit review criteria described in the FOA, presentations by the applicants, and visits by the merit review panel to the applicants sites. As a result of the peer review, MSU's application was chosen for the award. MSU also offered a direct cost share to the project. In addition, DOE performed an environmental critique in accordance with NEPA's DOE procurement, financial assistance, and joint ventures regulations (10 CFR 1021.216). The environmental critique concluded (based on the information disclosed in the proposals as well as DOE accelerator experience) that “the physical, environmental impacts identified for both of the applications would be minor and localized, and could be successfully managed to further reduce them, and hence, little discrimination between the applications was possible on an environmental basis.”

On December 11, 2008, MSU was selected to design and construct the FRIB (DOE 2008b). Following selection of the MSU proposal, an environmental synopsis (i.e., summary) of the information in the environmental critique was filed with EPA. This synopsis is presented in Appendix E.

A Cooperative Agreement with DOE was signed on June 8, 2009, establishing terms and conditions for the work to be performed (MSU 2009a). The agreement specifies the joint commitment by DOE and MSU to fund the construction of the FRIB; and as it is a DOE National User Facility, DOE's substantial involvement in the design, construction, and operation. Operation of the FRIB would be addressed in subsequent cooperative agreements.

1.1.2 Technology

The purpose of an accelerator in basic research is to accelerate ions, protons, or electrons to high speed and collide these beams of energetic particles with a fixed target (or sometimes another counter-rotating beam). By studying the products of these collisions, scientists can gain a better understanding of the properties of the atomic nucleus and the forces that keep it together.

Currently, the NSCL operates two superconducting accelerators (cyclotrons), the K500 and the K1200. The K500 was the world's first cyclotron to use superconducting magnets and the K1200 is the highest energy continuous beam accelerator in the United States. Using these and other related devices, scientists are able to create rare isotopes and learn more about the origins of elements in the cosmos. Coupling these two cyclotrons, accelerating the beam from the first machine in the second one, results in making even rarer isotopes and affords scientists the capability to better understand atomic nuclei. For example, these beams are also used to study the effect of cosmic rays on electronic devices in satellites, and on humans during long space-flight missions to Mars.

The function and scope of operations of the FRIB would be similar to those of the NSCL, but the FRIB would have substantially more power. The existing NSCL research program relies on a coupled cyclotron driver accelerator with up to 200 megaelectron volts per unit atomic mass (MeV/u) of energy and 1 to 2 kilowatts of beam power. The FRIB would be capable of 200 MeV/u of energy for all species and higher energies for lighter ions, up to 600 MeV/u for protons, with up to 400 kilowatts of beam power. This is made possible by the use of Superconducting Radio Frequency cavities.

1.2 Environmental Review Process

The National Environmental Policy Act (NEPA) requires Federal agencies to examine the impacts of their proposed actions before decisions are made. Pursuant to NEPA, as amended (42 U.S.C. 4321 et seq.), and in accordance with the Council on Environmental Quality's Regulations for Implementing the Procedural Provisions of NEPA (40 CFR 1500–1508) and DOE's implementing regulations (10 CFR 1021), DOE prepared an environmental critique and environmental synopsis during the solicitation process, and now has prepared this draft environmental assessment (EA). The objectives of this EA are to inform the public and

decisionmakers by:

- Stating the underlying purpose and need for the DOE Proposed Action to design, construct, and operate the FRIB
- Describing the Proposed Action and identify the alternatives that satisfy the purpose and need for DOE action
- Describing the baseline environmental conditions at the alternative site location
- Analyzing the potential indirect, direct, and cumulative impacts on the existing environment from construction, operation, and decommissioning the FRIB and from the No Action Alternative
- Comparing the impacts from implementation of the construction, operation, and decommissioning of the FRIB with those of the No Action Alternative
- Enabling DOE to determine whether an environmental impact statement (EIS) is required to fully understand the potential significant impacts associated with the Proposed Action

1.2.1 Public Involvement in Developing the Scope of this EA

Scoping is a process in which the public, regulators, and other interested parties provide comments directly to a Federal agency on the scope of a NEPA document. Although scoping is generally associated with an EIS, DOE felt this enhanced public involvement opportunity would increase its ability to understand and, more importantly, address any public interest regarding the FRIB. This process was initiated by publication of a Notice of Intent (NOI) in the *Federal Register*. The NOI for this *FRIB EA* (74 FR 55221) was published on October 27, 2009, and initiated a 45-day public scoping period ending on December 11, 2009. The NOI, as published, is provided in Appendix A.

On December 31, 2009, President Obama stated “Today, my Administration will recognize NEPA’s enactment by recommitting to environmental quality through open, accountable, and responsible decision making that involves the American public.” In keeping with the Obama Administration’s inaugural commitment to an open NEPA process, DOE hosted a public meeting on November 11, 2009, on the MSU campus in East Lansing. Approximately 35 members of the general public, including public officials, attended this meeting at which DOE provided information on the Proposed Action and the NEPA process. Preceding the scoping meeting, MSU hosted an educational open house, also attended by approximately 35 people, and provided tours of the NSCL. At both events, attendees had the opportunity to view informational materials and discuss issues directly with DOE and MSU officials and subject matter experts.

At the scoping meeting, DOE gave a presentation and invited attendees to provide comments. Oral comments were recorded by a court reporter; written comments were also accepted. In addition, the public was provided with other methods to submit comments: e-mail, mail, toll-free fax, and a project website.

1.2.2 Public Comments on the Scope of this EA

DOE received 21 comment documents during the scoping period in addition to the oral comments made by 11 individuals at the public meeting. When the comment documents and transcript were analyzed they yielded 112 comments categorized under the following issues: alternatives, design/construction/operation/decommission, human health and safety, infrastructure, NEPA process, regulatory compliance, socioeconomics, and other. A report entitled *Facility for Rare Isotope Beams Environmental Assessment Scoping Report* (DOE 2009a) was prepared. Each comment category from the report is summarized in the following paragraphs and a response is provided for each summary.

Alternatives: The majority of the commenters expressed their strong support for the FRIB to be constructed and operated on the MSU campus. One commenter favored the folded linear accelerator because it would make better use of the space and minimize the footprint. Another commenter suggested an area off campus to alleviate potential safety and health issues.

Response: Chapter 3, Section 3.1.1, of this EA describes the alternative under consideration. MSU's proposal only identified one location for the proposed FRIB, which would take advantage of the existing NSCL and is located in a previously disturbed area. However, the EA explores different configurations intended to demonstrate the bounding conditions. Chapter 3, Section 3.3, discusses alternatives considered but eliminated from further study.

Design/Construction/Operation/Decommission: Commenters expressed their support for constructing and operating the FRIB on the MSU campus because of the university's strong track record in managing the NSCL and high standards for protecting and enhancing the environment, including actively promoting "green" practices on campus. By way of comparison, many commenters pointed out that MSU routinely handles major construction projects worth millions of dollars and has demonstrated over time its ability to supervise a large, complex project such as the FRIB and operate it in a safe and environmentally sensitive manner.

One commenter voiced concern in securing the construction site because of its close proximity to undergraduate dorms and another was concerned about the heavy equipment necessary for construction. One commenter pointed out that there may be a temptation to minimize wall thickness in order to save money during construction, which could potentially result in the transmission of hydrogen-3, also known as tritium, to groundwater outside the tunnel walls. Further, a concern was raised regarding staff not adequately trained to work in an unsecured facility that operated at orders of magnitude higher power than the NSCL. Another concern dealt with low-level radioactive waste resulting from the eventual decommissioning of the FRIB.

Response: Chapter 3, Sections 3.1.4 and 3.1.5, describe the construction and operations envisioned for the proposed FRIB. Appropriate administrative and engineered barriers would be employed during construction and operation to ensure that all applicable Federal, state, and local environment, health, and safety laws, regulations, and permit requirements are met, including adherence to MSU's "Be Spartan Green" campaign and commitment to environmental stewardship. Security considerations will also be met. Decommissioning is addressed in Section 3.1.6. If necessitated by issues not contemplated at the time this EA was prepared, further NEPA review would be implemented prior to decommissioning.

Human Health and Safety: MSU President Lou Anna Simon has committed to ensuring that the FRIB is designed, constructed, and operated in such a manner that it maintains the NSCL's excellent environmental and safety record by continuing the MSU ALARA program. The FRIB would be designed and operated following the same strategy of radiation safety management that has been successfully used at the NSCL. That strategy is to: 1) abide by all limits and license commitments, 2) maintain, as a goal, individual and collective doses as low as reasonably achievable, and 3) manage the facility consistent with MSU and FRIB safety management practices (currently certified Internal Organization for Standardization (ISO) and Occupational Health and Safety Assessment Series (OHSAS) programs). The strategy has been effective for the NSCL and would also be effective for the FRIB. For NSCL, incidents and near-misses since the institution of the current NSCL certified ISO 9001 (Quality Management Systems), ISO 14001 (Environmental Management Systems) and OHSAS 18001 (Occupational Health and Safety Management Systems) programs have been localized and were not considered to pose significant hazards to personnel, the public, or the environment. Potential health and safety impacts are presented in Chapter 5, Section 5.1.9.

Accident conditions (including radiological) are initially analyzed as part of the development of a conceptual design, which is ongoing for the FRIB. These analyses continually evolve as the design effort progresses to ensure all credible hazards are evaluated and appropriate controls are included in the design to safeguard the public, FRIB personnel, environment, and FRIB mission. For the FRIB, hazards that have been identified include electrical and chemical hazards, non-ionizing radiation (lasers), and waste handling, as well as ionizing radiation, oxygen--deficient atmosphere, and cryogenic hazards for the accelerator, target building, and support systems. The design and operational controls being included in the FRIB design are intended to provide a robust level of protection against these postulated events and provide protection for the public, FRIB workers, and environment. Based on the experience of other accelerator facilities, the evaluations presented in Chapter 5, Section 5.1.9, and Appendix C, and MSU's commitment to environment, safety, and health related administrative limits for the FRIB, it is expected that the health and safety risk from foreseeable accidents can be managed at acceptably low levels through the facility design process and control of operations.

Response: The FRIB would be designed and constructed using modern technology and materials, and operated by trained staff to ensure protection of human health and the environment in accordance with all applicable Federal, state, and local laws, regulations, and permits. Potential health and safety impacts are presented in Chapter 5, Section 5.1.9.

Infrastructure: Several commenters pointed out that there was ample infrastructure available in the form of office space and plots to build homes to accommodate the expected ancillary business and house the new employees and their families. One commenter was concerned about the associated noise, vibrations, and potential fluctuations in utilities, particularly water and electricity, during construction and operation of the FRIB and its effect on sensitive experiments conducted on campus.

Response: Chapter 5, Section 5.1.12, discusses the potential need for office and housing as it relates to the construction and operation of the FRIB. Chapter 4, Sections 4.6 and 4.7, describe the ambient noise situation and current infrastructure requirements to support the MSU campus; Chapter 5, Sections 5.1.6 and 5.1.7, the potential impacts regarding the FRIB. While construction

would likely increase noise levels due to equipment and vehicles, routine and special mitigation measures would be employed to ensure the impacts are within acceptable limits. Likewise, any needed infrastructure improvements to ensure service reliability on campus would be identified in accordance with the final facility design.

NEPA Process: While one commenter reviewed available material and agreed with DOE's approach to preparing an EA because the impacts are expected to be small, another commenter wanted an EIS to be prepared. One commenter commended DOE for the detailed and thorough NEPA process it has undertaken regarding the FRIB project.

Response: Based on DOE's environmental critique and taking into consideration previous experience from the construction and operation of linear accelerators and the current conditions at the proposed site on MSU's campus, DOE believes the environmental impacts would be small and thus determined an EA is appropriate. However, because of the potential for public interest, DOE has decided to engage in more public outreach during this EA process, similar to what is normally performed during an EIS process. Early on, DOE implemented an open process for determining the scope of issues to be addressed, as well as identifying any significant issues related to the Proposed Action. This EA is being developed to ascertain whether construction or operation of the FRIB has the potential to significantly affect the environment. If the conclusion of this EA is that significant impacts are likely, an EIS will be prepared so those impacts can be fully delineated.

Regulatory Compliance: Several commenters made note of MSU routinely being recognized for its environmental stewardship and the NSCL's receiving ISO and OHSAS certifications of registration regarding environmental management, and health and safety management systems. It was also pointed out that organizations and activities at MSU abide by all state and university requirements to ensure that contractors, vendors, employees, and subcontractors comply with environmental regulations.

Response: As noted in Chapter 3, Section 3.1, the NSCL is regulated by the State of Michigan, U.S. Environmental Protection Agency, U.S. Department of Transportation, U.S. Department of Labor, and U.S. Nuclear Regulatory Commission. It also is registered under ISO 9001 (Quality Management Systems), ISO 14001 (Environmental Management Systems), and OHSAS 18001 (Occupational Health and Safety Management Systems) and was recognized for its best-in-class safety record. Like the NSCL, the FRIB would also be regulated, certified, and registered by these agencies and organizations.

Socioeconomics: Many commenters enumerated the benefits of having the FRIB built and operated in their community, from bringing jobs that would stimulate the area's economy and ensuring Michigan students are exposed to the most advanced nuclear research in the world, to the potential of transforming Michigan from the epicenter of the Rust Belt to a powerhouse of innovation, entrepreneurship, and vitality. Another commenter surmised that the FRIB would increase connectivity across a multitude of government and educational institutions and advance knowledge, transform lives, and allow important contributions to be made in areas that have yet to be discovered.

Response: Temporary jobs would be created during the construction phase and permanent jobs upon completion of the Proposed Action as discussed in Chapter 5, Section 5.1.12. Because many jobs at the FRIB would be highly specialized, it is expected that many of the new employees would relocate to the area from elsewhere in the country. In addition, both household spending by these new residents and the operations of the FRIB from the anticipated draw of up to 1,000 national and international users are expected to create job opportunities that would be filled by the local labor force. In addition to the users, 160 direct and 214 indirect jobs would be created. See Section 5.1.12.

Other: A commenter requested that a scoping summary report be posted to the project website.

Response: The *Facility for Rare Isotope Beams Environmental Assessment Scoping Report* (DOE 2009a) was posted on the FRIB project website at <http://www.frib.msu.edu/NEPA/>.

1.2.3 Public Involvement During the Draft FRIB EA Comment Period

On March 16, 2010, DOE published the *Draft FRIB EA*, which analyzed the Proposed Action and No Action Alternative. A 30-day comment period followed, during which DOE held a public meeting on March 24, 2010, on the MSU campus in East Lansing.

In addition, the public was encouraged to provide comments via e-mail, mail, toll-free fax, or through the project website. All comments received during the comment period, which ended on April 16, 2010, were considered in finalizing the *FRIB EA* and developing the draft Finding of No Significant Impact (FONSI).

An open house was held prior to the meeting to allow attendees to view informational materials, register to present oral comments, and speak informally with DOE and MSU officials and subject matter experts. Approximately 16 people attended the meeting during which DOE presented an overview of the project, as well as the results of the analyses contained in the *FRIB EA* and the NEPA process and schedule. Subsequently, attendees who had signed up to provide oral comments had the chance to speak and were documented by a court reporter.

DOE received four comment documents in addition to the two oral commenters at the public meeting. Portions of Sections 4.10, 5.1.9.2.2.5, 5.2, and 5.12, as well as Figure 4-4 and Table 5-6, were revised in response to the comments received to clarify information in the *FRIB EA*. Appendix F contains the comment documents, as well as the transcript from the public meeting, along with DOE's responses to the specific comments.

Chapter 2

PURPOSE AND NEED

The purpose of the Proposed Action—design, construct, and operate the Facility for Rare Isotope Beams (FRIB)—is to support the U.S. Department of Energy’s (DOE’s) mission to advance our basic understanding of science. The purpose of the Proposed Action is consistent with the outcome of DOE’s procurement process for the design, construction, and operation of a particle acceleration facility.

The mission of the Office of Nuclear Physics in DOE’s Office of Science is to discover, explore, and understand all possible forms of nuclear matter. The Office of Nuclear Physics supports experimental and theoretical research; builds and operates world-class scientific user facilities such as particle accelerators; and develops advanced technologies to create, detect, and describe the different forms and complexities of nuclear matter that can exist in the universe, from its infancy to the present.

As noted in Chapter 1, Section 1.1, DOE determined that the establishment of the FRIB is a high priority for the future of U.S. nuclear science research. Future research will require driver beams one to two orders of magnitude more powerful than currently available, a greater variety of production techniques, more efficient and rapid delivery, and the ability to quickly stop and re-accelerate beams.

The development of the FRIB would establish a highly sophisticated research laboratory that would produce intense beams of rare isotopes. These beams would enable scientists to study the nuclear reactions that power stars and generate the elements found on Earth; explore the structure of the nuclei of atoms, which form the core of all matter, and the forces that bind them together; test current theories about the fundamental nature of matter; and play a role in developing new nuclear medicines and other societal applications of rare isotopes. Scientific research at the FRIB holds the promise to vastly expand our understanding of nuclear astrophysics and nuclear structure.

Chapter 3

DESCRIPTION OF THE PROPOSED ACTION AND ALTERNATIVES

The *Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan (FRIB EA)* evaluates two alternatives. These alternatives include the No Action Alternative and the Proposed Action—the design, construction, and operation of the Facility for Rare Isotope Beams (FRIB) adjacent to and ultimately encompassing the National Superconducting Cyclotron Laboratory (NSCL) on the Michigan State University (MSU) campus. The design for the FRIB is still in the conceptual design phase and a variety of technical and configuration options are still being considered. Thus, the final design and schedule as ultimately approved for construction may differ from those discussed in the EA.

As it is still early in the design phase of the FRIB, the description in this *FRIB EA* attempts to present a range of configurations that would provide a reasonable “bound” of the environmental impacts of constructing, operating, and decommissioning the FRIB. Hybrid configurations or entirely different configurations which may ultimately be selected would be expected to be substantially reflective of and be bounded by the environmental impacts from the configuration options identified/analyzed in this EA. In the event the projected environmental impacts would exceed impacts identified, this EA would be modified to reflect that configuration and it would again be circulated for comment prior to any decision being made. In the event that the configuration design changes such that it is no longer bounded by the parameters in this EA, a new NEPA review will be performed to determine if the environmental impacts would be significant.

3.1 Description of the Proposed Action

The U.S. Department of Energy’s (DOE’s) role in the Proposed Action is funding and other substantial involvement in the construction and operation of the FRIB as a National User Facility. The “*funding opportunity announcement*” indicates: “the Department of Energy’s Office of Science recognizes that effective management of scientific facilities, programs, and projects is critical to the success of research and the achievement of project goals. It is essential that the FRIB have well-designed management plans for the establishment of the facility in order to successfully contribute to the Nuclear Physics program, the Office of Science, and the DOE mission. In common with other major Office of Science supported programs, the FRIB will be subject to regular and rigorous peer review of its scientific goals, project performance, and management structure, policies, and practices. MSU would manage the Facility.” The FRIB will be planned and built in phases corresponding to critical decision points in accordance with the general principles outlined in DOE Order 413.3A. DOE would have substantial involvement.

As described in more detail below, the FRIB project includes construction of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities, and offices. Construction would be adjacent to the existing NSCL, which would ultimately be incorporated into the FRIB.

DOE’s “funding opportunity announcement” for the FRIB established the following minimum parameters: “the minimum technical specifications of the FRIB are that the facility be based on a 200 MeV/u, 400 kW superconducting heavy-ion driver linac. The initial capabilities of the FRIB should include fragmentation of fast heavy-ion beams combined with gas stopping and reacceleration. The technical scope should include necessary facilities and equipment for the establishment and operation of the FRIB, including driver linac and switchyard, target facilities, cryogenics facilities, gas stopper, fragment separator(s), radioactive ion beam (RIB) post accelerator, experimental areas and instrumentation that will allow the community of facility users to shed light on important scientific issues.” (DOE 2008a)

FRIB would provide research opportunities for an international community of approximately 1,000 scientists, postdoctoral associates, and graduate students. The research conducted at the FRIB would involve experimentation with intense beams of rare isotopes—short-lived nuclei not normally found on Earth—that would enable researchers to address innovative scientific questions in nuclear structure and nuclear astrophysics. Operation may result in low levels of activation of air and groundwater, which MSU intends to manage according to U.S. Nuclear Regulatory Commission (NRC) license requirements and U.S. Environmental Protection Agency (EPA) regulations. Doses to workers and members of the public are anticipated to be less than one-tenth of NRC and EPA radiation protection standards. Physical hazards to workers will be regulated by the State of Michigan Occupational Safety and Health Administration (MIOSHA).

Table 3–1 identifies the estimated timeline for construction and operation of the FRIB. Dates are believed to be accurate within 2 years, however, depending on authorized budget profiles and Congressional allocations, they could change substantially more.

Table 3–1. Estimated Timeline for Construction and Operation

Design (all phases)	2009 through 2013
Construction (some overlap with design and preoperational testing)	2012 through 2016
Preoperational testing (if applicable)	2016 through 2019
Normal operation	2019 through 2049

3.1.1 Accelerator Configuration Options

The structures that would house the accelerator would be thick-walled, reinforced concrete structures. The linear accelerator (linac) would be located in a tunnel below ground. A trench up to 1,800 feet (550 meters) in length (varying between 30 and 75 feet [9 and 23 meters] below grade) would be excavated for the accelerator, necessitating the closure of Bogue Street between Wilson Road and Shaw Lane for up to 3 years and possible closure of portions of Shaw Lane for

a number of months. More compact versions of the accelerator with shorter lengths are also considered as technical options. Regardless of configuration, the high-energy end of the accelerator and target facilities building would join with the existing NSCL building. The site where the FRIB would be located has been previously disturbed from prior construction on the MSU campus. Like the NSCL, the FRIB would be licensed by NRC and registered with the State of Michigan Department of Community Health. The combination of below-grade construction and thick-walled concrete and steel would shield the environment from the accelerator.

Figure 3–1 illustrates the straight linear accelerator FRIB configuration option that could be built as part of the Proposed Action. Another comparable layout may ultimately be chosen to be constructed. However, the main structures in any layout are:

- A front-end building. A belowground facility would house the ion sources and support equipment at the low-energy end of the linac
- Underground linac tunnels between the front-end building and the switchyard
- Switchyard to connect the linac to the target facility
- Underground target facilities on the south side of the NSCL near Wilson Road
- A south high bay extension and connector high bay between the NSCL and the high bay extension
- An experimental area addition to the east end of the NSCL, similar to current experimental areas
- Research infrastructure including: fragment separator, gas stoppers, reaccelerator, and experimental areas
- A new liquid helium production building (cryoplant), similar to the current cryoplant, but with a larger capacity to produce liquid helium
- Airborne confinement system for treating and otherwise managing potentially contaminated air, including elevated stacks
- Supporting infrastructure

Figure 3–1. Potential FRIB Configuration: Straight Linear Accelerator Configuration Option

These components are discussed in more detail in Section 3.1.2. The actual orientation and location of the various components may change slightly as part of the design process, as is discussed in section 3.1.1.

Three basic configuration options for the linac are being considered during this EA process. These configuration options include a straight-linear accelerator configuration option, a folded accelerator configuration option with a partial surface facility across Bogue Street from the NSCL, and a double-folded accelerator configuration option with a folded linac south of the NSCL. Even though the final design has not been selected, the analysis of these three configuration options bounds the impacts from numerous possible hybrid and other configurations.

Under the straight-line configuration option, the low-energy end of the accelerator would be located in an existing grassy area across Shaw Lane near McDonel Hall. An aboveground front-end building would connect to the underground tunnel at the low-energy end of the accelerator. This configuration option is illustrated in Figure 3–2.

Figure 3–2. Proposed FRIB Location – Straight Linear Accelerator Configuration Option

The folded linear accelerator configuration option would include a front-end building to be located on the southeast corner of Shaw Lane and Bogue Street in a future building site south of Shaw Lane. This configuration option is illustrated in Figure 3–3.

Figure 3–3. Proposed FRIB Location– Folded Linear Accelerator Configuration Option

The double-folded linear accelerator configuration option would have a folded linac with the entire structure immediately south of the existing NSCL and north of Wilson Road. This configuration option is illustrated in Figure 3–4.

Figure 3–4. Proposed FRIB Location– Double-folded Linear Accelerator Configuration Option

3.1.2 Major Linear Accelerator Components

As already stated in Section 3.1.1, the overall FRIB project would require construction of several structures to house the various components of the accelerator and supporting infrastructure. Because the design is still at the conceptual stage, the design details would likely change between the preliminary and final designs. The design details presented here should therefore only be considered conceptual. Important details such as beam power and beam energy are the same in all designs, as required by the project objectives. Details such as whether the linac is folded only change some details, such as tunnel length or front-end building location, not whether they are needed. Where detailed numbers are presented, an attempt was made to present the “reasonable, bounding” estimate from the configuration options identified.

For the linear and both folded design configuration options, the key components could consist of the following facilities and systems.

Front-End Building

The front-end building will house the ion sources and the beginnings of the acceleration chain. Access to the concrete box-like linac tunnels from the front-end building would be provided through access shafts constructed at the end of the linac tunnel farthest from the cyclotron building. This end structure may either be located north of Shaw Lane, with the linear configuration option, or constructed adjacent to the linac tunnel, with either of the folded over options.

Accelerator Tunnel

The Accelerator Tunnel houses the main accelerator components, including the linac. The tunnel could include construction of up to three underground enclosures (two linac enclosures and a

utility support enclosure). The tunnels could consist of enclosures for the linac and an enclosure for support conduits varying in length from approximately 500 feet up to approximately 1,700 feet (150 meters to 520 meters) and could be constructed in a side-by-side or top-and-bottom configuration. In order to access the equipment at the NSCL building, one end of the parallel concrete box configuration would be located near the southwest corner of the existing cyclotron building. One box would house the FRIB linac, while the second box would house support equipment and provide access to the FRIB linac.

A second option includes construction of a single underground linac tunnel and an aboveground linac support building in lieu of an underground utility tunnel. This option would reduce the impacts of excavation for the facility.

Target Building

The Target Building houses the Beam Delivery System, the target and the fragment separator system (plus ancillary equipment). The target area shaft would be located near the southwest corner of the existing NSCL building, immediately west of the south high bay building. The target structure would be approximately 50 feet (15 meters) deep, up to approximately 35,000 square feet (3,300 square meters) on the surface. The new target structure is expected to be located within approximately 20 feet (6 meters) of the existing biochemistry building. In addition, the target area would extend to the south where it would connect to the proposed conduits, within about 40 feet (12 meters) of Wilson Road. Key infrastructure including water, chilled water, sewer, steam tunnels, and electrical and telecommunications duct banks would be present.

Cryoplant Expansion

The Cryoplant Building houses the liquid helium plant and ancillary equipment require to produce and maintain the cryogenic conditions necessary for the superconducting devices. In addition, current plans call for constructing a facility of about 4,000 square feet (370 square meters) on grade, with a possible second level for a utility support cryoplant expansion building. The cryoplant expansion building would be north of Wilson Road and west of Bogue Street for the linear and folded designs. For the double folded design, it would be part of the linac support structures north of Wilson Road. This facility would be constructed concurrently with the installation of the concrete box structures, and may be partially located over the box structures.

The FRIB superconducting elements require a refrigeration system (cryogenic plant) to cool down and maintain superconducting temperatures. The cryogenic plant would have a capacity of approximately 12.7 kilowatts (at 4.5 Kelvin) to ensure reliable operations. Additionally, the cryogenic plant cooling water capacity and building would be sized so that additional compressors could be added to increase capacity.

Linac Airborne Confinement System

The linac would be designed and operated in such a manner that any airborne radionuclides generated during both normal operations and accidents would be confined, controlled, and only released to the environment in a planned manner that would ensure that all regulatory

considerations are met. In this manner, short-lived airborne radionuclides could be allowed to decay to harmless levels prior to release. MSU would design and install engineered barriers so that the FRIB would meet the as low as reasonably achievable (ALARA) goals. The systems for the two main areas, the linac and service area supporting the linac and the target area, would be treated separately.

Because the linac operation would activate the air in the tunnel, the facility would limit air exchanges between the linac tunnel and the surrounding environments. Additionally, the air in the tunnel would be circulated and filtered to remove significant radionuclides from the atmosphere. Before the tunnel air is exchanged or personnel enter the tunnel, a delay would be administratively provided to allow short-lived radionuclides to decay. Other than radioactive material, this process is used to manage other hazardous material such as ozone and nitrogen oxide that may be in the linac tunnel. These hazards are only applicable during and immediately following linac operation. During maintenance or other down times, without linac operation, these are not generated beyond negligible quantities.

The target would generate less air activation. Due to the much larger beam losses in the target area, this area contains local shielding that limits activation of the air. However, the potential for release of airborne radioactive material is higher in the target systems area than in the linac tunnel. A multi-confinement system approach for the target systems area currently in use at other accelerator facilities, or another approach, may be used to ensure emissions are within regulatory limits and MSU ALARA goals.

Ventilation requirements for the FRIB were estimated based on their counterparts at the NSCL and other accelerator facilities. A more-detailed source determination for the FRIB would be made to estimate the magnitude of potential releases and onsite and offsite doses from these releases before any final decision is made concerning the type of ventilation system required for the FRIB.

A conceptual design of the FRIB ventilation system for the target facility is presented in Figure 3–5. Airflow would be from areas with lower contamination risk into areas that have a higher contamination risk; therefore, three basic ventilation systems were assumed. These are primary confinement, secondary confinement, and hot offgas treatment. Concepts for these three systems are discussed below, along with their components, size requirements, and locations.

Figure 3–5. Conceptual Layout of a Proposed Ventilation System for the Target Facility

The primary confinement exhaust (PCE) system for the Target Facility would consist of ventilation of primary confinement areas. Primary confinement areas are assumed to contain the maximum potential for contamination, for example, the target facility hot cell environment. The first component in the exhaust system would be a filter housing that would feed air to the PCE areas. The air would flow through the PCE area and exit through another bank of filters. For exhaust, air would flow from the filters through two redundant fans to an elevated stack located on a building roof. Care would be exercised to locate this exhaust point remotely from any building air intake structure. The primary filtration system (e.g., activated charcoal) will be identified during later design stages.

The secondary confinement exhaust (SCE) system would ventilate spaces containing equipment and systems. It would be maintained at a nominal negative pressure that would be adequate for confinement of facilities. Secondary confinement areas would be ventilated by a once-through ventilation system. Air would flow from the makeup air system into the SCE spaces, then to the filter trains co-located with the PCE filter trains, and then through redundant fans to the same elevated stack.

These PCE and SCE systems would principally interface with the cooling water loops. The water cooling loop that contains the most radioactivity is the one associated with a water-cooled beam dump considered for the FRIB. The anticipated dominant radioisotopes created in the water loops from a uranium primary beam are listed in Table 3–2. Depending on the primary beam used the set of isotopes created may be very different. It is anticipated that the purge gas would contain the first nine isotopes as well as hydrogen and moisture from the loop.

Table 3–2. Volatile Radioisotopes produced by the Uranium Ion Beam

Isotope	Classification	Volatile
Oxygen-14	Short-lived gas water spallation product	Yes
Oxygen-15	Short-lived gas water spallation product	Yes
Nitrogen-13	Short-lived gas water spallation product	Yes
Nitrogen-16	Short-lived gas water spallation product	Yes
Carbon-11	Short-lived gas water spallation product	Yes
Hydrogen-3 (tritium)	Liquid water spallation product	Yes
Xenon-133	Noble gas fission product	Yes
Iodine-131	Halogen fission product	Yes
Ruthenium-103	Volatile particulate fission product	Yes

Current design concepts for the hot offgas systems include an offgas treatment system to keep the volatile radionuclides confined within the system. Components that could be used include a copper oxide column to convert hydrogen in the offgas into water that is then fed back into the loop and a decay tank to allow short-lived radionuclides to decay prior to release. The effluents from the offgas treatment system, along with other hot-offgas-vented equipment such as vacuum pumps could be fed to a charcoal and HEPA filter train and from there to the elevated stack.

The FRIB would have one or more ventilation exhaust stacks. The current planned approach is to use a Strobic[®] style stack for airborne contaminants. The most likely locations for these stacks are the top of the cryogenic building and the target building/high bay. Specific locations would be defined based on the expected radiological isotopic releases. Noise would also be considered in placing the stacks. Stacks would be used for normal operation and for some accident conditions. For example, the required air exhaust would be different when operating the linac with personnel in the service tunnel and accessible portions of the experimental building than it would be when personnel are working in the linac.

Supporting Infrastructure

New 25-megawatt electrical lines would bring the power for the cryoplant and the radio frequency systems for the linac. An existing 14-megawatt gas turbine in the MSU Power Plant can provide 3 megawatts of power to the FRIB. The backup power generator would be sufficient

to keep the facility at 4 Kelvin for several hours or to warm it up in a controlled way. Water and sewer utilities adequate for the FRIB site would be provided as part of the MSU infrastructure.

Electrical distribution would be brought to the site from the campus utility plant and feed utility transformers, switchgear, and main distribution panels as required to meet the individual buildings' loads. Power would be supplied to the campus from either a commercial source or the existing MSU Power Plant. Subpanels would feed light fixtures, switches, receptacles, and equipment required to operate the buildings.

3.1.3 Experimental Area and Research Infrastructure

In addition to the accelerator components, the FRIB project includes facilities for the use of users, students, and staff, including office space, laboratories, and computers. Accommodations for short-term and long-term users would be made available.

The infrastructure required to accomplish the science goals of the FRIB is shown in Figures 3–1 through 3–4. Existing NSCL offices, augmented by a new office wings contributed by MSU, would provide office space for staff and users. The current NSCL includes 189,390 square feet (17,594 square meters) of existing civil infrastructure.

Laboratory space would consist of about 164,000 square feet (15,000 square meters) of existing NSCL laboratory space, plus approximately 10,000 square feet (930 square meters) of space in the new experimental hall.

Assembly space for the linac components would be provided by an 11,000-square foot (1000-square meter) extension of the present south high bay. Class 100 (480-square foot [45-square meter]) and Class 10,000 (720-square foot [70-square meter]) clean rooms with high-pressure water rinse and chemical processing are available. Existing support space includes a full machine shop, detector laboratory, and target-making facility.

The present NSCL experimental and ancillary equipment would continue to be used once the FRIB linac becomes operational. The two cyclotrons would no longer be used to accelerate the primary stable ion beams, although there are plans for using the K1200 cyclotron as an accelerator for higher energy rare isotopes. The K500 could continue to be used to do accelerator physics experiments or may be decommissioned. Decommissioning would involve disposal or re-use of components.

Table 3–3 summarizes the approximate building characteristics of the existing NSCL and the new construction needed for the proposed FRIB.

Table 3–3. Approximate Building Characteristics

	Existing NSCL Facility/ Operations	FRIB Construction/and Operations ^a
Building area	189,390 square feet (17,595 square meters) including existing office space	Conceptual facility approximate size for both underground and above ground spaces: 200,000 gsf (19,000 square meters)
Circulation and immediate frontage roadway	1,600 linear feet (500 meters)	800 linear feet [restoration of roads disturbed by tunnel construction] 7,000 linear feet including temporary road for access to Wharton Center
Curb and gutter	6,000 linear feet (1800 meters)	
Stack or vent height(s)	The NSCL has a low stack for normal ventilation, but it is not designed as a contaminant discharge stack.	The FRIB would have a stack, but the location and height are not defined, but would likely be located on top of the high bay or the cryoplant building.

^a Includes NSCL operations.

Key: FRIB=Facility for Rare Isotope Beams; NSCL=National Superconducting Cyclotron Laboratory.

Source: MSU 2010a.

The possible facility layout is shown schematically in Figure 3–6. As part of the details outlined in the procurement, MSU would share in the construction cost for the FRIB and make other, non-monetary contributions. Under the Proposed Action, MSU would furnish those portions of the FRIB labeled “MSU” in Figure 3–6. These portions are described in detail below.

Figure 3–6. Block Diagram of the Facility for Rare Isotope Beams

Ion Source and Front End

Electron cyclotron resonance ion sources developed in collaboration with Lawrence Berkley National Laboratory, and from the MSU Superconducting Source for Ions would produce the ions required for acceleration by removing multiple electrons to produce positive ions.

The ions would be transported in a low-energy beam transport system to a radio frequency quadrupole (RFQ) accelerator where the ions would be accelerated to about 2 percent of the speed of light. The medium-energy beam transport system would deliver the beam from the RFQ accelerator to Driver Linac Segment 1 at an energy level of 0.3 MeV/u, where the superconducting radio frequency cavities would take over the acceleration process. Superconducting technology would be used in the driver linac as it most efficiently achieves the 100 percent duty factor operation needed to reach the required beam power. The driver linac (shown in segments in Figure 3–6) would meet intensity requirements by acceleration of multiple charge states, because the ion sources aren't capable of supplying the number of particles needed in a single charge state.

Driver Linac and Stripper Sections

Driver Linac Segment 1 would accelerate the beam to 17.5 MeV/u, or about 10 percent of the speed of light. At that point the ions need to have more electrons removed to provide more effective acceleration. Electrons would be removed in the stripper section when they pass through a thin layer of material. Following stripping in the stripping section, Driver Linac Segment 2 would accelerate up to five charge states to energies of at least 200 MeV/u for uranium with a beam power of 400 kilowatts. At this point the ions would be traveling at their full velocities of about half the speed of light. Driver Linac Segment 3 of the linac would initially have only focusing and diagnostic elements, with the possible addition of cryomodels to achieve 400 MeV/u.

The stripping system would be located between Driver Linac Segments 1 and 2 and would increase the downstream acceleration efficiency by increasing the charge state of the beam, because the energy gain is directly proportional to the number of electrons removed. It would consist of a stripper and an analysis section. Electrons would be removed from the beam ions by passing through a thin material such as a rotating-wheel carbon foil or other stripping method such as liquid metals, gas, or plasma. The material would be located at the object point of an achromatic and isochronous analyzing beam-line section used to remove unwanted charge states. The beam, consisting of many different ion charge states, would be focused so they all go through the stripper in the same place and same time. After the stripper, the different beams would be spread out for removal of unwanted charge states. Unwanted charge states would be removed by aperture slits at the dispersive midplane of the analyzing section; i.e., at the point where there is a physical separation between them so they can be caught on moveable plates. The compact design uses a second stripper to further increase the charge states. Local shielding and possibly remote handling systems would be used in this area to accommodate these controlled beam losses of about 20 percent of the beam power. The controlled beam losses would result from energy deposited in the stripper material and in the unwanted charge states. Simulations indicate that uncontrolled losses, losses due to particles straying from the central group, would be orders of magnitude less. The remaining analysis-system elements would bring

up to five charge states of uranium back to the linac axis in an achromatic and isochronous manner appropriate for acceleration in Driver Linac Segment 2. The beam would then be back in a tight group, ready for further acceleration.

Space would be included in the linac design for extensive diagnostics. Beam-loss monitors would be placed along the linac to ensure that losses do not exceed 1 watt per meter. Non-intercepting beam probes, beam position monitors, would be placed between each cryomodule. At selected locations, longitudinal timing detectors would be included. For the entire length of the linac, a basic list of diagnostic elements and their locations would be established, and distances between components of the accelerating lattice would be chosen to accommodate the diagnostic elements. The many diagnostic elements would be used to assure the beam follows the prescribed path and does not end up in some place it's not supposed to be, like the vacuum tube wall.

Beam Transport and Switchyard

The beam transport system from the end of the linac to the production target (shown in Figure 3–6 as Segment 3 and the switchyard) would accommodate a beam energy of up to 400 MeV/u for uranium of charge state 79^+ and correspondingly higher for lighter ions for a possible future upgrade. For reference purposes, the 79^+ charge state means there are only 13 electrons remaining around the nucleus.

Target Building

The rare isotope beam production systems would consist of the high-power production target and a fragment pre-separator with its high-power beam dump. It is expected that remote handling capability would be required to assist target changes and frequent maintenance tasks. A possible conceptual design for the equipment in the target building is presented in Figure 3–7. Shielding would be designed such that radiation produced by the high-energy beam from the driver linac interacting with the production target and beam dump would be kept below ALARA goals for personnel and the public. Different production targets are likely to be required to be able to provide a wide range of rare isotopes for science with FRIB. In addition to a carbon-based solid target a liquid lithium target may also be used. To accommodate the latter, the system would be designed such that in the case of accidental in-vacuum water leaks lithium water reactions do not occur or can be kept under control. Beam dumps may include water-cooled and gas-cooled dumps as well as liquid-metal-based dumps. Design of this system would be such that high-activity waste would be minimized. Remote handling of highly-activated components would ensure safe and efficient operation and minimum radiation exposure to personnel.

Figure 3–7. Target Building and Installed Components

Experimental Areas

Figure 3–8 illustrates both the existing NSCL cyclotron driver and experimental areas (in green) and how the FRIB fragment separator would be connected to the existing experimental area once operational.

Figure 3–8. Existing National Superconducting Cyclotron Laboratory Experimental Areas with a Concept of the Change Necessary to Incorporate the Facility for Rare Isotope Beam

Other Technical Design Options and Configurations

Many aspects of the FRIB design are still at the conceptual design stage. Therefore, some of technical features of the design may still change. For example, alternatives to the front end of the accelerator are still under consideration. Alternatives to the experimental areas being considered, including alternative geometries for the target facility, include shielding, remote handling systems, and other infrastructure appropriate for a particle fragmentation target capable of not only the baseline facility specifications, but also the upgraded 400-kilowatt beams from implementation of Segment 3 of the linac. Alternative concepts for the particle fragmentation separator layout are being considered, with safety performance being an important discriminator in the concept selection criteria. In addition, there is space sufficient to add additional targets in the future. The necessary space would either already be foreseen in the baseline target building or could be added as a separate target building at a later stage. A three-stage particle fragmentation separator layout with a horizontally oriented pre-separator is a technical option currently being studied. Different types of experimental equipment, based on input from the user community, may also be used.

3.1.4 Construction

The description of potential construction activities in this *FRIB EA* attempts to “bound” the types of construction activities that might occur. Some details on construction methods that might be used would be decided by the construction contractor ultimately selected to build the proposed FRIB. The projected construction details presented in this section also attempt to “bound” the linac configurations under consideration. Most of the configuration options under consideration by the conceptual and preliminary design teams are not expected to substantially change the high-level details of the projected construction resources.

It is anticipated, with any of the configuration options, the aboveground structures would be conventional construction similar to the adjacent buildings on campus. This includes the above-grade portion for the front-end building, south high bay extension, cryoplant facility, connector high bay, experimental area addition, and the ventilation structures. Foundations would have spread footings; cast-in-place concrete walls and piers; concrete floor slabs; concrete masonry unit exterior walls with brick veneer to match the existing buildings; concrete masonry unit shaft walls; structural steel and steel framing; galvanized steel roofs, floors, and decks; single-ply roofing on rigid insulation; hollow metal doors and frames; drywall; and metal stud interior walls.

The plumbing systems would include minimal fixtures and toilet rooms throughout the new facilities. All estimates include emergency shower and eyewash equipment for the safety and protection of personnel in the facilities. Domestic water, where required, would connect to the existing campus water loop and provide point-of-use water heaters if needed. All structures that do not have a sloped roof would receive primary and secondary storm drainage systems.

The fire protection system in each building would consist of a connection to the site mains, backflow preventers, upright or sidewall heads, and all associated piping. A fully integrated fire alarm system that ties into the campus system would be provided at all buildings along with the extension of telephone and data conduits and cables throughout the buildings.

The heating, ventilation, and air conditioning system would consist of air handling units with steam heating and chilled water cooling. All buildings would be equipped with electric duct reheat coils and exhaust fans to meet the heating and ventilation loads. All grills, diffusers, and ductwork would be provided for a proper and complete air distribution system.

Tunnel and Cryoplant Building

The tunnel would be constructed in a conventional “open cut and cover” process with shoring to reduce the impact on adjacent structures as well as impacts of excavation. The tunnel would be cast-in-place concrete, encased in waterproofing and covered with compacted native materials. These native materials would be sorted on site or at the soil disposal area located south of the railroad tracks and north of East Mount Hope Road to create engineered fill. The proposed surface restoration would be similar to existing conditions.

Construction would require the use of approximately 15 acres (6 hectares) in the NSCL area, 25 acres (10 hectares) at the soil disposal area, and an additional temporary laydown area. Excavated soils would be stockpiled either on the construction site or at the soil disposal area. The high water table would require well points placed strategically around the excavated areas to temporarily lower the water table. The groundwater would be filtered and discharged into the existing storm drainage system. Structural fill would be installed below the foundations along with a dewatering system. After the tunnel has the opportunity to cure, waterproofing material would be installed and the excavation would be backfilled and compacted.

The cryoplant building would be constructed concurrently with the tunnels. The new cryoplant building would be similar to the existing facility, only with a larger footprint. Construction would be typical of MSU utility and support buildings. Other aboveground facilities would be

constructed as soon as a stable base can be provided. As the construction is completed, landscaping would be restored, and the tunnels, target area, cryoplant building, and aboveground facilities would be turned over to MSU upon completion for installation of scientific equipment.

Site utilities, pedestrian lanes, and traffic lanes would be constructed or relocated to provide MSU faculty, staff, students, and visitors safe passage around the construction site and to provide for the continuous operation of the university. The utility relocations would be phased in order to minimize interruptions to existing facilities. A utility bridge over the proposed linac tunnel would be constructed. Earth retention systems would be installed to protect adjacent facilities and vegetation.

Table 3–4 summarizes the bounding parameters and characteristics of the construction of the FRIB.

Table 3–4. Approximate Estimates of Construction Requirements

Material/Resource Requirements During Construction	
Surface water or groundwater (raw water)	
Average usage	800 gallons per day (3,000 liters per day)
Peak usage	10,000 gallons per day (38,000 liters per day)
Total usage	240,000 gallons (910,000 liters)
Potable water	
Average usage	200 gallons per day (760 liters per day)
Peak usage	800 gallons per day (3,000 liters per day)
Total usage	240,000 gallons (910,000 liters)
Electricity	
Average usage per day	3,200 kilowatt-hours
Peak power usage	450 kilowatts
Total usage	960 megawatt-hours
Gasoline	27,500 gallons (104,000 liters)
Diesel fuel	161,000 gallons (609,000 liters)
Propane	12,000 gallons (45,000 liters)
Concrete	39,000 cubic yards (30,000 cubic meters)
Steel	6,100 metric tons
Crushed stone	3,000 cubic yards

Material/Resource Requirements During Construction	
Sand & Gravel	35,600 cubic yards (mostly excavated materials)
Table 3–4. Approximate Estimates of Construction Requirements (continued)	
Material/Resource Requirements During Construction	
Asphalt	9,000 cubic yards
Lumber	12,000 board feet
Other materials	Concrete Cure and Seal – 3,500 gallons (13,000 liters)
	Concrete Admixtures – 9,500 gallons 6,000 (36,000 liters)
	Concrete Form Oil – 2,500 gallons (9,500 liters)

Source: MSU 2010a.

The construction would require excavation of approximately 325,000 cubic yards (248,000 cubic meters) of material. With the linear design configuration, the excavation would be generally 100 to 175 feet (30 to 55 meters) wide by 1,880 feet (570 meters) long. Tunnel construction is expected to require 24 months to complete.

The peak estimated workforce is 175 workers. Construction is estimated to require approximately 7,500 offsite truck trips for raw materials and supplies, 15,000 onsite truck trips for temporary storage and return of dirt removed during construction, 3,500 truck trips for nonhazardous waste disposal, and 10 rail trips for raw materials for facility construction.

During construction, bounding airborne emissions from construction-related activities include approximately 8,800 pounds (4,000 kilograms) per year of hydrocarbons, 66,000 pounds (30,000 kilograms) per year of carbon monoxide, 4,400 pounds (2,000 kilograms) per year of nitrogen oxides, and 1,260,000 pounds (570,000 kilograms) per year of carbon dioxide. Construction of the FRIB would be conducted using processes typical of MSU on-campus construction. Construction would be in compliance with all Federal, state, local, and university rules. Table 3–5 summarizes the bounding estimates of wastes that would be generated with construction of the proposed FRIB.

Table 3–5. Approximate Estimates of Construction Wastes

Waste generated during construction	
Solids	36 metric tons (All Michigan State University construction waste is recycled)
Liquids	12 metric tons (All MSU construction waste is recycled)
Waste Concrete	10 percent of total used in construction
Waste Steel	10 percent of total used in construction
Other	10 percent of total used in construction
Nonhazardous liquids	
Sanitary	10,000 cubic meters
Other	400,000 cubic meters for construction dewatering

Source: MSU 2010a.

3.1.5 Operations

The function and scope of FRIB operations would be similar to those of the NSCL; however, the FRIB would have substantially more beam power. The existing NSCL research program relies on a coupled cyclotron driver accelerator with 200 MeV/u of energy and 1 to 2 kilowatts of beam power. The FRIB would be capable of a minimum of 200 MeV/u of energy for all ions and up to 400 kilowatts of beam power. A reaccelerator, with energy up to 12 MeV/u for uranium and up to 20 MeV/u for lighter ions, is also planned for the facility.

The NSCL has approximately 700 scientific users globally, 300 employees, and approximately \$20 million annually in National Science Foundation funding. The NSCL’s two coupled superconducting cyclotrons accelerate and fragment atomic nuclei for basic nuclear science experiments. Rare isotope beams are produced by primary beams with 1 to 2 kilowatts of power. The existing NSCL is, and proposed FRIB would be, regulated by the State of Michigan, EPA, U.S. Department of Transportation, U. S. Department of Labor, and NRC. In addition, the NSCL has an International Organization for Standardization (ISO) 9001-registered Quality Management System, an ISO 14001-registered Environmental Management System, an Occupational Health and Safety Assessment Series (OHSAS) 18001-registered Integrated Safety Management System, and a best-in-class safety record.

The NSCL would continue to operate approximately until the FRIB is completed as a National User Facility operated by MSU and funded by the National Science Foundation through a Cooperative Agreement. With the Proposed Action, the FRIB Project would establish the FRIB facility which would be a DOE Office of Science National User Facility operated by MSU funded through a Cooperative Agreement with DOE. Instead of two coupled cyclotrons as the basic particle accelerator currently being used at the NSCL, the FRIB would use a superconducting linac to accelerate and fragment atomic nuclei in basic nuclear science experiments. Rare isotope beams would continue to be made from primary beams, but the beam intensity could range up to 400 kilowatts of beam power. For some experiments, this would increase the intensity of the rare isotope beams by a factor of 400, greatly increasing the ability

to perform the scientific experiments and allowing for new experiments that could be done with the higher beam intensities. As with the NSCL, the FRIB would be regulated by the State of Michigan, EPA, the Department of Transportation, the Department of Labor, and NRC. It would have the same ISO and OHSAS registrations as the NSCL.

The principal difference between the existing NSCL and the proposed FRIB would be the linac as a new particle accelerator with which to perform the research. Many of the existing experimental facilities and areas would continue to be used. Under the current plans, research operations would continue at the NSCL while the construction activities supporting the FRIB are underway. Once construction is finished on the major facilities, installation and examination of the equipment would occur over several months. Operations at the NSCL would continue during most of this period. After installation of much of the equipment in the new facilities supporting the FRIB, a transition period would occur during which cyclotron operations at the NSCL would cease and transition to the linac operations would occur. The staffing levels of the fully operational FRIB would be higher than current NSCL levels. Preliminary estimates are that the facility operations staff would increase from 269 to 330, the daily number of visiting scientists would increase from 20 to 100, maintenance staff would increase from 30 to 40, and administrative support staff would increase from 22 to 30 (MSU 2010a).

The environment, safety, and health programs that are currently used at the NSCL and throughout the MSU campus would form the foundation for the FRIB programs. These include programs to protect the environment, minimize waste generation, prevent pollution, protect the FRIB workforce, and protect the MSU community.

The shielding design together with the radiation safety and security interlocks and search-and-evict procedures would ensure that no personnel or any members of the general public are exposed to any levels of radiation above the ALARA goals. Current regulatory limits require that NSCL workers receive exposures that are ALARA and less than 5000 millirem per year, and the general public receives less than 100 millirem per year or less than 2 millirem in any one hour. The design goal for anticipated exposure levels at FRIB conform to or are less than those permitted in the MSU NRC license and are consistent with the ALARA goals.

Radiological issues at the NSCL and the FRIB would fall under the MSU NRC broad scope license. As such the controls are typically implemented by NSCL staff with oversight by the independent MSU Office of Radiation, Chemical, and Biological Safety.

The FRIB would be managed in such a way as to maintain risks, exposures, and releases in compliance with applicable limits and ALARA goals.

The FRIB would follow the MSU ALARA program and be in accordance with limits for exposures, risks, and releases. As the design evolves, the FRIB safety needs would be compared with the NSCL practices and procedures to identify where changes are needed. Evaluation of and practices for control of any increased risks as compared to the current risks would be used to evolve the program.

Based on initial conservatively calculated activation products associated with FRIB operations, design allowances would be included to mitigate potential consequences for workers and the

public. For example, activities such as accelerator or target maintenance would be dependent on the details of the design built in to allow for removal of activated air to minimize potential exposure and abnormal impacts.

The FRIB would have a multi-tiered approach to radiological release confinement. Potential releases include gaseous releases from activated water, hydrogen-3 (also known as tritium) in the cryogenic helium, and activated air in the linac tunnel, among other possibilities. Releases of airborne contaminants could be expected from the linac tunnel and from cryogenic helium releases. Although releases of helium are not a normal operational condition, they are anticipated. Because the linac operation would activate the air in the tunnel, the facility would limit air exchanges between the linac tunnel and the surrounding environments. The FRIB would be designed to preclude uncontrolled releases of airborne radionuclides during normal operations and postulated accidents.

Applicable controls would be put in place to manage the isotope releases within EPA's National Emissions Standards for Hazardous Air Pollutants (40 CFR Part 61) and limit the overall effective dose equivalent to less than 10 millirem per year. The conceptual design goal is to maintain the total dose limit to 1 millirem per year or less from the air pathway. These hazards would be only applicable during and immediately following linac operation. During maintenance or other times when the linac is not in operation, these would not be generated beyond negligible quantities.

3.1.6 Decommissioning FRIB

MSU expects the FRIB to be a long-term endeavor. The lifecycle of modern accelerators is approximately 30 years of operation. However, in the event that MSU decides not to continue the operation of the FRIB, either renovation or demolition of the facilities would be required. This could result in underground structures being decontaminated or otherwise managed, per NRC requirements, and buried in place and aboveground structures being removed or redeployed (MSU 2010a). Fill material would be required to fill in underground structures. The source of and quantity of fill material would be determined at the time of demolition. Environmental rules and regulations similar to construction of the FRIB would be applicable, including the National Environmental Policy Act (NEPA) if Federal agencies are involved with the process. All equipment within the structures would be expected to be removed and reused to the extent applicable. It is possible that some of the equipment would have become radioactive due to long-term irradiation and would be handled in accordance with MSU, NSCL, and FRIB standard practices and NRC regulations.

3.2 Description of the No Action Alternative

As required by the Council on Environmental Quality's implementing regulations (40 CFR 1502.14d), this *FRIB EA* considers a No Action Alternative to serve as a basis for comparison of the environmental impacts with the action alternatives. Under the No Action Alternative, the FRIB would not be constructed and operated at MSU and the scientific research proposed by DOE and others for the FRIB would be deferred or not performed. Operations at the NSCL would continue with funding from the National Science Foundation until NSCL becomes obsolete.

3.3 Alternatives Considered But Eliminated

Prior to the FRIB project, MSU had considered a south campus site for construction and operation of a rare isotope accelerator. That site, while technically possible, was rejected for a combination of technical, scientific, practical, and financial reasons (MSU 2006a).

As part of the procurement process, DOE considered only the NSCL site for which an application was received in response to the FRIB funding opportunity announcement (FOA). DOE published the FOA on May 20, 2008, seeking applications for the conceptual design, and establishment of a particle acceleration facility—the FRIB—as a National User Facility (DOE 2008a). The applications received were subject to a merit review process conducted by a panel of world-renowned experts from universities, national laboratories, and Federal agencies. The appraisal included rigorous evaluation of the proposals based on the merit review criteria described in the FOA, presentations by the applicants, and visits by the merit review panel to each applicant’s site. MSU’s application was chosen for award based upon the peer review results. MSU also offered a direct cost share to the project. In addition, DOE performed an environmental critique in accordance with NEPA’s DOE procurement, financial assistance, and joint ventures regulations (10 CFR 1021.216). The environmental critique concluded (based on the information disclosed in the proposals as well as on DOE accelerator experience) that “the physical, environmental impacts identified for both of the applications would be minor and localized, and could be successfully managed to further reduce them, and hence, little discrimination between the applications was possible on [an environmental] basis.”

On December 11, 2008, MSU was selected to design and construct the FRIB (DOE 2008b). Following selection of the MSU proposal, an environmental synopsis of the information in the environmental critique was filed with EPA. This synopsis is provided in Appendix E.

Based on this DOE selection process and environmental synopsis, no significant environmental impacts were expected from the design, construction, operation, and decommissioning of the FRIB at either the MSU NSCL or the other site. A decision, therefore, was made to prepare an EA for construction, operation, and decommissioning of the FRIB at MSU. Therefore, for purposes of this *FRIB EA*, the other site is not evaluated further.

THIS PAGE INTENTIONALLY LEFT BLANK

Chapter 4

AFFECTED ENVIRONMENT

This chapter contains four types of information related to the Facility for Rare Isotope Beams (FRIB) project Area. This information includes:

- data on the status of important natural cultural, social, or economic resources and systems;
- data that characterize important environmental or social stress factors;
- a description of pertinent regulations, administrative standards, and development plans; and
- data on environmental and socioeconomic trends.

The information provides the context for interpreting the impacts from the construction and operation of the FRIB project, which are described in Chapter 5, Environmental Consequences. As such, it serves as a baseline against which any changes resulting from implementation of the Proposed Action can be identified and evaluated.

4.1 Land Use

Michigan State University (MSU) was established in 1855 as the Agricultural College of the State of Michigan as a prototype for 69 land-grant institutions to be established under the Morrill Act of 1862. MSU was the first institution of higher learning in the United States to teach scientific agriculture (MSU 2009b).

MSU is located in East Lansing, Michigan, 3 miles (1.6 kilometers) east of Michigan's capitol, Lansing, Michigan. MSU is a 5,200-acre (2,100-hectare) campus including 2,100 acres (850 hectares) in existing or planned development and 553 buildings, 83 of which have instructional space. In addition, MSU owns 15,000 acres (6,000 hectares) throughout Michigan that are used for agricultural, animal, and forestry research (MSU 2009b).

The National Superconducting Cyclotron Laboratory (NSCL) is located in the southeastern section of the MSU campus. The NSCL is home to the Coupled Cyclotron Facility and receives strong funding support from MSU as well as from the National Science Foundation and the U.S. Department of Energy (DOE) (NSCL 2009).

The proposed facility would be constructed and operated adjacent to the existing NSCL in previously disturbed areas (see Figure 4-1 (project area indicated in red) or <http://maps.msu.edu/files/MSUcampus.pdf>). During construction, an existing soil disposal area located south of the railroad tracks, east of Farm Lane, and immediately north of East Mount Hope Road would be used (see Figure 4-1 (soil disposal area indicated in purple)). This 25-acre (10-hectare) site is an existing construction staging area within an area of undeveloped fields and has been used for numerous construction projects at MSU.

Final Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan

Figure 4-1. Project Location on Michigan State University Campus

In December 2001, the MSU Board of Trustees adopted the Campus Master Plan (MSU 2007a). Since that time, the university has built approximately 800,000 gross square feet (74,000 square meters) of new facilities with another 500,000 gross square feet (46,000 square meters) of facilities currently under construction. The Campus Master Plan has also resulted in numerous roadway reconstruction efforts that have positively redefined traffic patterns at the center of campus and significantly reduced injury accidents, as well as various enhancements to the open spaces on campus.

In 2007, the MSU offices of Campus Planning and Administration and Facilities Planning and Space Management completed a 5-year update of the Campus Master Plan (MSU 2007a). The purpose of the Campus Master Plan is to guide the long-term development of the MSU campus. The plan attempts to look forward 20 years with as much specificity as possible, while acknowledging that change will require flexibility to adapt within the context of the campus planning principles.

The plan serves as a decisionmaking tool, allowing planners and administrators to view each proposed change to the campus within the full context of all other expected changes, allowing future decisions to be made in a holistic manner. Figure 4–2 shows the building opportunity framework as outlined in the Campus Master Plan (MSU 2007a). The building opportunities planned for the project site include academic and research facilities (shown in red in Figure 4–2).

Continued use of the triangular 25-acre (10-hectare) soil disposal area south of the railroad tracks and immediately north of Mount Hope Road illustrated in Figure 4–1 is consistent with the Campus Master Plan.

4.2 Geology and Soils

A geotechnical report was completed for the project site in August 2009 (NTH 2009). The purpose of the study was to obtain preliminary geotechnical data along the proposed site alignment to advance current design concepts and provide additional information required for calculations associated with the FRIB. The site topography is generally sloped from north to south with minor grade changes for roadways, parking lots, and sidewalks. The ground surface elevation at the test boring locations ranges from approximately 849 to 868 feet (259 to 265 meters) above mean sea level (NTH 2009).

Soil conditions at the site are variable, but generally consist of topsoil or fill deposits that are underlain by granular or cohesive materials of varying densities and consistencies (NTH 2009).

Pavement and Surficial Topsoil – The pavement thickness ranges from 0.4 to 0.5 feet (0.12 to 0.15 meters). The surficial soils between 0.5 and 1.5 feet (0.15 to 0.5 meters) consist of silty sand, clayey sand, or sandy clay.

Fill Soil – Granular or cohesive fill soils are encountered to depths ranging from approximately 1 to 16 feet (0.3 to 5 meters). The granular fill soils consist of very loose to medium compact gravel, sandy gravel, gravelly sand, sand, silty sand, or clayey sand. The cohesive fill soils consist of medium to hard sandy clay or silty clay.

Natural Granular and Cohesive Soil – The natural soil at the site is highly variable and consisted of interspersed granular and cohesive soil deposits. Stratified soil conditions are expected along the proposed FRIB tunnel alignment as well as the target area. Occasional cobbles and boulders were encountered within the test borings.

In general, the granular soils consist of very loose to very compact sandy gravel, gravelly sand, sand, silty sand, clayey sand, sandy silt, silt, and clayey silt. The cohesive soils consist of soft to very hard gravelly clay, sandy clay, silty clay, and clay (NTH 2009). These soils are characteristic of glacially influenced surface features.

Bedrock first occurs at depths ranging from 42 to 80 feet (13 to 24 meters). Bedrock is sedimentary and consists of limestone, sandstone, siltstone, or shale (NTH 2009).

The soil disposal area is a 25-acre (10-hectare) open field located east of Farm Lane, south of the railroad tracks, and immediately north of East Mount Hope Road. This soil disposal area is an existing construction staging area within an area of undeveloped fields and would be used during the construction of the proposed facility.

Seismic Risk

Magnitude and intensity measure different characteristics of earthquakes. Magnitude measures the energy released at the source of the earthquake. Magnitude is determined from measurements on seismographs. Intensity measures the strength of shaking produced by the earthquake at a certain location. Intensity is determined from effects on people, human structures, and the natural environment (USGS 2010a).

Michigan lies in a region of very low risk for earthquake occurrence. Shocks are characterized by intensities from I to VI on the Modified Mercalli Intensity (MMI) scale of observed earthquake effects. The nearest areas of substantial earthquake damage risk are located in the more seismically active regions that include southern Illinois, southwestern Indiana, and upstate New York. Earthquakes with epicenters in these areas may be felt in Michigan. Damage from earthquakes in Michigan has generally been limited to broken dishes, cracked plaster, and damaged chimneys, although two earthquakes with intensities of VIII on the MMI scale have been recorded (Bricker 1977; USGS 2010b). Intensity VIII effects are those with the potential to cause slight damage in specially designed structures but considerable damage in ordinary buildings.

The earliest record of earthquake tremors felt in Michigan were from a series of shocks centered near New Madrid, Missouri, in 1811 and 1812, associated with the area known now as the New Madrid seismic zone. As many as nine tremors from the New Madrid earthquake series were reportedly felt distinctly in Detroit (USGS 2010b). The New Madrid earthquake sequence of 1811–1812 ranks as one of the largest in the United States since European settlement. The three largest shocks produced shaking as high as MMI X to XII (i.e., extreme to nearly total damage to man-made structures) at their epicenters, with estimated magnitudes ranging from 7.2 to 8.1. Estimated shaking across central Michigan was in the range of MMI V (USGS 2010c). Since the New Madrid earthquake sequence, earthquakes occurring within but mainly beyond the state have sporadically been felt in Michigan. Between 1872 and 1883, a number of moderate earthquakes were centered within Michigan. A minor earthquake was reported outside of Detroit on August 17, 1877. On February 4, 1883, an earthquake cracked windows and shook buildings in Kalamazoo, Michigan (MMI VI). This shock was felt in southern Michigan and northern Indiana. Cities as distant as Bloomington, Illinois, and St. Louis, Missouri, also reported feeling this earthquake (USGS 2010b).

More recently and most notably, the earthquake of August 9, 1947, damaged chimneys and cracked plaster over a large area of south-central Michigan and affected a total area of about 50,000 square miles (130,000 square kilometers), including points north to Muskegon and Saginaw and parts of Illinois, Indiana, and Wisconsin. The cities of Athens, Bronson, Coldwater, Colon, Matteson Lake, Sherwood, and Union City in the south-central part of the state all experienced MMI VI effects. Reports of damage to chimneys and some instances of cracked or fallen plaster, broken windows, and merchandise thrown from store shelves were common in the epicentral area (USGS 2010b). This is the only earthquake listed in the National Geophysical Data Center Significant Earthquake Database as having occurred within about 120 miles (200 kilometers) of MSU. This event was centered approximately 61 miles (98 kilometers) southwest of MSU and had a recorded magnitude of 4.7 (USGS 2010d).

Overall, in the central United States east of the Rocky Mountain Front, the distribution of historical earthquakes is a reasonable guide to seismic hazard (Crone and Wheeler 2000: 7, 183). Since 1973, a total of only seven earthquakes have been recorded within a 124-mile (200-kilometer) radius of MSU, with magnitudes ranging from 2.5 to 3.5. The closest was a magnitude 3.5 event (MMI V) located approximately 7 miles (12 kilometers) from MSU (USGS 2010e).

Probabilistic earthquake ground-motion data that include peak (horizontal) ground acceleration (PGA) were specifically evaluated to provide a more quantitative assessment of seismic risk. Estimates of probabilistic ground motion at a particular location consider earthquake-shaking at all future possible earthquake magnitudes and at all possible distances from the location (USGS 2010f). Earthquake-produced ground motion is expressed in units of percent “g” (force of acceleration relative to that of Earth’s gravity). PGA is one parameter used by the U.S. Geological Survey National Seismic Hazard Mapping Project. The U.S. Geological Survey hazard maps have been adapted for use in the seismic design portions of the latest building codes (USGS 2008a). The latest PGA data from the U.S. Geological Survey were used to assess the site. The PGA values cited are based on a 2 percent probability of exceedance in 50 years. This corresponds to an annual probability (chance) of occurrence of about 1 in 2,500. For MSU, the calculated PGA is approximately 0.037 g (USGS 2008b) (see Figure 4–3). PGA values in the range of 0 to 0.04 g indicate a very low seismic risk.

Source: USGS 2010g

Figure 4–3. National Seismic Hazard Mapping–Michigan

According to the NTH report, the site may be classified as Site Class D (reflecting a soft soil profile) in accordance with the definitions given in Section 1615.1.1 of the 2003 Michigan Building Code (NTH 2009). The 2003 Michigan Building Code adopts the 2003 International Building Code for seismic classifications (ICC and MDCIS 2004).

4.3 Water Resources

Surface Water

MSU is located in Ingham County, Michigan, which crosses two major watersheds, the Upper Grand and the Huron. As shown in Figure 4-4, the southwestern portion of Ingham County, where the campus is located, is located in the Upper Grand River Watershed and lies within the Red Cedar River drainage basin (EPA 2009). The Upper Grand River Watershed is a 572,376-acre (231,640-hectares) watershed that traverses Hillsdale, Jackson, Eaton, Washtenaw, and Ingham Counties. The Upper Grand River Watershed contains the headwaters of one of the largest river basins in Michigan, with its outlet into Lake Michigan.

Figure 4-4. The Upper Grand River Watershed

The project site is located in a well-developed area of MSU. As shown on Figure 4-5, the nearest surface waters are the Red Cedar River to the north and two bodies of water to the southwest of the project site on opposite sides of Farm Lane. The project site is approximately 1,000 feet (300 meters) from the nearest point of the Red Cedar River, which discharges into Grand River approximately 3 to 4 miles (5 to 6 kilometers) west of the site. There are no surface-water bodies in immediate proximity to the construction laydown area for equipment staging and soils storage. Directly north of the construction laydown area on Farm Lane, the two bodies of water (north of Service Road) are approximately 2,250 feet (690 meters) from the closest part of the laydown area. A larger body of water directly to the south of the U.S. Department of Agriculture Regional Poultry Research Laboratory is approximately 2,500 feet (760 meters) from the closest part of the construction laydown area.

Figure 4-5. Bodies of Water Near the Project Site

There are no floodplains on the proposed project site, or in the potential area of effect. The floodplains in the area are upgradient from the proposed site, and therefore would not receive stormwater from the construction area. These include the 100-year floodplain along the Red Cedar River (FEMA 1980) north of the project site, and the 76-acre (30.8-hectare) native floodplain (MSU 2010b) north of the project site (approximately 8,250 feet [2,515 meters] from the site). Therefore, the Proposed Action would not require a floodplain assessment under DOE

regulations for implementing Executive Order 11988 (*Floodplain Management*) (10 CFR Part 1021), or a permit from the State of Michigan Floodplain Regulatory Authority, under Part 31, Water Resources Protection, of the Natural Resources and Environmental Protection Act (NREPA), 1994 Public Act 451, as amended (MDNRE 2010a). The Water Bureau within the Michigan Department of Natural Resources and Environment (MDNRE) has responsibility for processing National Pollution Discharge Elimination System (NPDES) permits under the authority of the Federal Water Pollution Control Act (33 U.S.C. 1251 et seq.), and NREPA Part 31, (1994 PA 451), as amended. [Note that until recently, MDNRE was two separate state agencies: Michigan Department of Natural Resources (MDNR) and the Michigan Department of Environmental Quality (MDEQ) and most of the regulations are still under the MDNR and MDEQ names.] The purpose of this permit is to control the discharge of pollutants into surface waters of the state to protect the environment. In addition to the NPDES permit, MDNRE's Certificate of Entry, Industrial Stormwater Guidance Document, identifies the process whereby MSU has received a Certificate of Coverage under the MDNRE Storm Water from Industrial Activities General Permit that regulates all stormwater discharges on campus (MDEQ 2010). The NSCL is covered under the Certificate of Coverage. Although stormwater from FRIB construction would be covered by MSU's existing Certificate of Coverage, construction of the FRIB would require a soil erosion and sedimentation plan approval from MDNRE. Currently, stormwater runoff from roof and ground surface drains flows to the MSU stormwater system. Discharges are authorized under the Certificate of Coverage issued by MDNRE.

MDNRE utilizes a Permit-by-Rule process to obtain Certificate of Coverage authorization to discharge. Construction activities of 5 acres (2.02 hectares) or more, with a point source discharge to the surface waters of the state, are required to submit a Notice of Coverage (NOC) to obtain coverage under the Permit-by-Rule process. Prior to submitting the NOC, the permittee must obtain coverage under NREPA, Part 91 (1994 PA 451), either by obtaining a Soil Erosion and Sedimentation Control (SESC) permit from the local SESC permitting agency or be designated an Authorized Public Agency by MDNRE pursuant to Part 91. The permittee must submit the NOC along with a site location map, copy of the SESC permit (if applicable), a copy of the SESC plan, and application fee to MDNRE at the address identified on the NOC.

One of the primary requirements of the Permit-by-Rule process is that all permitted sites must be inspected weekly, as well as within 24 hours of any rain or snowmelt event that results in a discharge from the site. The inspections must be conducted by a stormwater operator trained and certified by MDNRE and documented in an inspection report or log.

The issuance of a Certificate of Coverage does not authorize violations of any Federal, state, or local laws or regulations, nor does it obviate the necessity of obtaining such permits, including any other MDNRE permits, or approvals from other units of government as may be required by law (MDNRE 2010b).

Groundwater

The majority of the mid-Michigan area obtains its drinking water supply from the Saginaw Formation. This formation is an important aquifer that generally has very high water quality. The Saginaw Formation consists of mostly sandstone with interbedded shale, limestone, coal,

and gypsum. In most places, the thickness ranges from 100 to 200 feet (31 to 61 meters) (MSU 2010c).

The MSU Physical Plant Division supplies water to campus facilities. The MSU campus relies entirely on groundwater for its water supply needs. MSU has 17 Type I groundwater supply wells located on campus. All but one of the supply wells are located south of Mount Hope Road; the remaining well is located on the north campus, north of Mount Hope Road (MSU 2010c). Wells are completed at depths ranging from 285 to 435 feet (87 to 313 meters). On a daily average, MSU pumps approximately 4 million gallons (15 million liters) and has a maximum capacity of approximately 6.6 million gallons (25 million liters) (MSU 2010c). The water is delivered directly to facilities south of Mount Hope Road or to a central reservoir, where the water is treated prior to pumping to buildings north of Mount Hope Road. Before delivery to the main campus, the water is treated with fluoride, chlorine, and phosphate to provide potable water to users.

MSU monitors the quality of its water supply for a variety of potential contaminants in accordance with state and Federal regulations. The MSU Physical Plant Division prepares an annual Water Quality Report (MSU 2002) that provides key information about the quality of MSU's water supply. The Water Quality Report indicates that contaminants are either not detectable or are present in concentrations well below drinking water standards.

Ground surface elevation at the various test boring locations ranges from approximately 849 to 868 feet (259 to 265 meters) above mean sea level. Water-level observations were made at each of the test borings within the project site during and upon completion of drilling operations, except for within six test borings where drilling fluids were used or monitoring wells were installed and observations could only be made during drilling (NTH 2009). Additionally, groundwater could not be observed within two test borings due to soil collapsing within the test boring above the water table. Water was encountered at depths ranging from approximately 13.5 to 34.2 feet (4 to 10.4 meters) below ground surface with elevations ranging from 827 to 839 feet (252 to 255 meters) above mean sea level. Groundwater was observed upon completion of drilling operations at depths ranging from 18 to 37.5 feet (5.5 to 11.4 meters) below ground surface with elevations ranging from 825.7 to 850 feet (252 to 259 meters) above mean sea level. (NTH 2009).

Fluctuations in groundwater levels are anticipated due to seasonal variations and following periods of prolonged precipitation or drought (NTH 2009). For example, relatively shallow groundwater may be encountered at the site, depending on the season of the year and recent precipitation. Additionally, groundwater-level observations made within fine-grained soils, such as those encountered at the project site, are not always indicative of long-term groundwater levels due to low hydraulic conductivity and the tendency of drilling operations to seal off natural paths of groundwater flow. Groundwater at the site has the potential to be affected by the level of the water in the nearby Red Cedar River (NTH 2009).

Wetlands

Michigan's wetland statute, NREPA, Part 303 (1994 PA 451), defines a wetland as "land characterized by the presence of water at a frequency and duration sufficient to support, and that

under normal circumstances does support, wetland vegetation or aquatic life, and is commonly referred to as a bog, swamp, or marsh” (1994 PA 451). The definition applies to public and private lands regardless of zoning or ownership.

Wetlands and soil area including wetland soils have been identified in an Ingham County Final Wetland Inventory (MDEQ 2006). These wetlands primarily exist along the Red Cedar River bank and in the Inland Lakes Research and Study Area; none are located in the area of effect for the project site or the soil disposal area. Accordingly, no wetland assessment is required to comply with Executive Order 11990 (*Protection of Wetlands*), and DOE regulations for implementing this Executive Order as set forth in *Compliance with Floodplain and Wetland Environmental Review Requirements* (10 CFR 1022).

4.4 Climate and Air Quality

4.4.1 Climate

The climate of the East Lansing area is continental, characterized by larger temperature ranges and colder temperatures than similar latitudes near the Great Lakes. The area experiences some minimal lake effects (Michigan State Climatologist’s Office 2009a). Meteorological data are collected on the MSU campus in East Lansing and additional data are available from the meteorological station in Lansing. The long-term average wind direction is from the west (NCDC 1998). Average annual historical precipitation is 28.7 inches (72.9 centimeters). Precipitation is due to rain and thunderstorm activity in spring, summer, and fall, and snow in the winter. Average annual snowfall is 38.7 inches (98.3 centimeters). Severe weather events include hail, tornados, thunderstorms and high wind speeds, and snow and ice (NCDC 2010). The average monthly historical temperature is 47.4 degrees Fahrenheit (°F) (8.6 degrees Celsius [°C]), with a high average temperature of 70.7 °F (21.5 °C) in July and a low average temperature of 21.8 °F (-5.7 °C) in January (Michigan State Climatologist’s Office 2009b).

4.4.2 Greenhouse Gas

The “natural greenhouse effect” is the process by which part of terrestrial radiation is absorbed by gases in the atmosphere, warming the Earth’s surface and atmosphere. This greenhouse effect and the Earth’s radiation balance are affected largely by water vapor, carbon dioxide, and trace gases, which absorb infrared radiation and are referred to as greenhouse gases. Other greenhouse gases include nitrous oxide, halocarbons, and methane.

There is consensus among scientists, including those on the Intergovernmental Panel on Climate Change (IPCC), that increases in atmospheric concentrations of certain pollutants can produce changes in the Earth’s atmospheric energy balance and thereby influence global climate. These pollutants are commonly referred to as greenhouse gases, and this warming effect is referred to as global warming. Water vapor (1 percent of the atmosphere) is the most common and dominant greenhouse gas; only small amounts of water vapor are produced as the result of human activities. The principal greenhouse gases resulting from human activities are carbon dioxide, methane, nitrous oxide, and halocarbons. Halocarbons include chlorofluorocarbons; hydrofluorocarbons, which are replacing chlorofluorocarbons as refrigerants; and perfluorocarbons, which are a byproduct of aluminum smelting. Other gases of concern include

sulfur hexafluoride, which is widely used in insulation for electrical equipment. These gases are released in different quantities and have different potencies in their contributions to global warming (IPCC 2007; Justus and Fletcher 2006).

Sources of anthropogenic carbon dioxide include combustion of fossil fuels such as natural gas, oil, gasoline, and coal. It is estimated that carbon dioxide atmospheric levels have risen by more than 35 percent since the preindustrial period (since 1750) as a result of human activities. Emissions of other greenhouse gases have also risen. Annual global emissions of carbon dioxide are estimated to be 26.4 billion metric tons from fossil fuel use (IPCC 2007:3). Carbon dioxide is the most important anthropogenic greenhouse gas and is therefore of primary concern in this EA.

The IPCC concluded that warming of the earth's climate system is unequivocal, and that most of the observed increase in global average temperatures is very likely due to the observed increase in anthropogenic greenhouse gas concentrations. The IPCC reports potential impacts from warming of the climate system, including expansion of sea water volume; decreases in mountain glaciers and snow cover resulting in sea level rise; changes in arctic temperatures and ice; changes in precipitation, ocean salinity, and wind patterns; and changes in extreme weather (IPCC 2007:3-8).

4.4.3 Air Quality

Ingham County is located in the South Central Michigan Intrastate Air Quality Control Region (40 CFR 81.196). Ingham County is designated as being located in an attainment area for all criteria pollutants (see Table 4–1). An attainment area is a specific geographic area considered to have air quality as good as or better than the national ambient air quality standards as defined in the Clean Air Act. The designation is made for each criteria pollutant.

Table 4–1. Attainment Designations for Ingham County

Criteria Pollutant	Designation
Sulfur Dioxide	Better than National Standards
Carbon Monoxide	Unclassifiable/attainment
Ozone (1-hour)	Unclassifiable/attainment
Ozone (8-hour)	Attainment
Particulate Matter with a diameter of 10 micrometers or less	Unclassifiable
Particulate Matter with a diameter of 2.5 micrometers or less	Unclassifiable/attainment
Nitrogen Dioxide	Cannot be classified or better than national standards

Source: 40 CFR 81.323.

Air pollutant emission sources at MSU include vehicles, generators, boilers, a power plant, and incinerators. There are no air pollutant emissions from operation of the NSCL (MSU 2010a). MSU has an air quality operating permit covering two waste incinerators and the MSU Power Plant.

The NSCL does not currently have airborne radiological emissions (MSU 2010a). There are no NSCL emissions identified in MSU's air permit. Radioactive emissions do not reach regulatory levels. Hazardous air pollutants contained at MSU are specific to the MSU Power Plant.

4.5 Biological Resources

Biological resources include native or naturalized plants and animals and their habitats. Protected and sensitive biological resources include specific habitats and the plant and animal species listed as threatened or endangered by the U.S. Fish and Wildlife Service or the Michigan Department of Natural Resources and Environment or are otherwise protected under Federal or state law.

Existing Habitat

The landscape on the MSU campus and its immediate vicinity consists of scattered undeveloped parcels located within a larger and more developed and urbanized area. Although most of the land has been developed for teaching and research facilities, three types of natural areas can be found on the MSU campus (MSU 2010d).

- Category 1 – Natural Area – managed at the highest level of protection and lowest level of usage
- Category 2 – High Quality Undeveloped Area – only limited impact allowed for teaching and research
- Category 3 – Undeveloped Area of Scientific Value – limited manipulation for research and demonstration may be allowed, subject to review and approval

The Category 1 areas located near the project site are the Sanford Natural Area, the Baker Woodlot and Rachana Rajendra Neotropical Migrant Bird Sanctuary, and the Red Cedar Natural Area. The Sanford Natural Area is a 34-acre (14-hectare) floodplain forest that is part of the 676.57 acres (273.8 hectares) of forested land purchased in 1855 for the original Michigan Agricultural College campus. The closest portion of the Sanford Natural Area is located approximately 350 feet (100 meters) from the proposed site tunnel entrance on the north side of East Shaw Lane. The Baker Woodlot and Rachana Rajendra Neotropical Migrant Bird Sanctuary constitute a 78-acre (32-hectare) beech–maple forest. The Baker Woodlot and Rachana Rajendra Neotropical Migrant Bird Sanctuary are located approximately 1,700 feet (520 meters) from the project site. The Red Cedar Natural Area is a 76-acre (31-hectare) native floodplain forest split by Kalamazoo Street and is located approximately 7,000 feet (2100 meters) from the project site (MSU 2010b, 2010d, 2010e, 2010f).

Existing habitat at the project site is consistent with that of the surrounding area and includes a mix of industrial, urban, and natural habitat. Most of the site consists of large buildings, parking areas, and roads interspersed with mowed lawns. Most of the site is highly disturbed from past and present MSU activities and contains relatively small areas of natural vegetation. Vegetation primarily consists of planted grass lawns, shrubs, and trees that are mainly used for landscaping near buildings. Wildlife found within the immediate vicinity of the project site consists of species capable of living within a disturbed landscape and tolerant of human activity. Bird

species include the European starling, American robin, and house sparrow, while mammals include raccoon, gray squirrel, and small rodents.

The soil disposal area is an existing construction staging area within an area of undeveloped fields. The wildlife composition found at the disposal area is similar to that of the surrounding area; however, due to a lesser degree of development, greater species diversity is present. Bird species include the song sparrow, eastern bluebird, and mourning dove, while mammals found at the site include red fox, striped skunk, and the field mouse.

Threatened and Endangered Species

The Michigan Department of Natural Resources and Environment lists 55 species with some level of Federal or state status located in Ingham County. Of these 55 species, one species, the Indiana bat, is listed as a federally endangered species, while the eastern massasauga rattlesnake is listed as a species being considered for Federal status. See Appendix B for a complete listing, including scientific nomenclature. Due to the industrial and disturbed nature of the MSU campus, none of these species or critical habitat is known to be present at the project site. Although the soil disposal area is located within a less developed setting, no listed species or critical habitat is known to occur (MSUE 2009).

4.6 Noise

Sources of noise at MSU in the area around the NSCL and the FRIB site include vehicular traffic, building equipment such as ventilation equipment, transformers, generators, a cryogenic plant, and water pumps. The primary noise areas in the NSCL, although soundproofed, are the compressor room in the cryogenic plant and a number of mechanical equipment rooms. Some of this equipment is indoors, which controls noise levels from these sources at noise-sensitive receptors nearby.

As the project site is in an area of campus that has undergone substantial construction in recent years, noise from building and road construction has been common in the general area around the project site. Recent construction in the project site vicinity has included the Wharton Center, the Biomedical and Physical Sciences building, building additions to the NSCL, and road construction. Each of these construction activities was conducted in such a manner to reduce noise impacts on the MSU staff and residents.

Noise-sensitive receptors near the project site include dormitories, classrooms, laboratories, offices, the performing arts center, and pedestrians (MSU 2010a).

4.7 Utilities

This section addresses the existing capacity and usage of utilities (i.e., electricity, fuel, and water) at the NSCL for use in current operations.

Electricity

While electricity is supplied to the NSCL by the MSU Power Plant, electricity for the FRIB would be supplied from the offsite commercial grid. Average rate of electric power use at the

NSCL is about 3.7 megawatts, with a peak usage rate of 4.1 megawatts, and a total usage of 26,016 megawatt-hours per year (MSU 2010a). This is well within the MSU Power Plant capacity of 60 megawatts.

Fuel

Diesel generator (for a backup generator) testing at the NSCL utilizes approximately 10 gallons (38 liters) per year of diesel fuel and No. 2 diesel fuel oil. Gasoline and natural gas are not currently used at the NSCL. Small quantities of propane are currently used at the NSCL to operate a fork lift. Industrial gases utilized at the NSCL consist of approximately 7.8 million pounds (3,500 metric tons) per year of nitrogen and approximately 10,000 pounds (4.7 metric tons) per year of helium (MSU 2010a).

Water

The MSU Physical Plant Division provides water utilities to campus facilities. Potable water usage at the NSCL averages 370,000 gallons (1,400,000 liters) per day. The MSU potable water system currently pumps an average of 9,000 gallons (34,000 liters) per minute (MSU 2010a). Nonpotable water is not used for NSCL operations.

4.8 Cultural and Historical Resources

All surface areas in the vicinity of the NSCL area have been previously extensively disturbed. According to the MSU Campus Archaeology Program Director, no cultural or historical resources are likely to be found in these disturbed areas. Surveys, however, have identified one historical resource near the eastern portion of the Mount Hope Road soils storage/disposal area, i.e., an early 20th century historic farmstead (Goldstein 2010).

4.9 Human Health and Safety

The existing human health and safety conditions in the vicinity of the NSCL provide a background against which the consequences of the Proposed Action and the No Action Alternative may be understood.

4.9.1 Radiological Environment

According to the National Council on Radiation Protection and Measurements (NCRP 2009), the average annual ionizing radiation dose to a member of the general public in the United States is 0.624 rem. Table 4-2 presents the various contributions to this total. These averages are considered to be generally applicable to the population of East Lansing and to the students and staff of MSU.

Estimates of human health impacts of ionizing radiation can be expressed in terms of the probability of a latent cancer fatality (LCF) for an individual or the number of LCFs in a population. For purposes of presenting such estimates in this environmental assessment, a dose-to-LCF factor of 0.0006 LCF per person-rem is used, consistent with the recommendation of the DOE Office of Environmental and Policy Guidance (DOE 2003).

Table 4–2. Comparison of Annual Average Doses Received by a U.S. Resident from All Sources

	Source	Dose (millirem per year) ^a	Percent of Total
Ubiquitous background	Radon and thoron	228	37
	Space	33	5
	Terrestrial	21	3
	Internal (body)	29	5
	Subtotal	311	50
Medical	Computed tomography	147	24
	Medical x-ray	76	12
	Nuclear medicine	77	12
	Subtotal	300	48
Consumer	Construction materials, smoking, air travel, mining, agriculture, fossil fuel combustion	13	2
Other	Occupational	0.5 ^b	0.1
	Nuclear fuel cycle	0.05 ^c	0.01
Total		624	100

^a To convert millirem per year to millisieverts per year, divide by 100.

^b Occupational dose is regulated separately from public dose and is provided here for informational purposes.

^c Calculated using 153 person-sieverts per year from Table 6.1 of NCRP Report 160 using a 2006 U.S. population of 300 million.

Source: NCRP 2009.

4.9.2 Occupational Health and Safety

Over the 5-year period from 2004 to 2008, the total number of recordable injuries and illnesses at MSU averaged 1.4 per 200,000 labor hours, compared to an average of 2.0 for all Michigan colleges, universities, and professional schools. The average for all U.S. universities was 2.5 during the same time period. The NSCL rate of injury/illness cases involving days away from work, job restriction, or transfer (DART cases) during the same period was 0.2, compared to 0.6 for Michigan colleges, universities, and professional schools, and 1.0 for all U.S. universities. During that time, the NSCL experienced no fatalities. The NSCL record of occupational injury and illnesses is summarized in Table 4–3.

Table 4–3. Occupational Injury and Illness Rates, 2004 – 2008

	Total Recordable Case Rate	DART ^a Case Rate
National Superconducting Cyclotron Laboratory ^b	1.4	0.2
Michigan Universities ^{c,d}	2.0	0.6
U.S. Universities ^e	2.6	1.0

^a Cases with days away from work, job restriction, or transfer (DART).

^b Source: MSU 2010a.

^c Source: BLS 2010a.

^d Values are approximate. Data for “colleges, universities, and professional schools” were not explicitly stated in the 2005 published data.

^e Source: BLS 2009.

During the period 2004 to 2008, an average of approximately 381 persons were monitored (i.e., assigned a personal radiation dosimeter) for occupational radiation exposure at the NSCL. The average annual recorded dose for these workers was about 13 millirem. The highest dose received by any worker in the reporting period from October 2008 through September 2009 was 388 millirem. These values are well below the U.S. Nuclear Regulatory Commission annual dose limit of 5,000 millirem and the NSCL “as low as reasonably achievable” administrative goal of 500 millirem.

4.10 Waste Management

Waste management includes activities related to the transportation, treatment, storage, and/or disposal of wastes. Waste management activities may be a component of, but are not limited to, routine site operations, facility management, capital improvements, and/or ongoing remediation efforts. Waste minimization activities include various site-specific programs that support efforts to reduce the quantity and toxicity of site wastes, conserve resources and energy, reduce hazardous substance use, and prevent or minimize pollutant releases into the environment.

The Office of Radiation, Chemical, and Biological Safety (ORCBS) manages the following waste forms on the MSU campus: low-level radioactive waste, mixed low-level radioactive waste, hazardous waste, and nonhazardous waste. Current operation of the NSCL results in the generation of a variety of wastes. In general, hazardous wastes generated at MSU are managed in three separate groups: radioactive, chemical, and biohazardous wastes (although biohazardous wastes are not generated at the NSCL and are not foreseen to be generated at the FRIB). Hazardous wastes generated at the NSCL are collected in specified waste containers, documented, and packaged according to MSU guidance on the safe handling and packaging of waste (MSU 2009c). All hazardous waste (including chemical waste) generated at the NSCL is delivered by licensed carriers to Resource Conservation and Recovery Act (RCRA) or Toxic Substances Control Act–permitted treatment, storage, and disposal facilities. Low-level radioactive waste and/or mixed low-level radioactive waste (e.g., flammable, corrosive, or toxic waste such as scintillation vials) generated at the NSCL is collected by MSU and delivered by

licensed carriers to a licensed low-level radioactive waste disposal facility. No transuranic waste is generated from operations at the NSCL.

MSU holds an MDNRE, RCRA Part B Permit that allows MSU to store containers at the Waste Storage Facility before they are shipped off site to RCRA-permitted treatment, storage, and disposal facilities. ORCBS provides hazardous waste pick-up and disposal services for all MSU facilities. Typically, individual facilities collect hazardous wastes in ORCBS-supplied containers, label the material properly, provide secondary packing if necessary, and submit an electronic pickup request form on the ORCBS website (MSU 2009c).

General refuse (i.e., nonhazardous solid waste) is discarded into dumpsters strategically located at MSU facilities. To avoid improper disposal of hazardous or chemical wastes (e.g., discarded commercial chemical products), established procedures guide MSU personnel as to which wastes can be placed in dumpsters. Work practices must be followed by all MSU laboratory staff in disposing and separating nonhazardous waste from hazardous waste (MSU 2009c). Wastes placed in dumpsters are collected by a commercial waste hauler and transported to the hauler's processing facility where recyclable materials are removed. The remaining waste is transported for disposal to an MDNRE-permitted sanitary landfill. All MSU construction and demolition waste is transported by commercial haulers to processing facilities where recyclable materials are removed.

The total volume of waste generated and disposed of at MSU is reduced by an active recycling program managed by the Office of Recycling and Waste Management. MSU has set clear goals to reduce its environmental footprint. By 2015, MSU will reduce waste by 30 percent (MSU 2010g). The "Be Spartan Green" campaign promotes environmental stewardship as a priority at MSU. Faculty, staff, and students are highly encouraged to eliminate waste through source reduction or material substitution, by reusing or recycling potential waste materials that cannot be minimized or eliminated, by reeducating through research on climate change, through environmental friendly "redesign" and green leadership in energy and environmental standards for new construction, and by rethinking purchasing habits and methods (MSU 2010g).

Wastewater is generated by a number of activities at MSU and consists of sanitary wastewater (from restrooms, kitchens, and sinks in certain buildings and laboratories), laboratory wastewater (from laboratory sinks and floor drains in most buildings), and stormwater runoff. Cooling water and cooling tower blowdown waters are discharged into the sanitary wastewater treatment system. The sanitary wastewater collection and treatment system collects wastewater from sanitation facilities, kitchens, office buildings, and other portions of the campus that do not contain radioactive or hazardous materials. Trace amounts of radioactivity may be found in sink water, shower water, and liquids from cleaning glassware in the NSCL facility laboratories. Liquid wastes from laboratories are discharged in accordance with procedures in the ORCBS Waste Disposal Guide (MSU 2009c).

Campus wastewater is collected and conveyed to the nearby City of East Lansing Waste Water Treatment Plant located just off campus on Trowbridge Road. Under the provisions of an existing agreement with the City of East Lansing, all sanitary wastewater and other industrial waste streams including cooling water and cooling tower blowdown water, coal pile runoff and

other industrial wastes, including those containing trace amounts of radioactivity, are received and treated at the East Lansing Plant.

The volume of industrial wastewater discharged from current NSCL operations is approximately 100 gallons (379 liters) per day.

4.11 Transportation

The regional ground transportation network consists of several interstate highways, urban roadways surrounding and entering the MSU campus, and a campus road network. Interstate highways in the Lansing/East Lansing area include Interstate 69 and Interstate 96, which circle the Lansing/East Lansing urban area, and Interstate 496, an expressway that gives access to the Lansing/East Lansing urban areas from Interstates 69 and 96.

Figure 4–1 shows the road and rail network traversing the campus. Figure 4–5 shows the transportation network in the vicinity of the project site. All roads on campus are public roads (MSU 1996). The primary area of the campus is bounded by Grand River Avenue (State Route 43) to the north, Hagadorn Road to the east, Mount Hope Road to the south, and Harrison Road to the west. Within the campus are roadways and access roads, parking areas and garages, pedestrian and bicycle lanes, and footpaths. Two rail lines pass through the southern half of the campus.

The project site is bounded by South Shaw Lane (carrying eastbound traffic) to the north, Bogue Street to the east, and Wilson Road to the south. A traffic circle is located to the northeast of the project site at the intersection of North Shaw Lane, South Shaw Lane, East Shaw Lane, and Bogue Street. The portion of Bogue Street that passes in front of the project site has a grass median. All of these roads act as connectors to the urban area surrounding the campus.

The Wharton Center surface parking lot is located northeast of the project site and across Bogue Street on the south side of East Shaw Lane. The Shaw Lane parking deck is located across South Shaw Lane from the project site. The Wharton Center parking deck is located on the east side of the Wharton Center. The NSCL, adjacent to the project site, has 400 parking spaces available for use around the building (MSU 2010a).

A 25-acre (10-hectare) staging area located 1.2 miles (2 kilometers) south of the project site (Glasmacher and Koch 2009) is commonly used for storage or disposal of soil. The staging area is accessible from the project site area by traveling westbound on Wilson Road or North Shaw Lane to Farm Lane, and traveling south on Farm Lane past Mount Hope Road (see Figure 4–1 for this route). The staging area is bordered by the railroad tracks, Farm Lane, and Mount Hope Road (MSU 2010a).

The Capital Area Transportation Authority uses Shaw Lane, Bogue Street, and Wilson Road as part of its bus routes (CATA 2010). Figure 4–6 shows Capital Area Transportation Authority bus stops on these roads that are closest to the project site as well as the bicycle paths on campus.

Figure 4–6. Transportation Network In The Vicinity Of The Project Site

Traffic accidents can occur on campus between vehicles or involve bicyclists and/or pedestrians. Table 4–4 shows the accident rates for these types of accidents for the years 2005–2009.

Table 4–4. On-Campus Traffic Accident Annual Rates

Year	Total - all accidents ^a			Vehicle - bicyclist accidents			Vehicle - pedestrian accidents		
	Number per year	Number of Injuries	Number of Fatalities	Number per year	Number of Injuries	Number of Fatalities	Number per year	Number of Injuries	Number of Fatalities
2005	326	49	0	19	13	0	5	5	0
2006	264	27	0	22	19	0	7	5	0
2007	214	23	0	11	9	0	5	7	0
2008	283	38	0	15	13	0	4 ^b	3 ^b	0
2009	206	32	0	15	10	0	10	8	0

^a Includes 3 auto/bus collisions in 2007, 1 auto-bus collision in 2008, and 2 auto/bus collisions in 2009, with no resulting injuries.

^b Includes 2 accidents only involving bicycles, resulting in 2 injuries.

Source: Fox 2010.

These accidents and resulting injuries reflect a certain level of construction that occurs on campus each year. No traffic fatalities have occurred on campus in at least 5 years, while an average of approximately 30 injuries occur each year.

Traffic studies have been performed by MSU. Table 4–5 shows the average daily traffic count for traffic corridors near the project site for 1997 and 2005 with the resulting percent change in traffic. Traffic has decreased in the area of campus where the project site is located with the largest decrease along Farm Lane. Traffic has decreased approximately 16 percent on Bogue Street in front of the project site with approximately 6,300 vehicles using this section of road each day. Traffic along Shaw Lane between Bogue Street and Hagadorn Road has decreased 16 percent to 40 percent, depending on which side of Wilson Road the traffic counts were taken.

Table 4–5. Average Daily Traffic Count

Location (counts taken between the streets shown)	1997 ADT Volume	2005 ADT Volume	Change
Bogue Street Corridor			
Grand River Avenue – Dormitory Road	17,000	11,869	-30.2%
Dormitory Road – Waters Edge Drive	17,000	13,227	-22.2%
Waters Edge Drive – Business complex	17,000	13,928	-18.1%
Business complex – Shaw Lane	17,000	13,168	-22.5%
Shaw Lane – Wilson Road	7,500	6,274	-16.3%
Wilson Road – Railroad track	6,100	4,087	-33.0%
Railroad track – Service Road	6,100	4,064	-33.4%
Farm Lane Corridor			
Auditorium Road – Red Cedar River	19,700	10,088	-48.8%
Red Cedar River – North Shaw Lane	19,700	10,347	-47.5%
South Shaw Lane – Wilson Road	12,100	9,352	-22.7%

4.12 Socioeconomics and Environmental Justice

MSU is located in the city of East Lansing in Ingham County, Michigan. East Lansing and Ingham County have 2008 populations of 45,931 and 277,528, respectively (DOC 2009a, 2010a). Ingham County is part of the Lansing-East Lansing Metropolitan Statistical Area (MSA), which also includes Clinton and Eaton Counties. The 2008 population of the Lansing-East Lansing MSA was 454,035 (DOC 2009b). During the 2008–2009 school year, MSU had a total of 46,648 students, including 36,337 undergraduate students and 10,311 graduate and professional students. MSU employs approximately 5,052 faculty and academic staff and 6,166 support staff (MSU 2009b).

Table 4–6 summarizes the total population, low-income population, labor force, employment, and unemployment rate in Ingham County and the Lansing-East Lansing MSA from 2001 through 2008. The total populations of the county and MSA remained relatively stable over this time period, with the county population decreasing by approximately 1 percent and the MSA population increasing by approximately 1 percent. The percent of the population living below the poverty level in Ingham County and the Lansing-East Lansing MSA increased approximately 4 and 5 percent, respectively. Both areas experienced increases in the unemployment rate over this time. The unemployment rate of these areas during 2008 was lower than the state average of 8.4 percent, but higher than the national average of 5.8 percent (BLS 2010b, 2010c). Through 2016, education and health care occupations are projected to have the strongest growth in the Lansing-East Lansing MSA (MDELEG 2010a).

Table 4–6. Economic Characteristics of Ingham County and the Lansing-East Lansing Metropolitan Statistical Area

Table 4–7 shows the distribution of minority populations in the city of East Lansing, Ingham County, and the surrounding Lansing-East Lansing MSA in 2008. Minority individuals are defined as members of the following population groups: Black or African American, American Indian or Alaska Native, Asian or Pacific Islander, Hispanic or Latino, some other race, and two or more races. The minority population percentage of East Lansing (20 percent) is slightly lower than the minority population percentages of Ingham County (24 percent), the State of Michigan (23 percent) and the United States (35 percent). The total minority population percentage of the Lansing-East Lansing MSA was slightly lower than that of the city of East Lansing.

The Isabella Indian Reservation is located approximately 70 miles (112.7 kilometers) north of East Lansing. In 2008 the total population of the reservation was 26,384 people, including a 13 percent minority population and an 18 percent low-income population. American Indian and Alaska Native was the largest minority group at this time, accounting for approximately 6 percent of the total reservation population (DOC 2010a).

Table 4–7. 2008 Minority Populations

Population	City of East Lansing	%	Ingham County	%	Lansing-East Lansing MSA	%
White, non-Hispanic	36,823	80%	212,153	76%	369,138	81%
White, Hispanic ^a	784	2%	9,038	3%	13,336	3%
Black or African American ^a	2,792	6%	26,949	10%	33,965	7%
American Indian and Alaska Native ^a	163	0%	822	0%	1,025	0%
Asian ^a	3,619	8%	12,248	4%	14,368	3%
Native Hawaiian and Other Pacific Islander ^a	73	0%	453	0%	787	0%
Some other race ^a	499	1%	4,443	2%	6,021	1%
Two or more races ^a	1,178	3%	11,422	4%	15,395	3%
Total	45,931	100%	277,528	100%	454,035	100%
Total Hispanic^b	1,523	3%	16,647	6%	22,889	5%
Total Minority	9,108	20%	65,375	24%	84,897	19%

^a Includes Hispanic or Latino persons.

^b Includes all persons designated as Hispanic or Latino, regardless of race.

Chapter 5

ENVIRONMENTAL CONSEQUENCES

This chapter describes the environmental consequences of the Proposed Action and the No Action Alternative, as well as the cumulative impacts of the Proposed Action when added to other past, present, and reasonably foreseeable future actions. The Proposed Action includes construction, operation, and decommissioning of the Facility for Rare Isotope Beams (FRIB) at the National Superconducting Cyclotron Laboratory (NSCL) at Michigan State University (MSU).

5.1 Effects of the Proposed Action

The impacts presented in this section are expected to “bound” the potential environmental impacts of any of the linac design configurations currently being considered and described in Chapter 3, Section 3.1. The impacts of the final design should be bounded by the configurations considered in this environmental assessment (EA). None of the configuration options, or hybrids thereof, under consideration by the conceptual and preliminary design teams are expected to substantially change the projected environmental impacts of construction, operation, or decommissioning of the FRIB. In the discussion that follows, impacts not ascribed to one configuration option can be assumed to apply to all three. When specific configuration options are mentioned, the intent is to document the bounding or a unique impact. As discussed in Chapter 3, if a new configuration is adopted that has impacts that fall outside of the bounds of this EA, a new National Environmental Policy Act (NEPA) analysis would be initiated to determine whether the impacts are significant.

5.1.1 Land Use and Visual

Construction

MSU would construct the proposed project on a previously disturbed site directly adjacent to the existing NSCL. The existing soil disposal area located on East Mount Hope Avenue would be used during the construction of the proposed facility. Continued use of this site as a soils storage and disposal area is consistent with past and projected future use of this site. Construction of the proposed project would be consistent with the planned academic and research facilities outlined in the Campus Master Plan (MSU 2007a). During construction the site would be significantly disturbed, similar to other large construction projects that have been conducted on the campus.

During construction, use of Bogue Street and Shaw Lane could be disrupted under the straight and folded configuration options and Wilson Road could be disrupted under the double folded configuration option. Bogue Street between Shaw Lane and Wilson Road would be closed for approximately 2 years during construction of the proposed facility. In addition, the Wharton Center surface parking area would be closed and used as a laydown area during the construction period. Shaw Lane between Bogue Street and Hagadorn Road would be closed to through-traffic for approximately 2 months under the straight linear option (Glasmacher and Koch 2009). These road closures would impact vehicle traffic volume, bicycle and pedestrian traffic, parking availability, and use of city buses.

Operation

No land use impacts from the operation of the FRIB are anticipated. Newly constructed facilities would slightly change the current visual landscape but would be consistent with the appearance of the MSU campus and surrounding buildings. The experimental area addition, cryogenics facilities, and connector high bay and south high bay extension would be built adjacent to existing facilities and would have similar exterior finishes to the existing facilities. Under the straight linear option, the heavy ion linear accelerator (linac) front-end building would be built near existing dormitories. It is planned that these buildings would be similar in style to existing buildings. These new structures would have a negligible effect on the visual characteristics of the campus.

Decommissioning

MSU expects the FRIB to be a long-term endeavor. Typically, modern accelerators have an operating life of 30 years. However, in the event that MSU decides not to continue the operation of the FRIB, either renovation or demolition of the facilities would be required. Transferable decontamination would be removed from underground structures and the structures assessed by MSU for potential future use. Final dispensation could include burying them in place per U.S. Nuclear Regulatory Commission (NRC) requirements and any aboveground structures removed or redeployed (MSU 2010a).

5.1.2 Geology and Soils

Construction

The FRIB would be constructed using cut-and-fill construction techniques. Under the straight option, approximately 325,000 cubic yards (250,000 cubic meters) of soil would be excavated during the construction of the tunnel associated with the FRIB (MSU 2010a). The tunnel would be constructed using a conventional “open cut and cover” process with earth retention systems to reduce the impact on adjacent structures and to reduce required excavation. Concrete, foundations, walls, floors and ceilings for the tunnels would be formed and placed during construction. The cryoplant building would be constructed concurrently with the tunnel. Other aboveground facilities would be constructed as soon as a stable base can be provided. The project site would be landscaped in a manner consistent with surrounding landscapes.

The high water table found at the site could require well points to be placed strategically around the excavated areas to temporarily lower the water table. The groundwater would be filtered and discharged into the existing storm drainage system. The tunnel would be cast-in-place concrete with appropriate waterproofing provided (e.g., encasing the tunnel in waterproofing or applying water proofing with the concrete) and it would be covered with either engineered fill or compacted native materials. These cover materials would be sorted on site or at the existing soil disposal area on East Mount Hope Road to create engineered fill (MSU 2010a).

The project site would be cleared and excavated during the construction of the FRIB. Earth retention systems would be installed to protect adjacent facilities and vegetation. Excavated soils would be stockpiled either on the construction site or at the existing soil disposal area. Structural fill would be installed below the foundations along with a dewatering system. If coal ash or

other impacted soils are encountered, those materials would be handled properly and separated from clean fill and would not be used as backfill.

Based on visual observations, the existing topsoil at the site contains appreciable amounts of organic matter and is therefore susceptible to decomposition. Accordingly, the topsoil is not considered suitable for the support of building foundations, floor slabs, or pavements, nor for use as engineered fill material. This current fill material is generally variable in composition, has various amounts of organic or deleterious material, and was placed in an unknown fashion. Where fill material is encountered below planned foundation depths, the soil would need to be removed and replaced with clean, properly compacted, granular material (NTH 2009).

A finished floor elevation of 820 feet (250 meters) above sea level is proposed for the concrete box conduits and the accelerator facility located at the east end of the tunnel alignment. A finished floor elevation of 790 feet (241 meters) is proposed for the target gallery located near the NSCL. Based on the current plans, the finished floor of the concrete box conduits and the accelerator facility on the east end of the tunnel alignment would be approximately 30 to 50 feet (9 to 15 meters) below the ground surface. During site evaluation, rock was encountered at elevations of 784.5 to 792.5 feet (239 to 242 meters) above sea level; the target area would be founded at the elevation 790 feet (241 meters) above sea level. It is anticipated that the target area would be founded on bedrock consisting of sandstone, siltstone, or shale. The competent rock is adequate to support the proposed facility (NTH 2009).

Based on the existing geologic and soil conditions, there are no major impediments or hazards from construction activities associated with the FRIB. Grading, excavation, and site development activities could cause soil erosion and compaction. To minimize the potential for adverse impacts, best management practices, including appropriate erosion prevention and sediment control measures, would be implemented. The use of these measures would be in compliance with a construction-specific Storm Water Pollution Prevention Plan (SWPPP) and any required permits. There are no identified construction accident conditions that would have more than a temporary environmental impact (erosion) on the geology and soils of the proposed site.

Operation

No impacts on geology and soils from the operation of the FRIB are anticipated. Potential impacts associated with irradiation of groundwater and soil are discussed in Section 5.1.9.2.2.5.

Decommissioning

In the event that MSU decides not to continue the operation of the FRIB, either renovation or demolition of the facilities would be required. Transferable decontamination would be removed from underground structures and the structures assessed by MSU for potential future use. Final dispensation could include burying them in place or otherwise managed per NRC requirements and any aboveground structures removed or redeployed (MSU 2010a). Fill material would be required to bury underground structures. The source of and quantity of fill material would be determined at the time of demolition.

5.1.3 Water Resources

5.1.3.1 Surface Water

In response to the 1987 amendments to the Clean Water Act, the U.S. Environmental Protection Agency developed Phase 1 of the National Pollutant Discharge Elimination System (NPDES) Storm Water Program. The Phase 1 program addressed sources of stormwater runoff from various designated groups; one of those groups included construction activities that disturb 5 or more acres. In 2003 the Phase II NPDES stormwater requirements took effect, which lowered the size of disturbance to 1 acre (MDNRE 2010b). FRIB construction (e.g., clearing, grading, and excavation) would require a permit from the Michigan Department of Natural Resources and Environment (MDNRE) for the discharge of stormwater associated with construction activity. This National Pollutant Discharge Elimination System (NPDES) permit would require implementation of a SWPPP prior to initiating construction. The construction laydown area for equipment staging and stockpile area for excavated rock and soil, would also be managed under the SWPPP for this project. Proper containment and erosion controls would be provided to prevent transport of soil or sediment and machinery lubricants and other construction chemicals into surface waters during storm events. Hazardous materials used during construction (e.g., oil, gasoline, paint) would be stored within secondary containment to prevent spills or leaks from being carried by stormwater into surface waters.

There are no surface-water bodies in close proximity to the construction laydown area for equipment storage and soils stockpiling, nor to the proposed FRIB site (see Figure 4–1). The closest body of water to the project site is the Red Cedar River, located approximately 1,000 feet (305 meters) from the project site. Temporary, indirect surface-water quality impacts during construction could occur; impacts would be mitigated through the use of administrative controls (e.g., delineating work areas) and physical controls (e.g., best management practices to decrease erosion, sedimentation, and stormwater runoff). Best management practices, as applicable, would include erosion and sediment control structures, runoff interceptor trenches or swales, filter or silt berms/fences, sediment barriers or basins, rock-lined ditches/swales, slope shaping and retaining fences, surface-water runoff management, waste management systems, and stormwater drainage structures.

The Proposed Action would not involve activities within a 100-year or 500-year floodplain (FEMA 1980), nor does it involve any wetlands. No impacts on floodplains or wetlands would occur from implementation of the Proposed Action.

5.1.3.2 Groundwater

Construction

One hundred percent secondary containment and sumps would be in place prior to commencement of construction to contain and remove any spill or release of material and to prevent contact with groundwater. Hazardous materials used during construction (e.g., oil, gasoline, paint) would be properly stored within secondary containment to prevent spills or leaks from releasing into groundwater.

As stated in Section 5.1.2, the high water table would require well points placed strategically around the excavated areas to temporarily lower the water table. After construction, the groundwater levels would be expected to return to normal with no long-term impacts or changes in groundwater flow or levels. The groundwater would be filtered and discharged into the existing stormwater drainage system (MSU 2010a).

During construction, moderate to heavy volumes of groundwater would likely be encountered where excavations extend below the groundwater table. Additionally, due to the proximity of the Red Cedar River, the encountered groundwater would have a readily available source of water for efficient recharge.

Based on anticipated depths of the required excavations and the soil characteristics at the project site, a dewatering system consisting of gravity wells could be used for dewatering the soil. In areas where the soil contains more silt, the use of eductor wells (appropriate for depths greater than about 30 feet [9 meters]) or well points (appropriate for depths less than about 30 feet [9 meters]) with a vacuum system may be necessary to dewater the soils (NTH 2009).

The spacing, diameter, and depth of the wells would depend on the excavation depth, groundwater levels, extent of granular soils, and the granular soil hydraulic conductivity value(s). The dewatering system would be designed by a qualified engineer, and reviewed and approved by the project engineer prior to commencement of work. The system would be designed and operated such that the groundwater level is lowered to at least 2 feet (0.61 meters) below excavation (NTH 2009).

Prior to construction, pump tests may be performed to obtain more data on the hydraulic conductivity of the aquifers impacting construction, and to allow for adequate design of the groundwater control measures for construction and for the permanent structure (NTH 2009). Designing a watertight structure and utilizing construction techniques that reduce the risk of future groundwater infiltration would be achieved by applying appropriate waterproofing (e.g., encasing the tunnel in waterproofing or applying water proofing with the concrete) to the tunnel structure. The tunnel excavation would be backfilled and compacted (MSU 2010a).

Operations

The research conducted at the FRIB would involve experimentation with intense beams of rare isotopes. Neutrons that penetrate the thick concrete walls of the linac tunnels and are capable of activating groundwater would result in low levels of activation of any groundwater immediately adjacent to the FRIB tunnels, which MSU would manage according to NRC license requirements. These NRC license requirements would require that the concentrations of radionuclides in the groundwater be below the NRC water effluent limits presented in Table 5–1. The NRC requirements identify concentrations of contaminants that correspond to NRC established dose limits for workers (Subpart C) and members of the public (Subpart D), given certain conservative assumptions NRC has made about exposure. Consistent with the MSU ALARA program, the FRIB project design team has established a more stringent design and operations goal, which is over a factor of 10 times lower than the NRC requirements reported in Appendix B of Title 10 of the *Code of Federal Regulations*, Part 20 (10 CFR 20). Moreover, the FRIB project design goal is to keep the average groundwater radionuclide concentrations in the

region around the linac tunnel walls to below the level that corresponds to EPA-established drinking water limits, shown in Table 5–1. Ensuring that the water adjacent to the FRIB tunnels would meet drinking water standards, which would normally only be applied to water provided by a drinking water supplier after pumping and filtering, would provide a very high degree of protection to both the environment and the public.

The FRIB approach to meeting the groundwater activation limits provides for an initial conservative evaluation against the FRIB design goal and ultimate comparison against the water effluent limits in 10 CFR 20 Appendix B. Table 5–1 provides FRIB applicable groundwater regulatory limits and project design goals. All identified radionuclides will be evaluated for compliance, but the two limiting radionuclides for compliance are ^3H and ^{22}Na .

Table 5–1. Groundwater Environmental Impact Limits and Project Design Goals

Target Receptor	Limits and Project Design Goals	
Groundwater ^a (<i>in situ</i>) NRC Water Effluent Limits	^3H Effluent Limit (water) 1000 picocuries per milliliter	^{22}Na Effluent Limit (water) 6 picocuries per milliliter
Groundwater ^b (<i>in situ</i>) Project Design Goal ^c	^3H Drinking Water Standard ^b : 20 picocuries per milliliter	^{22}Na Drinking Water Standard ^b : 0.4 picocuries per milliliter

^a Standard refers to 10 CFR 20 (Nuclear Regulatory Commission) limits for radionuclides in effluents. Ingestion of these concentrations continuously over the course of a year would produce a total effective dose equivalent of 50 millirem (0.5 millisieverts). (Table 2 of Appendix B to 10CFR20)

^b Standard refers to 40 CFR 141 (Environmental Protection Agency) limits for drinking water from community water systems. (40 CFR 141.66 provides the limits) Generally this corresponds to an equivalent 4 millirem per year to the whole body or any individual organ for beta and photon radioactivity.

^c Conservative project design goals are used to provide flexibility at the conceptual design stage in support of meeting regulatory limits in the design for commissioning and operation of FRIB and accommodate future upgrades or changes in mission.

Potential groundwater activation was assessed using the MARS15 computer code (FERMILAB 2009) for a range of particle beam types typical of (yet bounding) expected operations and energies for an assumed 1 watt per meter (W/m) continuous beam loss from the linac along the tunnel. A 1 W/m continuous loss is a conservative design basis beam loss for groundwater activation based on experience at other linacs and is higher than would be expected with the FRIB design. Localized losses which may exceed the 1 W/m will have localized shielding applied to limit losses (e.g., stripper region). These assumptions maximize the potential for activation of elements in the groundwater.

The initial evaluation against regulatory limits and design goals is based on the maximum generation rate, and therefore the maximum equilibrium concentration, of radioactive material in soil and water outside the tunnel. For the purpose of assessing compliance with the 10 CFR 20 effluent limits and the project design goals, the radionuclide concentration is being averaged over the volume of soil within which 99.9 percent of the activation will occur (referred to as the 99.9 percent volume within this EA). Calculations indicate that the 99.9 percent volume extends approximately 3 meters from the outside of the linac tunnel wall. The average radionuclide concentrations in groundwater within that volume will meet the project design goals (i.e., be less than the EPA drinking water standard) and be well below the applicable NRC effluent limits.

A preliminary evaluation of the potential for groundwater activation indicates that the baseline design for the tunnel walls and use of soldier piles for shoring provides adequate shielding to meet these goals (MSU 2010h). This conclusion is based on a conservative modeling approach that assumes the water in the region to remain stagnant for 30 years so that calculated radionuclide concentrations are at their maximum values. Any groundwater migration into this region, such as from rainwater or snow melt, would reduce the concentrations and drive the results further below the design goal. This current analysis has been conservatively performed to assure that actual operation of FRIB is bounded by these results (MSU 2010h).

Detailed results for the initial evaluation of bounding mixed-beam operations with the baseline FRIB tunnel wall design are presented in Table 5–2. The beam energies listed in the table are for a proton beam at 400 kW. The assumed second beam ^{18}O , which was assumed to operate half the time was assessed at the equivalent energy for that beam at the same beam power. These results are an average of the 99.9 percent volume concentrations of ^3H and ^{22}Na at various locations along the linac tunnel. The values presented are based on operating the linac with mixed beam for the entire facility lifetime.

Table 5–2. Preliminary Modeling Results for Expected Mixed Beam Operations

	^3H (picocuries per milliliter)	^{22}Na (picocuries per milliliter)
NRC Water Effluent Limit (Appendix B of 10 CFR 20)	1,000	6
EPA Drinking Water Limits (40 CFR 141.66)	20	0.4
Mixed Beam Operation at:		
200 Megaelectron volts	1.5	0.05
611 Megaelectron volts	6.1	0.20
1 Gigaelectron volts	10	0.32

Source: MSU 2010h

The preliminary, very conservative modeling results indicate that potential ground water concentrations of ^3H and ^{22}Na in the 99.9 percent volume around the tunnels are far below the NRC water effluent limits and even below EPA drinking water standards. The NRC regulation defines the concentrations of radionuclides in water that would be permitted for unrestricted release to the environment. By applying the much lower FRIB project goal of meeting EPA drinking water limits, there will be negligible impact on the environment from groundwater activation.

Decommissioning

Dismantling the FRIB would require implementation of stormwater runoff controls similar to those used during construction. No impacts on surface water are expected from FRIB decommissioning activities. Water quality impacts on groundwater during decommissioning are expected to be less than operations impacts. With the cessation of operations, there would no

longer be low levels of groundwater activation. Liquids would be removed from the accelerator and the tunnel would be in 100 percent volume secondary containment or the liquid would be pumped through closed-loop systems to prevent releases to groundwater.

5.1.4 Climate and Air Quality

Construction

Construction of the Proposed Action, especially excavation of the linac tunnel, would involve a significant amount of earthmoving over a period of about 2 years. These activities would involve the use of excavation equipment, trucks, other heavy construction equipment, and stationary equipment that would emit various air pollutants. There would be emissions of particulate matter from equipment activity and wind-blown dust. In addition to these air pollutant sources there would be emissions from construction worker vehicles, emissions from architectural coatings, and various chemicals. Emissions from construction equipment have been estimated using U.S. Environmental Protection Agency air pollutant emission factors for diesel and gasoline engines (EPA 1996) and estimated fuel use. Emissions from trucks and employee vehicles have been estimated using the Mobile 6.2 mobile source emission factor model (EPA 2003) and estimated vehicle mileage. These estimated emissions from construction are summarized in Table 5–3. Emissions associated with construction of the proposed facility would be less than 68 tons (61 metric tons) per year of particulate matter with a diameter of 10 micrometers or less. These emissions would be limited to the construction period and would have no long-term impacts on air quality. In addition to the criteria pollutants listed and carbon dioxide, diesel equipment would emit small quantities of other toxic pollutants including aldehydes; benzene; toluene; xylenes; propylene; 1,3-butadiene; formaldehyde; acetaldehyde; acrolein; and various polycyclic aromatic hydrocarbons (EPA 2003).

Table 5–3. Estimated Construction Emissions

Pollutant	Construction Equipment (metric tons per year)	Dust from Construction Activity (metric tons per year)	Trucks (metric tons per year)	Employee Vehicles (metric tons per year)
Carbon monoxide	0.24	N/A	0.45	20
Nitrogen dioxide	0.1	N/A	1.7	1.9
Volatile organic compounds	0.18	N/A	0.09	1.2
PM₁₀	0.07	61.1	0.04	0.058
PM_{2.5}	0.07	9.2	0.04	0.04
Sulfur dioxide	<0.01	N/A	<0.01	<0.01
Carbon dioxide	40.	N/A	300	760

Key: N/A=not applicable, PM_n=particulate matter with an aerodynamic diameter less than or equal to *n* microns.

Air pollutant emissions from construction activity would be mitigated by using standard dust control practices such as water sprays and surfactants, proper maintenance of equipment, use of low-sulfur fuels, minimization of disturbed soil area, area revegetation as soon as possible, administrative controls such as sequencing and scheduling, and other measures as required by MDNRE and MSU. Other measures, if needed, could be taken to minimize emissions such as using electric equipment.

The use of construction equipment, trucks, and employee vehicles is expected to cause some increase in greenhouse gas emissions in the form of carbon dioxide. These are summarized in Table 5–3. To a lesser degree, mobile sources emit methane and nitrous oxide during fossil fuel combustion. These emissions can be decreased with less idling and improved maintenance of equipment. Carbon dioxide emissions and other greenhouse gases from electric generation resulting from increased electric use during construction have been estimated to be 685 metric tons per year total CO₂ equivalent. The EPA has released guidelines for the proposed reporting of greenhouse gases (74 FR 16447), but there are currently no laws or standards for greenhouse gas emissions. The Michigan Climate Action Council has recently published its Climate Action Plan which recommends policies and actions to achieve greenhouse gas reduction in Michigan (MDEQ 2009).

Operation

No continuous emissions of criteria air pollutants are expected directly from the proposed facility during operations; however, the increased electricity requirements during operation of the FRIB (discussed in Section 5.1.7) will be more than 6 times the power consumed by the NSCL. Current plans are to use existing offsite, commercial power sources for FRIB operations. Testing of existing emergency generators would continue but would not increase as a result of FRIB operation. Emissions of radionuclides are discussed in Section 5.1.9. Periodic ventilation of the confined systems would include some emissions of nitrogen oxides and ozone. These emissions are expected to be negligible. Trace emissions of evaporated solvents, acids, and other chemicals would be released from fume hoods. These emissions would be associated with research and development activities, and would therefore be exempt from Federal and Michigan State permitting requirements (MSU 2010a).

The Clean Air Act, as amended, requires that Federal actions conform to the host state’s “state implementation plan.” The final rule, “Determining Conformity of General Federal Actions to State or Federal Implementation Plans,” requires a conformity determination for certain-sized projects in nonattainment areas. MSU is within an area currently designated as attainment for criteria air pollutants. Therefore, a conformity determination for this project is not necessary to meet the requirements of the final rule (40 CFR 51.850–51.860).

The generation of steam and electricity for operation of the FRIB facilities will cause some increase in greenhouse gas emissions in the form of carbon dioxide. Periodic testing of emergency generators is not expected to result in any increase in carbon dioxide emissions. Carbon dioxide emissions and other greenhouse gases from electric generation resulting from increased electric use during operation have been estimated to be 100,000 metric tons per year total CO₂ equivalent based on the estimated annual electric use and annual emission rates for greenhouse gases for electric generation in Michigan (EPA 2010). Incremental greenhouse gas

emissions attributable to FRIB operation would be about 0.0014 percent of the total annual United States greenhouse gas emissions in 2005 (7.3 billion metric tons) (EPA 2007). Future greenhouse gas emissions reporting of carbon dioxide, methane, and nitrous oxide for large fossil-fuel fired electric generating units and boilers may be necessary per EPA's proposed rule (74 FR 16447). Currently there are no emission standards for greenhouse gas emissions.

Decommissioning

During decommissioning, construction-type activities would occur. There would be emissions from various pieces of equipment and from trucks moving material to fill the linac tunnels, if that decommissioning option is selected. It is expected that these activities would be more limited in emissions and duration than the original construction because the present decommissioning plans do not include a major excavation. In the event of a major excavation, impacts would be similar.

5.1.5 Biological Resources

As the project site has been previously disturbed and has a high degree of development, impacts on protected flora and fauna are not expected. The existing soil disposal site has also been previously disturbed through soil disposal activities similar to those that would be required for the Proposed Action, so impacts on protected flora and fauna are not expected. No threatened or endangered species or critical habitats exist at the project site or soil disposal area. As neither threatened and endangered species nor critical habitat occur in the project area the U.S. Fish and Wildlife Service and the MDNRE were consulted informally. As determined by the S7 Consultation Technical Assistance tool on the U.S. Fish and Wildlife Service website, the project was judged to have "no effect" on threatened and endangered species. The results of these consultations are summarized in Appendix D. Both agencies concurred with the conclusion of the EA that no impacts on rare or unique natural features are expected.

5.1.6 Noise

Construction

Noise impacts were analyzed by comparing the expected noise levels to a baseline level and its possible effects on people in the area. Construction noise was evaluated for typical construction equipment operating on a construction site. Typical construction equipment was assumed to be used (see Table 5-4).

Table 5–4. Maximum Noise Levels at 50 Feet for Common Construction Equipment

Equipment Type	Maximum Noise Level (L_{max}) at 50 feet (dBA, slow) ^a
Compactor (ground)	80
Dozer	85
Dump Truck	84
Excavator	85
Generator	82
Grader	85
Pickup Truck	55
Warning Horn	85
Crane	85

Key: dBA = decibels A-weighted; L_{max} = maximum noise level.

^a dBA, slow refers to a sound level meter sampling speed

Source: DOT 2006.

For purposes of analysis, it was assumed that the primary sources of noise during these activities would be truck and vehicle traffic, heavy earthmoving equipment, and other construction equipment or infrastructure powered by internal combustion engines used on site.

Construction equipment and construction worker vehicles would emit noise and result in an increase in noise levels around the project site, along routes used to access the site, and near the soil storage area. There may be some railroad activity associated with delivery of materials to the campus. Changes in noise level would be temporary, although they could occur over several years, and would be in accordance with MSU construction guidelines.

Using the Federal Highway Administration’s Roadway Construction Noise Model, construction equipment was assumed for construction activities to produce noise levels at various distances from the project site. Noise levels were evaluated for receptors at 100-foot increments. Noise abatement measures were not considered in this analysis. Noise levels were calculated as an equivalent noise level (average acoustic energy) over an 8-hour period ($L_{eq(8)}$). The maximum noise level (L_{max}) shows the noise level of the loudest piece of equipment, which is generally the largest contributor of the $L_{eq(8)}$ noise level.

Potential noise sources would include variable pitch and volumes from vehicles and equipment involved in clearing and grading the site, creating and/or placing engineered structures, and conducting interior/exterior finish work. Table 5–5 shows the noise levels expected at distances in 100-foot increments, as well as at the receptor sites, from the use of construction equipment.

Table 5–5. Noise Levels at Specific Distances from the Construction Site

Distance from Construction Site (feet)	Maximum Noise Level ^a (L _{max}) dBA	Equivalent Combined Noise Level (L _{eq}) dBA
100	79.0	81.2
200	73.0	75.2
300	69.4	71.7
400	66.9	69.2
500	65.0	67.3
1,000	59	61.2
1,500	55.5	57.7
2,000	53	55.2

Key: dBA = decibels A-weighted; L_{max} = maximum noise level; L_{eq} = equivalent noise level.

^a This is the noise level of the loudest piece of equipment; it is not a cumulative

Workers associated with construction activities would be expected to wear appropriate hearing protection as required by the Michigan Occupational Safety and Health Administration Department of Labor and Economic Growth (MIOSHA) standards-MIOSHA-STD-1405, Part 680 and BSR-STD-1210, Part 380 (MIOSHA 2005, 2003). Sustained exposure to noise levels exceeding 80 decibels may result in hearing loss.

Under the straight configuration option, the nearest noise-sensitive receptors include dormitories north of Shaw Lane that are within about 140 feet (43 meters) of the proposed tunnel excavation location and within 50 feet (15 meters) of the proposed front-end building location. Other noise-sensitive facilities within 150 feet (46 meters) of the excavation could include the Wharton Center for Performing Arts, the plant biology laboratories, and the Biochemistry Building. Under the double folded configuration, the Biochemistry Building, which includes laboratories that contain vibration-sensitive experiments, is within about 50 feet (15 meters) of the tunnel excavation and the connector high bay and south high bay extensions. Pedestrians in the area near the construction site would be impacted by construction noise. Construction noise could be mitigated by employing standard construction noise mitigation, including use of quieted equipment, shielding of noisy equipment and activities, careful location of noisy equipment, proper maintenance of equipment, and administrative controls such as scheduling to avoid interfering with noise-sensitive activities.

Operation

Noise sources associated with operation of the FRIB would include ventilations systems, possibly including one or more stacks; the cryogenics system compressors; and pumps. Some stacks and pressure relief valves would operate occasionally. During the design of these facilities, noise impacts on sensitive receptors from stacks and other sources would be

considered. There would be some traffic noise from deliveries to the facility and from employee and researcher vehicles. It is expected that the number of truck trips from deliveries would be similar to existing trips for the NSCL (MSU 2010a).

Decommissioning

During decommissioning, noise sources would be similar to those during construction, although the amount of earthmoving activity would be much less. Therefore, noise impacts from decommissioning would be expected to be less.

5.1.7 Utilities

Construction and Operation

For the Proposed Action, connections would be made to existing utilities (e.g., power, potable water). Current utility easements would be maintained, to the extent practicable. If necessary, additional easements, or an extension to an existing easement, would be established for installation of required utilities.

Electricity

As indicated in Chapter 4, power for the proposed FRIB would be supplied by existing commercial power providers. As noted, the MSU Power Plant has a 60 megawatt capacity with current usage at 42 megawatts and is served by an existing substation that can bring commercially produced power off of the Michigan electric grid. MSU is proposing to use the existing 21 MW substation at the power plant and a new duct bank to bring power to FRIB. An upgrade of the power plant is therefore not needed. Emergency power would be supplied by an uninterruptible power supply (MSU 2010a).

Electricity requirements for FRIB construction would be 3.2 megawatt-hours per day, with a peak usage of 0.45 megawatts, and a total usage of 960 megawatt-hours. A local, existing MSU power plant substation would be adequate for FRIB construction.

No environmental impacts are expected as a result of utility line extensions and power distribution improvements. Existing site utilities would be relocated prior to the tunnel excavation. The utility relocations (e.g., a utility bridge over the linac tunnel) would be phased in order to minimize interruptions to existing facilities. (MSU 2010a). Prior to construction, certain infrastructure that cannot be relocated (i.e., existing steam tunnels, large sewer, chilled water, electrical, and telecommunications duct banks located along Bogue Street and South Shaw Lane) would require proper design and planning to assure their protection (NTH 2009). Any earth-retention system design would incorporate the location of these utilities and provide a method to protect the utilities during FRIB construction (e.g., provide a method to support the utilities within the excavation inside the earth retention system). During the design phase of this action, each utility would be reviewed to determine its tolerance for movement, potential impacts of various support methods on the utilities, and the appropriate method to support each utility (NTH 2009).

Estimated power requirements for FRIB operations are about 18 megawatts (MSU 2010a). The recent electric energy usage at the NSCL has been equivalent to about 18,000 to 29,000 megawatt-hours per year (MSU 2010a). Assuming continuous operating requirements for FRIB of about 18 megawatts, the annual FRIB electric energy usage would be about 158,000 megawatt-hours, or an increase of about 129,000 to 140,000 megawatt-hours annually from current NSCL operations. This would increase the overall MSU annual electric energy usage of about 370,000 megawatt-hours (MSU 2010a) by about 35 to 38 percent.

Fuel

Fuel necessary for construction of the proposed facility would consist of propane, diesel fuel, and gasoline. Fuel consumption for construction is estimated to be 12,000 gallons (45,000 liters), 161,000 gallons (610,000 liters), and 27,500 gallons (102,000 liters), respectively. (MSU 2010a).

FRIB operations fuel use is anticipated to be similar to the limited usage of fuels at the existing NSCL operations due to the fact that fuels will not be used for heating or other industrial purposes.

Inert Gas

Industrial gases estimated to be utilized during FRIB operations consist of approximately 19 million pounds (8,600 metric tons) per year of nitrogen and approximately 33,000 pounds (15 metric tons) per year of helium (MSU 2010a).

Water

Nonpotable water usage for FRIB construction is estimated to average 800 gallons (3,000 liters) per day, with a peak usage of 10,000 gallons (38,000 liters) per day. The estimated total use of nonpotable water necessary for FRIB construction is 240,000 gallons (908,000 liters). The average potable water usage for FRIB construction is estimated to be 200 gallons (750 liters) per day, with a peak usage of 800 gallons (3,000 liters) per day. The estimated total use of potable water required for FRIB construction is 60,000 gallons (227,000 liters) (see Chapter 3, Table 3-1).

FRIB operations would not require the use of nonpotable water. Although the total amount of potable water required to support FRIB operations is undetermined at this time, it is anticipated that the MSU Physical Plant Division would have the ability/capacity to supply the necessary water needed.

The estimated volume of industrial wastewater discharge from FRIB operations is 300 gallons (1,100 liters) per day. Potable water usage for operations of the FRIB is undetermined at this stage of design; however, potable water usage is anticipated to be similar to current potable water usage for the NSCL's operations.

Decommissioning

The utility requirements for FRIB decommissioning are anticipated to be less than those necessary to support operations. Decommissioning would likely require the same or less than the amount of utilities required during FRIB construction.

5.1.8 Cultural and Historical Resources

All surface areas of the project site have been previously disturbed. Based on archaeological and architectural surveys previously conducted on the MSU campus in the vicinity of the NSCL (Goldstein 2010), no impacts are expected on cultural or historical resources during FRIB construction, operations, or decommissioning, including excavation or equipment storage and rock/soils stockpiling in the proposed construction staging or soil disposal areas.

Hence DOE has made a determination pursuant to 36 CFR 800.4(d)(1) that no historic properties will be affected (see Appendix D). Supporting documentation (Goldstein 2010) included in Appendix D mentions a historic farmstead in the vicinity of the soil disposal area. However, this farmstead is outside of the FRIB undertaking's area of potential effect. Consultation with the Michigan State Historic Preservation Officer is ongoing. A copy of this consultation is provided in Appendix D. If the Michigan State Historic Preservation Office responds to DOE's determination, appropriate documentation will be included in the Final FRIB EA.

5.1.9 Human Health and Safety

5.1.9.1 Construction

Construction workers normally would not be working in any radiation areas associated with operation of the existing NSCL facility and would be expected to receive radiation doses no more than is allowed to the general public under the ALARA program. When the final connection of the new target building is made to the existing experimental areas, some workers may require radiation worker training before they are allowed into existing NSCL areas. Most radiation exposure potential associated with the construction activities, such as use of radiography sources or other licensed radioactive material, would be managed by the contractor(s) in accordance with the applicable regulations and the terms of their license(s). The primary source of health and safety impacts from construction would be work-related accidents and illnesses typical of excavation and heavy construction activities. The Michigan average injury/illness incidence summaries for "Heavy and Civil Engineering Construction" for 2004–2008 (BLS 2010a) indicate an average rate of total recordable cases of 5.3 cases per 200,000 labor hours. "Recordable cases" refers to occupational injuries and illnesses that are recordable under U.S. Occupational Safety and Health Administration regulations (29 CFR 1904). The FRIB project schedule shows construction proceeding from November 1, 2012, to September 30, 2016 (47 months or 3.92 years), and a peak workforce of 175. Assuming each worker is on the job 2,000 hours per year, a bounding estimate of construction labor hours is 1.37 million. At a rate of 5.3 recordable cases per 200,000 labor hours, it is calculated that there would be 36 recordable illness/injury cases during the 47-month construction period. The probability of a single construction worker fatality during that same period would be about 0.07.

As noted in Section 3.1, construction of the linac tunnel would involve excavating a trench up to 1,800 feet (550 meters) long to a depth of between 30 and 75 feet (9 and 23 meters) across the campus, necessitating the closure of Bogue Street between Wilson Road and Shaw Lane for up to 3 years and possible closure of portions of Shaw Lane for a number of months. The hazards to students and passers-by from moving equipment and from the excavation itself may require mitigation. State of Michigan Occupational Safety and Health Administration (MIOSHA) regulations requiring the construction contractor to provide for appropriate shoring of excavations, maintain stable slopes within the excavations and on any soil stockpiles, and limit the possibility for unauthorized and inadvertent entry into hazardous areas would also provide protection for students and passers-by. By rerouting roads and sidewalks and installing physical barriers, warning signs, and informational postings directed at the campus population, MSU and the local public safety agencies could further reduce the potential for accidents or injuries resulting from construction traffic or inadvertent entry into the active construction area.

Vehicle accidents are a source of possible health and safety impacts from construction. The construction-related traffic on public roads on and near the MSU campus and the accident, injury and fatality rates are developed in Section 5.1.11. The total number of construction vehicle-miles is estimated to be 477,100. For this total mileage, fewer than 2 accidents could be anticipated and the probability of an injury in an accident would be 0.36, or about one chance in three. The probability of a fatality would be 0.005 or about five chances in one thousand. The miles driven by workers commuting to and from the project site would total about 5.3 million during the construction phase of the project. About 17 accidents and 4 injuries could be anticipated, and the probability of a single fatality in an accident would be about 0.05. Because transportation of excavated soil to the staging area accounts for less than one-tenth of the total construction vehicle miles, stockpiling excavated material at the construction site instead of transporting it to the staging area would not appreciably decrease the overall impacts.

The accident frequency statistics used in these estimates are for all types of motor vehicle accidents, including those involving pedestrians and cyclists. About one-tenth of the overall fatality rate per motor vehicle mile is due to pedestrian fatalities, and about one-fiftieth (0.02) of the overall rate is due to cyclist fatalities. Accordingly, the probability of a construction-related motor vehicle accident that results in pedestrian fatality would be about 0.006. The probability of a cyclist fatality resulting from a construction-related motor vehicle traffic accident would be about 0.001. This calculation makes use of average accident, injury and fatality rates and the results do not mean that a particular number of accidents, injuries, or fatalities would actually occur. They do, however, provide a means to compare vehicle accident risk with other types of health and safety impacts associated with the Proposed Action. Mitigation measures such as construction of new traffic or pedestrian lanes or closure of on-campus roads and rerouting of non-construction traffic during peak periods of activity could reduce construction vehicle accident rates below those indicated by the statistics. Similarly, measures that result in increased use of public transit or carpooling may reduce both the total number of vehicle miles associated with construction and the per-mile accident rates for commuting workers.

5.1.9.2 Operations

5.1.9.2.1 Worker Impact from Normal Operations

Occupational Health and Safety

The occupational health and safety program at the NSCL is registered as Occupational Health and Safety Assessment Series 18001-compliant. The record of worker injuries and illnesses suggests that the program is effective. As noted in Section 4.9 of this EA, the NSCL rates of recordable and lost work-time injuries/illnesses are significantly lower than the averages for universities in the United States and for colleges, universities, and professional schools in Michigan. Completion of the FRIB would increase the number of NSCL staff from about 340 to about 500; however, the general nature of the operations and the adequacy of the existing Occupational Health and Safety program to manage workplace hazards should not change. Assuming that the average injury/illness rates shown in Chapter 4, Table 4-3 (1.4 recordable injury/illness cases and 0.2 lost work-time cases per 200,000 labor hours) remain unchanged, the addition of 160 full-time staff (320,000 person-hours per year) would be expected to result in an increase in the number of NSCL staff reportable injuries/illnesses from about 4.8 per year to about 7 per year. The average number of lost work-time injuries/illnesses per year among the NSCL staff would be expected to increase from 0.7 to 1.0.

Radiological Safety

The stated strategy of radiation safety management at the NSCL is to: 1) abide by all limits and license commitments, 2) maintain, as a goal, individual and collective doses consistent with the MSU and FRIB as low as reasonably achievable (ALARA) program goals, and 3) manage the facility consistent with integrated safety management (ISM) practices through its certified ISO and OHSAS programs. Incidents and near-misses are investigated and subjected to causal analysis and corrective or preventative actions are developed, implemented and communicated to personnel. The strategy appears to be effective. Incidents and near-misses at NSCL since the institution of the current NSCL certified ISO 9001 (Quality Management Systems), ISO 14001 (Environmental Management Systems), and OHSAS 18001 (Occupational Health and Safety Management Systems) programs have been localized and were not considered to pose significant hazards to personnel, public or the environment. Since 1990, MSU has implemented and maintained an ALARA program, which has been implemented for NSCL operation and will be extended to the FRIB.

Construction workers would not normally be radiation workers and would be expected to receive radiation doses no more than is allowed to the general public under ALARA goals. When the final connection of the new target building is made to the existing experimental areas, some workers may require radiation worker training before they are allowed into existing NSCL areas.

For the October 2008 through September 2009 period, 443 personnel were monitored (i.e., assigned a personal radiation dosimeter). Of that number, 125 individuals received doses over 10 millirem/person/year. The highest dose recorded by any of these individual workers was 388 millirem, well below the regulatory limit of 5,000 millirem per year and the ALARA (i.e., MSU administrative) goal of 500 millirem per year. These values are representative of the

radiation safety record at the NSCL over the past 5 years. During that time no individual worker has exceeded the MSU ALARA goal.

The operation of the FRIB is expected to add about 160 technical staff positions (facility operations staff, visiting scientists, occupational safety and facility maintenance staff) to the existing NSCL complement. Many, if not all, of the new staff would be expected to be radiation workers and receive some radiation dose in the course of a year. The increased number and complexity of the operations associated with the FRIB may have the potential to increase the average worker doses. However, based on the evidence of past performance, the existing NSCL radiation safety management strategy should provide a suitable framework for developing specific controls needed to maintain individual and collective doses within the ALARA goals and well below regulatory limits.

Assuming that each of the approximate 600 FRIB radiation workers (443 current plus 160 additional for the FRIB) receives an average annual dose of 13 millirem/person/year, the projected collective dose to the whole worker population would be about 7.8 person-rem per year (the collective sum of all individual doses for 600 workers). Based on a dose-to-LCF factor of 0.0006 LCF per person-rem for both workers and the general public (DOE 2003), the probability of a single latent cancer fatality (LCF) resulting from radiation is estimated to be 0.0047. In other words, the probability that there would be 1 LCF among the 600 workers is about 0.005 or one-half of 1 percent per year. Over a 30-year facility operating life, the chance that there would be 1 LCF resulting from radiation among the worker population is about 0.14 or 14 percent.

5.1.9.2.2 Public Impact from Normal Operations

5.1.9.2.2.1 Impacts from Traffic

The estimated increase in local vehicle travel resulting from FRIB operations is presented in Table 5–6. Table 5–7 presents the projected accident and injury impacts of the increased traffic. Each year of operation of the FRIB is expected to result in approximately 2 additional traffic accidents in the surrounding region. Assuming accident, injury, and fatality rates remain unchanged, about 65 additional traffic accidents are expected over the 30-year projected operational life of the facility. About 16 additional injuries are expected during that period and the probability of a fatality would be about 0.2 or 2 chances in 10.

5.1.9.2.2.2 Impacts from Direct Radiation

NRC regulations and MSU Environmental Safety and Health (ESH) policies limit the total dose to individual members of the public to 100 millirem per year, with a limit of 2 millirem in any one hour from external (direct radiation) sources (10 CFR 20). Consistent with its ALARA program, MSU has committed to design goals for the FRIB of less than 10 millirem per year to the public with a maximum of 2 millirem in any one hour from external sources.

The direct radiation sources and potential dose impacts associated with operation of an accelerator facility can be estimated based on such factors as the properties of the particle beam, the physical configuration of the facility, the materials used in key components, and equipment performance characteristics. Documentation of these factors supports the ALARA program implementation and assures that the key elements of the program are maintained. Making

estimates of the public dose impacts and refining the facility design to meet radiological safety goals is an integral part of the design effort. Several iterations of the process are expected as the design progresses from conceptual to final. The buried configuration of the linac tunnel should be a positive attribute in this regard because of the shielding provided by the natural shielding of the soil covering the tunnels. At other large accelerators, shielding, beam dumps, and accelerator controls have been successfully designed and implemented to keep direct radiation impacts on the public well below applicable standards and the radiological safety performance of those facilities is being considered in the FRIB design. After FRIB operations begin, operational controls would be implemented and surveillance would be required to ensure that the regulatory limits are met, and also to assess performance against the design goal.

5.1.9.2.2.3 Impacts from Release of Radioactive Material to the Atmosphere

During the operation of the linac, radioactive material that could potentially be released to the atmosphere would be produced by two primary mechanisms: activation of air in the linac tunnel and target area by radiation produced by the beam interacting with matter, and activation of the water in the closed cooling loops for the target and beam stop. U.S. Environmental Protection Agency regulations (40 CFR 61) limit the annual dose to members of the public as a result of air emissions from a facility to 10 millirem. For the FRIB, MSU has committed to a design goal of 10 percent of the regulatory limit (1 millirem per year) as a result of airborne emissions to the nearest receptor. Based on a dose-to-LCF factor of 0.0006 LCF per person-rem, consistent with the recommendation of the DOE Office of Environmental and Policy Guidance (DOE 2003), this translates to an annual LCF probability of 6×10^{-7} or 6 chances in 10 million.

Linac tunnel air. Operation of the linac would activate the air in the tunnel, producing radioactive isotopes of nitrogen, oxygen, hydrogen, carbon, and other elements. To achieve the design goal of limiting radiation exposures to the public and workers consistent with the ALARA program, the exchange of air between the linac tunnel and the surrounding environments would need to be controlled. The facility conceptual design calls for the air in the tunnel to be continuously circulated and filtered to reduce the quantity of radioactive material in the air. When entry into the tunnel for maintenance is required, administrative controls would be used to delay the opening of the tunnel and the exchange of air with the outside environment until the short-lived (primarily gaseous) isotopes have decayed. The air would then be sampled to confirm that any release of radioactive or other hazardous material to the atmosphere is within acceptable limits. Because many of the radioactive isotopes that are expected to be produced in the tunnel have half-lives ranging from fractions of a second to a few hours, delaying the release of tunnel air for a period of hours following shutdown of the linac would make it possible to effectively manage the radioactive emissions. The design approach is that public radiation dose from release of the tunnel air to the environment immediately after shutdown of the linac several times per year would be at or below the regulatory limit, and that delaying the releases for even a few hours after shutdown would result in doses well below the design goal of 1 millirem per year.

Target and Beam Dump Cooling Water. The energy of the FRIB particle beam would be largely deposited in the targets and the beam dump, both of which require continuous cooling. The conceptual design accomplishes the heat removal function with closed cooling water loops. Activation of the cooling water by the beam would produce a number of different isotopes of

nitrogen, oxygen, hydrogen, carbon, and other elements. In addition, hydrogen gas would be produced by radiolysis of the water. The use of closed cooling loops controls the release of volatile radioisotopes. To control the accumulation of hydrogen gas in the cooling water, a gas-liquid separator tank will be placed at a high point in the system. Gas that collects in the gas-liquid separator tank could be circulated through a closed system to convert the hydrogen gas to water while allowing the other gases and volatile radionuclides to accumulate in the gas phase until each reaches an equilibrium concentration dependent on its production rate and half-life or be processed via the FRIB offgas treatment system. The entire amount of mobile radioactivity created by the beam in the water would thereby be retained within the water loops and the offgas treatment system. To allow for periodic system maintenance, the conceptual design provides for the accumulated gases to be purged to a holding (decay) tank, where the radioactivity would be allowed to decrease before the contents are sampled, filtered, and released to the atmosphere.

At the conceptual design stage, the cooling water and offgas treatment systems are being configured to meet the regulatory limits on radioactive air emissions and to achieve the public dose design goal. The design features under consideration are straightforward and the technologies are mature.

5.1.9.2.2.4 Impacts from Release of Chemicals to the Atmosphere

Scattered radiation from the linac beam losses create ozone and oxides of nitrogen in the tunnel air. Preliminary calculations and experience at other accelerator facilities indicate that the concentrations of both ozone and nitrogen oxides in the tunnel air at the time of shutdown would be below the applicable emergency exposure guidelines (DOE 2009b) at the time of shutdown. Both materials are chemically reactive and degrade fairly rapidly through interactions with other materials in the air. As discussed in Section 5.1.9.2.3.1, opening of the tunnel following operations would need to be delayed to allow decay of the short-lived radionuclides in the air, and the air concentrations of both ozone and oxides of nitrogen should drop well below applicable emissions limits in that time.

5.1.9.2.2.5 Impacts from Irradiation of Groundwater

Neutrons produced from scattered linac beams that penetrate the tunnel wall activate various elements in the surrounding soil and groundwater. Radioactive material thus produced might contribute to public dose from the FRIB operation, primarily by the groundwater consumption pathway, if steps were not taken during the design and operation of the FRIB to ensure that the concentrations in the groundwater adjacent to the tunnels were very small.

Activation of soil and groundwater has been observed in connection with the operation of other high-energy particle accelerators. The FRIB is being designed to incorporate lessons learned from past experience at other accelerators in order to minimize the amount of groundwater activation with FRIB operations.

Depending on the final design, the FRIB linac tunnel could be beneath the groundwater table over its entire length. In addition, rainwater and snowmelt may also be in the region close to the tunnel walls. Scattered radiation from the beam that penetrates the tunnel walls and structural materials would have the potential to activate both soil and water directly outside the tunnel

walls. The water that may be outside the tunnel walls and subject to activation would not be readily available for consumption by the public. That water would have to migrate and would be diluted with time and distance. The nearest wells to the FRIB are on the south campus (over 900 meters or 0.56 miles away) and used for agricultural purposes. The radioactive material concentrations in any water that ultimately migrated away from the tunnels would be highly diluted and well below concentrations at the FRIB, and therefore well below any regulatory standard.

Design Goals to Ensure Minimal Impacts. As indicated in Section 5.1.3.2, FRIB operations could result in low levels of activation of groundwater, which MSU would manage according to NRC license requirements. The FRIB project has established a design goal that would keep the average radioactive material concentrations in groundwater in the region around the linac tunnel walls (within about 10 feet (3 meters)) below the drinking water limits established by EPA and therefore well below the NRC water effluent limits. The EPA limits apply to water provided by a drinking water supplier after pumping and filtering. Hence, ensuring that the water in the 99.9 percent volume adjacent to the FRIB tunnels would meet drinking water standards for radioactive materials provides a very high degree of protection of both the public and the environment. The FRIB design goals and regulatory limits are presented in Table 5–1. The FRIB goal of protecting the groundwater adjacent to the FRIB tunnels to EPA drinking water standards would ensure that the radioactive material concentrations in any water that ultimately migrated away from the tunnels to a point that it might be utilized as drinking water would be highly diluted and well below concentrations at the FRIB.

Preliminary Results of Modeling. Activation of groundwater outside the linac tunnel is being addressed at the conceptual design stage. A conservative, preliminary evaluation of the potential for groundwater activation has been performed as described in Section 5.1.3.2 and indicates that the baseline design for the tunnel walls and use of soldier piles for shoring provides adequate shielding to meet the FRIB project design goals (MSU 2010h). See Section 5.1.3.2 for more details. Thus if the groundwater concentration in the vicinity of the FRIB tunnels can be maintained below EPA drinking water standards, the potential for human impacts are small.

To ensure that the FRIB impacts from irradiation of groundwater are managed over the long term, the FRIB will use the combination of good design, operational controls, and surveillances during operation.

Design. The FRIB design process would reduce the potential for groundwater impacts by (1) reducing beam losses that would penetrate the linac and tunnel walls, and (2) ensuring that the tunnel wall design provides adequate shielding to reduce impacts on adjacent soils and groundwater.

Managing the routine beam losses (scattering) through design is important for several reasons. In addition to activating soil and water outside the tunnel, excessive beam loss may degrade both the operational capacity (useful beam energy) and activate equipment and materials inside the tunnel, thereby creating elevated radiation levels and doses to workers in the tunnel after shutdown. Therefore the entire linac system would be designed to minimize beam loss.

In addition, the tunnels walls would be designed to provide adequate shielding given the maximum beam loss from normal operations consistent with the design approach used at other linear accelerators

Operational Controls. The preliminary, conservative modeling approach assumes a continuous beam loss of 1 W/m over the entire length of the linac tunnel. It is also assumed that the groundwater adjacent to the tunnel remains stagnant for 30 years so that the calculated radionuclide concentrations in the water are at their maximum values. Diagnostic and protective features should reduce the average beam loss to less than the assumed value. The diagnostic and protective features would also limit temporary beam diversions to a few seconds or less and in the worst case would terminate the operation of the linac upon detection of abnormal conditions for which the control system could not correct. These features would be expected to limit the duration and intensity of any scattered or misdirected beam that might activate soil and groundwater outside the tunnel so that these abnormal operations have only a negligible contribution to soil activation.

Surveillance. Periodic measurements of radiation levels in the tunnel provide means to detect excessive beam scattering before the concentration of radioactive material in groundwater approaches a level of concern. Comparison of surveillance results with the radiation levels that are expected (based on the facility operating status and history) should highlight abnormal trends and cause them to be investigated. This would be corroborated with periodic groundwater samples. As time progresses, a groundwater sampling program would be developed in consultation with the pertinent regulatory agencies to ensure that any radioactive material in the groundwater is well characterized.

5.1.9.2.3 Impacts from Accidents

In accordance with National Environmental Policy Act guidelines, an assessment of the environmental impacts of proposed actions should include consideration of the potential impacts of “reasonably foreseeable accidents” and intentional destructive acts (DOE 2002). The results of the accident impact analyses provide information to the decision process with regard to the possible (as opposed to the expected) impacts from choosing a given alternative or course of action.

5.1.9.2.3.1 Reasonably Foreseeable Accidents

Accident conditions (including radiological) are initially postulated as part of the development of a conceptual design, which is ongoing for the FRIB. These analyses continually evolve as the design effort progresses to ensure all credible hazards are evaluated and appropriate controls are included in the design to safeguard the public, FRIB personnel, environment, and FRIB mission. For the FRIB, hazards that have been identified include electrical and chemical hazards, non-ionizing radiation (lasers), and waste handling, as well as ionizing radiation, oxygen-deficient atmosphere, and cryogenic hazards for the accelerator, target building, and support systems. Appendix C presents a summary of the results of the ongoing process of accident/hazard identification and evaluation and presents a listing of some of the more significant event types that are being addressed through the design process. Appendix C includes the range of accident conditions identified during the conceptual design effort and lists the possible causes or initiating

events, the nature of the impacts, and the design features or operational controls that would prevent the accident or mitigate the consequences. The adequacy of the initial suite of potential controls for these postulated accident scenarios is best understood when assessed for the individual accident scenarios as presented in Appendix C. The listed controls demonstrate both that controls can be selected to assure that the hazard can be adequately controlled and that there is adequate defense in depth within the design to assure that the facility can operate safely.

At the conceptual design stage, the details of possible accident scenarios and their associated frequencies are often very uncertain and it is difficult or impossible to distinguish “reasonably foreseeable” scenarios from those that are purely hypothetical. For some accidents, the radiological source terms can be estimated at the conceptual design stage based on the experience of other accelerator facilities and the expected performance of FRIB systems. For others, the source terms are more difficult to estimate until the design progresses. At this early stage of design, conservative and/or bounding conditions and analysis for the more significant types of events have been performed. Six representative accident scenarios that are being used to guide the design evolution are summarized below.

- **Loss of beam control.** Although some very small beam losses are anticipated for normal FRIB linac operation, a conservative analysis was performed for a focused 400-kilowatt proton beam loss at a single location on the linac beam pipe. The concrete tunnel wall was assumed to be 20 inches (51 centimeters) thick with nominally 23 feet (7 meters) of soil serving as additional shielding. Although typical beam diagnostics and control systems would be expected to automatically shut down the beam within a fraction of a second, it was determined that shutting the beam down within approximately 13 seconds would prevent the direct radiation dose to the public at ground level from exceeding the normal operation regulatory limit of 2 millirem in any one hour. If the beam loss is over a larger area (which is more likely than its being focused at single location) the dose rate at the ground level receptor location would be even lower.
- **Release of air activation products from the linac tunnel.** Some activation of air within the FRIB linac tunnel and target regions occurs during operation, resulting primarily in the production of short-lived radionuclides. Release of the activated air from the tunnel following shutdown of the accelerator would be controlled to allow most of the short-lived activity to decay before it is released. It was conservatively assumed that 100 percent of the activated air in the tunnel would be inadvertently released to the atmosphere immediately after shutdown of the linac after a full year of operation with a proton beam. The results indicate that administrative and engineered controls (e.g., filtration) would be needed to reduce the level of radioactivity in the tunnel air such that this event would not result in a significant dose to an individual at the surface. This accident is considered unlikely and even partially effective controls and safety systems would serve to delay the release and reduce the dose.
- **Fires in the linac tunnel or target building.** The most conservative cases were associated with a fire in either the graphite or lithium target within the target building. Analysis of the resulting maximum (100 percent) release to the environment from either accident indicates the need for safety controls to maintain the frequency and potential consequences of the postulated event at low levels. As indicated in Appendix C, the

controls in place for the beam operation (inert atmosphere, fire suppression system, and confinement system design) would either prevent the event entirely or appropriately reduce the consequences. The potential for a graphite target fire was postulated, but determined to be of such low likelihood that it was determined not to be credible. The lithium fire associated with a lithium-water reaction is presented below.

- **Lithium reaction with water.** Lithium, which has potential uses in the FRIB target and stripper, is assumed to react with cooling water as a result of a failure in either the water-filled beam dump or cooling water system within the vacuum confinement system. It was conservatively assumed that 100 percent of the activated target material (primarily beryllium) would become airborne in the target facility as a result of the reaction. Design and operational controls, such as the target facility configuration preventing water from directly impacting the lithium and primary and secondary confinement systems (each of which is filtered) would be expected to reduce the probability of this event or to appropriately mitigate the consequences if it were to occur. With safety controls in place, the resulting release to the environment would be very small.
- **Loss of helium inventory with maximum tritium concentration.** A conservative estimate of the tritium generated within the cryogenic helium in the linac tunnel was used to estimate the maximum tritium that could be released. If all the tritium and helium were released, the concentration in breathable air would be less than the regulatory limits for normal operations. As indicated in Appendix C, installed oxygen monitors and properly designed egress routes are needed to protect personnel in the linac tunnel or service areas from an oxygen deficient atmosphere hazard resulting from a postulated release of cryogenic helium.
- **Loss of confinement for the activated cooling water.** Small leaks are an anticipated event during FRIB operation. Accordingly, the systems would be designed to assure that leaks in heat exchangers cannot lead to a release directly to the environment. Activated cooling water loops would be within a controlled area (e.g., tunnel confinement) to provide positive control over any release of activated material. Secondly, a positive means of control would be provided to assure that the cooling water cannot go directly to the environment through the cooling towers (e.g., by providing intermediate cooling loops or double-walled heat exchangers). Thus, although leaks of these systems are anticipated, they are easily managed within the facility to prevent impacts on the environment or the public. Protection for FRIB workers would be incorporated in the facility design to limit their potential exposure.

Although there is a non-negligible possibility for radiation exposure to workers, the FRIB design and operational teams plan to make full use of the successful approaches to personnel protection that have been worked out during the last 60 years of accelerator development in the United States and abroad. All of the postulated scenarios above have the potential to impact workers or the public through exposure to radiation above MSU administrative and regulatory thresholds for normal operations if they are not prevented or mitigated. Levels of potential exposure cannot be precisely quantified without a specific detailed design, but given the controls and mitigations discussed, while exposures might exceed MSU ALARA goals, they would be prevented or if they occurred would not be expected to exceed established EPA and NRC regulatory standards.

Hence, considering the project approach to integrate safety and design and accounting for the anticipated administrative and engineered features in the facility, the maximum anticipated exposure to a worker would be less than 5 rem and a member of the public, 100 millirem total or 2 millirem in any one hour. This corresponds respectively to a LCF probability of .003 or three chances in 1,000 and a LCF probability of 1.2×10^{-6} or 1.2 chances in 1 million.

Part of the evolving design process is to identify and analyze design basis accidents, as well as to develop the features and strategies to prevent or mitigate them to ensure that the consequences and risk are well understood and appropriately controlled. The design and operational controls included in the FRIB design are intended to provide a robust level of protection against these postulated events and provide protection for the public, FRIB workers, and the environment. Based on the experience of other accelerator facilities, the evaluations presented in Appendix C and MSU's commitment to certain design features and safety controls for the FRIB, it is expected that the health and safety risk from foreseeable accidents can be managed at acceptably low levels through the facility design process and control of operations.

5.1.9.2.3.2 Intentional Destructive Acts

It is U.S. Department of Energy (DOE) policy that the environmental impacts of intentional destructive acts be considered in National Environmental Protection Act analyses (DOE 2006). DOE's *Recommendations for Analyzing Accidents under the National Environmental Policy Act* (DOE 2002) states that the consequences of an act of sabotage or terrorism could be addressed by comparison to those of a severe accident because the forces that could result in a release of radioactive or hazardous material would be similar to those considered in accident analyses. As discussed in Section 5.9.2.3.1, the radiological source terms for some postulated FRIB operational accident scenarios can be estimated at the conceptual design stage based on the experience of other accelerator facilities and the expected performance of FRIB system. Bounding source terms and conditions from these operational accident scenarios can be used to assess the potential impact of intentional destructive acts.

Because of its mission and design, the FRIB would not produce, use, or store large inventories of the types of materials that represent the primary sabotage/terrorist concern at DOE sites (i.e., radioactive materials and toxic chemicals that can be readily dispersed into the environment). The production of radiation ceases when the accelerator is turned off and much of the radioactive material created by its operation disappears (decays) within seconds or minutes. In general, the accident source terms being used for design purposes would bound the possible source terms for intentional destructive acts because design analyses assume that each of the several factors contributing to the source term is somehow maximized. To produce a comparable source term, a successful act of terror or sabotage would require both the effective dispersal of the radioactive material (through fire or explosion) and the defeat or compromise of preventive or mitigating features (possibly several). Because the most highly radioactive materials produced within the FRIB (targets) are located deep underground and heavily shielded by concrete structures, an overt external attack would pose little threat of dispersal.

The list of FRIB accident types in Section 5.1.9.2.3.1 suggests some possible destructive act scenarios that might apply. The environmental impacts of any intentional destructive acts directed against the FRIB would be comparable to those of the reasonably foreseeable accidents.

5.1.9.3 Decommissioning Impacts

It is expected that decommissioning of the FRIB would involve the following general types of work activities:

1. Removal of materials and equipment items for reuse or recycling
2. Removal of targets and other transferable radioactive or hazardous materials for disposal as waste
3. MSU assessment of the area for potential alternate use and potentially sealing the underground structures and isolating (burying) them in place
4. Removal or redeployment/reuse of aboveground structures

At the end of the operational life of a complex facility the operations and maintenance staff is often redirected to carry out the initial phases of stabilization and decommissioning (items 1 and 2 above). This practice takes advantage of the staff's existing work control processes and detailed knowledge of the facility and hazards. Because many of the actions to be taken in this phase of decommissioning (such as removal of components and packaging of waste) are similar to activities that would have been performed during the routine operation of the facility, it is reasonable to expect that accident/illness rates and occupational radiation exposures would be similar to those described in Section 5.1.9.2.1. Therefore, the net occupational health and safety impact of these initial stages of decommissioning should be comparable to those that would result from an additional 1 to 2 years of facility operation.

For work of the type suggested by items 3 and 4 above (isolation of underground structures and the removal/redeployment of aboveground structures), the work activities and resulting worker accident/illness rates should be more comparable to those for construction activities (assessed in Section 5.1.9.1) than those for facility operations. The number of labor hours needed to conduct the isolation and removal/redeployment phase of decommissioning should be a small fraction of the initial construction effort and the occupational health and safety impacts would be proportionately lower. For industrial facilities, the labor requirement for decommissioning is typically estimated at less than 10 percent of that required for construction. Impacts on workers can be scaled accordingly.

5.1.10 Waste Management

Construction

Construction of the FRIB would result in the generation of hazardous and nonhazardous waste. The estimated quantity of hazardous waste generated during construction is 79,000 pounds (36 metric tons) for hazardous waste solids and 3,600 gallons (13.7 cubic meters) for hazardous waste liquids. The estimated quantity of nonhazardous solids generated during construction is 3,900 cubic yards (3,000 cubic meters) of concrete; 610 cubic yards (470 cubic meters) of steel; and 4,760 cubic yards (3,600 cubic meters) of miscellaneous nonhazardous solid wastes including crushed stone, asphalt, and sand and gravel (i.e., mostly excavated waste material.) In addition, 1,200 board feet (2.8 cubic meters) of lumber is estimated to be generated as

nonhazardous solid waste during FRIB construction. Overall, construction wastes are expected to be generated in relatively small volumes (i.e., 10 percent of the total volume used during construction). Existing waste management capacities/processes at MSU easily absorb any temporary increases to waste volumes from FRIB construction activities. Nearly all MSU non-hazardous construction wastes would be recycled, consistent with the “Be Spartan Green” campaign to eliminate waste. It is concluded that FRIB non-hazardous construction wastes would have minimal impact on licensed waste disposal facilities.

Hazardous materials used during FRIB construction (e.g., oil, gasoline, paint) would be properly stored and secondary containment would be used to prevent spills or leaks. Waste material would be treated and disposed according to applicable regulatory compliance requirements. After collection in specified waste containers, proper documentation, and packaging, hazardous waste would be collected by a licensed waste hauler for treatment and disposal at a licensed facility, in accordance with the MSU Office of Radiation, Chemical, and Biological Safety (ORCBS) Waste Disposal Guide (MSU 2009c).

Operations

The types of waste generated during FRIB operations can be estimated from those generated by current NSCL operations (Table 5–6). The quantities waste volumes would increase to allow for the increased operations of the FRIB. Similar to the NSCL, the types of waste would include low-level radioactive waste, mixed low-level radioactive waste, hazardous waste (nonradioactive waste), and nonhazardous wastes typically associated with the operation of any industrial or laboratory facility. It is expected that all of these waste types and volumes would be managed within the capacities of the existing MSU disposal processes and facilities.

The volume of industrial wastewater discharged from current NSCL operations is approximately 100 gallons (380 liters) per day. The estimated volume of industrial wastewater discharge from FRIB operations is 300 gallons (1,100 liters) per day. Sanitary wastewater generation from the NSCL operations is approximately 12,000 gallons (45,000 liters) per day based on a conservative use estimate of 35 gallons (130 liters) of water per person per day with 340 people at the facility. The estimated quantity of sanitary wastewater to be generated from FRIB operations is 17,500 gallons (66,000 liters) per day using the same conservative estimate of 35 gallons (130 liters) of water per person per day with 500 people using the facility. The subsequent volume increase of sanitary wastewater during operations is approximately 47 percent. However, given the capacity of the MSU sanitary wastewater system with the ability to process wastewater from a student, faculty, and staff population of approximately 58,000 on campus (MSU 2009b), the volume of sanitary wastewater generated during FRIB operations is relatively small in comparison and the discharges would be well within the existing capacity of the MSU Physical Plant Division system.

Table 5–6. Annual Waste Generation from NSCL and FRIB Operations

Waste Generation During Operations	Existing NSCL Facility Operations	New FRIB (with NSCL) Operations
Hazardous/chemical solid waste	569 pounds (258 kilograms)	The quantities used would be scaled up conservatively 50 percent to support the increased use of these materials.
Hazardous/chemical liquid waste	1,500 gallons ^a (5680 liters) <ul style="list-style-type: none"> • Sulfuric acid: 1,320 gallons (5000 liters) • Biocide: 75 gallons (280 liters) • Scale & corrosion dispersant: 140 gallons (530 liters) • Additional small/negligible quantities of hazardous liquid waste (i.e., less than one drum) are processed annually and nominally one drum of solid waste (absorbent materials) to clean up spills are processed annually. 	The quantities used would be scaled up nominally by a factor of 4 to support the increased use of these materials for additional cooling towers.
Nonhazardous solids	Building waste: 250 cubic yards (190 cubic meters)	Solid wastes would increase with increased staffing. Disposal impact would be minimized with the increased capability of MSU's recycling program. See Chapter 4, Section 4.10, of this environmental assessment.
Sanitary wastewater	4,400,000 gallons (16,000,000 liters)	6,400,000 gallons (24,000,000 liters)
Industrial wastewater	36,000 gallons (140,000 liters)	110,000 gallons (420,000 liters)
Radiological Waste ^b	400 pounds (190 kilograms)	Radiological waste would be similar to NSCL waste, with the exception of some higher activity items. Disposal of these items would be handled on a case-by-case basis in accordance with U.S. Nuclear Regulatory Commission requirements.

^a Cooling tower wastewater treatment. NSCL uses two cooling towers.

^b Only low-level radioactive waste would be generated, no transuranic or high-level radioactive waste would be generated.

Key: FRIB=Facility for Rare Isotope Beams; NSCL=National Superconducting Cyclotron Laboratory.

Source: MSU 2010a.

Decommissioning

The types of waste generated during decommissioning of the FRIB are estimated to be similar to the types generated during construction and could be handled by existing facilities. Underground structures would be buried in place or otherwise managed per NRC requirements and any aboveground structures removed or redeployed (MSU 2010a) consistent with best management practices in a manner protective of the environment.

5.1.11 Transportation

Transportation impacts are presented for the following aspects:

- Traffic volume
- On-Campus Infrastructure
- Traffic accidents
- Waste shipments during operations

Chapter 4, Table 4–5, presents the 2005 average daily traffic volume for campus streets in the vicinity of the project site. These data were analyzed to determine the impacts of closing the section of Bogue Street between Shaw Lane and Wilson Road, and the section of Shaw Lane between Bogue Street and Wilson Road. In addition, the number of vehicle trips associated with construction and operations of the proposed facility were compared to the 2005 average daily traffic volumes of nearby roads to determine the additional impact on the roads, taking into account road closures due to construction.

Traffic accidents are determined by using statistics collected by the Michigan State Police (MSP 2009). Statistics representing roadway accidents in Michigan were available for the following factors:

- Total number of miles driven
- Number of vehicle accidents
- Number of fatalities resulting from accidents
- Number of injuries resulting from accidents
- Number of bicyclists killed
- Number of pedestrians killed

For the purposes of this analysis, data from the years 2006 through 2008 were used to develop an average frequency per mile for each of the above factors to reflect the most current trends. These frequencies are shown in Table 5–7.

Table 5–7. Frequency of Accidents and Related Consequences (per mile)^a

	Vehicle Accidents	Fatalities	Injuries	Bicyclist Fatalities	Pedestrian Fatalities
Average	3.09×10^{-06}	1.02×10^{-08}	7.66×10^{-07}	2.27×10^{-10}	1.24×10^{-09}

^a Represents a 3-year average of data from 2006 through 2008.

Note: These statewide statistics represent all motor vehicles (automobiles, trucks, and buses).

Source: MSP 2009.

These frequencies were used to calculate the projected number of motor vehicle accidents, fatalities, and injuries that would result from construction and operational activities; and to qualitatively determine the impacts on bicyclists and pedestrians. Assumptions were made as to how many miles would be driven. For example, an average one-way distance of 15 miles (24 kilometers) was used to determine impacts on employees commuting to the project site for work, whereas a one-way distance of 1 mile (1.6 kilometers) was used to estimate impacts associated with on-campus travel. The number of trips made for different activities was also estimated and multiplied by the number of miles per trip and the frequencies to quantitatively estimate the number of motor vehicle accidents, fatalities, and injuries.

ORCBS is responsible for ensuring radioactive materials and wastes are packaged and shipped in accordance with both NRC and U.S. Department of Transportation regulations. Transporting may involve walking or driving radioactive material across campus, or shipping off campus. All packages used to transport radioactive material must be strong, tight containers that would not leak under normal transportation conditions (such as dropping, jarring, or temperature extremes) (MSU 1996). In addition, ORCBS is responsible for collecting and shipping other regulated chemical and biological wastes (although neither NSCL nor the proposed FRIB generate biological wastes). Waste shipments usually contain wastes from several University departments to minimize the number of shipments made (MSU 2010a).

5.1.11.1 Construction

Under the straight configuration option, Bogue Street between Shaw Lane and Wilson Road would be closed for approximately 2 years during construction of the proposed facility. In addition, the Wharton Center surface parking area would be closed and demolished and used as a laydown area during the construction period. Shaw Lane between Bogue Street and Hagadorn Road would be closed to through-traffic for approximately 2 months if the linear option is selected (Glasmacher and Koch 2009). These road closures would impact vehicle traffic volume, bicycle and pedestrian traffic, parking availability, and use of city buses. Traffic would be rerouted or diverted to accommodate the road closures

Traffic Volume

Based on Table 4–5 in Section 4.11, approximately 6,300 vehicles per day travel on Bogue Street between Shaw Lane and Wilson Road. If this section of road is closed for 2 years, southbound traffic on Bogue Street (north of Shaw Lane) would be diverted onto North Shaw Lane or Shaw Lane. In general, traffic using Bogue Street to access the campus from Grand River Avenue

would decrease as people would access the campus from Grand River Avenue by using Hagadorn Road or Farm Lane. Northbound traffic on Bogue Street would be diverted onto Wilson Road. Because the traffic currently using Bogue Street between Shaw Lane and Wilson Road would disperse among several roads, it is expected that the increased traffic on the other streets would remain below the 1997 average daily traffic volume for each of these streets. The impact of using Wilson Road for temporary equipment stationing is not anticipated to have a significant impact on traffic due to the planned occasional use of this road.

The 2-month closure of Shaw Lane between Bogue Street and Wilson Road would divert approximately 11,000 to 12,000 vehicles per day to other connecting roads. It is anticipated that this east-west bound traffic through the middle of campus would primarily divert to Wilson Road, which also travels east-west. The 2005 average daily traffic for Wilson Road ranges from approximately 4,000 vehicles near the east athletic field to approximately 7,000 vehicles west of Bogue Street. Diversion of traffic from Shaw Lane to Wilson Road would most likely cause traffic levels to exceed the 1997 average daily traffic on Wilson Road for the 2-month period. Shaw Lane is also a primary route for traffic traveling to football games at Spartan Stadium; therefore, the 2-month closure of a portion of Shaw Lane would not be planned to occur during football season.

Construction activities would cause an increase of approximately 400 vehicles per day due to the shipment of construction materials and wastes, and the commuting of construction workers. The construction traffic would cause less than a 4 percent increase in total traffic on the surrounding roads. This impact assumes each construction worker drives a car and travels to the construction site on campus, workers do not carpool or use the bus, nor do the workers park in other parts of campus.

Temporary closures of Bogue Street and Shaw Lane would also impact pedestrian and bicycle traffic. Temporary walkways would be established, with sufficient safety features such as fencing to direct pedestrian and bicycle traffic around the construction site.

On-Campus Infrastructure

There are currently 400 parking spaces associated with the NSCL. Construction of the FRIB would eliminate these parking spaces and the Wharton Center surface parking lot during the construction period. Other nearby parking space is available within a one-block distance from the NSCL in the Shaw Lane parking ramp and the Wharton Center parking ramp. Currently, the Shaw Lane parking ramp is typically used near 100 percent capacity during the week while the Wharton Center parking ramp is typically at approximately 70 percent capacity for faculty and staff and 60 percent capacity for visitors (Fox 2010); therefore, available parking in the Wharton Center should provide sufficient parking during daytime hours despite the loss of 400 parking spaces as a portion of the visitor spaces could be re-assigned to faculty and staff. In addition, NSCL personnel and construction workers could use the bus system or park in other lots on campus.

Large entertainment events that occur on campus can create temporary increases in traffic. The Wharton Center is a location where events occur that require a large number of parking spaces and can increase traffic around the NSCL. The closure of a segment of Bogue Street would

impact the flow of traffic to these events; however, street signage would be used and campus police would be available for these events to direct traffic to and from the Wharton Center parking deck using Hagadorn Road and Wilson Road. Closure of a segment of Shaw Lane for 2 months would be more problematic when managing Wharton Center event traffic because (1) a large percentage of the daily number of vehicles that use Shaw Lane would be diverted to Wilson Road, and (2) the entrance to the Wharton Center parking ramp from Shaw Lane would be closed, leaving one entrance to the ramp off Wilson Road that could be used.

A bus stop is located on East Shaw Lane near Hagadorn Road. This bus stop is normally used by city buses traveling along Shaw Lane. During the 2-month construction period when East Shaw Lane would be closed, the bus stop on East Shaw Lane would be inaccessible. The buses that use this bus stop could most likely be re-routed south on Farm Lane to Wilson Road, traveling east-bound where passengers who would normally use the East Shaw Lane bus stop could instead use the bus stop in front of the Wharton Center. Since it is only about a one-block distance between the East Shaw Lane and Wharton Center bus stops, the additional walking distance required by passengers who would normally use the East Shaw Lane bus stop would be minimal.

Traffic Accidents

Table 5–8 shows the approximate number of shipments that would be made to support construction activities, the assumed distance for each type of trip, and the total miles. Excavated soil would either be shipped 1.2 miles (1.9 kilometers) to the soil disposal area located on East Mount Hope Road (Glasmacher and Koch 2009), or stored at the construction site. For purposes of analysis, it is assumed that the excavated soil would be transported to the staging area. For the other activities in Table 5–8, the assumed one-way mileage is considered conservative.

Table 5–8. Number of Trips and Total Miles Traveled for Construction Activities

Activity	Number of Trips ^a	Miles (one-way)	Total miles (two-way)
Excavated dirt from site	15,000	1.2 ^b	36,000
Truck trips for materials/supplies	7,500	20	300,000
Nonhazardous waste disposal	3,500	20	140,000
Hazardous waste shipments	11	50	1,100
Total - construction miles			477,100

^a MSU 2010a.

^b Glasmacher and Koch 2009.

Table 5–9 presents the estimated vehicle accident consequences using the frequency data in Table 5–7. The estimates for determining worker commuting impacts are based on a peak number of 175 workers commuting to the construction site for the total construction period, driving a two-way average of 30 miles.

Table 5–9. Estimated Impacts of Traffic Accidents

Activity	Number of Accidents	Number of Fatalities	Number of Injuries
Excavated dirt from site	0.11	3.66×10^{-04}	2.76×10^{-02}
Truck trips for materials/supplies	0.93	3.05×10^{-03}	2.30×10^{-01}
Nonhazardous waste disposal	0.43	1.42×10^{-03}	1.07×10^{-01}
Hazardous waste shipments	0.0034	1.12×10^{-05}	8.42×10^{-04}
Total - Construction Vehicles	1.47	4.9×10^{-03}	3.7×10^{-01}
Total - Worker Commute	16.5	5.44×10^{-02}	4.09

Based on Table 5–9, it is estimated that there could be fewer than 2 construction-related accidents involving a motor vehicle, with no fatalities or injuries. Construction workers commuting to the site could experience approximately 17 accidents, no fatalities, and 4 injuries over the duration of the construction period. These estimates are based on statewide statistics for both automobiles and trucks, and do not account for local factors such as traffic safety devices, police enforcement, and shared use of roads and parking areas with pedestrians and bicyclists.

5.1.11.2 Operations

Traffic Volume

Based on information in Table 5–10, approximately 160 additional FRIB personnel and visiting scientists would travel to the FRIB compared to current operations. Assuming this increase in personnel increases local traffic by approximately 160 vehicles, the impact on nearby roads would be less than 1 or 2 percent, a negligible increase in traffic (see Table 4–5). It is anticipated that visiting scientists would stay in nearby hotels and would potentially carpool or use mass transit to visit the FRIB, lessening the impact further.

Traffic Accidents

Table 5–10 shows the approximate number of personnel who travel daily to work under current operations at the NSCL, the increase in number of personnel who would be expected to work at the FRIB, and the assumed distance for each type of trip. For conservatism, it is assumed that there would be one person per vehicle (the analysis does not account for use of carpooling, buses, or cycling). Operations staff are assumed to live within an average distance of 15 miles (24 kilometers) off campus. Visiting scientists are assumed to stay in a hotel within the Lansing/East Lansing area and travel by car to the FRIB. Trips made by facility maintenance staff and administrative support staff are assumed to be within the campus area.

Table 5–10. Personnel Traveling to and from the National Superconducting Cyclotron Laboratory (NSCL)

Personnel Type	NSCL Number of Personnel*	Number of Additional FRIB Personnel	Miles Per Trip (one-way)
Operations staff	268	62	15
Visiting scientists (per day)	20	80	5
Facility maintenance staff	30	10	1
Admin support staff	22	8	1
One daily trip for supplies	1	1	2
Total	341	161	24

* MSU 2010a.

Table 5–11 shows the estimated number of additional accidents, fatalities, and injuries that would occur during FRIB operations as compared to the current NSCL operations. During FRIB operations, there would be an additional 2 traffic accidents that would not result in any injuries or fatalities as compared to current operations. Over a 30-year period, there would be an additional 65 traffic accidents with a total of 16 injuries but no fatalities.

Table 5–11. Transportation Impacts During Operations

Type of Transport	Current NSCL Operations			Proposed Action		
	Number of Accidents	Number of Fatalities	Number of Injuries	Number of Additional Accidents	Number of Additional Fatalities	Number of Additional Injuries
Regulated Waste Shipments	1.05×10^{-02}	3.46×10^{-05}	2.60×10^{-03}	0	0	0
Daily trips for supplies	3.21×10^{-03}	1.06×10^{-05}	7.96×10^{-04}	3.21×10^{-03}	1.06×10^{-05}	7.96×10^{-04}
Additional Personnel for the FRIB						
Operations staff	6.45	2.13×10^{-02}	1.60	1.49	4.92×10^{-03}	3.70×10^{-01}
Visiting scientists (per day)	1.61×10^{-01}	5.29×10^{-04}	3.98×10^{-02}	6.42×10^{-01}	2.11×10^{-03}	1.59×10^{-01}
Facility maintenance staff	4.82×10^{-02}	1.59×10^{-04}	1.19×10^{-02}	1.61×10^{-02}	5.29×10^{-05}	3.98×10^{-03}
Admin support staff	3.53×10^{-02}	1.16×10^{-04}	8.76×10^{-03}	1.28×10^{-02}	4.23×10^{-05}	3.19×10^{-03}
Total (per year)	6.71	2.21×10^{-02}	1.66	2.17	7.14×10^{-03}	5.38×10^{-01}
Total (30 years)	$2.01 \times 10^{+02}$	6.63×10^{-01}	$4.99 \times 10^{+01}$	$6.50 \times 10^{+01}$	2.14×10^{-01}	$1.61 \times 10^{+01}$

Key: FRIB=Facility for Rare Isotope Beams; NSCL=National Superconducting Cyclotron Laboratory.

Radioactive Waste

In 2009, there were approximately 35 truck trips to the NSCL by qualified waste management staff to pick up regulated wastes (MSU 2010a). These trips were not necessarily trips taken to the NSCL only, and may be part of a route of pickups performed by qualified waste management staff. The number of these trips should remain approximately the same during FRIB operations (MSU 2010a); therefore, there are no increased nonradiological risks associated with transport of radioactive, chemical, or biological wastes from FRIB with no additional traffic accidents or resulting fatalities or injuries occurring.

The radiological composition of radioactive waste that would be generated by FRIB operations would be comparable to radioactive waste generated by NSCL operations, with the exception of some higher activity radiological waste. The disposal of these higher activity items would be handled on a case-by-case basis and sent to a licensed facility for disposal (MSU 2010a). As there would be no additional trips to transport radioactive waste for disposal above what is currently conducted, and the radiological waste would be packaged as required by U.S. Department of Transportation regulations, the additional radiological risks to the driver and the public would be negligible. No transuranic waste would be generated from operations at the FRIB.

On-Campus Infrastructure

Under the folded configuration option, once construction is complete, there would be approximately 300 parking spaces available at the FRIB, which is 100 fewer parking spaces than what is currently available (MSU 2010a). It is expected that the loss of these spaces would be offset by available parking space in the Wharton Center parking ramp. Use of the bus stop on South Shaw Lane would resume.

The update to the Campus Master Plan recognizes the need for future improvements to reduce traffic within the center of campus and provide additional parking. The need for future improvements to the mass transit system and establishment of a coordinated bicycle system are also identified in the plan as a means to reduce on-campus automobile use (MSU 2006b).

5.1.12 Socioeconomics and Environmental Justice

This section describes the impacts on employment and the local economy from construction and operation of the proposed facility. This section also addresses environmental justice.

Construction

Construction of the FRIB is expected to last from 2012 through 2016. Annual construction employment is expected to peak at 175 employees (MSU 2010a). This equates to approximately 3.4 percent of construction industry employment in the Lansing-East Lansing Metropolitan Statistical Area (MSA). Construction occupations in the MSA are projected to increase 5.5 percent by 2016 (MDELEG 2010a; BLS 2010d). The majority of new employees would likely be supplied by the local labor force. The direct construction employment is estimated to generate indirect employment of 145 jobs in the local area, for a total impact of 320 jobs. The

average worker in the construction industry earned \$49,036 in wages and an estimated \$21,317 in benefits (MDELEG 2010b; BLS 2010d). It is estimated that total earnings of construction workers would be \$12.3 million during the peak year of construction. Earnings of indirect workers are estimated using the average annual wage for all industries in the Lansing-East Lansing MSA of \$37,856 and estimated benefits of \$16,457. Earnings of indirect workers are estimated to be \$7.9 million during the peak year. Total peak year earnings from both direct and indirect employment are estimated to be \$20.2 million. Total spending to build the facility is estimated to be approximately \$550 million, of which \$348 million is assumed to be spent locally (AEG 2008). Indirect economic output generated by that spending is estimated to be \$279 million, for a total economic impact of \$627 million during the construction phase. The value added to the local economy from construction spending in terms of final goods and services directly comparable to gross domestic product (GDP) is estimated to be \$64 million annually. This equates to approximately 0.4 percent of the Lansing-East Lansing MSA's 2008 GDP, and 11.2 percent of the MSA's 2008 output in the construction industry (BEA 2009).

Operations

When the facility is fully operational it is estimated that it would require approximately 500 operations and support staff. When compared to employment at the existing NSCL, the FRIB would add approximately 160 new jobs. This equates to approximately 2 percent of employment in the "professional and technical services" industry of the Lansing-East Lansing MSA. Due to the specialized nature of the facility, it is assumed that new operations employment would be supplied by an in-migration of workers from other areas. The new jobs at the FRIB would generate indirect employment of approximately 214 jobs throughout the MSA. The average worker in the professional and technical services industry earned \$54,236 in wages and an estimated \$23,577 in benefits (AEG 2008; MDELEG 2010b; BLS 2010d). It is estimated that the annual earnings of operations employees would be \$12.5 million. Earnings of indirect workers are calculated in the same manner as described above under construction. The annual earnings of indirect workers are estimated to be \$11.6 million, for a total earnings impact of approximately \$24 million annually. The annual operating budget of \$50 million (AEG 2008) is estimated to generate an indirect economic output of approximately \$40 million for a total impact of \$90 million in economic output. The value added from FRIB operations to the local economy in terms of final goods and services directly comparable to GDP is estimated to be \$56 million. This equates to approximately 0.3 percent of the Lansing-East Lansing MSA's 2008 GDP.

Environmental Justice

Chapter 4, Section 4.12 describes the population demographics for the city of East Lansing, Ingham County, and the Lansing-East Lansing MSA. The impact assessments presented in the various resource areas throughout this EA have not identified any high and adverse impacts on the general public resulting from the Proposed Action. Because there are no high and adverse impacts on the general public, there would be no disproportionately high and adverse impact on minority or low-income populations, regardless of whether these populations are distributed homogeneously across the general population or clustered in certain census blocks.

5.2 Cumulative Impacts of the Proposed Action

Cumulative impacts are those that may result from the incremental impacts of an action considered additively with the impacts of other past, present, and reasonably foreseeable future actions. Cumulative impacts are considered regardless of the agency or person undertaking the other actions (40 CFR 1508.7; CEQ 1997) and can result from the combined or synergistic effects of actions that are minor when considered individually over a period of time.

No past, present, or reasonably foreseeable future actions that are considered pertinent to the analysis of cumulative impacts for the Proposed Action have been identified at this time. The cumulative contribution of impacts that the conveyance and subsequent development of the property would make on the various environmental resources is expected to be minor.

Construction

The construction of the FRIB would take place in the developed area of the MSU campus. Construction of a NSCL upgrade of 206,500 gross square feet (19,180 square meters) to include construction of the FRIB is included in the Campus Master Plan. Construction of new facilities and renovation are common on this campus; it is estimated that the campus has added an average of approximately 200,000 gross square feet (18,600 square meters) every fiscal year since the issuance of the current Campus Master Plan in 2001 (MSU 2007a). The proposed facility would be consistent with current and expected development on the MSU campus. Construction of the addition to the Physical Science Building near the project site is scheduled to be completed in 2011. Construction of the FRIB would not begin until 2013. Because most of the major equipment and facilities in the NSCL would be subsumed into the FRIB, any NSCL decommissioning impacts have been incorporated into the FRIB impacts evaluated in this EA. No concurrent construction projects are anticipated to occur near the project site during the construction of the FRIB, thus no cumulative impacts from concurrent construction activities would occur.

Operation

The FRIB linac would replace the operation of the NCSL cyclotrons. The linac would be incorporated into the existing facilities over a period of approximately 6 months, during which neither the cyclotrons nor the linac would be operational. Thus, there would be no period during which both would be operational, and no cumulative impacts resulting from concurrent operation of the two facilities.

5.3 No Action Alternative

As described in Chapter 3, Section 3.2, under the No Action Alternative, the linac accelerator and its support facilities would not be constructed, and therefore, there would be no increase in construction-related emissions, waste generation, stormwater runoff, accidents, or traffic. The current NSCL operations would continue. As the types of research presently conducted at the facility would continue at the current level, the operations impacts of the No Action Alternative would be those described in Chapter 4, as the affected environment is the existing operations of the NSCL.

No alternative uses of the site have been identified for the campus area near the NSCL, and therefore, there are no reasonably foreseeable changes in impacts if the FRIB project does not go forward.

Chapter 6

AGENCIES AND PERSONS CONSULTED

6.1 Federal, State, and Local Agencies and Organizations

City of East Lansing, Michigan

Michigan State Historic Preservation Office

Michigan Department of Natural Resources and Environment, Wildlife Division

DEPARTMENT OF ENERGY

Notice of Intent To Prepare an Environmental Assessment, To Open a Public Scoping Period, and To Conduct a Public Scoping Meeting

AGENCY: Office of Science, Department of Energy.

ACTION: Notice of Intent to Prepare an Environmental Assessment, to open a public scoping period, and to conduct a public scoping meeting for the funding of the construction and operation of the Facility for Rare Isotope Beams at Michigan State University, East Lansing, Michigan.

SUMMARY: The Department of Energy (DOE) announces its intent to prepare an Environmental Assessment (EA) pursuant to the National Environmental Policy Act (NEPA) and to hold a public scoping meeting on the proposed Federal action to fund the construction and operation of the Facility for Rare Isotope Beams (FRIB) on the campus of Michigan State University (MSU) in East Lansing, Michigan. FRIB's design is composed of buildings and/or building additions for a heavy ion/proton accelerator, ancillary laboratories, and support facilities. Construction/operation would occur adjacent to the existing National Superconducting Cyclotron Laboratory (NSCL), which would ultimately be subsumed into FRIB. The EA will identify and assess potential environmental impacts from the Proposed Action and a range of reasonable alternatives so DOE can determine whether to prepare an environmental impact statement (EIS) or issue a finding of no significant impact (FONSI). DOE is also opening a 45-day scoping period to allow the public the opportunity to voice any concerns it might have and to make recommendations about the analytical approach and alternatives. During the scoping period, a public meeting will be held. If at any point during the preparation of the EA DOE determines that it is necessary to prepare an EIS, this scoping process will serve as the scoping process that would normally follow a Notice of Intent to prepare an EIS.

DATES: The public scoping period starts with the publication of this Notice in

the **Federal Register** and will continue until December 11, 2009. DOE will consider all comments received or postmarked by that date in defining the scope of the EA. Comments received or postmarked after that date will be considered to the extent practicable.

DOE invites public comment on the scope of this EA during a public scoping meeting from 6:30 p.m. to 10 p.m. on November 11, 2009 in room 1400 of the Biomedical and Physical Sciences Building (BPS) on the campus of Michigan State University, in East Lansing, Michigan. The scoping meeting will be preceded by an educational open house to be held from 4 p.m. to 6 p.m. at the NSCL, which is adjacent to BPS.

ADDRESSES: Written comments or suggestions on the scope of the EA may be submitted by mail to: FRIB Comments, U.S. Department of Energy, Office of Science, Chicago Office (STS), 9800 South Cass Avenue, Argonne, Illinois 60439; by toll free fax to 1-888-676-3672; by e-mail to frib.comments@ch.doe.gov; or through the EA Web site at <http://www.frib.msu.edu/NEPA/>.

The Pre-approval Draft EA is expected to be completed in the Spring of 2010. Advance requests for copies can also be made at this time via the methods above. In making your request, please specify whether you would like a paper copy, a compact disc, or notification of its availability on the Internet.

FOR FURTHER INFORMATION CONTACT: For further information on the proposed project, contact Mr. James Hawkins, FRIB Program Manager, U.S. Department of Energy, SC-26.2/ Germantown Building, 1000 Independence Avenue, SW., Washington, DC 20585-1290, by telephone at 301-903-3613, or via e-mail at James.Hawkins@science.doe.gov; or Dr. Thomas Glasmacher, FRIB Project Manager, Facility for Rare Isotope Beams, Michigan State University, East Lansing, MI 48824-1321, by telephone at 517-908-7750, or via e-mail at glasmacher@frib.msu.edu. The FRIB project is described in detail at the FRIB Web site, <http://www.frib.msu.edu/>.

For general information concerning DOE's NEPA process, contact Peter Siebach, NEPA Compliance Officer, U.S. Department of Energy, Office of Science-Chicago Office (STS), 9800 South Cass Avenue, Argonne, Illinois 60439, by telephone at 603-252-2007, or via e-mail at Peter.Siebach@ch.doe.gov. This Notice of Intent and general information on the DOE NEPA process are available at <http://www.gc.energy.gov/NEPA/>.

SUPPLEMENTARY INFORMATION:

Background

DOE published a "funding opportunity announcement" on May 20, 2008 seeking applications for the design and establishment of a particle acceleration facility—the FRIB—as a National User Facility. The FRIB would take about a decade to design and build and would cost an estimated \$550 million, including cost sharing from MSU. MSU would also make other, non-monetary contributions. The research conducted at FRIB would involve experimentation with intense beams of rare isotopes—short-lived nuclei not normally found on earth—that will enable researchers to address pressing questions in nuclear structure and nuclear astrophysics. Two applications were received. The results of an independent merit review process, as well as an environmental critique, i.e., a comparison of environmental information provided in the applications, were considered by DOE and on December 11, 2008, MSU was selected to design and establish the FRIB. A cooperative agreement with DOE was signed on June 8, 2009, establishing terms and conditions for the work to be performed and ensuring DOE's substantial ongoing involvement in the project.

Purpose and Need for Action

DOE has a mission to advance our basic understanding of science. Scientific research at a FRIB holds the promise to vastly expand our understanding of nuclear astrophysics and nuclear structure. DOE determined that the establishment of the FRIB is a high priority for the future of U.S. nuclear science research. The FRIB establishes a highly sophisticated research laboratory that would produce intense beams of rare isotopes. These beams enable scientists to study the nuclear reactions that power stars and generate the elements found on earth; explore the structure of the nuclei of atoms, which form the core of all matter and the forces that bind them together; test current theories about the fundamental nature of matter; and play a role in developing new nuclear medicines and other societal applications of rare isotopes.

The FRIB concept has undergone numerous studies and assessments within DOE and by independent parties such as the National Research Council of the National Academy of Sciences. These studies—in addition to the joint DOE/National Science Foundation (NSF) Nuclear Science Advisory Committee (NSAC) 2007 Long Range Plan—concluded that such a facility is

a vital part of the U.S. nuclear science portfolio, complements existing and planned international efforts, and will provide capabilities unmatched elsewhere.

Proposed Action and Alternatives

DOE and MSU propose to construct and operate the FRIB on approximately 10 acres on its East Lansing, Michigan campus. Its design is composed of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities such as a cryomodule, and offices. Construction/operations would occur on campus, adjacent to the existing NSCL, which would ultimately be subsumed into FRIB. The function and scope of operations of FRIB would be similar to NSCL, but FRIB would have substantially more power. The existing NSCL research program relies on a 200 MeV/u coupled cyclotron driver accelerator with 1–2 kW beam power. FRIB would be capable of 200 MeV/u energy for all species, higher energies for lighter ions up to 600 MeV/u for protons with up to 400 kW beam power. A 12 MeV/u reaccelerator is also planned for the facility. Upgrade is possible, but not currently planned.

Most of the structures that would house the accelerator would be thick-walled, reinforced concrete structures. The heavy ion linear accelerator (linac) would be located in a tunnel below grade. A trench (varying between 30 and 75 feet below grade up to 1,800 feet long) would be excavated for the accelerator, necessitating that Bogue Street be closed between Wilson Road and East Shaw Lane two years and portions of East Shaw Lane possibly to be closed for a number of months. The high energy end of the accelerator would join with the existing NSCL building.

The ground where FRIB would be located has been previously disturbed. Like the NSCL, the FRIB would be licensed by the Nuclear Regulatory Commission (NRC). Operation would result in low levels of activation of air and groundwater, which MSU would manage in accordance with NRC license requirements and Environmental Protection Agency regulations. Radiation doses to workers and members of the public from operation of the FRIB would be limited to well below NRC radiation protection standards.

As required by NEPA, the EA will evaluate a No Action alternative to serve as a basis for comparison with the action alternatives. Under the No Action alternative, a FRIB would not be constructed and operated at MSU,

although other use of the site could not be ruled out.

Preliminary Identification of Environmental Issues

In the EA, DOE will examine public health and safety effects and environmental impacts from the construction and operation of the proposed FRIB at MSU. This notice is to inform the public of the proposed project and to solicit comments and suggestions for consideration in the preparation of the EA. To help the public frame its comments, this notice contains a preliminary list of potential environmental issues that DOE has tentatively identified for analysis. It is not intended to be comprehensive, nor to imply any predetermination of impacts. These issues include:

1. Impacts from construction accidents;
2. Impacts to both workers and the public from potential exposure to radiation and other hazards under routine operations and credible accident scenarios including natural disasters (e.g., floods, hurricanes, tornadoes, and seismic events);
3. Transportation related impacts;
4. Impacts on surface and groundwater and on water use and quality;
5. Impacts on air and soil;
6. Socioeconomic impacts;
7. Disproportionately high and adverse impacts on minority and low income populations;
8. Impacts on land-use plans, policies and controls, and visual resources;
9. Pollution prevention and waste management practices and activities;
10. Unavoidable adverse impacts and irreversible and irretrievable commitments of resources;
11. Cumulative environmental effects of past, present, and reasonably foreseeable future actions;
12. Status of compliance with all applicable Federal, state and local statutes and regulations, international agreements, and required Federal and State environmental permits, consultations, and notifications; and
13. Impacts of intentional destructive acts, including sabotage and terrorism.

Since the proposed site is adjacent to a currently operating accelerator facility and would involve digging and construction in previously disturbed areas now occupied primarily by parking lots and roads, impacts in several areas are expected to be minor. These impact areas will therefore not be evaluated in detail:

- Impacts on protected, threatened, endangered, or sensitive species of animals or plants, or their critical habitats;

- Impacts on cultural or historic resources; and
- Impacts on floodplains and wetlands.

Scoping Process

DOE invites Federal agencies, State, local and Tribal governments, the general public and international community to participate in the scoping process both to refine the environmental issues to be analyzed and to identify the reasonable range of alternatives. Both oral and written comments will be considered and given equal weight by DOE. The public scoping period starts with the publication of this Notice in the *Federal Register* and will continue until December 11, 2009. DOE will consider all comments received or postmarked by then in defining the scope of the EA. Comments received or postmarked after that date will be considered to the extent practicable.

The scoping meeting will be held at the location, date, and times indicated above under the DATES section. It will provide interested parties the opportunity to ask questions about the project and comment on the EA scope. A facilitator will establish procedures needed to ensure that everyone who wishes to speak has the opportunity to do so. Should any speaker desire to provide further information that cannot be presented within the designated time, such additional information may be submitted in writing by the date listed in the DATES section. Both oral and written comments will be considered and given equal weight by DOE.

The scoping meeting will be preceded by an educational open house, to be held at the location, date, and times indicated above under the DATES section. During the open house, members of the public can register to provide oral comments at the scoping meeting, provide written comments, view FRIB informational materials, engage project staff, and tour the existing NSCL.

The Pre-approval Draft EA is planned to be issued for state and public review by the Spring of 2010. Persons submitting comments during the scoping process will receive a copy. Others who would like to receive a copy of the draft EA when it is issued should notify DOE per the ADDRESSES section above.

If at any time during preparation of the EA DOE determines that potentially significant environmental impacts might occur with the implementation of the Proposed Action and that an EIS would be needed, DOE will issue a Notice of Intent to prepare an EIS in the *Federal*

Register. In that case, this scoping process will serve as the scoping process that normally would follow a Notice of Intent to prepare an EIS. Accordingly, DOE will consider any comments on the scope of the EA received during this scoping process in preparing such an EIS.

Issued in Washington, DC on October 20, 2009.

DEPARTMENT OF ENERGY

Environmental Management Site-Specific Advisory Board, Northern New Mexico

AGENCY: Department of Energy.
ACTION: Notice of open meeting.

SUMMARY: This notice announces a meeting of the Environmental Management Site-Specific Advisory Board (EM SSAB), Northern New Mexico. The Federal Advisory Committee Act (Pub. L. 92-463, 86 Stat. 770) requires that public notice of this meeting be announced in the **Federal Register**.

DATES: Wednesday, November 18, 2009, 1 p.m.–8 p.m.

ADDRESSES: Holiday Inn Santa Fe, 4048 Cerillos Road, Santa Fe, New Mexico.

FOR FURTHER INFORMATION CONTACT: Menice Santistevan, Northern New Mexico Citizens' Advisory Board (NNMCAB), 1660 Old Pecos Trail, Suite B, Santa Fe, NM 87505. Phone (505) 995-0393; Fax (505) 989-1752 or e-mail: msantistevan@doeal.gov.

SUPPLEMENTARY INFORMATION:

Purpose of the Board: The purpose of the Board is to make recommendations to DOE in the areas of environmental restoration, waste management, and related activities.

Tentative Agenda

- 1 p.m. Call to Order by Co-Deputy Designated Federal Officers, Ed Worth and Lee Bishop.
- Establishment of a Quorum, Lorelei Novak:
- Roll Call;
- Excused Absences.
- Welcome and Introductions, Ralph Phelps.
- Approval of Agenda.
- Approval of September 30, 2009 Meeting Minutes.
- 1:15 p.m. Old Business:
- Written reports;

- Other items.

- 1:30 p.m. New Business.
- 1:45 p.m. Co-Deputy Designated Federal Officers' Report, Ed Worth and Lee Bishop.
- 2:15 p.m. NNMCAB Annual Evaluation Report, Pam Henline.
- 2:45 p.m. Break.
- 3 p.m. Matters From Board Members.
- 3:30 p.m. Presentation on Los Alamos National Laboratory Groundwater Monitoring System (Existing and New Wells), Danny Katzman.
- 5 p.m. Dinner Break.
- 6 p.m. Public Comment Period.
- 6:15 p.m. Consideration and Action on Recommendation(s).
- 7:00 p.m. End of Year Report, Michael Graham.
- 7:45 p.m. Meeting Feedback.
- 8 p.m. Adjourn, Ed Worth and Lee Bishop.

Public Participation: The EM SSAB, Northern New Mexico, welcomes the attendance of the public at its advisory committee meetings and will make every effort to accommodate persons with physical disabilities or special needs. If you require special accommodations due to a disability, please contact Menice Santistevan at least seven days in advance of the meeting at the telephone number listed above. Written statements may be filed with the Board either before or after the meeting. Individuals who wish to make oral statements pertaining to agenda items should contact Menice Santistevan at the address or telephone number listed above. Requests must be received five days prior to the meeting and reasonable provision will be made to include the presentation in the agenda. The Deputy Designated Federal Officer is empowered to conduct the meeting in a fashion that will facilitate the orderly conduct of business. Individuals wishing to make public comment will be provided a maximum of five minutes to present their comments.

Minutes: Minutes will be available by writing or calling Menice Santistevan at the address or phone number listed above. Minutes and other Board documents are on the Internet at: <http://www.nnmcab.org/>.

Issued at Washington, DC on October 20, 2009.

Rachel Samuel,
Deputy Committee Management Officer.

APPENDIX C

PRELIMINARY ASSESSMENT OF FRIB ACCIDENT HAZARDS

The event summaries provided in this section are a summary of the results of the ongoing process of accident/hazard identification and evaluation and represent some (not all) of the more significant event types that are being addressed through the design process. These scenarios are provided to demonstrate that credible controls are available to prevent or mitigate the postulated accident scenarios identified for operation of the Facility for Rare Isotope Beams (FRIB). As the design and safety basis evolves, so do the control strategy and specific controls identified for each of the hazards and postulated events where the potential exists for a significant exposure to FRIB workers or the public. This selection process is integral to the preliminary design process.

Preliminary Assessment of Accident Hazards at the Facility for Rare Isotope Beams

Event/Hazard	Possible Cause or Initiating Condition	Possible Prevention or Mitigation Measures
<p>Tunnel Air Loss of Confinement – Air in the linac tunnel becomes activated during operation. Unmitigated, the activated air could be above 10 CFR Part 20^a limits for release to the environment.</p>	<ul style="list-style-type: none"> • Operator error -- entering the tunnel before short-lived radionuclides adequately decay • Ventilation system failure allowing air to be exhausted to the environment • External events that cause loss of confinement of the tunnel entry/exit locations • Failure of the isolation system between the linac tunnel and the utility service area. 	<ul style="list-style-type: none"> • Closed loop air handling system during linac operation limiting air exchange with the environment • Tunnel air handling system would include appropriate filtering and conditioning of the air to reduce activated materials. This could include humidity control, which would limit tritium activity and filtration (e.g., a combination of industrial, HEPA, and activated charcoal filters) to remove material. • Delay of 4 hours after beam trip before personnel reentry or starting air exchange between the linac tunnel and the environment. If industrial hygiene monitoring determines that the air quality meets defined parameters, then reentry could be permitted at an earlier time. • Pressure in the linac tunnel would be monitored and maintained at a pressure lower than the environment or the utility services area. • Ventilation system damper design (“fail as is” and monitoring of damper position) and interlock with administrative controls to verify position prior to operation. • Robust linac tunnel design and entry points provide a passive barrier between the activated air in the tunnel and either the service area or public environment.
<p>Target Facility Air Loss of Confinement – Air in the Target Facility becomes activated during operation. Unmitigated, the activated air could be above 10 CFR Part 20 limits for release to the environment.</p>	<ul style="list-style-type: none"> • Operator error -- entering the confinement before short lived radionuclides adequately decay • Ventilation system failure allowing air to be exhausted to the environment • External events that cause loss of confinement of the Target Facility entry/exit locations • Failure of the isolation system between the Target Facility confinement and the personnel access areas. 	<ul style="list-style-type: none"> • Closed loop air handling system during operation limiting air exchange with the environment • Target Facility air handling system would include appropriate filtering and conditioning of the air to reduce activated materials. This could include humidity control which would limit tritium activity and filtration (e.g., a combination of industrial, HEPA, and activated charcoal filters) to remove material. • Delay after beam trip before personnel reentry or starting air exchange between the Target Facility confinement and the environment. Industrial hygiene monitoring determines air quality meets defined parameters before reentry. • Pressure in the Target Facility confinement would be

Preliminary Assessment of Accident Hazards at the Facility for Rare Isotope Beams

Event/Hazard	Possible Cause or Initiating Condition	Possible Prevention or Mitigation Measures
<p>Coolant water leak - Failure of the cooling water system allows activated cooling water to spill in the utility service area or cooling tower area with potential exposure to workers.</p>	<ul style="list-style-type: none"> • Piping or component failure, including seal or packing failure. • Heat exchanger tube failure • Human error during maintenance or operations • Impact from equipment (e.g., lifting or moving heavy equipment). 	<p>monitored and maintained at a pressure lower than the environment or the personnel access areas.</p> <ul style="list-style-type: none"> • Water activation control via resin beds, tritium getter, etc. as needed to limit (mitigate) the potential release consequences from a spill. • Heat exchanger design (potentially double-walled heat exchanger design) • Monitoring and removal and disposal of highly activated water system components as necessary. • Including an intermediate loop between the primary cooling loop and the cooling tower.
<p>Failure of the cryogenic system causing an ODH (oxygen deficient hazard) for workers or the public.</p>	<ul style="list-style-type: none"> • Mechanical failure • Human error during maintenance • Loss of cooling/insulation for the cryogenic system 	<p>Linac tunnel:</p> <ul style="list-style-type: none"> • Oxygen detection and alarms along the tunnel when personnel are in the tunnel • Egress locations in the tunnel designed to limit lighter than air gases from entering the egress area and thus limits the potential for ODH issues in the stairs used for egress. • Additional ventilation for the tunnel for the region of the tunnel where oxygen monitoring detects a potential ODH concern. This would pull fresh air toward the break and preferentially exhaust the leaking helium. • Cryogenic system design requires multiple barriers to leakage, limiting the potential for direct leakage to the environment. • Cryogenic system pressure relief devices to remove helium from the line and prevent rupture or other failures of the helium into the tunnel. <p>Target Building:</p> <ul style="list-style-type: none"> • Oxygen detection and alarm in the facility when personnel are in the area. • Additional ventilation for the room or region of the facility where oxygen monitoring detects a potential ODH concern. This would pull fresh air toward the break and preferentially exhaust the leaking helium. • Cryogenic system design requires multiple barriers to leakage, limiting the potential for direct leakage to the environment.

Preliminary Assessment of Accident Hazards at the Facility for Rare Isotope Beams

Event/Hazard	Possible Cause or Initiating Condition	Possible Prevention or Mitigation Measures
		<ul style="list-style-type: none"> • Cryogenic system pressure relief devices to remove helium from the line and prevent rupture or other failures of the helium into the facility. <p>Cryoplant:</p> <ul style="list-style-type: none"> • Oxygen detection and alarm within all regions of the facility. • Egress locations in the plant are designed to limit lighter than air gases from entering the egress area and thus limits the potential for ODH issues in the egress site. • Additional ventilation for the room where oxygen monitoring detects a potential ODH concern. This would pull fresh air toward the break and preferentially exhaust the leaking helium. • Cryogenic system design requires multiple barriers to leakage, limiting the potential for direct leakage to the environment. • Cryogenic system pressure relief devices to remove helium from the line and prevent rupture or other failures of the helium into the facility.
<p>Failure of the cryogenic system causing a release of the tritium resulting in exposure to workers or the public.</p>	<ul style="list-style-type: none"> • Mechanical failure • Human error during maintenance • Loss of cooling/insulation for the cryogenic system 	<ul style="list-style-type: none"> • Activation of the helium within the linac tunnel and the target facility results in low to negligible levels of tritium in the cryogenic system. A release of the cryogenic helium that, when mixed with air to get a 5 percent oxygen concentration, would be well below radiological exposure limits. The major concern is ODH and not radiological exposure. • The same mitigating features as for ODH hazards are also applicable for this event.
<p>Failure of the activated cooling water lines leading to a release directly to the environment.</p>	<ul style="list-style-type: none"> • Mechanical failure • Human error during maintenance 	<ul style="list-style-type: none"> • Activated cooling water loops include either a double-walled heat exchanger or an intermediate loop preventing activated water from leaving the controlled (primary or secondary) confinement within the facility. • Cooling lines that exit the confinement system are monitored for activation. • Pressure differences are maintained to assure that activated water would not leak to a system that could fail with a release directly to the public environment.

Preliminary Assessment of Accident Hazards at the Facility for Rare Isotope Beams

Event/Hazard	Possible Cause or Initiating Condition	Possible Prevention or Mitigation Measures
		<ul style="list-style-type: none"> • Cooling water activation and contamination would be monitored and the water cleaned or disposed of as needed. • Filter systems to remove radioactivity from the water would be included in primary cooling loops.
<p>Direct exposure to workers or the public from loss of beam control (direction) leading to beam impacting beam pipe wall.</p>	<ul style="list-style-type: none"> • Loss of control for magnet (cryogenic or warm) • Mechanical failure • Human error during maintenance or beam tuning • Change in beam rigidity due to a magnet malfunction. 	<ul style="list-style-type: none"> • Machine Protection System detecting beam losses and tripping the beam when radiation levels in the tunnel, target facilities, or the fragment pre-separator exceed expected conditions. • Personnel Protection System detecting beam losses and tripping the beam to limit potential exposure to a member of the public to less than 2 millirem in any 1 hour or exposure to a worker above MSU ALARA goals. • In known high-loss areas (e.g., stripper region), local shielding would be provided to mitigate the potential consequences from these regions.
<p>Lithium Target release due to lithium/water reaction resulting from a loss of confinement for the water-cooled beam dump.</p>	<ul style="list-style-type: none"> • Mechanical failure of water-cooled beam dump allows water to leak into the common vacuum system with lithium target (if this concept is chosen) • Leaks in cooling lines for shielding and other components that lead to system overpressure leading to confinement breach 	<ul style="list-style-type: none"> • Minimize lithium quantity in the target module. • Layout of water filled beam dump and cooling lines prevents liquid water direct contact with the lithium target. • Target module design with shutters that close on fault detection and isolate the lithium target from the remainder of the system. • System inert atmosphere provided on system failure. The lithium target is isolated by shutters from the remainder of the system and the internals flooded with inert gas (expected to be argon) to limit/prevent lithium/water reaction.
<p>Graphite Target Fire – During and for a very short time after beam operation on the graphite target, the material is hot enough that if it were to come in contact with air it would result in a fire.</p>	<ul style="list-style-type: none"> • Confinement system boundary failure. 	<ul style="list-style-type: none"> • Robust vacuum system designed as confinement for the target material. • Inherent design of the target cooling system which cools the target within a few revolutions reducing the frequency of a fire. • Venting of vacuum system with inert gas before target removal • Target Facility confinement system with filtered HVAC

Preliminary Assessment of Accident Hazards at the Facility for Rare Isotope Beams

Event/Hazard	Possible Cause or Initiating Condition	Possible Prevention or Mitigation Measures
		preventing material from being released to the environment.
<p>Water Beam Dump System Failure – A failure in the water beam dump system would release activated water within the Target Building.</p>	<ul style="list-style-type: none"> • Mechanical failure of the water dump outer boundary. • Change in beam rigidity due to improper controls on beam operations, with increased beam energy leading to failure of the beam dump confinement. • Beam dump rotation inappropriate for operation. A dump that is operating a reduced rotation rate would lead to premature failure of the water beam dump walls • Failure of the rotational seal causing leaks or affecting system rotation. • Loss of water flow leads to steam buildup and system failure. 	<ul style="list-style-type: none"> • Vacuum system would be designed such that water from an in-vacuum leak can be locally contained in easily removed • Area is managed as a contaminated area limiting the impact of leaks in this region. • Water cooling loop for the beam dump include water contamination control which limits the impact of a system failure. • The floor design in this area includes a floor sump to capture any leakage. • Vacuum system is monitored and can be automatically isolated as needed. • Water cooling system monitoring would verify water dump cooling is adequate for the beam operation.

Key ALARA=as low as reasonably achievable; HEPA= high-efficiency particulate air; HVAC=heating, ventilation, and air conditioning; MSU=Michigan State University; ODH=oxygen-deficient hazard; tritium=hydrogen-3.

APPENDIX D
CULTURAL RESOURCE STUDY AND CONSULTATIONS

D.1 Cultural Resource Study and Consultations

MICHIGAN STATE UNIVERSITY

DATE: February 25, 2010
TO: Whom It May Concern
FROM: Lynne Goldstein, Ph.D., RPA
Professor of Anthropology
Director, Campus Archaeology Program
RE: Potential archaeological resources in planned F-RIB project area

The MSU Campus Archaeology Program has completed a preliminary review of the area included within the proposed F-RIB project area. Although there is a possibility that some historic and prehistoric resources may be affected by the excavation and construction of the accelerator and adjacent spaces, it is our view that this possibility is unlikely in all but one area.

The Campus Archaeology Program has conducted a number of archaeological assessments across MSU's campus. The F-RIB project area, near Bogue Street, and bounded on the north and south by Shaw Lane and Wilson Road, has already been extensively modified by buildings, roads, and utility installations. Historical maps, archives, and aerial photographs do not indicate the presence of historical structures in this area prior to campus expansion during the 1950s and 60s. Although a number of the extant structures in this area were built in the early 1960s (such as Owen and McDonel Hall), the F-RIB project as currently proposed will not affect these buildings or their surrounding areas.

The project area is within 1200 feet of the Red Cedar River, but the extensive modification to the landscape by the University all but negates the possibility of prehistoric sites being present. Nonetheless, an MSU Campus Archaeologist must monitor the excavation and construction for the F-RIB project in order to mitigate any potential disturbances to culturally sensitive materials. Further, the excavations for this project will go deeper than any survey method or technique that archaeologists commonly use. Close monitoring of the excavations will be especially important for this reason, since we will be able to examine profiles and horizons that we do not ordinarily have the opportunity to see. The F-RIB construction team understands this, and has indicated their willingness to allow access to the site so that we can monitor the area during excavations.

Our area of concern is not related directly to the project area itself, but to where the excavation materials will be deposited along Mt. Hope Road. This space, known as Lot-89, is bounded by Mt. Hope, Farm Lane, and the C & O Railroad. Its most recent use has been as an unpaved parking lot. Historical documentation indicates the presence of an early 20th century farmstead in the eastern portion of the lot. In the near future, this lot is slated to become a paved parking lot. We recommend that Campus Archaeology be provided resources to mitigate this site, as it will be directly impacted by activities of the F-RIB project.

We have attached a map indicating the location of the F-RIB project area and the location of Lot-89 and the early 20th century farmstead.

Lansing, MI 48909-8240

Dear Sir or Madam:

SUBJECT: SECTION 106 CONSULTATION FOR FACILITY FOR RARE ISOTOPE BEAMS (FRIB), MICHIGAN STATE UNIVERSITY (MSU), EAST LANSING, MICHIGAN

The U.S. Department of Energy (DOE) and MSU are partnering on the construction and operation of the FRIB on the MSU campus. The purpose of this letter is to provide a determination to your office to satisfy the consultation requirements of Section 106 of the National Historic Preservation Act (16 U.S.C. § 470f), as amended (NHPA).

FRIB will enable physicists to study the nuclear reactions that power stars and that have generated the elements found on Earth; explore the structure of the nuclei of atoms, which form the core of all matter and the forces that bind them together; test current theories about the fundamental nature of matter; and play a role in developing new nuclear medicines and other societal applications of rare isotopes. The total project cost is estimated to be approximately \$550M. Because of the Federal contribution, it qualifies as a "Federal undertaking" under NHPA and is therefore subject to the requirements of the Advisory Council on Historic Preservation regulations for Protection of Historic Properties (36 CFR Part 800).

DOE has worked with MSU to complete the enclosed Application for Section 106 Review. Based on the Application and associated supporting information, DOE has determined, pursuant to 36 CFR § 800.4(d)(1), that no historic properties will be affected.

Printed on Recycled Paper

Environmental Review Coordinator

-2-

March 1, 2010

I note that a historic farmstead was identified by MSU's Campus Archaeology Program during their internal review (see enclosed memorandum from Dr. Lynne Goldstein). However, DOE and MSU have no plans to engage in the "type of activity that has the potential to cause effects on historic properties" (36 CFR § 800.3(a)) in the vicinity of the farmstead. Moreover, while the farmstead site would be adjacent to the area designated for FRIB related soils storage and disposal, the site would be outside of the storage/disposal area and would be protected to ensure it is left undisturbed. Please also note that while MSU is considering constructing a paved parking lot which would have the potential to impact the farmstead, it is entirely unrelated to the Federal undertaking or the FRIB Project in general.

Please feel free to contact me via telephone at 630-252-2007, or by e-mail at peter.siebach@ch.doe.gov. Alternatively, you can contact our Federal Project Director, Mr. Ronald Lutha via telephone at 630-252-8173 or via e-mail at ronald.lutha@ch.doe.gov.

Sincerely,

Peter R. Siebach, Acting Director
Program Support Services

D.2 Biological Resources Consultations

Informal biological resources consultations were conducted with the U. S. Fish and Wildlife Service and the Michigan Department of Natural Resources and Environment. An assessment of the potential impacts was conducted in accordance with the process identified in the following comments from Tameka Dandridge of the U.S. Fish and Wildlife Service. Discussions with the agency indicated its concurrence with the “no effect” conclusion.

Subsequent discussions with Lori Sargent, Nongame Wildlife Biologist with the Michigan Department of Natural Resources & Environment, indicated her agreement that the potential for harm was minimal. Those discussions resulted in the letter from the Michigan Department of Natural Resources & Environment that concluded “The projects should have no impact on rare or unique natural features at the location specified above if it proceeds according to the plans provided.”

U.S. Fish and Wildlife Service, Tameka Dandridge:

Endangered Species Act Section 7 Consultation - electronic initiation

Page 1 of 2

EE01

From: Tameka_Dandridge@fws.gov
Sent: Thursday, April 01, 2010 11:52 AM
To: FRIB Comments
Subject: Endangered Species Act Section 7 Consultation - electronic initiation

Please refer to the below information for initiating section 7 consultations with the U.S. Fish and Wildlife Service as well as obtaining species lists.

Region 3 of the U.S. Fish and Wildlife Service has designed a regional endangered species website to help federal agencies and their non-federal representatives complete section 7 consultations under the Endangered Species Act. The website is intended to be very useful for both federal agencies with section 7 obligations and non-federal entities. Please initiate consultations pursuant to the Endangered Species Act electronically, using the below websites. Some consultations may be concluded with this process without contacting this office. The following provides a brief description of the website.

Section 7 Consultation Main Page -
<http://www.fws.gov/midwest/endangered/section7/index.html>
This main Endangered Species Act Section 7 consultation webpage has been designed to provide a broad range of information, and includes links to the following specific pages:

- Section 7(a)(2) Consultation – An explanation of the consultation process
- Section 7(a)(2) Technical Assistance
- Guidelines for Preparing a Biological Assessment
- Section 7(a)(2) Guidance for Specific Species
- Section 7 Consultation Handbook

Section 7(a)(2) Technical Assistance page -
<http://www.fws.gov/midwest/endangered/section7/s7process/index.htm>
This page is designed to guide you through the consultation process step by step. By following the instructions, agencies can determine their action area, whether listed species may be found within the action area, and if the project may affect listed species.

Federal agencies and non-federal representatives will find several products on the site that can streamline the consultation process. When determining if listed species may be located within a project area, agencies can download county specific species lists for all of the states in Region 3. Species specific best management practices will also eventually be available. Example letters and templates are available to assist with documenting “no effect” determinations and preparing requests for concurrence on “not likely to adversely affect” determinations.

In addition, refer to the Michigan Department of Natural Resources and Environment Endangered Species Assessment website, www.mcgi.state.mi.us/esa and contact Ms. Lori Sargent at SargentL@michigan.gov for information regarding the protection of threatened and endangered species under state law. State law may require a permit in advance of any work that could potentially damage, destroy or displace state-listed species.

Bald eagle information
Bald eagles are no longer federally listed under the Endangered Species Act (ESA). However, bald eagles, along with their foraging and winter roosting habitat, remain protected pursuant to the Bald and Golden Eagle Protection Act (BGEPA) and Migratory Bird Treaty Act (MBTA). Disturbance of these birds should be minimized and any resulting take must be permitted by the

Endangered Species Act Section 7 Consultation - electronic initiation

Page 2 of 2

US Fish and Wildlife Service (Service). The National Bald Eagle Management Guidelines offer guidance on minimizing any disturbance that may be caused by project activities near eagle nests.

EE01

Limited permits to disturb nesting eagles and, in some cases, remove nest trees are available from the Service. Applicants must meet the permit requirements as specified in the BGEPA and the resulting disturbance or take must be compatible with the ongoing preservation of the species, as determined by the Service. For more information on eagle protections, permit requirements, and to view the Bald Eagle Management Guidelines, please visit <http://www.fws.gov/migratorybirds/baldeagle.htm>. For technical assistance with assessing your project's impacts on bald eagles or applying for a permit, please contact Matt Stuber at 517-351-8469.

Chicago, Illinois 60439

**SUBJECT: Proposed Construction and Operation of the Facility for Rare Isotope Beams at
Michigan State University in East Lansing**

Dear Mr. Siebach:

The location of the proposed projects were checked against known localities for rare species and unique natural features, which are recorded in a statewide database. This continuously updated database is a comprehensive source of existing data on Michigan's endangered, threatened, or otherwise significant plant and animal species, natural plant communities, and other natural features. Records in the database indicate that a qualified observer has documented the presence of special natural features at a site. The absence of records in the database for a particular site may mean that the site has not been surveyed. The only way to obtain a definitive statement on the status of natural features is to have a competent biologist perform a complete field survey.

Under Act 451 of 1994, the Natural Resources and Environmental Protection Act, Part 365, Endangered Species Protection, "a person shall not take, possess, transport, ... fish, plants, and wildlife indigenous to the state and determined to be endangered or threatened," unless first receiving an Endangered Species Permit from the Department of Natural Resources & Environment, Wildlife Division. The presence of threatened or endangered species does not preclude activities or development, but may require alterations in the project plan. *Species may be present that have not been recorded in the database.*

The following is a summary of the results of the review in Ingham County, section 18, T4N R1W:

The projects should have no impact on rare or unique natural features at the locations specified above if it proceeds according to the plans provided. Please contact Ms. Lori Sargent for an evaluation if the project plans are changed.

Thank you in for your coordination in addressing the protection of Michigan's natural resource heritage. Responses and correspondence can be sent to: Michigan Department of Natural Resources & Environment, Wildlife Division, PO Box 30444, Lansing, MI 48909. If you have further questions, please contact Ms. Sargent at 517-373-9418, or at SargentL@michigan.gov.

Sincerely,

A handwritten signature in black ink, appearing to read "Russ Mason".

Russ Mason, Ph.D., Chief
Wildlife Division
517-373-1263

APPENDIX E ENVIRONMENTAL SYNOPSIS

Prior to award, DOE underwent a competitive procurement process and selected MSU based on the merits of its application. Part of that process was the preparation of an "environmental critique," which is a comparative analysis of environmental issues pertinent to the decision (10 CFR, Section 1021 .216). A publicly available summary, which DOE refers to as an "environmental synopsis" is also enclosed.

ENVIRONMENTAL SYNOPSIS: FACILITY FOR RARE ISOTOPE BEAMS

PURPOSE

Department of Energy (DOE) National Environmental Policy Act (NEPA) regulations found at Title 10 Code of Federal Regulations, Section 1021.216 establish environmental review requirements for DOE competitive procurements. The requirements include preparation of an “environmental critique” of proposals in the competitive range to include:

- A brief discussion of the purpose of the procurement and each offer, including any site, system, or process variations among the offers having environmental implications;
- A discussion of the salient characteristics of each offeror's proposed site, system, or process as well as alternative sites, systems, or processes;
- A brief comparative evaluation of the potential environmental impacts of the offers, which will address direct and indirect effects, short-term and long-term effects, proposed mitigation measures, adverse effects that cannot be avoided, areas where important environmental information is incomplete and unavailable, unresolved environmental issues and practicable mitigating measures not included in the offeror's proposal; and
- To the extent known for each offer, a list of Federal, Tribal, state, and local government permits, licenses, and approvals, if any, that must be obtained.

The intent is to help the selection official in decision-making. The “environmental synopsis” is a publicly available summary of the environmental critique.

BACKGROUND

DOE published a “funding opportunity announcement” on May 20, 2008 seeking applications for the design, construction, and operation of a particle acceleration facility - the Facility for Rare Isotope Beams (FRIB). The research conducted at FRIB would involve experimentation with intense beams of rare isotopes—short-lived nuclei not normally found on earth—that will enable researchers to address pressing questions in nuclear structure and nuclear astrophysics. Two applications were received. The results of an independent merit review process, as well as the environmental critique, were considered by DOE and on December 11, 2008, Michigan State University (MSU) was selected to design and establish the FRIB.

SITE SUMMARY/SALIENT CHARACTERISTICS OF APPLICATIONS

Michigan State University

Michigan State University (MSU) proposed to construct and operate the FRIB on 10.5 acres on its East Lansing, Michigan campus. Its design is composed of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities such as a cryomodule, and offices. Construction/operations would occur in the middle of campus,

Environmental Synopsis -- Facility For Rare Isotope Beams

adjacent to the existing National Superconducting Cyclotron Laboratory (NSCL), which would ultimately be subsumed into FRIB. The function and scope of operations of FRIB would be similar to NSCL, but FRIB would have substantially more power. The existing NSCL research program relies on a 200 MeV/u coupled cyclotron driver accelerator with 1-2 kW beam power. FRIB would be capable of 200 MeV/u energy and up to 400 kW beam power. A 12 MeV/u reaccelerator is also planned for the facility. Upgrade is possible, but limited space is available. The linac tunnel would be situated in an excavation up to 50 ft below grade. The ground where FRIB would be located has been previously disturbed. The Nuclear Regulatory Agency would have regulatory jurisdiction over the FRIB. MSU's broad scope license would be modified to cover oversight of all accelerator related activities.

Application B

Construction and operation were proposed to occur at an existing National Laboratory operated by a contractor for the Department of Energy. The proposed design included construction of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, technical support facilities such as a cryomodule, and offices. Construction/operations were proposed to occur at the fringes of the developed part of the Laboratory, within and adjacent to complementary operations, e.g., a small heavy ion linac. The FRIB was proposed to use a 200 MeV/u heavy ion and 600 MeV/u proton linac driver with up to 400 kW beam power. Existing infrastructure was proposed to be modified and redeployed as a reaccelerator. Space was available for substantial upgrade within the 40 acres to be set aside for FRIB. The FRIB linac tunnel was proposed to be situated at or near grade, covered by an earthen berm. The site where FRIB (including the linac, target area, laboratories, and offices) was proposed to be located had been previously disturbed. It was intended that oversight occur per DOE Orders.

COMPARATIVE EVALUATION

The following table provides a comparison of the Environmental Critique criteria discussed above:

	Environmental Critique Criteria			
	1 Applicant's awareness of project-related requirements	2 Potential environmental impacts of the proposed work	3 Proposed mitigation measures	4 Adverse effects that cannot be avoided
Offeror Michigan State University	Acceptable	Acceptable	Acceptable	Acceptable
"Application B"	Acceptable	Acceptable	Acceptable	Acceptable

Other possible adjectival ratings were "marginal" and "unacceptable/unknown".

Both applications had the potential to activate air and water in close proximity to the beam line; however, levels of activation would be low, and historically (at other existing accelerators) these

Environmental Synopsis -- Facility For Rare Isotope Beams

have been routinely and safely controlled well below applicable safety standards. In both cases, potential radiation exposure to workers and the public were estimated to be well below standards. It was noted that the greater potential for public interest at MSU, as a result of proximity to students and the public, could be largely addressed through enhanced public participation, identical or similar to what is performed during an Environmental Impact Statement process.

CONCLUSION

It was determined that all of the physical, environmental impacts identified for both of the applications would be minor and localized, and could be successfully managed to further reduce them, and hence, little discrimination between the applications was possible on this basis.

Prepared by:

**Peter R. Siebach, NEPA Compliance Officer
U.S. Department of Energy

APPENDIX F COMMENTS AND RESPONSES

F.1 Background

On March 16, 2010, the U.S. Department of Energy (DOE) published the *Draft Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing Michigan (FRIB EA)*, which analyzed the Proposed Action, as well as the No Action Alternative. A 30-day comment period followed, during which DOE received four comment documents.

During the comment period, DOE held a public meeting on March 24, 2010, on the campus of Michigan State University (MSU) in East Lansing. In addition, the public was encouraged to provide comments via e-mail, mail, toll-free fax, or through the project website. All comments received during the comment period, which ended on April 16, 2010, were considered in finalizing the *FRIB EA* and developing the draft Finding of No Significant Impact (FONSI).

F.2 Public Meeting Format

The public meeting was announced in local newspapers (*Lansing State Journal*, *The State New*, and *City Pulse*) one week prior to the meeting, in addition to the direct notification of stakeholders by DOE and MSU.

Prior to the meeting an open house was held to allow attendees to view informational materials, register to present oral comments, and speak informally with DOE and MSU officials and subject matter experts. The open house was followed by a welcoming statement by Dr. J. Ian Gray, Vice President of MSU's Office of Research and Graduate Studies. Mr. Ronald Lutha, DOE's Office of Science FRIB Project Director, provided a project overview and Mr. Peter Siebach, the NEPA Compliance Officer for DOE's Office of Science, presented the results of the analyses contained in the *Draft FRIB EA* as well as the National Environmental Policy Act (NEPA) process and schedule. Attendees were then given the opportunity to ask clarifying questions on the material presented, although none did so. The meeting ended with attendees offering oral comments that were recorded by a court reporter to ensure accuracy.

F.3 Comment Documents and Responses

Approximately 16 individuals attended the public meeting and 2 provided oral comments. Comment collection efforts are summarized in Table F-1.

Table F-1. Commenters by Submission Method

Submission Method	Commenters
E-mail	U.S. Fish and Wildlife Service Tameka Dandridge
Fax	Michigan Department of Natural Resources and Environment Liane J. Shekter Smith
Mail	Michigan State Historic Preservation Office Martha MacFarlane-Faes Michigan Department of Natural Resources and Environment Russ Mason
Public Meeting (Transcript)	City of East Lansing Timothy Dempsey Rosenman, Kenneth

The comment documents and transcript yielded 16 comments, categorized by subject as shown in Table F-2.

Table F-2. Comments by Issue Category

Issue Category	Number of Comments Received
Alternatives	1
Cultural Resources	3
Design/Construction/ Operation/Decommissioning	2
Biological Resources	2
Geology and Soils	1
Human Health and Safety	2
NEPA Process	2
Waste Management	2
Water Resources	1

Images of the comment documents and meeting transcript are presented along with DOE's response to specific comments by submission method as shown in Table F-1.

Section 7(a)(2) Technical Assistance page -
<http://www.fws.gov/midwest/endangered/section7/s7process/index.htm>
This page is designed to guide you through the consultation process step by step. By following the instructions, agencies can determine their action area, whether listed species may be found within the action area, and if the project may affect listed species.

Federal agencies and non-federal representatives will find several products on the site that can streamline the consultation process. When determining if listed species may be located within a project area, agencies can download county specific species lists for all of the states in Region 3. Species specific best management practices will also eventually be available. Example letters and templates are available to assist with documenting “no effect” determinations and preparing requests for concurrence on “not likely to adversely affect” determinations.

In addition, refer to the Michigan Department of Natural Resources and Environment Endangered Species Assessment website, www.mcgi.state.mi.us/esa and contact Ms. Lori Sargent at SargentL@michigan.gov for information regarding the protection of threatened and endangered species under state law. State law may require a permit in advance of any work that could potentially damage, destroy or displace state-listed species.

Bald eagle information
Bald eagles are no longer federally listed under the Endangered Species Act (ESA). However, bald eagles, along with their foraging and winter roosting habitat, remain protected pursuant to the Bald and Golden Eagle Protection Act (BGEPA) and Migratory Bird Treaty Act (MBTA). Disturbance of these birds should be minimized and any resulting take must be permitted by the

US Fish and Wildlife Service (Service). The National Bald Eagle Management Guidelines offer guidance on minimizing any disturbance that may be caused by project activities near eagle nests.

EE01

Limited permits to disturb nesting eagles and, in some cases, remove nest trees are available from the Service. Applicants must meet the permit requirements as specified in the BGEPA and the resulting disturbance or take must be compatible with the ongoing preservation of the species, as determined by the Service. For more information on eagle protections, permit requirements, and to view the Bald Eagle Management Guidelines, please visit <http://www.fws.gov/migratorybirds/baldeagle.htm>. For technical assistance with assessing your project's impacts on bald eagles or applying for a permit, please contact Matt Snuber at 517-351-8469.

EE01 Response:

1. Biological Resources

DOE determined that there were no threatened and endangered species or critical habitat in the vicinity of the project area, so formal consultation with the U.S. Fish and Wildlife Service (FWS) and the Michigan Department of Natural Resources and Environment are not necessary. The FWS website regarding threatened and endangered species was reviewed and corroborates the information provided in Chapter 4, Section 4.5, and listed in Appendix B.

FRIB Comments
U.S. Department of Energy (STS)
Chicago Office
9800 South Cass Avenue
Argonne, Illinois 60439

Dear Sir or Madam:

This is in response to the letter of March 16, 2010, from Mr. Peter R. Siebach, U.S. Department of Energy (DOE), announcing the 30-day comment period on the *Draft Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan (Draft FRIB EA)*.

Staff of the Michigan Department of Natural Resources and Environment (DNRE), Waste and Hazardous Materials Division (WHMD), has met with staff from both the DOE and Michigan State University on several occasions over the last year.

The WHMD coordinated the review of the Draft FRIB EA by other DNRE divisions and offices and believes that the Environmental Assessment adequately identifies and evaluates the potential environmental impacts of this project and that the issuance of a Finding of No Significant Impact is warranted. Nonetheless, we do have some comments for your consideration. These comments are presented in an enclosure with this letter. 1

If you have any questions regarding this matter, please feel free to contact me or you may also contact Mr. Thor Strong, Chief, Radiological Protection Section, WHMD, at 517-241-1252.

Sincerely,

Liane J. Shekter Smith, P.E., Acting Chief
Waste and Hazardous Materials Division
517-353-9523

Final Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan

Michigan Department of Natural Resources and Environment
 March 2010 Draft Environmental Assessment for DOE Funding of the
 Construction and Operation of the Facility for Rare Isotope Beams
 Michigan State University, East Lansing, Michigan

April 13, 2010, Comments

Page	Topic	Comment	
4-8	Diagram	The map does not depict the Upper Grand River Watershed.	2
4-19	Waste Management - "RCRA Part B Permit"	The description of hazardous waste management units is incorrect. The hazardous waste management facility operating license issued by the Michigan Department of Natural Resources and Environment allows Michigan State University (MSU) to store containers at one location, the Waste Storage Facility. MSU is not authorized to manage hazardous waste in tank storage units and treatment units. This would require an expansion to the existing operating license.	3
5-2	Soils	With respect to the plans for excavation and storage of soil materials, if coal ash or other impacted soils are encountered, those materials must be handled properly and separately from clean fill and not be used as backfill.	4
5-21	Surveillance - Groundwater Sampling	Need to include a plan for how the periodic groundwater samples will be taken.	5
5-28	Radiological Waste	Reference is made to "some higher activity items." Need to specify whether these items will be Class A, B, or C low-level radioactive waste (LLRW), and if Class B or C LLRW, a plan for storage should be presented.	6
	Non-Class A LLRW	Volume data should be entered into the cells for low-specific activity wastes.	
5-37	National Superconducting Cyclotron Laboratory (NSCL)	Because the FRIB "replaces" the operation of the NSCL, need to indicate whether there are plans to decommission portions of the NSCL and the impacts of such activity.	7

FE01 Responses:

1. NEPA Process

DOE acknowledges the commenter's observations that the *FRIB EA* adequately identifies and evaluates the potential environmental impacts and a FONSI should be issued.

2. Water Resources

Figure 4-4 was revised to add a legend that indicates the shaded area is the Upper Grand River Watershed.

3. Waste Management

The description of the hazardous waste management units in Section 4.10 was revised to clarify that the RCRA Part B Permit allows MSU to store containers at the Waste Storage Facility before being shipped off site.

4. Geology and Soils

Section 5.12 was expanded to indicate that if coal ash or other impacted soils are encountered the materials would be handled properly and separated from clean fill and not be used as backfill.

5. Design/Construction/Operation/Decommission

Section 5.1.9.2.2.5 was revised to indicate that as the project progresses, MSU would consult with MDNRE to develop a groundwater sampling program.

6. Management

Table 5–6 was revised to clarify that the expected radioactive waste generated by FRIB operations would be handled on a case-by-case basis.

7. Design/Construction/Operation/Decommission

Section 5.2 was revised to indicate that because most of the major equipment and facilities in the current NSCL would be subsumed into the FRIB, any NSCL decommissioning impacts have been incorporated into the FRIB impacts evaluated in this EA.

RE: ER-04-292 Facility for Rare Isotope Beams, NSCL/Cyclotron Laboratory, Michigan State University,
East Lansing, MI 48824, Section 19, T4N, R1W, Ingham County. (DOE)

Dear Mr. Siebach:

Under the authority of Section 106 of the National Historic Preservation Act of 1966, as amended, we have reviewed the above-cited undertaking at the location noted above. Based on the information provided for our review, it is the opinion of the State Historic Preservation Officer (SHPO) that **no historic properties are affected** within the area of potential effects of this undertaking. 1

The views of the public are essential to informed decision making in the Section 106 process. Federal Agency Officials or their delegated authorities must plan to involve the public in a manner that reflects the nature and complexity of the undertaking, its effects on historic properties and other provisions per 36 CFR § 800.2(d). We remind you that Federal Agency Officials or their delegated authorities are required to consult with the appropriate Indian tribe and/or Tribal Historic Preservation Officer (THPO) when the undertaking may occur on or affect any historic properties on tribal lands. **In all cases**, whether the project occurs on tribal lands or not, Federal Agency Officials or their delegated authorities are also required to make a reasonable and good faith effort to identify any Indian tribes or Native Hawaiian organizations that might attach religious and cultural significance to historic properties in the area of potential effects and invite them to be consulting parties per 36 CFR § 800.2(c-f). 2

This letter evidences DOE's compliance with 36 CFR § 800.4 "Identification of historic properties", and the fulfillment of DOE's responsibility to notify the SHPO, as a consulting party in the Section 106 process, under 36 CFR § 800.4(d)(1) "No historic properties affected".

The State Historic Preservation Office is not the office of record for this undertaking. You are therefore asked to maintain a copy of this letter with your environmental review record for this undertaking. If the scope of work changes in any way, or if artifacts or bones are discovered, please notify this office immediately. 3

If you have any questions, please contact Brian Greenell, Cultural Resource Protection Specialist, at (517) 335-2721 or by email at ER@michigan.gov. Please reference our project number in all communication with this office regarding this undertaking. Thank you for this opportunity to review and comment, and for your cooperation.

Sincerely,

Martha MacFarlane-Faes

ME01 Response:

1. Cultural Resources

DOE acknowledges the opinion of the Michigan State Historic Preservation Office that no historic properties would be affected by the construction of the FRIB as planned.

2. Cultural Resources

DOE would consult with the appropriate Indian tribe and/or Tribal Historic Preservation Office should any historic properties or artifacts are discovered during site preparation and construction.

3. Cultural Resources

DOE would consult with the Michigan State Historic Preservation Office should the scope of the FRIB project changes or any historic properties or artifacts are discovered during site preparation and construction.

SUBJECT: **Proposed Construction and Operation of the Facility for Rare Isotope Beams at Michigan State University in East Lansing**

Dear Mr. Siebach:

The location of the proposed projects were checked against known localities for rare species and unique natural features, which are recorded in a statewide database. This continuously updated database is a comprehensive source of existing data on Michigan's endangered, threatened, or otherwise significant plant and animal species, natural plant communities, and other natural features. Records in the database indicate that a qualified observer has documented the presence of special natural features at a site. The absence of records in the database for a particular site may mean that the site has not been surveyed. The only way to obtain a definitive statement on the status of natural features is to have a competent biologist perform a complete field survey.

Under Act 451 of 1994, the Natural Resources and Environmental Protection Act, Part 365, Endangered Species Protection, "a person shall not take, possess, transport, ... fish, plants, and wildlife indigenous to the state and determined to be endangered or threatened," unless first receiving an Endangered Species Permit from the Department of Natural Resources & Environment, Wildlife Division. The presence of threatened or endangered species does not preclude activities or development but may require alterations in the project plan. *Species may be present that have not been recorded in the database.*

The following is a summary of the results of the review in Ingham County, section 18, T4N R1W:

The projects should have no impact on rare or unique natural features at the locations specified above if it proceeds according to the plans provided. Please contact Ms. Lori Sargent for an evaluation if the project plans are changed.

Thank you in for your coordination in addressing the protection of Michigan's natural resource heritage. Responses and correspondence can be sent to: Michigan Department of Natural Resources & Environment, Wildlife Division, PO Box 30444, Lansing, MI 48909. If you have further questions, please contact Ms. Sargent at 517-373-9418, or at SargentL@michigan.gov.

Sincerely,

Russ Mason, Ph.D., Chief
Wildlife Division

MS. ROBINSON: So this is the formal comment period. We will have first Kenneth Rosenman followed by Tim Dempsey. Mr. Rosenman.

MR. ROSEMAN: Thank you. So my name is Tim Rosenman, and I'm a physician and I'm a professor here at MSU, and I wanted to look at the environmental assessment for two reasons. And I did; I looked at it.

One is I'm a five-minute walk from the cyclotron, so I'm a nearby neighbor, so I was an interested member of the community, of the faculty, and local community.

And the other, I have a part-time role as a consultant for the university physicians' office which is responsible for dealing with occupational health and safety on campus and of urgencies of the medical aspect.

So those were my reasons for looking at this, and I'm happy to say I'm reassured both as a local neighbor of the planned facility and also in terms of

1

MET01

1 the university's response to deal with what seemed like
2 unlikely emergencies that were listed in the
3 environmental assessment.

1,
con't.

4 We clearly have a very strong employee
5 health, occupational health. There are two of us on
6 campus who are particularly board certified in
7 occupational medicine and environmental medicine, and
8 we have ongoing programs.

9 There are health and safety people who are
10 dedicated at the university, or actually at this point
11 three or four health and safety people just assigned to
12 the cyclotron, and then the issue of emergency
13 response, and the university has emergency response for
14 dealing with potential evacuations or hazardous
15 releases, and I'm happy to say looking at the
16 environmental assessment and knowing what our plan is
17 that, you know, we could deal with it if something, you
18 know, unforeseeable, unlikely, were to occur.

2

19 So I guess that -- I guess I don't know if I
20 used my three minutes, but I was happily pleased by
21 reading of the environmental assessment.

22 MS. ROBINSON: Thank you, Dr. Rosenman. And
23 we didn't impose limits on tonight because we had a
24 small number. So now we will have Tim Dempsey.

25 MR. DEMPSEY: Thank you. Good evening. My

Page 3

MET01

1 name is Tim Dempsey. I'm the director of planning and
2 community development with the City of East Lansing. I
3 want to thank the Department of Energy and Michigan
4 State University for the opportunity to review the
5 draft document. I appreciate them sending the City a
6 copy of that.

7 On behalf of the City of East Lansing, I just
8 want to convey that the City is involved in annual
9 environmental assessments for the federal programs that
10 we manage through the federal appropriation process,
11 and having reviewed this document, we find it to be
12 extremely thorough, addressing really all of the risks
13 that the City of East Lansing would be concerned about,
14 whether it's dealing with public safety or waste water
15 treatment. So we were very pleased to see all those
16 issues addressed. And we would concur that this
17 process should really move forward to the fonsi (ph)
18 stage at this point given the thoroughness of the
19 documents.

20 So again, on behalf of the City of East
21 Lansing, we appreciate the opportunity for input, and
22 we look forward to seeing this project move forward, so
23 thank you.

24 MS. ROBINSON: Thank you, Mr. Dempsey. That
25 exhausts the people who have signed up. Are there any

1

2

Page 4

MET01

1 others in the audience who would like to make a comment
2 for the record?

3 Then I believe we have finished this segment
4 of the meeting, and now I'll invite Mr. Siebach for
5 closing remarks.

6 (Off the written record at 7:27 p.m.)

7 MR. SIEBACH: It's 9:22, 9:23. There are no
8 members of the public left in the meeting hall or
9 milling outside and so the meeting is hereby closed.

10 (Meeting concluded at 9:22 p.m.)

2. Human Health and Safety

DOE acknowledges the commenter's confidence that the university is prepared to respond in the unlikely event there is an accident at the FRIB.

Mr. Timothy Dempsey:

1. NEPA Process

DOE acknowledges the commenter's observations that the *FRIB EA* adequately covers the issues the City of East Lansing has with regards to the FRIB project and that DOE should move forward with a FONSI.

2. Alternative

DOE acknowledges the commenter's preference to construct the FRIB on MSU's campus.

THIS PAGE INTENTIONALLY LEFT BLANK

FINDING OF NO SIGNIFICANT IMPACT

DOE FUNDING OF THE CONSTRUCTION AND OPERATION OF THE FACILITY FOR RARE ISOTOPE BEAMS MICHIGAN STATE UNIVERSITY, EAST LANSING, MICHIGAN

AGENCY: U.S. Department of Energy

ACTION: Finding of No Significant Impact (FONSI)

SUMMARY: The U.S. Department of Energy (DOE) prepared the *Environmental Assessment for DOE Funding of the Construction and Operation of the Facility for Rare Isotope Beams, Michigan State University, East Lansing, Michigan, DOE/EA-1684 (FRIB EA)*. Based on the analyses of environmental impacts in the Environmental Assessment (EA) and in consideration of the public comments received on the draft EA, DOE has determined that the Proposed Action is not a major Federal action significantly affecting the quality of the human environment within the definition of the National Environmental Policy Act (NEPA) of 1969 (42 U.S.C. 4321, et seq.), the Council on Environmental Quality regulations (40 CFR 1500–1508), and DOE's NEPA implementing regulations (10 CFR 1021). Therefore, the preparation of an Environmental Impact Statement is not required.

DESCRIPTION OF THE PROPOSED ACTION: DOE published a "funding opportunity announcement" (FOA) on May 20, 2008, seeking applications for the conceptual design and establishment of a particle acceleration facility—the FRIB—that met the criteria described in the FOA for less than or equal to \$550 million over the next decade. Subsequent to construction, funding for operations would be allocated annually based on Congressional appropriations. In its review of the applications, DOE considered the results of an independent merit review process, as well as an environmental critique. On December 11, 2008, Michigan State University (MSU) was selected to design and establish the FRIB. Under the Proposed Action, MSU would design, construct, operate, and ultimately decommission the FRIB. DOE would maintain substantial involvement throughout the process

DOE and MSU propose to construct and operate the FRIB on approximately 15 acres (6.07 hectares) on MSU's East Lansing, Michigan, campus. Its design is composed of buildings and/or building additions for a heavy ion/proton accelerator and ancillary laboratories, support facilities such as a larger liquid helium production building, and offices. Construction and operations would occur on campus, adjacent to the existing National Superconducting Cyclotron Laboratory (NSCL), which would ultimately be subsumed into the FRIB. The function and scope of operations of the FRIB would be similar to those of the NSCL, but the FRIB would have substantially more power. The existing NSCL research program relies on a coupled cyclotron driver accelerator with an energy level of 200 megaelectron volt per atomic mass unit (MeV/u) and 1 to 2 kilowatts of beam power. The FRIB would be capable of a minimum energy of 200 MeV/u for all ions and up to 400 kilowatts of beam power. A reaccelerator, with energy up to 12 MeV/u for uranium and 20 MeV/u for lighter ions, is also proposed for the facility. The

linear accelerator tunnel would be situated in an excavation up to 75 feet below grade. The ground where the FRIB would be located has been previously disturbed. The U.S. Nuclear Regulatory Commission (NRC) and the State of Michigan would both have regulatory jurisdiction over nuclear activities at the FRIB, and the State of Michigan would regulate other aspects of construction and operation. MSU's broad-scope NRC license would be modified to cover oversight of all accelerator-related activities.

The FRIB would provide research opportunities for an international community of approximately 1,000 university and laboratory scientists, postdoctoral associates, and graduate students. The research conducted at the FRIB would involve experimentation with intense beams of rare isotopes—short-lived nuclei not normally found on Earth—that would enable researchers to address forefront scientific questions in nuclear structure and nuclear astrophysics. Operation would result in low levels of activation of air and groundwater, which MSU intends to manage according to NRC license requirements. Doses to workers and members of the public are anticipated to be less than one-tenth of the NRC radiation protection standards.

ALTERNATIVES: As required by Council on Environmental Quality regulations, the *FRIB EA* evaluates a No Action Alternative to serve as a basis for comparison with the action alternatives. Under the No Action Alternative, the FRIB would not be constructed and operated at MSU and the enhanced opportunities for scientific research would not be pursued. Other alternatives, including construction of the FRIB at another site, were considered and eliminated.

PURPOSE AND NEED: The purpose of the Proposed Action—the design, construction, and operation of the FRIB—is to support DOE's mission to advance our basic understanding of science. The purpose of the Proposed Action is consistent with the outcome of DOE's procurement process for the design, construction, and operation of an accelerator that produces rare isotope beams. DOE determined that the establishment of the FRIB is a high priority for the future of U.S. nuclear science research. The FRIB would establish a highly sophisticated research laboratory that would produce intense beams of rare isotopes. These beams enable scientists to study the nuclear reactions that power stars and generate the elements found on Earth; explore the structure of atomic nuclei, which form the core of all matter, and the forces that bind them together; test current theories about the fundamental nature of matter; and play a role in developing new nuclear medicines and other societal applications of rare isotopes.

AFFECTED ENVIRONMENT: The proposed FRIB would be constructed and operated adjacent to, and would eventually incorporate, the existing NSCL, which is located in the northeastern section of the MSU campus. The areas that would be utilized during construction are previously disturbed areas currently used for parking lots and support areas around the NSCL. During construction, an existing soil disposal area located south of the railroad tracks, east of Farm Lane, and north of East Mount Hope Road would be used for construction staging and soil disposal. This area is an open field within an area of undeveloped fields and has historically been used for these purposes. Both the FRIB construction site and the soil disposal site are

highly disturbed and contain no water bodies or streams, historic resources, wetlands, floodplains, and no threatened or endangered species.

ENVIRONMENTAL IMPACTS: The *FRIB EA* evaluates the potential environmental effects that could result from implementing the Proposed Action or the No Action Alternative. As it is still early in the design phase of the FRIB, the *FRIB EA* considers a range of potential designs or configuration options for the FRIB that would provide a reasonable “bound” of the environmental impacts of construction, operation, and decommissioning of the FRIB. The configuration options under consideration by the conceptual and preliminary design teams would not be expected to substantially change the projected environmental impacts of construction, operation, or decommissioning of the FRIB. Therefore, the options discussed in more detail in the *FRIB EA* are those that might have somewhat different, but still small, environmental impacts. These options may not precisely reflect the final design, but impacts of the final design would be bounded by the configurations considered in the *FRIB EA*.

Potential impacts identified for the resources evaluated in the *FRIB EA* include the following:

- Land Use and Visual Resources – MSU would construct the proposed project on a previously disturbed site directly adjacent to the existing NSCL and use an existing nearby soil disposal area for storage and disposal of soils. Both activities are consistent with current MSU planning. During construction, use of Bogue Street, Wilson Road, and Shaw Lane would be disrupted. In addition, the Wharton Center surface parking area would be closed and demolished and used as a laydown area during the construction period. Shaw Lane between Bogue Street and Hagadorn Road would be closed to through-traffic for approximately 2 months if the linear option is selected. Traffic would be rerouted to accommodate the road closures.

No land use impacts from the operation of the FRIB are anticipated. No adverse visual impacts were identified. During decommissioning, underground structures would be decontaminated and buried in place or otherwise managed per NRC requirements and any aboveground structures would be removed or redeployed.

With the No Action Alternative, these impacts would not occur.

- Geology and Soils – The FRIB would be constructed using cut-and-fill construction techniques. Approximately 325,000 cubic yards (248,000 cubic meters) of soil would be excavated during the construction of the tunnel associated with the FRIB. Construction is not expected to otherwise adversely impact the geology or soils of the area. Affected soils are stable and acceptable for standard construction requirements. Erosion prevention and sedimentation control measures would minimize the potential for adverse impacts. No impacts on geology and soils from the operation of the FRIB are anticipated. With decommissioning, underground structures would be buried in place or otherwise managed per NRC requirements that would be established at that time. Fill material would be required to bury underground structures. The source and quantity of fill material would be determined at the time of demolition.

With the No Action Alternative, these impacts would not occur.

- **Water Resources** – Erosion and sedimentation controls during construction would limit potential impacts on surface water. During construction, moderate to heavy volumes of groundwater would likely be encountered where excavations extend below the water table. A dewatering system could be used during construction to temporarily lower the water table below the level of the tunnels. The resulting groundwater would be filtered and discharged into the existing stormwater drainage system. After construction, the groundwater levels would be expected to return to normal with no long-term impacts or changes in groundwater flow or levels.

No impacts on wetlands or floodplains would occur from construction, operation, or decommissioning because none exist at the project site or soil disposal area.

Normal facility operations would not have adverse impacts on any surface water. During FRIB operation, neutrons produced from scattered beam particles that penetrate the thick concrete walls of the linear accelerator (linac) tunnels and that could activate groundwater would result in low levels of activation of any soil and groundwater adjacent to the FRIB tunnels, which MSU would manage according to NRC license requirements. These NRC license requirements require that the concentrations of radionuclides in the groundwater be below NRC water effluent limits. Consistent with the MSU as low as reasonably achievable (ALARA) program, the FRIB project design team has established a design and operations goal, which is more than a factor of 10 times better than the NRC requirements. Moreover, the FRIB project design goal is to keep the average groundwater radionuclide concentrations in the region around the linac tunnel walls below drinking water limits established by the U.S. Environmental Protection Agency (EPA). Ensuring that the water adjacent to the FRIB tunnels would meet drinking water standards, which would normally be applied to water provided by a drinking water supplier after pumping and filtering, would provide a very high degree of protection for both the environment and the public.

With the No Action Alternative, these impacts of construction would not occur.

- **Air Quality** – Construction emissions would be short-term, sporadic, and localized. Fugitive dust would be controlled to minimize emissions. No adverse impacts would occur from construction emissions. No continuous emissions of criteria air pollutants are expected to result from the Proposed Action during operations. With the No Action Alternative, the construction impacts would not occur.
- **Biological Resources** – As the project site has been previously disturbed and has a high degree of development, impacts on protected flora and fauna are not expected. The existing soil disposal site has also been previously disturbed by soil disposal activities similar to those that would be required for the Proposed Action, so impacts on protected flora and fauna are not expected. No threatened or endangered species or critical habitats exist at the project site or soil disposal area.

With the No Action Alternative, there would be no impacts on biological resources.

- **Noise Impacts** – Temporary and short-term noise would be generated during construction and would have the potential, without mitigation, to adversely affect any sensitive nearby receptors. The nearest noise-sensitive receptors include dormitories to the north of Shaw Lane that are within about 140 feet (43 meters) of the proposed tunnel excavation location and within 50 feet (15 meters) of the proposed front-end building location. Other noise-sensitive facilities within 150 feet (46 meters) of the excavation include the Wharton Center for Performing Arts, the plant biology laboratories, and the Biochemistry Building. The Biochemistry Building, which includes laboratories that contain vibration-sensitive experiments, is within about 50 feet (15 meters) of the tunnel excavation and the connector high bay and south high bay extensions. Pedestrians in the area near the construction site would be impacted by construction noise. Construction noise could be mitigated by employing standard construction noise mitigation, including use of quieted equipment, shielding of noisy equipment and activities, careful location of noisy equipment, proper maintenance of equipment, and administrative controls such as scheduling to avoid interfering with noise-sensitive activities. MSU would control the impact of construction activity on normal operation of the campus, especially on noise- and vibration-sensitive activities.

Workers would be expected to wear appropriate hearing protection during construction.

During operations, noise sources would be relatively minor and similar to ongoing NSCL activities.

During decommissioning, noise sources would be similar to those during construction, although the amount of earthmoving activity would be much less. Therefore, noise impacts from decommissioning are expected to be less.

With the No Action Alternative, operational noise impacts of the NSCL would remain and would be minor.

- **Utilities** – Existing nonpower utilities supporting the NSCL have adequate capacity to support construction and operation of the FRIB. Estimated power requirements for FRIB operations are about 18 megawatts, which would be supplied by offsite commercial power. The FRIB would use the existing 21-megawatt substation at the MSU Power Plant and require a new duct bank to deliver power to the FRIB.

With the No Action Alternative, these impacts would not occur.

- **Cultural and Historical Resources** – No intact cultural or historical resources are known to exist in potentially affected areas. All surface areas of the project site have been previously disturbed. Based on archaeological and architectural surveys previously conducted on the MSU campus in the vicinity of the NSCL, no impacts are expected on

cultural or historical resources during FRIB construction, operations, or decommissioning, including excavation or equipment storage and rock/soils stockpiling in the proposed construction staging area.

With the No Action Alternative, no impacts would be expected.

- Health and Safety – Construction workers would be subject to typical hazards and occupational exposures faced at other industrial construction sites. Contractors would be expected to comply with existing health and safety requirements. MSU would apply its existing occupational health and safety program to the new operations, and impacts on workers or the public would be low.

The FRIB would be designed and operated to ensure that no adverse impacts on the public would occur during operations from exposure to direct radiation in the vicinity of the FRIB tunnels, controlled airborne radiological releases from the FRIB stacks, ingestion of contaminated groundwater, or accidents. Existing radiation safety practices and experience at the NSCL and other particle accelerators are adequate to ensure that the radiological impacts of operation of the accelerator, including potential accidents, would be kept small and well within applicable NRC and EPA standards. MSU has committed to ensuring that the FRIB would be designed, constructed, and operated in a manner that maintains the NSCL's excellent environmental and safety record by continuing the MSU ALARA program. The FRIB would be designed and operated following the same strategy of radiation safety management that has been successfully used at the NSCL. That strategy is to: 1) abide by all limits and license commitments, 2) maintain, as a goal, individual and collective doses at or below as low as is reasonably achievable, and 3) manage the facility consistent with MSU and FRIB safety management practices (currently certified International Organization for Standardization [ISO] and Occupational Health and Safety Assessment Series [OHSAS] programs). The strategy has been effective for the NSCL and would also be effective for the FRIB. For the NSCL, incidents and near-misses since the institution of the current NSCL certified ISO 9001 (Quality Management Systems), ISO 14001 (Environmental Management Systems), and OHSAS 18001 (Occupational Health and Safety Management Systems) programs have been localized and were not considered to pose significant hazards to personnel, the public, or the environment.

As part of the design process, a range of potential accident scenarios is being considered to ensure that the FRIB would have adequate protections to minimize potential impacts. Accident conditions (including radiological conditions) are being analyzed as part of the development of a conceptual design, which is ongoing for the FRIB. These analyses continually evolve as the design effort progresses to ensure all credible hazards are evaluated and appropriate controls are included in the design to safeguard the public, FRIB personnel, environment, and the FRIB mission. For the FRIB, hazards that have been identified include electrical and chemical, non-ionizing radiation (lasers), and waste handling, as well as ionizing radiation, oxygen-deficient atmosphere, and cryogenic hazards for the accelerator, target building, and support systems. The design

and operational controls included in the FRIB design are intended to provide a robust level of protection against these postulated events and provide protection for the public, FRIB workers, and the environment. Based on the experience of other accelerator facilities, the evaluations conducted and MSU's commitment to certain design features and safety controls for the FRIB, it is expected that the health and safety impacts (risk) of foreseeable accidents can be managed at acceptably low levels through the facility design process and control of operations.

With the No Action Alternative, the health and safety impacts of NSCL operations would continue to be managed and would be low.

- Waste Management – Construction activities and operation of the FRIB would generate waste, possibly including hazardous waste. Waste would be characterized, stored, and disposed of in accordance with applicable regulations. Disposal would occur in existing facilities.

During operations, hazardous and radioactive waste streams would be similar to existing NSCL wastes and would be handled and disposed of using the existing MSU waste management program; no adverse impacts would occur. With the increased size and scope of operations, waste generation would increase but would be well within the existing capability and capacity of the MSU waste system.

With the No Action Alternative, the incremental waste generation associated with FRIB operation would not occur, and waste levels associated with the NSCL would remain the same.

- Transportation – No adverse impacts associated with the transport of construction materials are expected. Construction activities would cause an increase of approximately 400 vehicles per day due to the shipment of construction materials and wastes and the commuting of construction workers. The construction traffic would cause an increase of less than 4 percent in total traffic on the surrounding roads. Based on the estimated traffic volumes during construction, it is estimated that there would be fewer than 2 construction-related accidents involving a motor vehicle, with no fatalities or injuries. Construction workers commuting to the site would experience approximately 17 accidents, no fatalities, and 4 injuries over the duration of the construction period.

Road closures during FRIB construction would disrupt and divert traffic for periods of up to 2 years. Temporary closures of Bogue Street, Shaw Lane, and Wilson Road would also impact pedestrian and bicycle traffic. Temporary walkways would be established with sufficient safety features such as fencing to direct pedestrian and bicycle traffic around the construction site.

With the No Action Alternative, the traffic disruptions associated with FRIB construction and incremental impacts associated with FRIB operation would not occur.

- Socioeconomics and Environmental Justice – Construction of the FRIB is expected to last from 2012 through 2016 and annual construction employment is expected to peak at 175 employees. Total peak year earnings from both direct and indirect employment are estimated to be \$20.2 million. Total spending to build the facility is estimated to be approximately \$550 million, of which \$348 million is assumed to be spent locally. Indirect economic output generated by that spending is estimated to be \$279 million, for a total economic impact of \$627 million during the construction phase. When the FRIB is fully operational MSU estimates that it could require up to approximately 500 operations and support staff. When compared to employment at the existing NSCL, MSU estimates the FRIB could add up to approximately 160 new professional and technical service jobs. No high adverse human health or environmental impacts are anticipated as a result of the construction or operation of the FRIB; consequently, there would be no disproportionately high adverse effects on minority or low-income populations.

With the No Action Alternative, these impacts would not occur.

- Cumulative Impacts of the Proposed Action – No substantial cumulative impacts on the environment would be anticipated from implementing the Proposed Action. The cumulative impacts of construction of the FRIB and other construction projects at MSU during the FRIB construction timeframe would still be small. Operational impacts of the FRIB would be small and those impacts, collectively with other MSU operational impacts, are also expected to be small.

PROPOSED FONSI: On May 26, 2010, per 10 CFR § 1021.322 (d), DOE made a draft of this FONSI available for public comment. Three comment documents were received. One commenter encouraged DOE to proceed to a final FONSI. Another posed questions about the project largely addressed in the EA itself. The last commenter reminded DOE of the importance of minimizing generation of greenhouse gases. MSU is a member of the Chicago Climate Exchange and has pledged to reduce or offset six percent of its greenhouse gas emissions and is committed to looking for additional opportunities to limit its carbon footprint.

PUBLIC AVAILABILITY: Copies of the *FRIB EA* and FONSI may be viewed at the following locations:

DETERMINATION: Based on the analyses in the *FRIB EA*, and after careful consideration of all public and agency comments, DOE has determined that DOE funding of the construction and operation of the FRIB at MSU in East Lansing, Michigan (including any of the the configuration options analyzed, hybrids thereof, or similar options which have impacts that are bounded by those of the options analyzed), does not constitute a major Federal action that would significantly affect the quality of the human environment within the context of NEPA. Therefore, the preparation of an environmental impact statement is not required.

Issued in Washington, D.C., this 14 day of Sept, 2010.

W. F. Brinkman, Director
Office of Science
