Under Alternative 11B, transportation to and from Pantex would include the shipment of plutonium pits and clean plutonium metal via SST from sites throughout the DOE complex to the pit conversion facility. During dismantlement of the pits, some HEU and classified pit parts would be recovered. The pit conversion facility would ship HEU via SST to ORR for storage and pit parts via SST to LANL. After conversion, the plutonium in the pit conversion facility would be in the form of plutonium oxide. This material would be shipped to Hanford for immobilization.

It is assumed that depleted uranium hexafluoride needed for immobilization would be shipped via commercial truck to the uranium conversion facility, where it would be converted into uranium dioxide. After conversion, the depleted uranium dioxide would be shipped via commercial truck from the conversion facility to the immobilization facility at Hanford.

Immobilization at Hanford under this alternative would require that surplus nonpit plutonium in various forms, excluding clean metal, be shipped from current storage locations (i.e., SRS, Hanford, INEEL, LANL, and RFETS) to the immobilization facility at Hanford. Even though these materials are not clean plutonium metal or pits, the quantity of the plutonium contained in them would require that they be treated as materials that could be used in nuclear weapons, and thus that shipments be made in SSTs.

Under the preferred alternative for immobilization, the surplus plutonium would be immobilized in a ceramic matrix in small cans at the immobilization facility, placed in HLW canisters, and transported via specially designed trucks to HLWVF in 200 Area. This intrasite transportation—from 400 Area to 200 Area—could require the temporary shutdown of roads on Hanford. It would, however, provide for all the necessary security and for reduced risk to the public; SSTs would not be required.

After the immobilized plutonium was encased by HLW at HLWVF, it would be shipped to a geologic repository for ultimate disposition. Because HLW would be displaced by the cans of immobilized plutonium suspended in the HLW canister, additional canisters—to accommodate the displaced HLW—would be required over the life of the immobilization program. According to estimates, up to 340 additional canisters of HLW would be needed to meet the demands of surplus plutonium disposition under Alternative 11A. The WM PEIS documents an analysis of different options for the shipment of these canisters to a geologic repository using either trucks or trains. The analysis revealed that shipment by train would pose the lower risk. However, no ROD has yet been issued regarding these shipments. To bound the risks associated with these additional shipments, this SPD EIS, like the WM PEIS, takes the most conservative approach (i.e., the approach that results in the highest risk to the public): assumption that all of these shipments would be made by truck, one canister per truck.

Every alternative considered in this SPD EIS would require routine transportation of wastes from the proposed disposition facilities to treatment, storage, or disposal facilities on the sites. This transportation would be handled in the same manner as other site waste shipments, and as shown in Sections 4.21.1.2 and 4.21.2.2, would involve no major increase in the amounts of waste already being managed at these sites. The shipments would pose no greater risks than the ordinary waste shipments at these sites as analyzed in the WM PEIS.

However, TRU waste generated at Pantex was not covered by the WM PEIS ROD as there was no such waste at Pantex at the time the ROD was issued, and none was likely to be generated in ongoing site operations. Location of the pit conversion facility at Pantex would result in the generation of TRU waste, as described in Section 4.21.2.2. Moreover, a fairly large increase in the amount of LLW at Pantex (i.e., 25 percent of the site's current storage capacity) could be expected under this alternative. Currently, this type of waste is shipped to the NTS for disposal. In order to account for the transportation of TRU waste from Pantex to WIPP, and LLW from Pantex to NTS, additional shipments are analyzed in this SPD EIS.

In all, approximately 1,900 shipments of radioactive materials would be carried out by DOE under this alternative. The total distance traveled on public roads by trucks carrying radioactive materials would be 2.8 million km (1.7 million mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities entailed by this alternative has been estimated at 60 person-rem; the dose to the public, 62 person-rem. Accordingly, incident-free transportation of radioactive material associated with this alternative would result in 0.024 LCF among transportation workers and 0.031 LCF in the total affected

population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this alternative is 0.0090.

Impacts of Accidents During Ground Transportation. The maximum foreseeable offsite transportation accident under this Alternative (probability of occurrence: more than 1 in 10 million per year) is a shipment of surplus nonpit plutonium from a DOE storage facility to Hanford with an accident in a rural population zone under neutral (average) weather conditions. Because surplus nonpit plutonium shipments include plutonium oxide, an accident involving plutonium oxide is conservatively used to estimate the impacts of the maximum foreseeable accident. The accident could result in a dose of 145 person-rem to the public for an LCF risk of 0.07 and 159 rem to the hypothetical MEI for an LCF risk of 0.08. (The MEI receives a larger dose than the population because it is unlikely that a person would be in position, and remain in position, to receive this hypothetical maximum dose.) No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of accident, or occurrence in a more densely populated area were also evaluated, and estimated to have a probability lower than 1 chance in 10 million per year.

Estimates of the total ground transportation accident risks under Alternative 11B are as follows: a radiological dose to the population of 3 person-rem, resulting in a total population risk of 1.5×10^{-3} LCF; and traffic accidents resulting in 0.048 traffic fatalities.

4.21.2.7 Environmental Justice

As discussed in other parts of Section 4.21.2, routine operations conducted under Alternative 11B would pose no significant health risks to the public. The likelihood of an LCF for the MEI residing near Pantex would be approximately 1 in 3 million (see Table 4–182); the likelihood for the MEI residing near Hanford would be essentially zero. The number of LCFs expected among the general population residing near Pantex and Hanford from accident-free operations would increase by approximately 2.9×10^{-3} and 8.0×10^{-5}, respectively.

Design basis accidents at the sites would not be expected to cause cancer fatalities among the public (see Section 4.21.2.5). A beyond-design-basis earthquake at the sites would be expected to result in LCFs among the general population (see Tables 4–66, 4–176, and 4–177). However, it is highly unlikely that a beyond-design-basis earthquake would occur. Accidents at the sites pose no significant risks (when the probability of occurrence is considered) to the population residing within the area potentially affected by radiological contamination.

As described in Section 4.21.2.6, no radiological or nonradiological fatalities would be expected to result from accident-free transportation conducted under this alternative. Nor would radiological or nonradiological fatalities be expected to result from transportation accidents.

Thus, implementation of Alternative 11B would pose no significant risks to the public, nor would implementation of this alternative pose significant risks to groups within the general public, including the risk of disproportionately high and adverse effects on minority and low-income populations.

Next Section

4.22 ALTERNATIVE 12A

Alternative 12A would involve constructing and operating the pit conversion and immobilization facilities in new buildings in F-Area at SRS. Under this alternative, all surplus plutonium is immobilized; none is fabricated into MOX fuel.

4.22.1 Construction

4.22.1.1 Air Quality and Noise

Sources of potential air quality impacts of construction under Alternative 12A at SRS include emissions from fuel-burning construction equipment, soil disturbance by construction equipment and other vehicles, the operation of a concrete batch plant, trucks moving materials and wastes, and employee vehicles. Emissions from these sources are summarized in Appendix G.

A comparison of maximum air pollutant concentrations, including the contribution from SRS construction activities, with standards and guidelines is presented as Table 4–184. Concentrations of air pollutants, especially PM_{10} and total suspended particulates, would likely increase at the site boundary, but should not exceed the Federal or State ambient air quality standards. Air pollution impacts during construction would be mitigated by applying, as appropriate, standard dust control practices such as watering or sweeping of roads and watering of exposed areas.

Table 4–184. Evaluation of Air Pollutant Concentrations Associated With Construction Under Alternative 12A: Pit Conversion in New Construction and *Immobilization in* New Construction and DWPF at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	SPD Increment ($\mu g/m^3$)	Site Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	1.46	65.5	0.66
	1 hour	40,000	6.63	285	0.71
Nitrogen dioxide	Annual	100	0.0509	9.35	9.4
PM_{10}	Annual	50	0.0526	4.19	8.4
	24 hours	150	2.3	58.7	39
Sulfur dioxide	Annual	80	0.00492	15.1	19
	24 hours	365	0.121	219	60
	3 hours	1,300	0.727	962	74
Other regulated pollutants					
Total suspended particulates	Annual	75	0.108	14.8	20
Hazardous and other toxic compounds					
Other toxics[b]	24 hours	150	0	31.7	21

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction and were analyzed as benzene.
Key: DWPF, Defense Waste Processing Facility; SPD, surplus plutonium disposition.
Source: EPA 1997a; SCDHEC 1996.

Total vehicle emissions associated with activities at SRS would likely decrease somewhat from current emissions because of an expected decrease in overall site employment during this timeframe.

The proposed location of the surplus plutonium disposition facilities at SRS relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during construction would include heavy construction equipment, employee vehicles, and truck traffic. Traffic noise associated with construction of these facilities would occur on the site and along offsite local and regional transportation routes used to bring construction materials and workers to the site. Given the distance to the site boundary (about 8.7 km [5.4 mi]), noise emissions from construction equipment would not likely annoy the public. These noise sources would be far enough away from offsite areas that the contribution to offsite noise levels would be small. Some noise sources could result in onsite impacts, such as the disturbance of wildlife. Noise would not affect threatened and endangered species because there are no threatened and endangered species habitats near the facility site (see Section 4.26). Traffic associated with construction of these facilities would likely produce less than a 1-dB increase in noise levels along roads used to access the site, and thus would not result in any increased annoyance of the public.

Construction workers could be exposed to noise levels higher than the acceptable limits specified by OSHA in its noise regulations (OSHA 1997). However, DOE has implemented appropriate hearing protection programs to minimize noise impacts on workers. These include the use of standard silencing packages on construction equipment, administrative controls, engineering controls, and personal hearing protection equipment.

4.22.1.2 Waste Management

Table 4–185 compares the wastes generated during construction of surplus plutonium disposition facilities at SRS with the existing treatment, storage, and disposal capacity for the various waste types. It is anticipated that no TRU waste, LLW, or mixed LLW would be generated during the 3-year construction period. In addition, no soil contaminated with hazardous or radioactive constituents should be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies because the same size facility would be built under either scenario. For this SPD EIS, it is assumed that hazardous waste and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices.

Table 4–185. Potential Waste Management Impacts of Construction Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
Hazardous	61	NA	NA	NA
Nonhazardous				
Liquid	15,100	5[c]	NA	1[d]
Solid	1,820	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional annual waste generation. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year construction period.
[c] Percent of capacity of the F-Area's sanitary sewer.
[d] Percent of capacity of Central Sanitary Wastewater Treatment Facility.
Key: DWPF, Defense Waste Processing Facility; NA, not applicable (i.e., it is assumed that the majority of the hazardous waste and nonhazardous solid waste would be treated and disposed of off the site by the construction contractor).

Hazardous wastes generated during construction of surplus plutonium disposition facilities would be typical of those generated during construction of an industrial facility. Any hazardous wastes generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid wastes generated during construction of surplus plutonium disposition facilities would be packaged in conformance with standard industrial practice and shipped to offsite commercial facilities for recycling or disposal. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

To be conservative, it was assumed that all nonhazardous liquid wastes generated during construction of surplus plutonium disposition facilities would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation during construction of these facilities is estimated to be 5 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of these wastes at SRS should not have a major impact on the nonhazardous liquid waste treatment system during construction.

4.22.1.3 Socioeconomics

Construction-related employment requirements for Alternative 12A would be as indicated in Table 4–186.

Table 4–186. Construction Employment Requirements for Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Year	Pit Conversion	Immobilization	Total
2001	274	0	274
2002	417	312	729
2003	256	448	704
2004	0	282	282

Key: DWPF, Defense Waste Processing Facility.
Source: UC 1998e, 1998f, 1998g.

At its peak in 2002, construction of new pit conversion and immobilization facilities at SRS under this alternative would require 729 construction workers and generate another 585 indirect jobs in the region. This total employment requirement of 1,314 direct and indirect jobs in 2002 represents less than 0.5 percent of the projected REA workforce, and thus should have no major impacts on the REA. It should also have little effect on community services currently offered in the ROI. In fact, it should help offset the 20 percent reduction in SRS employment (i.e., from 15,000 to 12,000 workers) projected for the years 1997–2005.

4.22.1.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from construction activities. A summary of radiological impacts of construction activities on workers at risk is presented in Table 4–187. Construction worker exposure to radiation deriving from other activities at the site, past or present, would be limited to ensure that doses are kept as low as is reasonably achievable. To this end, construction workers would be monitored (badged) as appropriate.

Table 4–187. Potential Radiological Impacts on Construction Workers of Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Impact	Pit Conversion[a]	Immobilization[b]	Total
Total dose (person-rem/yr)	1.3	1.4	2.7
Annual latent fatal cancers[c]	5.2×10^{-4}	5.6×10^{-4}	1.1×10^{-3}
Average worker dose (mrem/yr)	4	4	4[d]
Annual latent fatal cancer risk	1.6×10^{-6}	1.6×10^{-6}	1.6×10^{-6}

[a] An estimated average of 316 workers would be associated with annual construction operations.
[b] An estimated average of 347 workers would be associated with annual construction operations at the new facility location adjacent to APSF. The number would be the same for immobilization in either ceramic or glass.
[c] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.
[d] Represents an average of the doses for both facilities.
Key: APSF, Actinide Packaging and Storage Facility; DWPF, Defense Waste Processing Facility.
Note: The radiological limit for construction workers is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: ICRP 1991; NAS 1990; UC 1998e, 1998f, 1998g.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of construction activities at SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.22.1.5 Facility Accidents

Construction of pit conversion and immobilization facilities at SRS could result in worker injuries or fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated 1,989 person-years of construction labor and standard industrial accident rates, approximately 200 cases of nonfatal occupational injury or illness and 0.28 fatality could be expected (DOL 1997a, 1997b). As all construction would be in nonradiological areas, no radiological accidents should occur.

4.22.1.6 Environmental Justice

As discussed in the other parts of Section 4.22.1, construction under Alternative 12A would pose no significant health risks to the public. The risks would be negligible regardless of the racial or ethnic composition or the economic status of the population. Therefore, construction activities under Alternative 12A at SRS would have no significant impacts on minority or low-income populations.

4.22.2 Operations

4.22.2.1 Air Quality and Noise

Potential air quality impacts of the operation of facilities under Alternative 12A at SRS were analyzed using ISCST3. Operational impacts would result from process emissions, emergency diesel generator testing, trucks moving materials and wastes, and employee vehicles. Emissions from these sources are summarized in Appendix G.

A comparison of maximum air pollutant concentrations, including those from the plutonium disposition facilities, with standards and guidelines is presented as Table 4–188. Concentrations for immobilization in the ceramic form are presented because they would be greater than those for the glass form. Concentrations of air pollutants would likely increase at the site boundary, but would not exceed the Federal or State ambient air quality standards. Air pollution impacts during operation would be mitigated; for example, HEPA filtration has been included in the design of these facilities.

Table 4–188. Evaluation of Air Pollutant Concentrations Associated with Operations Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	SPD Increment ($\mu g/m^3$)	Site Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.389	64.4	0.64
	1 hour	40,000	1.56	280	0.70
Nitrogen dioxide	Annual	100	0.0318	9.33	9.3
PM_{10}	Annual	50	0.00209	4.14	8.3
	24 hours	150	0.0326	56.4	38
Sulfur dioxide	Annual	80	0.0473	15.1	19
	24 hours	365	0.649	220	60
	3 hours	1,300	1.71	963	74
***Other regulated* pollutants**					
Total suspended particulates	Annual	75	0.00209	14.7	20
Hazardous and other toxic compounds					
Ethylene glycol	24 hours	650	0	0.195	0.03

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
Key: DWPF, Defense Waste Processing Facility; SPD, surplus plutonium disposition.
Source: EPA 1997a; SCDHEC 1996.

For a discussion of how the operation of the pit conversion and immobilization facilities at SRS would affect the ability to continue to meet NESHAP limits regarding airborne radiological emissions, see Section 4.32.4.4. There are no other NESHAP limits applicable to operation of these facilities.

The increases in concentrations of nitrogen dioxide, PM_{10}, and sulfur dioxide are a small fraction of the PSD Class II area increments as summarized in Table 4–189.

Table 4–189. Evaluation of Air Pollutant Increases Associated With Operations Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Pollutant	Averaging Period	Increase in Concentration ($\mu g/m^3$)	PSD Class II Area Allowable Increment ($\mu g/m^3$)	Percent of Increment
Nitrogen dioxide	Annual	0.0318	25	0.13
PM_{10}	Annual	0.00209	17	0.012
	24 hours	0.0326	30	0.11
Sulfur dioxide	Annual	0.0473	20	0.24
	24 hours	0.649	91	0.71
	3 hours	1.71	512	0.33

Key: DWPF, Defense Waste Processing Facility; PSD, prevention of significant deterioration.
Source: EPA 1997b.

Total vehicle emissions associated with activities at SRS would likely decrease somewhat from current emissions because of an expected decrease in overall site employment during this timeframe.

The combustion of fossil fuels associated with Alternative 12A would result in the emission of carbon dioxide, one of the atmospheric gases that are believed to influence the global climate. Annual carbon dioxide emissions from this alternative would represent less than 2×10^{-4} percent of the 1995 annual U.S. emissions of carbon dioxide from fossil fuel combustion and industrial processes, and therefore would not appreciably affect global concentrations of this pollutant.

The location of these facilities at SRS relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during operations would include new or existing machines (e.g., cooling systems, vents, motors, material-handling equipment), employee vehicles, and truck traffic. Traffic noise associated with operation of these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Given the distance to the site boundary (about 8.7 km [5.4 mi]), noise emissions from equipment would not likely annoy the public. These noise sources would be far enough away from offsite areas that their contribution to offsite noise levels would be small. However, some noise sources could have onsite impacts, such as the disturbance of wildlife. Noise impacts would not affect threatened and endangered species because there are no threatened and endangered species habitats near the facility site (see Section 4.26). Noise from traffic associated with operation of these facilities would likely produce less than a 1-dB increase in traffic noise levels along roads used to access the site, and thus would not result in any increased annoyance of the public.

Operations workers could be exposed to noise levels higher than the acceptable limits specified by OSHA in its noise regulations (OSHA 1997). However, DOE has implemented appropriate hearing protection programs to minimize noise impacts on workers. These include the use of administrative controls, engineering controls, and personal hearing protection equipment.

4.22.2.2 Waste Management

Table 4–190 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from operating surplus plutonium disposition facilities at SRS. Although HLW would be used in the immobilization process, no HLW would be generated by the surplus plutonium disposition facilities. Waste generation should be the same for the ceramic and glass immobilization technologies, except for nonhazardous sanitary wastewater generation.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995c).

TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation at surplus plutonium disposition facilities is estimated to be 8 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,440 m^3 (1,880 yd^3) of TRU waste would be generated over the 10-year operation period. If all the TRU waste were stored on the site, this would be 4 percent of the 34,400-m^3 (45,000-yd^3) storage capacity available

Table 4–190. Potential Waste Management Impacts of Operations Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b] Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	144	8	4	1 of WIPP
LLW	140	1	NA	5
Mixed LLW	2	<1	1	NA
Hazardous	32	<1	6	NA
Nonhazardous				
Liquid	53,000	19[d]	NA	5[e]
Solid	2,030	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional annual waste generation. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 10-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
[d] Percent of capacity of the F-Area sanitary sewer.
[e] Percent of capacity of Central Sanitary Wastewater Treatment Facility.
Key: DWPF, Defense Waste Processing Facility; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

at the TRU Waste Storage Pads. Assuming that the waste were stored in 208-l (55-gal) drums that could be stacked two high, and allowing a 50 percent factor for aisle space, a storage area of about 0.21 ha (0.52 acre) would be required. Therefore, impacts of the management of additional quantities of TRU waste at SRS should not be major.

The 1,440 m^3 (1,880 yd^3) of TRU wastes generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the new facilities before transfer for additional treatment and disposal in existing onsite facilities. A total of 1,400 m^3 (1,830 yd^3) of LLW would be generated over the operation period. LLW generation at surplus plutonium disposition facilities is estimated to be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,400 m^3 (1,830 yd^3) of waste would require 0.16 ha (0.40 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation at surplus plutonium disposition facilities is estimated to be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste would be packaged at the generating facility for treatment and disposal at a combination of onsite and offsite facilities. Assuming that all hazardous waste is managed on the site, hazardous waste generation at surplus plutonium disposition facilities is estimated to be less than 1 percent of the 17,830-m^3/yr

(23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system. If all LLW, mixed LLW, and hazardous wastes generated at the surplus plutonium disposition facilities were treated in the Consolidated Incineration Facility, this additional waste would be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent for offsite disposal. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous wastewater would be treated if necessary before being discharged to the F-Area sanitary sewer system, which connects to the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generated by surplus plutonium disposition facilities at SRS is estimated to be 19 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer and 5 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of nonhazardous liquid waste at SRS should not have a major impact on the treatment system.

4.22.2.3 Socioeconomics

After construction, startup, and testing of the pit conversion and immobilization facilities in 2005 under Alternative 12A, an estimated 671 new workers would be required to operate them (UC 1998e, 1998f, 1998g.) This level of employment would generate another 1,200 indirect jobs in the region. The total employment requirement of 1,871 direct and indirect jobs represents less than 0.7 percent of the projected REA workforce, and thus should have no major impact on the REA. It should also have a negligible impact on community services currently offered in the ROI. In fact, it should decrease to 28.9 percent the 33.3 percent reduction in SRS's total workforce (i.e., 15,000 to 10,000 workers) projected for the years 1997–2010.

4.22.2.4 Human Health Risk

During normal operation, there would be both radiological and hazardous chemical releases to the environment, and also direct in-plant exposures. The resulting doses to, and potential health effects on, the public and workers under this alternative are as follows.

Radiological Impacts. Table 4–191 reflects the potential radiological impacts on three individual receptor groups: the population living within 80 km (50 mi) of SRS in the year 2010, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected aggregate LCF risk to these groups from 10 years of operation. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Given incident-free operation of both facilities, the total population dose in the year 2010 would be 1.6 person-rem. The corresponding number of LCFs in this population from 10 years of operation would be 8.0×10^{-3}. The dose to the maximally exposed member of the public from annual operation of both facilities would be 3.8×10^{-3} mrem. From 10 years of operation, the corresponding LCF risk to this individual would be 1.9×10^{-8}. The impacts on the average individual would be lower.

Estimated impacts resulting from "Total Site" operations are given in the Cumulative Impacts section of this SPD EIS (see Section 4.32). Within that section, projected incremental impacts associated with the operation of the proposed surplus plutonium disposition facilities are added to the impacts of other past, present, and

Table 4–191. Potential Radiological Impacts on the Public of Operations Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Impact	Pit Conversion	Immobilization		Total[a]
		Ceramic	Glass	
Population within 80 km for year 2010				
Dose (person-rem)	1.6	4.9×10^{-3}	4.5×10^{-3}	1.6
Percent of natural background[b]	6.9×10^{-4}	2.1×10^{-6}	1.9×10^{-6}	6.9×10^{-4}
10-year latent fatal cancers	8.0×10^{-3}	2.5×10^{-5}	2.3×10^{-5}	8.0×10^{-3}
Maximally exposed individual				
Annual dose (mrem)	3.7×10^{-3}	5.0×10^{-5}	4.5×10^{-5}	3.8×10^{-3}
Percent of natural background[b]	1.3×10^{-3}	1.7×10^{-5}	1.5×10^{-5}	1.3×10^{-3}
10-year latent fatal cancer risk	1.9×10^{-8}	2.5×10^{-10}	2.3×10^{-10}	1.9×10^{-8}
Average exposed individual within 80 km[c]				
Annual dose (mrem)	2.0×10^{-3}	6.3×10^{-6}	5.7×10^{-6}	2.0×10^{-3}
10-year latent fatal cancer risk	1.0×10^{-8}	3.2×10^{-11}	2.9×10^{-11}	1.0×10^{-8}

[a] Totals are additive in all cases because the same groups or individuals would receive doses from both facilities. This total includes the higher of the values for the ceramic and glass immobilization alternatives.

[b] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 231,700 person-rem.

[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of the SRS APSF (785,400) in 2010.

Key: APSF, Actinide Packaging and Storage Facility; DWPF, Defense Waste Processing Facility.
Source: Appendix J.

reasonably foreseeable future actions at or near the candidate sites. These impacts are then compared against applicable regulatory standards established by DOE and EPA (such as DOE Order 5400.5, the Clean Air Act [NESHAP], and the Safe Drinking Water Act).

Doses to involved workers from normal operations are given in Table 4–192; these workers are defined as those directly associated with process activities. Under this alternative, the annual average dose to pit conversion facility workers would be 500 mrem; to immobilization facility workers, 750 mrem. The annual dose received by the total site workforce for each of these facilities has been estimated at 192 and 193 person-rem, respectively. The risks and numbers of LCFs among the different workers from 10 years of operation are included in Table 4–192. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of operation activities at SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.22.2.5 Facility Accidents

The potential consequences of postulated bounding accidents from operation of the pit conversion facility at SRS are substantially equivalent to those of Alternative 3A (see Table 4–40), and the potential consequences of such accidents from operation of the immobilization facility in new construction and DWPF at SRS are as presented in Tables 4–193 and 4–194. The relationship between the accident analysis results for the 50-t (55-ton) alternatives and the 17-t (19-ton) immobilization alternatives is discussed in Section 4.20.2.5. More details on the method of analysis, assumptions, and specific accident scenarios are presented in the discussion of Alternative 2 in Section 4.3.2.5.

Table 4–192. Potential Radiological Impacts on Involved Workers of Operations Under Alternative 12A: Pit Conversion in New Construction and Immobilization in New Construction and DWPF at SRS

Impact	Pit Conversion	Immobilization (Ceramic or Glass)	Total
Number of badged workers	383	257	640
Total dose (person-rem/yr)	192	193	385
10-year latent fatal cancers	0.77	0.77	1.5
Average worker dose (mrem/yr)	500	750	600[a]
10-year latent fatal cancer risk	2.0×10^{-3}	3.0×10^{-3}	2.4×10^{-3}

[a] Represents an average of the doses for both facilities.
Key: DWPF, Defense Waste Processing Facility.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998e, 1998f, 1998g.

Public. The most severe consequences of a design basis accident for the pit conversion facility and the immobilization facility would be equivalent to those discussed in Section 4.4.2.5.

A beyond-design-basis earthquake at SRS could result in collapse of the pit conversion and immobilization facilities, and an estimated 6.8 LCFs among the general population. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude at SRS is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

Noninvolved Worker. Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is a hypothetical individual working on the site but not involved in the proposed action, and assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. The consequences for this worker were estimated to be highest for the tritium release at the pit conversion facility. The consequences of such an accident would include an LCF probability of 7.0×10^{-5}.

Maximally Exposed Involved Worker. No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would either be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and the accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

Nonradiological Accidents. Plutonium disposition operations at SRS could result in worker injuries and fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated employment of 6,981 person-years of labor and the standard DOE occupational accident rates, approximately

Table 4–193. Accident Impacts of Alternative 12A: Ceramic Immobilization in New Construction at SRS (50-t Case)

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	1.0×10^{-2}	4.2×10^{-6}	1.6×10^{-3}	7.8×10^{-7}	1.5	8.0×10^{-4}
Explosion in HYDOX furnace	Unlikely	8.6×10^{-4}	3.4×10^{-7}	1.6×10^{-4}	8.1×10^{-8}	7.1×10^{-1}	3.5×10^{-4}

Hydrogen explosion	Unlikely	9.5×10^{-5}	3.8×10^{-8}	1.8×10^{-5}	9.0×10^{-9}	7.8×10^{-2}	3.8×10^{-5}
Glovebox fire (sintering furnace)	Extremely unlikely	3.8×10^{-7}	1.5×10^{-10}	7.2×10^{-8}	3.6×10^{-11}	3.1×10^{-4}	1.5×10^{-7}
Design basis earthquake	Unlikely	8.8×10^{-5}	3.5×10^{-8}	1.7×10^{-5}	8.3×10^{-9}	7.2×10^{-2}	3.6×10^{-5}
Beyond-design-basis fire	Beyond extremely unlikely	6.3×10^{-3}	2.5×10^{-6}	2.5×10^{-4}	1.2×10^{-7}	5.8×10^{-1}	2.9×10^{-4}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	5.3×10^{1}	2.1×10^{-2}	2.1	1.0×10^{-3}	4.8×10^{3}	2.5

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

Key: HYDOX, hydride oxidation.

223 cases of nonfatal occupational injury or illness and 0.22 fatality could be expected for the duration of operations.

4.22.2.6 Transportation

Under Alternative 12A, transportation to and from SRS would include the shipment of plutonium pits and clean plutonium metal via SST from sites throughout the DOE complex to the pit conversion facility. During dismantlement of the pits, some HEU and classified pit parts would be recovered. The pit conversion facility would ship HEU via SST to ORR for storage and pit parts via SST to LANL. After conversion, the plutonium in the pit conversion facility would be in the form of plutonium oxide. This material would be transferred through a secure tunnel to the MOX facility at SRS for fabrication into MOX fuel pellets.

It is assumed that depleted uranium hexafluoride needed for immobilization would be shipped via commercial truck to the uranium conversion facility, where it would be converted into uranium dioxide. After conversion, the depleted uranium dioxide would be shipped via commercial truck from the conversion facility to the immobilization facility at SRS.

Table 4–194. Accident Impacts of Alternative 12A: Glass Immobilization in New Construction at SRS (50-t Case)

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	1.0×10^{-2}	4.2×10^{-6}	1.6×10^{-3}	7.8×10^{-7}	1.5	8.0×10^{-4}

Key: HYDOX, hydride oxidation.

Immobilization at SRS under this alternative would also require that surplus nonpit plutonium in various forms, excluding clean metal, be shipped from current storage locations (i.e., SRS, Hanford, INEEL, LANL, and RFETS) to the immobilization facility at SRS. Even though these materials are not clean plutonium metal or pits, the quantity of the plutonium contained in them would require that they be treated as materials that could be used in nuclear weapons, and thus that shipments be made in SSTs.

Under the preferred alternative for immobilization, the surplus plutonium would be immobilized in a ceramic matrix in small cans at the immobilization facility, placed in HLW canisters, and transported via specially designed trucks to DWPF in S-Area. This intrasite transportation—from F-Area to S-Area—could require the temporary shutdown of roads on SRS. It would, however, provide for all the necessary security and for reduced risk to the public; SSTs would not be required.

After the immobilized plutonium was encased by HLW at DWPF, it would be shipped to a geologic repository for ultimate disposition. Because HLW would be displaced by the cans of immobilized plutonium suspended in the HLW canister, additional canisters—to accommodate the displaced HLW—would be required over the

life of the immobilization program. According to estimates, up to 340 additional canisters of HLW would be needed to meet the demands of surplus plutonium disposition under Alternative 12A. The WM PEIS documents an analysis of different options for the shipment of these canisters to a geologic repository using either trucks or trains. The analysis revealed that shipment by train would pose the lower risk. However, no ROD has yet been issued regarding these shipments. To bound the risks associated with these additional shipments, this SPD EIS, like the WM PEIS, takes the most conservative approach (i.e., the approach that results in the highest risk to the public): assumption that all of these shipments would be made by truck, one canister per truck.

Every alternative considered in this SPD EIS would require routine transportation of wastes from the proposed disposition facilities to treatment, storage, or disposal facilities on the sites. This transportation would be handled in the same manner as other site waste shipments, and as shown in Sections 4.22.1.2 and 4.22.2.2, would involve no major increase in the amounts of waste already being managed at these sites. The shipments would pose no greater risks than the ordinary waste shipments at these sites as analyzed in the WM PEIS.

In all, approximately 2,100 shipments of radioactive materials would be carried out by DOE under this alternative. The total distance traveled on public roads by trucks carrying radioactive materials would be 4.1 million km (2.6 million mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities entailed by this alternative has been estimated at 123 person-rem; the dose to the public, 127 person-rem. Accordingly, incident-free transportation of radioactive material associated with this alternative would result in 0.049 LCF among transportation workers and 0.063 LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this alternative is 0.019.

Impacts of Accidents During Ground Transportation. The maximum foreseeable offsite transportation accident under this Alternative (probability of occurrence: more than 1 in 10 million per year) is a shipment of surplus nonpit plutonium from a DOE storage facility to SRS with a severity category VIII accident in a rural population zone under neutral (average) weather conditions. Because surplus nonpit plutonium shipments include plutonium oxide, an accident involving plutonium oxide is conservatively used to estimate the impacts of the maximum foreseeable accident. The accident could result in a dose of 29 person-rem to the public for an LCF risk of 0.015 and 32 rem to the hypothetical MEI for an LCF risk of 0.016. (The MEI receives a larger dose than the population because it is unlikely that a person would be in position, and remain in position, to receive this hypothetical maximum dose.) No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of accident, or occurrence in a more densely populated area were also evaluated, and estimated to have a probability lower than 1 chance in 10 million per year.

Estimates of the total ground transportation accident risks under Alternative 12A are as follows: a radiological dose to the population of 1.8 person-rem, resulting in a total population risk of 9.0×10^{-4} LCF; and traffic accidents resulting in 0.074 traffic fatality.

4.22.2.7 Environmental Justice

As discussed in other parts of Section 4.22.2, routine operations conducted under Alternative 12A would pose no significant health risks to the public. The likelihood of an LCF for the MEI residing near SRS would be approximately 1 in 50 million (see Table 4–191). The number of LCFs expected among the general population residing near SRS from accident-free operations would increase by approximately 8.0×10^{-3}.

Design basis accidents at the sites would not be expected to cause cancer fatalities among the public (see Section 4.22.2.5). A beyond-design-basis earthquake would be expected to result in LCFs among the general population (see Tables 4–40, 4–194, and 4–195). However, it is highly unlikely that a beyond-design-basis earthquake would occur. Accidents at the sites pose no significant risks (when the probability of occurrence is considered) to the population residing within the area potentially affected by radiological contamination.

As described in Section 4.22.2.6, no radiological or nonradiological fatalities would be expected to result from accident-free transportation conducted under this alternative. Nor would radiological or nonradiological fatalities be expected to result from transportation accidents.

Thus, implementation of Alternative 12A would pose no significant risks to the public, nor would implementation of this alternative pose significant risks to groups within the general public, including the risk of disproportionately high and adverse effects on minority and low-income populations.

Next Section

4.23 ALTERNATIVE 12B

Alternative 12B would involve constructing and operating the pit conversion and immobilization facilities in F-Area at SRS. The immobilization facility would be located in the existing Building 221–F with the pit conversion facility located nearby in F-Area. Under this alternative, all surplus plutonium is immobilized; none is fabricated into MOX fuel.

4.23.1 Construction

4.23.1.1 Air Quality and Noise

Sources of potential air quality impacts of construction under Alternative 12B at SRS result from emissions from fuel-burning construction equipment, soil disturbance by construction equipment and other vehicles, the operation of a concrete batch plant, trucks moving materials and wastes, and employee vehicles. Emissions from these sources are summarized in Appendix G.

A comparison of maximum air pollutant concentrations, including the contribution from SRS construction activities, with standards and guidelines is presented as Table 4–195. Concentrations of air pollutants, especially PM_{10} and total suspended particulates, would likely increase at the site boundary, but should not exceed the Federal or State ambient air quality standards. Air pollution impacts during construction would be mitigated by applying, as appropriate, standard dust control practices such as watering or sweeping of roads and watering of exposed areas.

Table 4–195. Evaluation of Air Pollutant Concentrations Associated With Construction Under Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	SPD Increment ($\mu g/m^3$)	Site Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.979	65	0.65
	1 hour	40,000	4.41	283	0.71
Nitrogen dioxide	Annual	100	0.033	9.33	9.3
PM_{10}	Annual	50	0.0412	4.18	8.4
	24 hours	150	1.15	57.5	38
Sulfur dioxide	Annual	80	0.0031	15.1	19
	24 hours	365	0.0762	219	60
	3 hours	1,300	0.456	962	74
Other regulated pollutants					
Total suspended particulates	Annual	75	0.0908	14.8	20
Hazardous and other toxic compounds					
Other toxics[b]	24 hours	150	0	31.7	21

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction and were analyzed as benzene.
Key: DWPF, Defense Waste Processing Facility; SPD, surplus plutonium disposition.
Source: EPA 1997a; SCDHEC 1996.

Total vehicle emissions associated with activities at SRS would likely decrease somewhat from current emissions because of an expected decrease in overall site employment during this timeframe.

Noise impacts are about the same or less than those for Alternative 12A at SRS (see Section 4.22.1.1).

4.23.1.2 Waste Management

Table 4–196 compares the wastes generated during construction of surplus plutonium disposition facilities at SRS with the existing treatment, storage, and disposal capacity for the various waste types. It is anticipated that TRU waste and LLW would be generated during modification of Building 221–F. No mixed LLW would be generated. In addition, no soil contaminated with hazardous or radioactive constituents should be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies because the same size facility would be built under either scenario.

Table 4–196. Potential Waste Management Impacts of Construction Under Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of [b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	50	3	<1	<1
LLW	500	NA	NA	5
Hazardous	54	NA	NA	NA
Nonhazardous				
Liquid	14,500	5[d]	NA	1[e]
Solid	690	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional annual waste generation. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year construction period.
[c] Modification is not expected to generate remotely handled TRU waste or mixed waste.
[d] Percent of capacity of F-Area sanitary sewer.
[e] Percent of capacity of the Central Sanitary Wastewater Treatment Facility.
Key: DWPF, Defense Waste Processing Facility; LLW, low-level waste; NA, not applicable (i.e., the majority of the LLW is not routinely treated and stored on the site; it is assumed that the majority of the hazardous waste and nonhazardous solid waste would be treated and disposed of off the site by the construction contractor); TRU, transuranic.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive and hazardous wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995c).

TRU wastes would be packaged, and certified to WIPP waste acceptance criteria at the modification site. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU wastes generated during modification of Building 221–F is estimated to be 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 150 m^3 (196 yd^3) of TRU waste would be generated during the modification period. If all the TRU waste were stored on the site, this would be less than 1 percent of the 34,400-m^3 (45,000-yd^3) storage capacity available at the TRU Waste Storage Pads. If additional storage space were needed, and assuming that the waste would be stored in 208-l (55-gal) drums that would be stacked two high, and allowing a 50 percent factor for aisle space, a storage area of less than 0.1 ha (0.25 acre) would be required. Therefore, impacts of the management of additional quantities of TRU waste at SRS should not be major.

The 150 m^3 (196 yd^3) of TRU wastes generated during modification of Building 221–F would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the modification site before transfer for disposal in existing onsite facilities. A total of 1,500 m^3 (1,960 yd^3) of LLW would be generated during modification of Building 221–F. LLW generated during the modification period is estimated to be 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,500 m^3 (1,960 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Hazardous wastes generated during construction of surplus plutonium disposition facilities would be typical of those generated during construction of an industrial facility. Any hazardous wastes generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid wastes generated during construction of surplus plutonium disposition facilities would be packaged in conformance with standard industrial practice and shipped to offsite commercial facilities for recycling or disposal. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

To be conservative, it was assumed that all nonhazardous liquid wastes generated during construction of surplus plutonium disposition facilities would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation during construction of these facilities is estimated to be 5 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of these wastes at SRS should not have a major impact on the nonhazardous liquid waste treatment system during construction.

4.23.1.3 Socioeconomics

Construction-related employment requirements for Alternative 12B are presented in Table 4–197.

At its peak in 2002, construction of new pit conversion and immobilization facilities at SRS under this alternative would require 665 construction workers and generate another 534 indirect jobs in the region. This total employment requirement of 1,199 direct and indirect jobs represents only about 0.4 percent of the projected REA workforce, and thus should have no major impact on the REA. The requirement should also

Table 4–197. Construction Employment Requirements for Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Year	Pit Conversion	Immobilization	Total
2001	274	0	274
2002	417	248	665
2003	256	400	656
2004	0	330	330

Key: DWPF, Defense Waste Processing Facility.
Source: UC 1998e, 1998i, 1998j.

have little effect on the community services currently offered in the ROI. In fact, it should help offset the approximately 20 percent reduction in SRS employment (i.e., from 15,000 to 12,000 workers) projected for the years 1997–2005.

4.23.1.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from construction activities. A summary of radiological impacts of construction activities on workers at risk is presented as Table 4–198. Construction worker exposure to radiation deriving from other activities at the site, past or present, would be limited to ensure that doses are kept as low as is reasonably achievable. To this end, construction workers would be monitored (badged) as appropriate.

Table 4–198. Potential Radiological Impacts on Construction Workers of Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion[a]	Immobilization[b]	Total
Total dose (person-rem/yr)	1.3	4.7	6.0
Annual latent fatal cancers[c]	5.2×10^{-4}	1.9×10^{-3}	2.4×10^{-3}
Average worker dose (mrem/yr)	4	15	9.5[d]
Annual latent fatal cancer risk	1.6×10^{-6}	6.0×10^{-6}	3.8×10^{-6}

[a] An estimated average of 316 workers would be associated with annual construction operations.
[b] There would be 315 workers associated with construction and modification of the existing Building 221–F. The number would be the same for immobilization in either ceramic or glass.
[c] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.
[d] Represents an average of the doses for both facilities.
Key: DWPF, Defense Waste Processing Facility.
Note: The radiological limit for construction workers is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: ICRP 1991; NAS 1990; UC 1998e, 1998i, 1998j.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of construction activities at SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.23.1.5 Facility Accidents

Construction of a new pit conversion facility and modification of Building 221–F for plutonium conversion and immobilization at SRS could result in worker injuries or fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated 1,925 person-years of construction labor and standard industrial accident rates, approximately 190 cases of nonfatal occupational injury or illness and 0.27 fatality could be expected (DOL 1997a, 1997b). As all construction would take place prior to introduction of the radiological process inventory, no noteworthy radiological accidents should occur.

4.23.1.6 Environmental Justice

As discussed in the other parts of Section 4.23.1, construction under Alternative 12B would pose no significant health risks to the public. The risks would be negligible regardless of the racial or ethnic composition or the economic status of the population. Therefore, construction activities under Alternative 12B at SRS would have no significant impacts on minority or low-income populations.

4.23.2 Operations

4.23.2.1 Air Quality and Noise

Potential air quality impacts of the operation of facilities under Alternative 12B at SRS are about the same as those for Alternative 12A (see Section 4.22.2.1). Noise impacts would be similar to those for Alternative 12A (see Section 4.22.2.1).

The combustion of fossil fuels associated with Alternative 12B would result in the emission of carbon dioxide, one of the atmospheric gases that are believed to influence the global climate. Annual carbon dioxide emissions from this alternative would represent less than 2×10^{-4} percent of the 1995 annual U.S. emissions of carbon dioxide from fossil fuel combustion and industrial processes, and therefore would not appreciably affect global concentrations of this pollutant.

4.23.2.2 Waste Management

Table 4–199 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from operating surplus plutonium disposition facilities at SRS. Although HLW would be used in the immobilization process, no HLW would be generated by the surplus plutonium disposition facilities. Waste generation should be the same for the ceramic and glass immobilization technologies.

Table 4–199. Potential Waste Management Impacts of Operations Under Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	144	8	4	1 of WIPP
LLW	140	1	NA	5
Mixed LLW	2	<1	1	NA
Hazardous	32	<1	6	NA
Nonhazardous				
Liquid	55,000	20[d]	NA	5[e]
Solid	2,030	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional annual waste generation. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 10-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
[d] Percent of capacity of the F-Area sanitary sewer.
[e] Percent of capacity of Central Sanitary Wastewater Treatment Facility.
Key: DWPF, Defense Waste Processing Facility; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commerical facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SDP EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995c).

TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation at surplus plutonium disposition facilities is estimated to be 8 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,440 m^3 (1,880 yd^3) of TRU waste would be generated over the 10-year operation period. If all the TRU waste were stored on the site, this would be 4 percent of the 34,400-m^3 (45,000-yd^3) storage capacity available at the TRU Waste Storage Pads. Assuming that the waste were stored in 208-l (55-gal) drums that could be stacked two high, and allowing a 50 percent factor for aisle space, a storage area of about 0.21 ha (0.52 acre) would be required. Therefore, impacts of the management of additional quantities of TRU waste at SRS should not be major.

The 1,440 m^3 (1,880 yd^3) of TRU wastes generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the new facilities before transfer for additional treatment and disposal in existing onsite facilities. A total of 1,400 m^3 (1,830 yd^3) of LLW would be generated over the operation period. LLW generation at surplus plutonium disposition facilities is estimated to be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,400 m^3 (1,830 yd^3) of waste would require 0.16 ha (0.40 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation at surplus plutonium disposition facilities is estimated to be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste would be packaged at the generating facility for treatment and disposal at a combination of onsite and offsite facilities. Assuming that all hazardous waste is managed on the site, hazardous waste generation at surplus plutonium disposition facilities is estimated to be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system. If all LLW, mixed LLW,

and hazardous wastes generated at the surplus plutonium disposition facilities were treated in the Consolidated Incineration Facility, this additional waste would be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of that facility.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent for offsite disposal. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous wastewater would be treated if necessary before being discharged to the F-Area sanitary sewer system, which connects to the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generated by surplus plutonium disposition facilities at SRS is estimated to be 20 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer and 5 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of nonhazardous liquid waste at SRS should not have a major impact on the treatment system.

4.23.2.3 Socioeconomics

After construction, startup, and testing of the pit conversion and immobilization facilities at SRS in 2005 under Alternative 12B, an estimated 712 new workers would be required to operate them (UC 1998e, 1998i, 1998j). This level of employment should generate another 1,273 indirect jobs in the region. As this total employment requirement of 1,985 direct and indirect jobs represents less than 0.7 percent of the projected REA workforce, it should have no major impacts on the REA. The requirement should also have little impact on community services currently offered in the ROI. In fact, it should help to offset the reduction in the total SRS workforce of 33 percent (i.e., 15,000 to 10,000 workers) projected for the years 1997–2010.

4.23.2.4 Human Health Risk

During normal operation, there would be both radiological and hazardous chemical releases to the environment, and also direct in-plant exposures. The resulting doses to, and potential health effects on, the public and workers under this alternative are as follows:

Radiological Impacts. Table 4–200 reflects the potential radiological impacts on three individual receptor groups: the population living within 80 km (50 mi) of SRS in the year 2010, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected aggregate LCF risk to these groups from 10 years of operation. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Given incident-free operation of both facilities, the total population dose in the year 2010 would be 1.6 person-rem. The corresponding number of LCFs in this population from 10 years of operation would be 8.0×10^{-3}. The dose to the maximally exposed member of the public from annual operation of both facilities would be 3.8×10^{-3} mrem. From 10 years of operation, the corresponding LCF risk to this individual would be 1.9×10^{-8}. The impacts on the average individual would be lower.

Estimated impacts resulting from "Total Site" operations are given in the Cumulative Impacts section of this SPD EIS (see Section 4.32). Within that section, projected incremental impacts associated with the operation of the proposed surplus plutonium disposition facilities are added to the impacts of other past, present, and reasonably foreseeable future actions at or near the candidate sites. These impacts are then compared against applicable regulatory standards established by DOE and EPA (such as DOE Order 5400.5, the Clean Air Act [NESHAP], and the Safe Drinking Water Act).

Table 4–200. Potential Radiological Impacts on the Public of Operations Under Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion	Immobilization		Total[a]
		Ceramic	Glass	
Population within 80 km for year 2010				
Dose (person-rem)	1.6	4.9×10^{-3}	4.4×10^{-3}	1.6
Percent of natural background[b]	6.9×10^{-4}	2.1×10^{-6}	1.9×10^{-6}	6.9×10^{-4}
10-year latent fatal cancers	8.0×10^{-3}	2.5×10^{-5}	2.2×10^{-5}	8.0×10^{-3}
Maximally exposed individual				
Annual dose (mrem)	3.7×10^{-3}	5.0×10^{-5}	4.6×10^{-5}	3.8×10^{-3}
Percent of natural background[b]	1.3×10^{-3}	1.7×10^{-5}	1.6×10^{-5}	1.3×10^{-3}
10-year latent fatal cancer risk	1.9×10^{-8}	2.5×10^{-10}	2.3×10^{-10}	1.9×10^{-8}
Average exposed individual within 80 km[c]				
Annual dose (mrem)	2.0×10^{-3}	6.3×10^{-6}	5.6×10^{-6}	2.0×10^{-3}
10-year latent fatal cancer risk	1.0×10^{-8}	3.2×10^{-11}	2.8×10^{-11}	1.0×10^{-8}

[a] Totals are additive in all cases because the same groups or individuals would receive doses from both facilities. This total includes the higher of the values for the ceramic and glass immobilization alternatives.

[b] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive about 231,000 person-rem.

[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of the facilities (about 783,000) in 2010.

Key: DWPF, Defense Waste Processing Facility.
Source: Appendix J.

Doses to involved workers from normal operations are given in Table 4–201; these workers are defined as those directly associated with process activities. Under this alternative, the annual average dose to pit conversion facility workers would be 500 mrem; to immobilization facility workers, 750 mrem. The annual dose received by the total site workforce for each of these facilities has been estimated at 192 and 218 person-rem, respectively. The risks and numbers of LCFs among the different workers from 10 years of operation are included in Table 4–201. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–201. Potential Radiological Impacts on Involved Workers of Operations Under Alternative 12B: Pit Conversion in New Construction and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion	Immobilization (Ceramic or Glass)	Total
Number of badged workers	383	290	673
Total dose (person-rem/yr)	192	218	410
10-year latent fatal cancers	0.77	0.87	1.6
Average worker dose (mrem/yr)	500	750	608[a]
10-year latent fatal cancer risk	2.0×10^{-3}	3.0×10^{-3}	2.4×10^{-3}

[a] Represents an average of the doses for both facilities.

Key: DWPF, Defense Waste Processing Facility.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998e, 1998i, 1998j.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of operation activities at SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.23.2.5 Facility Accidents

The potential consequences of postulated bounding accidents from operation of the pit conversion facility at SRS are equivalent to those of Alternative 3A (see Table 4–40). The potential consequences of operation of the immobilization facility in Building 221–F at SRS are presented in Tables 4–202 and 4–203. As discussed in Section 4.20.2.5, inventories could differ with the 50-t (55-ton) throughput associated with this alternative, but most of that material would not be at risk in accidents. More details on the method of analysis, assumptions, and specific accident scenarios are presented in the discussion of Alternative 2 in Section 4.3.2.5.

Public. The potential consequences of postulated bounding accidents from operation of the pit conversion facility at SRS are substantially equivalent to those discussed in Section 4.4.2.5, and the potential consequences of such accidents from operation of the immobilization facility in Building 221–F and DWPF at SRS are presented in Tables 4–202 and 4–203.

A beyond-design-basis earthquake at SRS could result in collapse of the pit conversion and immobilization facilities, and an estimated 6.8 LCFs among the general population. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude at SRS is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

Noninvolved Worker. Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is a hypothetical individual working on the site but not involved in the proposed action, and assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. The consequences for this worker were estimated to be highest for the design basis earthquake. The consequences of such an accident would include an LCF probability of 4.2×10^{-3}.

Maximally Exposed Involved Worker. No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and the accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

Nonradiological Accidents. Plutonium disposition operations at SRS could result in worker injuries and fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated employment of 7,432 person-years of labor and the standard DOE occupational accident rates, approximately 238 cases of nonfatal occupational injury or illness and 0.24 fatality could be expected for the duration of operations.

Table 4–202. Accident Impacts of Alternative 12B: Ceramic Immobilization in Building 221–F at SRS (50-t Case)

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	1.0×10^{-2}	4.2×10^{-6}	1.6×10^{-3}	7.8×10^{-7}	1.5	8.0×10^{-4}
Explosion in HYDOX furnace	Unlikely	4.2×10^{-1}	1.7×10^{-4}	8.0×10^{-2}	4.0×10^{-5}	3.4×10^{2}	1.7×10^{-1}
Glovebox fire (calcining furnace)	Extremely unlikely	3.3×10^{-5}	1.3×10^{-8}	6.3×10^{-6}	3.2×10^{-9}	2.7×10^{-2}	1.3×10^{-5}
Hydrogen explosion	Unlikely	4.7×10^{-2}	1.9×10^{-5}	8.8×10^{-3}	4.4×10^{-6}	3.8×10^{1}	1.9×10^{-2}
Glovebox fire (sintering furnace)	Extremely unlikely	1.9×10^{-4}	7.4×10^{-8}	3.5×10^{-5}	1.8×10^{-8}	1.5×10^{-1}	7.5×10^{-5}
Design basis earthquake	Unlikely	1.1×10^{1}	4.2×10^{-3}	4.1×10^{-1}	2.0×10^{-4}	9.6×10^{2}	4.9×10^{-1}
Beyond-design-basis fire	Beyond extremely unlikely	6.3×10^{-3}	2.5×10^{-6}	2.5×10^{-4}	1.2×10^{-7}	5.8×10^{-1}	2.9×10^{-4}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	5.3×10^{1}	2.1×10^{-2}	2.1	1.0×10^{-3}	4.8×10^{3}	2.5

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value that assumes the accident has occurred.

Key: HYDOX, hydride oxidation.

4.23.2.6 Transportation

Because the only difference between Alternative 12A and 12B is the location of the immobilization facility within F-Area at SRS, the transportation required for Alternative 12B would be the same as that for Alternative 12A. Therefore, the transportation risks associated with Alternative 12B are equivalent to those discussed in Section 4.22.2.6.

4.23.2.7 Environmental Justice

As discussed in other parts of Section 4.23.2, routine operations conducted under Alternative 12B would pose no significant health risks to the public. The likelihood of an LCF for the MEI residing near SRS would be approximately 1 in 50 million (see Table 4–200). The number of LCFs expected among the general population residing near SRS from accident-free operations would increase by approximately 8.0×10^{-3}.

Design basis accidents at the site would not be expected to cause cancer fatalities among the public (see Section 4.23.2.5). A beyond-design-basis earthquake would be expected to result in LCFs among the

Table 4–203. Accident Impacts of Alternative 12B: Glass Immobilization in Building 221–F at SRS (50-t Case)

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	1.0×10^{-2}	4.2×10^{-6}	1.6×10^{-3}	7.8×10^{-7}	1.5	8.0×10^{-4}
Explosion in HYDOX furnace	Unlikely	4.2×10^{-1}	1.7×10^{-4}	8.0×10^{-2}	4.0×10^{-5}	3.4×10^{2}	1.7×10^{-1}
Glovebox fire (calcining furnace)	Extremely unlikely	3.3×10^{-5}	1.3×10^{-8}	6.3×10^{-6}	3.2×10^{-9}	2.7×10^{-2}	1.3×10^{-5}
Hydrogen explosion	Unlikely	4.7×10^{-2}	1.9×10^{-5}	8.8×10^{-3}	4.4×10^{-6}	3.8×10^{1}	1.9×10^{-2}
Melter eruption	Unlikely	1.7×10^{-4}	6.9×10^{-8}	3.3×10^{-5}	1.6×10^{-8}	1.4×10^{-1}	6.9×10^{-5}
Melter spill	Unlikely	4.0×10^{-5}	1.6×10^{-8}	7.7×10^{-6}	3.8×10^{-9}	3.3×10^{-2}	1.6×10^{-5}
Design basis earthquake	Unlikely	9.2	3.7×10^{-3}	3.6×10^{-1}	1.8×10^{-4}	8.5×10^{2}	4.3×10^{-1}
Beyond-design-basis fire	Beyond extremely unlikely	1.1×10^{-3}	4.6×10^{-7}	4.4×10^{-5}	2.2×10^{-8}	1.0×10^{-1}	5.3×10^{-5}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	4.7×10^{1}	1.9×10^{-2}	1.8	9.1×10^{-4}	4.3×10^{3}	2.2

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

Key: HYDOX, hydride oxidation.

general population (see Tables 4–40, 4–202, and 4–203). However, it is highly unlikely that a beyond-design-basis earthquake would occur. Accidents at the sites pose no significant risks (when the probability of occurrence is considered) to the population residing within the area potentially affected by radiological contamination.

As described in Section 4.23.2.6, no radiological or nonradiological fatalities would be expected to result from accident-free transportation conducted under this alternative. Nor would radiological or nonradiological fatalities be expected to result from transportation accidents.

Thus, implementation of Alternative 12B would pose no significant risks to the public, nor would implementation of this alternative pose significant risks to groups within the general public, including the risk of disproportionately high and adverse effects on minority and low-income populations.

Next Section

4.24 ALTERNATIVE 12C

Alternative 12C would involve constructing and operating the pit conversion facility in Zone 4 at Pantex and the immobilization facility at SRS. The immobilization facility would be located in a new building in F-Area. Activities at Pantex would be the same as described for Alternative 4A (see Section 4.6). Under this alternative, all surplus plutonium would be immobilized; none would be fabricated into MOX fuel.

4.24.1 Construction

4.24.1.1 Air Quality and Noise

Potential air quality and noise impacts of construction of the pit conversion facility under Alternative 12C at Pantex would be the same as those for Alternative 4A (see Section 4.6.1.1).

Potential air quality and noise impacts of construction of the immobilization facility of SRS under Alternative 12C would be the same as those for Alternative 6A (see Section 4.10.1.1).

4.24.1.2 Waste Management

At Pantex, construction impacts of this alternative would be the same as those for Alternative 4A. See Section 4.6.1.2 for a description of the impacts of this alternative on the waste management infrastructure at Pantex.

At SRS, construction impacts of this alternative would be the same as those for Alternative 6A.[1] See Section 4.10.1.2 for a description of the impacts of this alternative on the waste management infrastructure at SRS.

4.24.1.3 Socioeconomics

Construction-related employment requirements under Alternative 12C would be as indicated in Table 4–204.

Table 4–204. Construction Employment Requirements Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Year	Pit Conversion	Immobilization	Total
2001	298	0	298
2002	452	312	764
2003	275	448	723
2004	0	282	282

Key: DWPF, Defense Waste Processing Facility.
Source: UC 1998f, 1998g, 1998k.

At its peak in 2002, construction of the new pit conversion facility at Pantex under this alternative would require 452 construction workers and generate another 381 indirect jobs in the region. As the total employment requirement of 833 direct and indirect jobs represents only 0.3 percent of the projected REA workforce, it should have no major impact on the REA. It should also have little impact on community services within the ROI. In fact, it should help offset the nearly 40 percent reduction in the total Pantex workforce (i.e., from 2,900 to 1,750 workers) projected for the years 1997–2005.

At its peak in 2003, construction of the immobilization facility at SRS would require 448 construction workers and generate another 355 indirect jobs in the region. The total employment requirement of 803 direct and indirect jobs represents less than 0.3 percent of the projected REA workforce, and thus should have no major impact on the REA. This requirement should also have little impact on community services within the ROI. In fact, it should help offset the nearly 20 percent reduction in SRS' overall labor force (i.e., from 15,000 to 12,000 workers) projected for the years 1997–2005.

4.24.1.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from construction activities. A summary of radiological impacts of construction activities on workers at risk is presented in Table 4–205. According to a recent radiation survey (DOE 1997e) conducted in the Zone 4 area at Pantex, construction workers would not be expected to receive any additional radiation exposure above natural background levels in the area. Data indicate, however, that a construction worker in F-Area at SRS could receive exposures to radiation that derives from other activities, past or present, at the site. Regardless of location, construction worker exposures would be kept as low as is reasonably achievable, and workers would be monitored (badged) as appropriate.

Table 4–205. Potential Radiological Impacts on Construction Workers of Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Impact	Pit Conversion[a]	Immobilization[b]
Total dose (person-rem/yr)	0	1.4
Annual latent fatal cancers[c]	0	5.6×10^{-4}
Average worker dose (mrem/yr)	0	4
Annual latent fatal cancer risk	0	1.6×10^{-6}

[a] An estimated average of 342 workers would be associated with annual construction operations.
[b] An estimated average of 347 workers would be associated with annual construction operations at the new facility location adjacent to APSF. The number would be the same for immobilization in either ceramic or glass.
[c] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Key: APSF, Actinide Packaging and Storage Facility; DWPF, Defense Waste Processing Facility.
Note: The radiological limit for construction workers is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: DOE 1997e; ICRP 1991; NAS 1990; UC 1998f, 1998g, 1998k.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of construction activities at Pantex or SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.24.1.5 Facility Accidents

Construction of a new plutonium disposition facilities at Pantex and SRS could result in worker injuries or fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated 2,067 person-years of construction labor and standard industrial accident rates, approximately 200 cases of nonfatal occupational injury or illness and 0.29 fatality could be expected. As all construction would be in nonradiological areas, no radiological accidents should occur during construction.

4.24.1.6 Environmental Justice

As discussed in the other parts of Section 4.24.1, construction under Alternative 12C would pose no significant health risks to the public. The risks would be negligible regardless of the racial or ethnic composition or the economic status of the population. Therefore, construction activities conducted under Alternative 12C at Pantex and SRS would have no significant impacts on minority or low-income populations.

4.24.2 Operations

4.24.2.1 Air Quality and Noise

Potential air quality and noise impacts of operation of the new pit conversion facility under Alternative 12C at Pantex would be the same as those for Alternative 4A (see Section 4.6.2.1).

Potential air quality impacts of the operation of the immobilization facility under Alternative 12C at SRS were analyzed using ISCST3. Operational impacts would result from process emissions, emergency diesel generator testing, trucks moving materials and wastes, and employee vehicles. Emissions from these sources are summarized in Appendix G.

A comparison of maximum air pollutant concentrations, including the contribution from the immobilization facility, with standards and guidelines is presented as Table 4–206. Concentrations of air pollutants would likely increase at the site boundary, but would not exceed the Federal or State ambient air quality standards. Air pollution impacts during operation would be mitigated; for example, HEPA filtration has been included in the design of this facility.

Table 4–206. Evaluation of SRS Air Pollutant Concentrations Associated With Operations Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	SPD Increment[b] ($\mu g/m^3$)	Site Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.299	64.3	0.64
	1 hour	40,000	1.2	280	0.70
Nitrogen dioxide	Annual	100	0.0093	9.31	9.3
PM_{10}	Annual	50	0.000697	4.14	8.3
	24 hours	150	0.0125	56.4	38
Sulfur dioxide	Annual	80	0.0166	15.1	19
	24 hours	365	0.229	219	60
	3 hours	1,300	0.613	962	74
Other regulated pollutants					
Total suspended particulates	Annual	75	0.000697	14.7	20

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Includes the higher of the concentrations for the ceramic and glass immobilization options.
Key: DWPF, Defense Waste Processing Facility; SPD, surplus plutonium disposition.
Source: EPA 1997a; SCDHEC 1996.

For a discussion of how the operation of the immobilizatiion facility at SRS would affect the ability to continue to meet NESHAP limits regarding airborne radiological emissions, see Section 4.32.4.4. There are no other NESHAP limits applicable to operation of this facility.

The increases in concentrations of nitrogen dioxide, PM_{10}, and sulfur dioxide from the operation of this facility at SRS would be a small fraction of the PSD Class II area increments, as summarized in Table 4–207.

Table 4–207. Evaluation of Air Pollutant Increases Associated With Operations at SRS Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Pollutant	Averaging Period	Increase in Concentration ($\mu g/m^3$)	PSD Class II Area Allowable Increment ($\mu g/m^3$)	Percent of Increment
Nitrogen dioxide	Annual	0.0093	25	0.037
PM_{10}	Annual	0.000697	17	0.0041
	24 hours	0.0125	30	0.042
Sulfur dioxide	Annual	0.0166	20	0.083
	24 hours	0.229	91	0.25
	3 hours	0.613	512	0.12

Key: DWPF, Defense Waste Processing Facility; PSD, prevention of significant deterioration.
Source: EPA 1997b.

Total vehicle emissions associated with activities at SRS would likely decrease somewhat from current emissions because of an expected decrease in overall site employment during this timeframe.

The location of this facility at SRS relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during operation would include new or existing sources (e.g., cooling systems, vents, motors, material-handling equipment), employee vehicles, and truck traffic. Traffic noise associated with operation of this facility would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Given the distance to the site boundary (about 8.7 km [5.4 mi]), noise emissions from equipment would not likely annoy the public. These noise sources would be far enough away from offsite areas that the contribution to offsite noise levels would be small. However, some noise sources could have onsite impacts, such as the disturbance of wildlife. No noise impacts are expected to affect threatened and endangered species because there are no threatened and endangered species habitats near the facility site (see Section 4.26). Noise from traffic associated with operation of this facility would likely produce less than a 1-dB increase in traffic noise levels along roads used to access the site, and thus should not result in any increased annoyance of the public.

The combustion of fossil fuels associated with Alternative 12C would result in the emission of carbon dioxide, one of the atmospheric gases that are believed to influence the global climate. Annual carbon dioxide emissions from this alternative would represent less than 8×10^{-5} percent of the 1995 annual U.S. emissions of carbon dioxide from fossil fuel combustion and industrial processes, and therefore would not appreciably affect global concentrations of this pollutant.

4.24.2.2 Waste Management

Operational impacts of this alternative at Pantex would be the same as for Alternative 4A. See Section 4.6.2.2 for a description of the impacts of this alternative on the waste management infrastructure at Pantex.

Table 4–208 reflects a comparison of the existing site treatment, storage, and disposal capacities with the expected waste generation rates from operation of the surplus plutonium disposition facilities at SRS.

Table 4–208. Potential Waste Management Impacts of Operations at SRS Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Waste Type [a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of [b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	126	7	4	1 of WIPP
LLW	80	<1	NA	3
Mixed LLW	1	<1	1	NA
Hazardous	30	<1	6	NA
Nonhazardous				
Liquid	28,000	10[d]	NA	3[e]
Solid	230	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared to estimated additional waste generation on an annual basis. All other storage and disposal capacities are compared to total estimated additional waste generation assuming a 10-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
[d] Percent of capacity of F-Area sanitary sewer.
[e] Percent of capacity of Central Sanitary Wastewater Treatment Facility.
Key: DWPF, Defense Waste Processing Facility; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

Although HLW would be used in the immobilization process, no HLW would be generated by the facilities. Waste generation at SRS should be the same for the ceramic and glass immobilization technologies.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore it is assumed the TRU waste would be stored onsite until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of the treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995c).

TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities. Drum-gas testing, real-time radiography, and loading of the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

According to estimates, TRU wastes generated at the immobilization facility at SRS would amount to 7 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,260 m^3 (1,648 yd^3) of TRU waste would be generated over the 10-year operation period. If all the TRU waste were stored on the site, this would be 4 percent of the 34,400-m^3 (45,000-yd^3) storage capacity available at the TRU Waste Storage Pads. Assuming that the waste were stored in 208-l (55-gal) drums that could be stacked two high, and adding a 50 percent factor for aisle space, a storage area of about 0.18 ha (0.44 acre) would be required. Therefore, impacts of the management of additional quantities of TRU waste at SRS should not be major.

The 1,440 m^3 (1,884 yd^3) of TRU wastes generated by the facilities at Pantex and SRS would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of the disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

At SRS, LLW would be packaged, certified, and accumulated at the immobilization facility before transfer for additional treatment and disposal in existing onsite facilities. A total of 800 m^3 (1,050 yd^3) of LLW would be generated over the operational period. LLW generation at surplus plutonium disposition facilities has been estimated at less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incinerator Facility and 3 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Judging from the 8,687 m^3/ha disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 800 m^3 (1,050 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

At SRS, mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan. Mixed LLW generated at the immobilization facility would in all likelihood be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incinerator Facility, and 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

At SRS, any hazardous wastes generated during operation of the immobilization facility would be packaged for treatment and disposal at a combination of onsite and offsite facilities. Assuming that all hazardous waste were managed on the site, hazardous waste generation for this combination of facilities would be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. Management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system. If all LLW, mixed LLW, and hazardous wastes generated at the immobilization facility at SRS were treated in the Consolidated Incinerator Facility, this additional waste would be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of that facility.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent for offsite disposal. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at SRS.

At SRS, nonhazardous wastewater generated by the immobilization facilities would be treated if necessary before being discharged to the F-Area sanitary sewer system, which connects to the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generated by surplus plutonium disposition facilities would be an estimated 10 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer and 3 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of nonhazardous liquid waste at SRS should not have a major impact on the treatment system.

4.24.2.3 Socioeconomics

Under Alternative 12C, operation of the pit conversion facility at Pantex would begin in 2004 and should require 400 workers (UC 1998k). This level of employment should generate another 1,355 indirect jobs within the region. The total employment requirement of 1,755 direct and indirect jobs represents less than 0.7 percent

of the projected REA workforce, and thus should have no major impact on the REA. It should also have little impact on community services within the Pantex ROI. In fact, it should help offset the nearly 40 percent reduction in the total Pantex workforce (i.e., from 2,900 to 1,750 workers) projected for the years 1997–2010.

Startup and operation of the immobilization facility at SRS in 2005 under Alternative 12C would require an estimated 271 workers (UC 1998f, 1998g). This level of employment would be expected to generate another 485 indirect jobs within the region. The total employment requirement of 756 direct and indirect jobs represents less than 0.3 percent of the projected REA workforce, and thus should have no major impact on the REA. The additional required workers should also have little impact on community services within the ROI. In fact, they should help offset the 33 percent reduction in the total SRS workforce (i.e., 15,000 to 10,000 workers) projected for the years 1997–2010.

4.24.2.4 Human Health Risk

During normal operation, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses, to and potential health effects on, the public and workers for this alternative are described below.

Radiological Impacts. Presented in Table 4–209 are the potential radiological impacts on three individual receptor groups for Pantex and SRS: the population living within 80 km (50 mi) in the year 2010, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected aggregate LCF risk to these groups from 10 years of operation. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Table 4–209. Potential Radiological Impacts on the Public of Operations Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

		Immobilization	
Impact	**Pit Conversion**	**Ceramic**	**Glass**
Population within 80 km for year 2010			
Dose (person-rem)	0.58	4.9×10^{-3}	4.5×10^{-3}
Percent of natural background[a]	5.8×10^{-4}	2.1×10^{-6}	1.9×10^{-6}
10-year latent fatal cancers	2.9×10^{-3}	2.5×10^{-5}	2.3×10^{-5}
Maximally exposed individual			
Annual dose (mrem)	0.062	5.0×10^{-5}	4.5×10^{-5}
Percent of natural background[a]	0.019	1.7×10^{-5}	1.5×10^{-5}
10-year latent fatal cancer risk	3.1×10^{-7}	2.5×10^{-10}	2.3×10^{-10}
Average exposed individual within 80 km[b]			
Annual dose (mrem)	1.9×10^{-3}	6.3×10^{-6}	5.7×10^{-6}
10-year latent fatal cancer risk	9.5×10^{-9}	3.2×10^{-11}	2.9×10^{-11}

[a] The annual natural background radiation level at Pantex is 332 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 99,300 person-rem. The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 231,700 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Pantex (299,000) and APSF (785,400) in 2010.

Key: APSF, Actinide Packaging and Storage Facility; DWPF, Defense Waste Processing Facility.
Source: Appendix J.

Given incident-free operation of both disposition facilities, the total population dose in the year 2010 would be 0.58 person-rem. The corresponding number of LCFs in the populations around Pantex and SRS from 10 years of operation would be 2.9×10^{-3}. The dose to the maximally exposed member of the public from

annual operation of the pit conversion facility at Pantex would be 0.062 mrem. From 10 years of operation, the corresponding risk of LCF to this individual would be 3.1×10^{-7}. The impacts on the average individual would be lower. The total dose to the maximally exposed member of the public from annual operation of the immobilization facility at SRS would be 5.0×10^{-5} mrem. From 10 years of operation, the corresponding LCF risk to this individual would be 2.5×10^{-10}. The impacts on the average individual would be lower.

Estimated impacts resulting from "Total Site" operations are given in the Cumulative Impacts section of this SPD EIS (see Section 4.32). Within that section, projected incremental impacts associated with the operation of the proposed surplus plutonium disposition facilities are added to the impacts of other past, present, and reasonably foreseeable future actions at or near the candidate sites. These impacts are then compared against applicable regulatory standards established by DOE and EPA (such as DOE Order 5400.5, the Clean Air Act [NESHAP], and the Safe Drinking Water Act).

Doses to involved workers from normal operations are given in Table 4–210; these workers are defined as those directly associated with process activities. Under this alternative, the annual average dose to pit conversion workers would be 500 mrem; to immobilization facility workers, 750 mrem. The annual dose received by the total site workforce for each of these facilities has been estimated at 192 and 193 person-rem, respectively.

Table 4–210. Potential Radiological Impacts on Involved Workers of Operations Under Alternative 12C: Pit Conversion in New Construction at Pantex, and Immobilization in New Construction and DWPF at SRS

Involved Worker	Pit Conversion	Immobilization (Ceramic or Glass)	Total
Number of badged workers	383	257	640
Total dose (person-rem/yr)	192	193	385
10-year latent fatal cancers	0.77	0.77	1.5
Average worker dose (mrem/yr)	500	750	(a)
10-year latent fatal cancer risk	2.0×10^{-3}	3.0×10^{-3}	(a)

[a] This value holds no statistical relevance because the facilities are at different sites.

Key: DWPF, Defense Waste Processing Facility.

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: UC 1998f, 1998g, 1998k.

The risks and numbers of LCFs among the different workers from 10 years of operation are included in Table 4–210. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of operations at Pantex or SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.24.2.5 Facility Accidents

The potential consequences of postulated bounding facility accidents from operation of the pit conversion facility at Pantex would be equivalent to those of Alternative 4A (see Table 4–66); the potential consequences from operation of the immobilization facility at SRS, equivalent to those of Alternative 12A (see Tables 4–193 and 4–194).

Public. Thus, no LCFs would be expected among the public or the maximally exposed offsite individual from the design basis accidents at the facilities for Alternative 12C. For accidents for the pit conversion and immobilization facilities, see Sections 4.6.2.5 and 4.22.2.5, respectively.

The most severe consequences of design basis and beyond-design-basis accidents at the Pantex and SRS facilities would be equivalent to those described in Sections 4.6.2.5 and 4.22.2.5, respectively.

Noninvolved Worker. The noninvolved worker is a hypothetical individual working on the site but not involved in the proposed action, and assumed to be at a point 1,000 m (3,281 ft) downwind from the location of the accident. For design basis accidents, the radiological consequences for this worker were estimated to be highest for the tritium release at the pit conversion facility. Those consequences would include an LCF probability of 5.8×10^{-5}.

Maximally Exposed Involved Worker. No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and the accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

Nonradiological Accidents. Plutonium disposition operation activities at Pantex and SRS could result in worker injuries and fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated employment of 6,981 person-years of labor and the standard DOE occupational accident rates, approximately 223 cases of nonfatal occupational injury or illness and 0.22 fatality could be expected for the duration of operations.

4.24.2.6 Transportation

Under Alternative 12C, transportation to and from Pantex would include the shipment of plutonium pits and clean plutonium metal via SST from sites throughout the DOE complex to the pit conversion facility. During dismantlement of the pits, some HEU and classified pit parts would be recovered. The pit conversion facility would ship HEU via SST to ORR for storage and pit parts via SST to LANL. After conversion, the plutonium in the pit conversion facility would be in the form of plutonium oxide. This material would be shipped to SRS for immobilization.

It is assumed that depleted uranium hexafluoride needed for immobilization would be shipped via commercial truck to the uranium conversion facility, where it would be converted into uranium dioxide. After conversion, the depleted uranium dioxide would be shipped via commercial truck from the conversion facility to the immobilization facility at SRS.

Immobilization at SRS under this alternative would also require that surplus nonpit plutonium in various forms, excluding clean metal, be shipped from current storage locations (i.e., SRS, Hanford, INEEL, LANL, and RFETS) to the immobilization facility at SRS. Even though these materials are not clean plutonium metal or pits, the quantity of the plutonium contained in them would require that they be treated as materials that could be used in nuclear weapons, and thus that shipments be made in SSTs.

Under the preferred alternative for immobilization, the surplus plutonium would be immobilized in a ceramic matrix in small cans at the immobilization facility, placed in HLW canisters, and transported via specially designed trucks to DWPF in S-Area. This intrasite transportation—from F-Area to S-Area—could require the temporary shutdown of roads on SRS. It would, however, provide for all the necessary security and for reduced risk to the public; SSTs would not be required.

After the immobilized plutonium was encased by HLW at DWPF, it would be shipped to a geologic repository for ultimate disposition. Because HLW would be displaced by the cans of immobilized plutonium suspended in the HLW canister, additional canisters—to accommodate the displaced HLW—would be required over the life of the immobilization program. According to estimates, up to 340 additional canisters of HLW would be needed to meet the demands of surplus plutonium disposition under Alternative 12C. The WM PEIS documents an analysis of different options for the shipment of these canisters to a geologic repository using either trucks or trains. The analysis revealed that shipment by train would pose the lower risk. However, no ROD has yet been issued regarding these shipments. To bound the risks associated with these additional shipments, this SPD EIS, like the WM PEIS, takes the most conservative approach (i.e., the approach that results in the highest risk to the public): assumption that all of these shipments would be made by truck, one canister per truck.

Every alternative considered in this SPD EIS would require routine transportation of wastes from the proposed disposition facilities to treatment, storage, or disposal facilities on the sites. This transportation would be handled in the same manner as other site waste shipments, and as shown in Sections 4.24.1.2 and 4.24.2.2, would involve no major increase in the amounts of waste already being managed at these sites. The shipments would pose no greater risks than the ordinary waste shipments at these sites as analyzed in the WM PEIS.

However, TRU waste generated at Pantex was not covered by the WM PEIS ROD as there was no such waste at Pantex at the time the ROD was issued, and none was likely to be generated in ongoing site operations. Location of the pit conversion facility at Pantex would result in the generation of TRU waste, as described in Section 4.6.2.2. Moreover, a fairly large increase in the amount of LLW at Pantex (i.e., 25 percent of the site's current storage capacity) could be expected under this alternative. Currently, this type of waste is shipped to NTS for disposal. In order to account for the transportation of TRU waste from Pantex to WIPP, and LLW from Pantex to NTS, additional shipments are analyzed in this SPD EIS.

In all, approximately 2,100 shipments of radioactive materials would be carried out by DOE under this alternative. The total distance traveled on public roads by trucks carrying radioactive materials would be 4.2 million km (2.6 million mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities entailed by this alternative has been estimated at 122 person-rem; the dose to the public, 127 person-rem. Accordingly, incident-free transportation of radioactive material associated with this alternative would result in 0.049 LCF among transportation workers and 0.064 LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions associated with this alternative is 0.018.

Impacts of Accidents During Ground Transportation. The maximum foreseeable offsite transportation accident under this Alternative (probability of occurrence: about 1 in 10 million per year) is a shipment of surplus nonpit plutonium from a DOE storage facility to SRS with a severity category VIII accident in a rural population zone under neutral (average) weather conditions. Because surplus nonpit plutonium shipments include plutonium oxide, an accident involving plutonium oxide is conservatively used to estimate the impacts of the maximum foreseeable accident. The accident could result in a dose of 145 person-rem to the public for an LCF risk of 0.07 and 159 rem to the hypothetical MEI for an LCF risk of 0.08. (The MEI receives a larger dose than the population because it is unlikely that a person would be in position, and remain in position, to

receive this hypothetical maximum dose.) No fatalities would be expected to occur. The probability of more severe accidents, different weather conditions at the time of accident, or occurrence in a more densely populated area were also evaluated, and estimated to have a probability lower than 1 chance in 10 million per year.

Estimates of the total ground transportation accident risks under Alternative 12C are as follows: a radiological dose to the population of 4.6 person-rem, resulting in a total population risk of 2.3×10^{-3} LCF; and traffic accidents resulting in 0.074 traffic fatalities.

4.24.2.7 Environmental Justice

As discussed in other parts of Section 4.24.2, routine operations conducted under Alternative 12C would pose no significant health risks to the public. The likelihood of an LCF for the MEI residing near Pantex would be approximately 1 in 3 million; the likelihood for the MEI residing near SRS would be essentially zero (see Table 4–209). The number of LCFs expected among the general population residing near Pantex and SRS from accident-free operations would increase by approximately 8.0×10^{-3} and 2.5×10^{-5}, respectively.

Design basis accidents at the sites would not be expected to cause cancer fatalities among the public (see Section 4.24.2.5). A beyond-design-basis earthquake would be expected to result in LCFs among the general population (see Tables 4–66, 4–193, and 4–194). However, it is highly unlikely that a beyond-design-basis earthquake would occur. Accidents at the sites pose no significant risks (when the probability of occurrence is considered) to the population residing within the area potentially affected by radiological contamination.

As described in Section 4.24.2.6, no radiological or nonradiological fatalities would be expected to result from accident-free transportation conducted under this alternative. Nor would radiological or nonradiological fatalities be expected to result from transportation accidents.

Thus, implementation of Alternative 12C would pose no significant risks to the public, nor would implementation of this alternative pose significant risks to groups within the general public, including the risk of disproportionately high and adverse effects on minority and low-income populations.

Next Section

4.25 ALTERNATIVE 12D

Alternative 12D would involve constructing and operating the pit conversion facility in Zone 4 at Pantex and the immobilization facility at SRS. The immobilization facility would be located in the existing Building 221–F in F-Area. Activities at Pantex would be the same as under Alternative 4A (Section 4.6). Under this alternative, all surplus plutonium would be immobilized; none would be fabricated into MOX fuel.

4.25.1 Construction

4.25.1.1 Air Quality and Noise

Sources of potential air quality and noise impacts of construction of the pit conversion facility under Alternative 12D at Pantex are the same as those for Alternative 4A (see Section 4.6.1.1).

Sources of potential air quality and noise impacts of construction of the immobilization facility under Alternative 12D at SRS are the same as those for Alternative 6C (see Section 4.12.1.1).

4.25.1.2 Waste Management

At Pantex, construction impacts from this alternative would be the same as those for Alternative 4A. See Section 4.6.1.2 for a description of the impacts of this alternative on the waste management infrastructure at Pantex.

At SRS, construction impacts of this alternative would be the same as those for Alternative 6C. See Section 4.12.1.2 for a description of the impacts of this alternative on the waste management infrastructure at SRS.

4.25.1.3 Socioeconomics

Construction-related employment requirements for Alternative 12D would be as indicated in Table 4–211.

Table 4–211. Construction Employment Requirements Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Year	Pit Conversion	Immobilization	Total
2001	298	0	298
2002	452	248	700
2003	275	400	675
2004	0	330	330

Key: DWPF, Defense Waste Processing Facility.
Source: UC 19978, 1998j, 1998k.

At its peak in 2002, construction of the new pit conversion facility at Pantex under this alternative would require 452 construction workers and generate another 381 indirect jobs in the region. As the total employment requirement of 833 direct and indirect jobs represents only 0.3 percent of the projected REA workforce, it should have no major impact on the REA. It should also have little impact on community services within the ROI. In fact, it should help offset the nearly 40 percent reduction in the total Pantex workforce (i.e., from 2,900 to 1,750 workers) projected for the years 1997–2005.

At its peak in 2003, construction of the immobilization facility at SRS would require 400 construction workers and generate another 321 indirect jobs in the region. The total employment requirement of 721 direct and indirect jobs represents less than 0.3 percent of the projected REA workforce, and thus should have no major impacts on the REA. It should also have little impact on community services within the ROI. In fact, it should help offset the nearly 20 percent reduction in SRS employment (i.e., from 15,000 to 12,000 workers) projected for the years 1997–2005.

4.25.1.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from construction activities. A summary of radiological impacts of construction activities on workers at risk is presented in Table 4–212. According to the results of a recent radiation survey (DOE 1997e) conducted in the Zone 4 area at Pantex, construction workers would not be expected to receive any additional radiation exposure above natural background levels in the area. Data indicate, however, that a construction worker in F-Area at SRS could be exposed to radiation that derives from other activities, past or present, at the site. Regardless of location, construction worker exposures would be kept as low as is reasonably achievable, and workers would be monitored (badged) as appropriate.

Table 4–212. Potential Radiological Impacts on Construction Workers Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion[a]	Immobilization[b]
Total dose (person-rem/yr)	0	4.7
Annual latent fatal cancers[c]	0	1.9×10^{-3}
Average worker dose (mrem/yr)	0	15
Annual latent fatal cancer risk	0	6.0×10^{-6}

[a] An estimated average of 230 workers would be associated with annual construction operations.
[b] There would be 315 workers associated with construction and modification of the existing Building 221–F. The number would be the same for immobilization in either ceramic or glass.
[c] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Key: DWPF, Defense Waste Processing Facility.

Note: The radiological limit for construction workers is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: DOE 1997e; ICRP 1991; NAS 1990; UC 1998i, 1998j, 1998k.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of construction activities at Pantex or SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.25.1.5 Facility Accidents

Construction of new plutonium disposition facilities at Pantex and SRS could result in worker injuries or fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated 2,003 person-years of construction labor and standard industrial accident rates, approximately 200 cases of nonfatal occupational injury or illness and 0.28 fatality could be expected. As all construction would take place prior to introduction of the radiological process inventory, no noteworthy radiological accidents should occur during construction.

4.25.1.6 Environmental Justice

As discussed in the other parts of Section 4.25.1, construction under Alternative 12D would pose no significant health risks to the public. The risks would be negligible regardless of the racial or ethnic composition or the economic status of the population. Therefore, construction activities under Alternative 12D at SRS would have no significant impacts on minority or low-income populations.

4.25.2 Operations

4.25.2.1 Air Quality and Noise

Potential air quality and noise impacts of operation of the new pit conversion facility under Alternative 12D at Pantex are the same as those for Alternative 4A (see Section 4.6.2.1).

Potential air quality impacts of the operation of the immobilization facility under Alternative 12D at SRS were analyzed using ISCST3. Operational impacts result from process emissions, emergency diesel generator testing, trucks moving material and wastes, and employee vehicles. Emissions from these sources are summarized in Appendix G.

A comparison of maximum air pollutant concentrations, including the contribution from the immobilization facility, with standards and guidelines is presented as Table 4–213. Concentrations of air pollutants would likely increase at the site boundary but should not exceed the Federal or State ambient air quality standards. Air pollution impacts during operation would be mitigated; for example, HEPA filtration has been included in the design of the facility.

Table 4–213. Evaluation of SRS Air Pollutant Concentrations Associated With Operations Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	SPD Increment[b] ($\mu g/m^3$)	Site Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.31	64.3	0.64
	1 hour	40,000	1.21	280	0.70
Nitrogen dioxide	Annual	100	0.00968	9.31	9.3
PM_{10}	Annual	50	0.000724	4.14	8.3
	24 hours	150	0.013	56.4	38
Sulfur dioxide	Annual	80	0.0166	15.1	19
	24 hours	365	0.229	219	60
	3 hours	1,300	0.615	962	74
Other regulated pollutants					
Total suspended particulates	Annual	75	0.000724	14.7	20

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Includes the higher of the concentrations for the ceramic and glass immobilization options.
Key: DWPF, Defense Waste Processing Facility; SPD, surplus plutonium disposition.
Source: EPA 1997a; SCDHEC 1996.

For a discussion of how the operation of the immobilization facility at SRS would affect the ability to continue to meet NESHAP limits regarding airborne radiological emissions, see Section 4.32.4.4. There are no other NESHAP limits applicable to operation of this facility.

The increases in concentrations of nitrogen dioxide, PM_{10}, and sulfur dioxide from the operation of this facility at SRS would be a small fraction of the PSD Class II area increments, as summarized in Table 4–214.

Table 4–214. Evaluation of SRS Air Pollutant Increases Associated With Operations Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Pollutant	Averaging Period	Increase in Concentration ($\mu g/m^3$)	PSD Class II Area Allowable Increment ($\mu g/m^3$)	Percent of Increment
Nitrogen dioxide	Annual	0.00968	25	0.039
PM_{10}	Annual	0.000724	17	0.0043
	24 hours	0.013	30	0.043
Sulfur dioxide	Annual	0.0166	20	0.083
	24 hours	0.229	91	0.25
	3 hours	0.615	512	0.12

Key: DWPF, Defense Waste Processing Facility; PSD, prevention of significant deterioration.
Source: EPA 1997b.

Total vehicle emissions associated with activities at SRS would likely decrease somewhat from current emissions because of an expected decrease in overall site employment during this timeframe.

The combustion of fossil fuels associated with Alternative 12D would result in the emission of carbon dioxide, one of the atmospheric gases that are believed to influence the global climate. Annual carbon dioxide emissions from this alternative would represent less than 8×10^{-5} percent of the 1995 annual U.S. emissions of carbon dioxide from fossil fuel combustion and industrial processes, and therefore would not appreciably affect global concentrations of this pollutant.

The location of this facility at SRS relative to the site boundary and sensitive receptors was examined to evaluate the potential for onsite and offsite noise impacts. Noise sources during operation would include new or existing sources (e.g., cooling systems, vents, motors, material-handling equipment), employee vehicles, and truck traffic. Traffic noise associated with operation of this facility would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Given the distance to the site boundary (about 8.7 km [5.4 mi]), noise emissions from equipment would not likely annoy the public. These noise sources would be far enough away from offsite areas that the contribution to offsite noise levels would be small. However, some noise sources could have onsite impacts, such as the disturbance of wildlife. No noise impacts are expected to affect threatened and endangered species because there are no threatened and endangered species habitats near the facility site (see Section 4.26). Noise from traffic associated with operation of this facility would likely produce less than a 1-dB increase in traffic noise levels along roads used to access the site, and thus should not result in any increased annoyance of the public.

4.25.2.2 Waste Management

At Pantex, operational impacts of this alternative would be the same as those for Alternative 4A. See Section 4.6.2.2 for a description of the impacts of this alternative on the waste management infrastructure at Pantex.

At SRS, operational impacts of this alternative would be the same as for those for Alternative 12C. See Section 4.24.2.2 for a description of the impacts of this alternative on the waste management infrastructure at SRS.

4.25.2.3 Socioeconomics

Employment requirements for operation of the new pit conversion facility at Pantex under Alternative 12D would be the same as those for Alternative 4A (see Section 4.6.2.3).

Startup and operation of the immobilization facility at SRS in 2005 under Alternative 12D would require an estimated 312 workers (UC 1998i, 1998j). This level of employment would generate another 558 indirect jobs within the region. As the total employment requirement of 870 direct and indirect jobs represents only about 0.3 percent of the projected REA workforce, it should have no major impacts on the REA. The additional workers should also have little effect on community services within the ROI. In fact, they should help decrease the reduction in total site employment projected for the years 1997–2010 from 33.3 percent (i.e., 15,000 to 10,000 workers).

4.25.2.4 Human Health Risk

During normal operations, there would be both radiological and hazardous chemical releases to the environment and also direct in-plant exposures. The resulting doses to, and potential health effects on, the public and workers for this alternative are described below.

Radiological Impacts. Presented as Table 4–215 are the potential radiological impacts on three individual receptor groups for Pantex and SRS: the population living within 80 km (50 mi) in the year 2010, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected aggregate LCF risk to these groups from 10 years of operation. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Given incident-free operation of both plutonium disposition facilities, the total population dose in the year 2010 would be 0.58 person-rem. The corresponding number of LCFs in the populations around Pantex and SRS from 10 years of operation would be 2.9×10^{-3}. The dose to the maximally exposed member of the public from annual operation of the pit conversion facility at Pantex would be 0.062 mrem. From 10 years of operation, the corresponding LCF risk to this individual would be 3.1×10^{-7}. The impacts on the average individual would be lower. The total dose to the maximally exposed member of the public from annual operation of the immobilization facility at SRS would be 5.0×10^{-5} mrem. From 10 years of operation, the corresponding LCF risk to this individual would be 2.5×10^{-10}. The impacts on the average individual would be lower.

Estimated impacts resulting from "Total Site" operations are given in the Cumulative Impacts section of this SPD EIS (see Section 4.32). Within that section, projected incremental impacts associated with the operation of the proposed surplus plutonium disposition facilities are added to the impacts of other past, present, and reasonably foreseeable future actions at or near the candidate sites. These impacts are then compared against applicable regulatory standards established by DOE and EPA (such as DOE Order 5400.5, the Clean Air Act [NESHAP], and the Safe Drinking Water Act).

Doses to involved workers from normal operations are given in Table 4–216; these workers are defined as those directly associated with process activities. Under this alternative, the annual average dose to pit conversion facility workers would be 500 mrem; to immobilization facility workers, 750 mrem. The annual

Table 4–215. Potential Radiological Impacts on the Public of Operations Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion	Immobilization	
		Ceramic	Glass
Population within 80 km for year 2010			
Dose (person-rem)	0.58	4.9×10^{-3}	4.4×10^{-3}
Percent of natural background[a]	5.8×10^{-4}	2.1×10^{-6}	1.9×10^{-6}
10-year latent fatal cancers	2.9×10^{-3}	2.5×10^{-5}	2.2×10^{-5}
Maximally exposed individual			
Annual dose (mrem)	0.062	5.0×10^{-5}	4.6×10^{-5}
Percent of natural background[a]	0.019	1.7×10^{-5}	1.6×10^{-5}
10-year latent fatal cancer risk	3.1×10^{-7}	2.5×10^{-10}	2.3×10^{-10}
Average exposed individual within 80 km[b]			
Annual dose (mrem)	1.9×10^{-3}	6.3×10^{-6}	5.6×10^{-6}
10-year latent fatal cancer risk	9.5×10^{-9}	3.2×10^{-11}	2.8×10^{-11}

[a] The annual natural background radiation level at Pantex is 332 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 99,300 person-rem. The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive about 231,000 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of SRS Building 221–F (781,500) in 2010.

Key: DWPF, Defense Waste Processing Facility.

Source: Appendix J.

operation are included in Table 4–216. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–216. Potential Radiological Impacts on Involved Workers of Operations Under Alternative 12D: Pit Conversion in New Construction at Pantex, and Immobilization in Building 221–F and DWPF at SRS

Impact	Pit Conversion	Immobilization (Ceramic or Glass)	Total
Number of badged workers	383	290	673
Total dose (person-rem/yr)	192	218	410
10-year latent fatal cancers	0.77	0.87	1.6
Average worker dose (mrem/yr)	500	750	(a)
10-year latent fatal cancer risk	2.0×10^{-3}	3.0×10^{-3}	(a)

[a] This value holds no statistical relevance because the facilities are at different sites.

Key: DWPF, Defense Waste Processing Facility.

Note: The radiological limit for an individual worker is 5,000 mrem/year (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: UC 1998i, 1998j, 1998k.

Hazardous Chemical Impacts. No hazardous chemicals would be released as a result of operations at Pantex or SRS under this alternative; thus, no cancer or adverse, noncancer health effects would occur.

4.25.2.5 Facility Accidents

The potential consequences of postulated bounding facility accidents from operation of the pit conversion facility at Pantex are equivalent to those of Alternative 4A (see Table 4–66); potential consequences of operation of the immobilization facility at SRS would be equivalent to those of Alternative 12B (see Tables 4–202 and 4–203).

Public. The design basis and beyond-design-basis accidents at Pantex and SRS would be equivalent to those discussed in Sections 4.6.2.5 and 4.5.2.5, respectively.

Noninvolved Worker. Consistent with the analysis presented in *the Storage and Disposition Final PEIS*, the noninvolved worker is a hypothetical individual working on the site but not involved in the proposed action, and assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be highest for the design basis earthquake at SRS. The consequences of such an accident would include an LCF probability of 4.2×10^{-3}.

Maximally Exposed Involved Worker. No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved worker would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, the immediate emergency response actions should reduce the consequences to workers near the accident.

Nonradiological Accidents. Plutonium disposition operation activities at Pantex and SRS could result in worker injuries and fatalities. DOE-required industrial safety programs would be in place to reduce the risks. Given the estimated employment of 7,432 person-years of labor and the standard DOE occupational accident rates, approximately 238 cases of nonfatal occupational injury or illness and 0.24 fatality could be expected for the duration of operations.

4.25.2.6 Transportation

Because the only difference between Alternative 12C and 12D is the location of the immobilization facility within F-Area at SRS, the transportation required for Alternative 12D would be the same as that for Alternative 12C. Therefore, the transportation risks associated with Alternative 12D are equivalent to those discussed in Section 4.24.2.6.

4.25.2.7 Environmental Justice

As discussed in other parts of Section 4.25.2, routine operations conducted under Alternative 12D would pose no significant health risks to the public. The likelihood of an LCF for the MEI residing near Pantex would be approximately 1 in 3 million; the likelihood for the MEI residing near SRS would be essentially zero (see Table 4–215). The number of LCFs expected among the general population residing near Pantex and SRS from accident-free operations would increase by approximately 2.9×10^{-3} and 2.5×10^{-5}, respectively.

Design basis accidents at the sites would not be expected to cause cancer fatalities among the public (see Section 4.25.2.5). A beyond-design-basis earthquake would be expected to result in LCFs among the general population (see Tables 4–66, 4–202, and 4–203). However, it is highly unlikely that a beyond-design-basis earthquake would occur. Accidents at the sites pose no significant risks (when the probability of occurrence is considered) to the population residing within the area potentially affected by radiological contamination.

As described in Section 4.25.2.6, no radiological or nonradiological fatalities would be expected to result from accident-free transportation conducted under this alternative. Nor would radiological or nonradiological fatalities be expected to result from transportation accidents.

Thus, implementation of Alternative 12D would pose no significant risks to the public, nor would implementation of this alternative pose significant risks to groups within the general public, including the risk of disproportionately high and adverse effects on minority and low-income populations.

Next Section

4.26 ADDITIONAL ENVIRONMENTAL RESOURCE ANALYSES

4.26.1 Hanford

For Hanford, the maximum impacts on environmental resources would be experienced if Alternative 2 were implemented. Under this alternative, the pit conversion and immobilization facilities would be collocated in FMEF, and a new MOX facility would be built nearby. This alternative would require the maximum amount of ground disturbance, thereby maximizing the potential impacts on related resources such as geology and soils, ecological, and cultural. This alternative would also require the most water and place the maximum strain on infrastructure at the site. All the other Hanford alternatives evaluated in this SPD EIS would have fewer land and resource requirements, so none would result in greater impacts than those associated with Alternative 2.

4.26.1.1 Geology and Soils

4.26.1.1.1 Construction

Construction of all the surplus plutonium disposition facilities at Hanford with the MOX facility in a new building would have negligible impact on the geologic or soils resources. In the *Storage and Disposition Final PEIS*, hazards from the large-scale geologic conditions at Hanford were analyzed in detail. The analysis determined that these conditions pose an acceptable risk to the proposed long-term storage facilities. That decision is not revisited in this SPD EIS. More detailed descriptions of impacts of the potential geologic hazards at Hanford are included in the *Storage and Disposition Final PEIS* (DOE 1996a: 4-45–4-47).

The soils at Hanford are considered acceptable for standard construction techniques. Other than crushed rock, sand, and gravel, no economically viable geologic resources have been identified at Hanford. New construction could increase the use of crushed rock, sand, and gravel; however, large volumes of these materials are present, and the impact should be negligible. No soils at Hanford are currently classified as prime farmland.

4.26.1.1.2 Operations

Operation of all the facilities at Hanford would have no impact on the geologic or soils resources.

4.26.1.2 Water Resources

4.26.1.2.1 Construction

Surface water is not proposed to be used under any of the alternatives being evaluated for Hanford (UC 1998a, 1998b, 1998c, 1998d). Therefore, no impacts on water availability for downstream users would be expected.

According to estimates, construction of all the proposed surplus plutonium disposition facilities at Hanford would require a maximum of 63 million l/yr (16.6 million gal/yr) of water (UC 1998a, 1998b, 1998c, 1998d). When added to current usage, this represents about 26 percent of the 400 Area groundwater capacity. This volume also represents about 13 percent of the total capacity of the 400 Area water treatment plants, which are approved to withdraw 500 million l/yr (131.4 million gal/yr) of groundwater (Mecca 1997:180). This amount of water would not have a major affect on water availability to other users in the area. Wastewater would not be directly discharged to the groundwater aquifer. Therefore, no impacts on groundwater quality would be expected.

All wastewater would be held in the 400 Area water treatment facilities prior to discharge into the WPPSS treatment system, which is designed to meet National Pollution Discharge Elimination System (NPDES) permit limitations. Therefore, no impacts on water quality would be expected (Mecca 1997:180).

Proven construction techniques would be used to mitigate the impact of soil erosion on receiving streams. Because of the effectiveness of these techniques, no long-term impacts from soil erosion due to construction activities would be expected.

The proposed facilities would be constructed in the 400 Area and would be located outside the 100-year flood area and the probable-maximum-flood area. Flooding in the latter area is more severe than the 500-year flood (DOE 1996a:3-32; ERDA 1976:1-11). Therefore, the proposed facilities would neither affect nor be affected by flooding.

4.26.1.2.2 Operations

Surface water would not be used in the operation of the proposed surplus plutonium disposition facilities, and there would be no direct discharges of wastewater from the facilities (UC 1998a, 1998b, 1998c, 1998d). Therefore, no impact on surface water quality or availability would be expected from the proposed activities.

The annual maximum water usage for operation of all the proposed surplus plutonium disposition facilities at the 400 Area would be about 132 million l (34.5 million gal) (UC 1998a, 1998b, 1998c, 1998d). When added to current usage, this represents about 44 percent of the 400 Area groundwater capacity. This also represents about 26 percent of the capacity of the 400 Area water treatment plant, which has an approved capacity of 500 million l/yr (131.4 million gal/yr) (Mecca 1997:180). Because other uses for water from this facility are small, this increased flow would not cause the plant to exceed its approved withdrawal rate. There would be no impact on the availability of groundwater for other users if all of the facilities were operated at Hanford.

There would be no direct discharge of wastewater into the groundwater aquifer (UC 1998a, 1998b, 1998c, 1998d). All wastewater would be treated prior to discharge in facilities designed to meet NPDES permit limitations. Therefore, no impact on groundwater quality would be expected from the operation of all facilities at Hanford.

4.26.1.3 Ecological Resources

Ecological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. However, habitat disturbance would be minimal; the land area required for construction activities is small in relation to regionally available habitat, and construction would take place in previously disturbed or developed areas. Operational impacts would also be minimal because facility emissions to the environment would be processed in accordance with applicable permitting procedures. Therefore, impacts on nonsensitive and sensitive habitats, plant and animal species, and the overall biodiversity of the candidate site would be minimal.

4.26.1.3.1 Construction

Nonsensitive Habitat. Siting the three proposed surplus plutonium disposition facilities at Hanford would disturb a total of about 15 ha (37 acres) of land in the 400 Area. Some of this land (2.1 ha [5.2 acres]) would be used only temporarily as a laydown area during the 3-year construction phase for the immobilization facility, and some (4.7 ha [12 acres]) for the same purpose during the 5-year construction and startup phases for the MOX facility. The existing construction laydown area used to build FMEF would be used for the pit

conversion facility (2 ha [4.9 acres]) (UC 1998a, 1998b, 1998c, 1998d). Vegetation in this area is characterized as post-fire shrub-steppe dominated by cheatgrass and small shrubs (Mecca 1997:Poston memo to Teal). Cheatgrass, a nonnative annual, would most likely recover the disturbed areas. This species can competitively exclude less vigorous native species that provide important food or shelter for insects, small mammals, and birds (DOE 1995a). The associated animal populations would be affected. Some of the less-mobile or established animals (e.g., mice, rabbits, snakes, and lizards) within the construction zone could perish during land-clearing activities and increased vehicular traffic. Furthermore, activities and noise associated with construction could cause larger mammals and birds to relocate to similar habitat in the area. Depending on the populations presently in those areas, the ecosystem dynamics could be altered, adding stress if food or shelter were limited. Prior to construction, the proposed site would be surveyed for nests of migratory birds in accordance with the Migratory Bird Treaty Act. There would be no impacts on aquatic habitat from surface water consumption because water required for construction would be drawn from groundwater sources (UC 1998a, 1998b, 1998c, 1998d).

Sensitive Habitat. Wetlands or critical habitat would not be affected because there are none in the construction zone. It is also unlikely that any federally listed threatened or endangered species would be affected because none have been sighted on or around the Central Plateau (DOE 1996e: 4-34). However, Washington State–classified special-status species associated with shrub-steppe habitat could be affected during land-clearing activities. Animal species include the burrowing owl, ferruginous hawk, golden eagle, long-billed curlew, sage thrasher, Swainson's hawk, pygmy rabbit, desert night snake, and striped whipsnake. It is doubtful that the loggerhead shrike and sage sparrow would be affected, because most of their habitat in the 400 Area has been destroyed by fire. Plant species (see Table 3–4) include crouching milkvetch, piper's daisy, squill onion, and stalked-pod milkvetch (DOE 1996e: 4-34; Dirkes and Hanf 1997:F.1–F.3; Mecca 1997:Poston memo to Teal). Preconstruction surveys and consultations with USFWS and the equivalent State agency would be conducted to ensure that impacts on sensitive species living in the vicinity of the 400 Area are negligible, and that appropriate mitigation actions are implemented as needed.

4.26.1.3.2 Operations

Nonsensitive Habitat. Activities associated with operation of the surplus plutonium disposition facilities could impact wildlife in the area due to noise and human presence. As a result, animal species could leave the area and take up residence in similar habitat nearby thus changing the ecosystem dynamics and adding stress to the habitat and its occupants. However, impacts associated with airborne releases of criteria pollutants, hazardous and toxic air pollutants, and radionuclides would be unlikely because scrubbers and filters would be used (UC 1998a, 1998b, 1998c, 1998d). Aquatic resources should not be affected because groundwater would be used and liquid effluents would be sampled, treated, and disposed of in accordance with approved permits and procedures (UC 1998a, 1998b, 1998c, 1998d).

Sensitive Habitat. Operational impacts on wetlands or critical habitat would be unlikely because airborne and aqueous effluents would be controlled and permitted. It is also unlikely that any federally listed threatened or endangered species would be affected because none have been sighted on or around the Central Plateau (DOE 1996e: 4-34). However, Washington State–classified special-status species could be affected by noise or human activity during operations, as discussed for construction (DOE 1996e: 4-34; Dirkes and Hanf 1997:F.1–F.3; Mecca 1997a:Poston memo to Teal).

4.26.1.4 Cultural and Paleontological Resources

Prehistoric, historic, Native American, and paleontological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. The land area required for construction activities is fairly small, however, and any such resource disturbance would be minimized by confinement of

the construction to previously disturbed or developed areas. Impacts of operations would be negligible because facility operations and security would restrict access to nearby prehistoric, historic, Native American, and paleontological resources. Continued compliance monitoring, before and after construction, would also help to limit or preclude impacts on these resources.

4.26.1.4.1 Construction

Siting all facilities at Hanford would disturb about 15 ha (37 acres) of land in the 400 Area. Some of this area (4.7 ha [12 acres]) would be used only temporarily as a laydown area during the 5-year construction and startup phases for the MOX facility, and some (2.1 ha [5.2 acres]), during the 3-year construction phase for the immobilization facility. The existing FMEF construction laydown area (2 ha [4.9 acres]) would be used for the pit conversion facility (UC 1998a, 1998b, 1998c, 1998d).

Cultural resource surveys have been conducted within the proposed construction areas in and adjacent to the 200 East and 400 Areas (DOE 1996a:3-49). No prehistoric archaeological resources have been identified within the proposed construction areas, and no historic resources in the 200 East or 400 Area. Accordingly, construction activities should not directly impact any prehistoric or historic resources. Preconstruction surveys (as required) and construction monitoring for previously unknown resources would be conducted within the framework of the *Hanford Cultural Resources Management Plan* (Battelle 1989).

Native American resources have not been identified within the construction areas in and adjacent to the 200 East and 400 Areas. For this reason, no direct impacts would be incurred. Thus far, no paleontological resources have been identified within the proposed construction areas; therefore, no direct impacts would be expected.

No indirect impacts on prehistoric, historic, Native American, or paleontological resources would occur under the proposed construction due to the lack of known resources in the vicinity. Consultations (see Chapter 5 for discussion) would be initiated with appropriate American Indian Tribal Governments on publication of this SPD EIS to address any concerns associated with the actions evaluated therein. Any potential for indirect visual impacts associated with potentially eligible historic structures in the 200 West Area would be assessed following completion of the ongoing evaluation by the Washington State Historic Preservation Officer consistent with the *Hanford Cultural Resources Management Plan* (Battelle 1989). Inadvertent discoveries of cultural resources will be handled in accordance with 36 CFR 800.11 (historic properties) or 43 CFR 10.4 (Native American human remains, funerary objects, objects of cultural patrimony, and sacred objects).

4.26.1.4.2 Operations

Operation of the proposed surplus plutonium disposition facilities should have no direct impacts on cultural or paleontological resources. Once the facilities were operational, no direct land disturbance or other action with impact potential would be conducted beyond the facility's perimeter fence. Activities associated with operation of the proposed surplus plutonium disposition facilities should also have no indirect impacts on any known cultural or paleontological resources.

4.26.1.5 Land Use and Visual Resources

Land resources (land use and visual resources) could be affected by construction and operation of the proposed surplus plutonium disposition facilities. The land-use impact analysis focused on the net land area affected, its relationship to conforming and nonconforming land uses, current growth trends and land values, and other socioeconomic factors pertaining to land use. Land-use impacts would vary from site to site depending on existing facility land-use configurations, adjoining land uses, and other environmental and containment factors.

The visual resource impact analysis emphasized changes in the existing landscape character that could result from the proposed action. The visual resource assessment was based on the VRM methodology.

4.26.1.5.1 Construction

Use of the planned HLW vitrification facility and support facilities in the 200 East and 200 West Areas would be consistent with existing and future land uses as described in the *Hanford Site Development Plan* (DOE 1994). No changes in existing or future land uses at the 200 East Area would occur under Alternative 2.

Land area requirements at Hanford would include sufficient land for the modification of FMEF in the 400 Area to support operation of the pit conversion and immobilization facilities, and for construction of the MOX facility adjacent to FMEF (UC 1998a, 1998b, 1998c, 1998d). Table 4–217 provides an estimate of the total footprint area required, in terms of newly disturbed land, for construction and operation of the proposed surplus plutonium disposition facilities. The land required for the construction of facilities at Hanford under Alternative 2 would be about 15 ha (37 acres). This includes approximately 6.5 ha (16 acres) of new building footprints, new parking lots, and security areas that would remain in use throughout operations.

Table 4–217. Maximum New Facility and Construction Area Requirements at Hanford

Land Requirement	Pit Conversion (Existing)	Immobilization (Existing)	MOX (New)
Construction area[a] (ha)	2	2.1	4.7
New operational area (ha)	0.5	0	6

[a] For uses such as construction laydown, construction worker parking, and waste storage.
Source: UC 1998a, 1998b, 1998c, 1998d.

The remaining 8.8 ha (22 acres) would be needed temporarily during construction for laydown, temporary storage, and parking. Construction areas would not be used after the facilities became operational. A number of these construction areas exist within the FMEF area but are currently inactive. Land area requirements for Alternative 2 would not be major, and no long-term or permanent loss of land would result from construction and operation of the proposed surplus plutonium disposition facilities at Hanford.

4.26.1.5.2 Operations

The pit conversion and immobilization facilities would be in FMEF in the 400 Area (UC 1998a, 1998b, 1998c). Operation of these facilities in FMEF would conform to existing and future land uses as described in the *Hanford Site Development Plan* (DOE 1994). The 400 Area land is designated for reactor operations, which can include other operational uses such as pit disassembly, conversion, and immobilization. The MOX facility would be operated adjacent to FMEF in the 400 Area and would likewise conform to existing and future land uses as described in the *Hanford Site Development Plan* (DOE 1994; UC 1998d). Other Hanford land uses or special-status lands would not be affected by facility operations. There would also be no impact on Native American Treaty land-use rights from any of the Hanford alternatives.

The appearance of the modified FMEF and new facilities adjacent to FMEF would remain consistent with the industrialized landscape character and current Visual Resource Management (VRM) Class 5 designation of the 400 Area. In height and size, the proposed facilities would be similar to existing buildings in the 400 Area (UC 1998a, 1998b, 1998c, 1998d). Construction and operation of the surplus plutonium disposition facilities would not effect a change in any natural features of visual interest in the area. The nearest sensitive viewpoint is Gable Mountain, which is 4.5 km (2.8 mi) away.

4.26.1.6 Infrastructure

4.26.1.6.1 Construction

Existing Hanford infrastructure would be capable of supporting the construction requirements for the proposed surplus plutonium disposition facilities included in Alternative 2. As shown in Table 4–218, construction would require only a fraction of the available resources and thus would not jeopardize the resources required to operate the site. Only 1.1 km (0.68 mi) of road would be required for construction deliveries and access to new and temporary facilities (UC 1998a, 1998d); this would not have a major impact. The total requirement for fuel oil during construction might be higher than currently available storage, but the majority of fuel oil usage would be associated with construction vehicle usage; therefore, storage would not be limiting. Table 4–218 reflects estimates of the additional annual infrastructure requirements for construction of the proposed surplus plutonium disposition facilities. Site resource availability and possible additional resource requirements are also presented.

Table 4–218. Maximum Annual Additional Site Infrastructure Requirements for Construction in 400 Area at Hanford

Resource	Facility Requirement				Availability[a]	Additional Requirement
	Pit Conversion	Immobilization	MOX	Total		
Transportation						
Roads (km)	0.1	0	1.0	1.1	420	1.1
Railroads (km)	0	0	0	0	204	0
Electricity						
Energy consumption (MWh/yr)	1,700	14,000	750	16,450	53,700	0
Peak load (MW)	1.0	2.6	1.0	4.6	22.5	0
Fuel						
Natural gas (m^3/yr)	NA	NA	NA	NA	NA	0
Oil (l/yr)	85,000	57,000	228,000	370,000	NA[b]	0
Coal (t/yr)	NA	NA	NA	NA	NA[b]	0
Water (l/yr)	2,000,000	45,000,000	16,000,000	63,000,000	356,260,000	0

4.26.1.6.2 Operations

Except for electricity, resources needed for operations under Alternative 2 are well within Hanford's capacity. The estimated total operational requirement for electricity is 63,700 MWh/yr, and availability to FMEF is 53,700 MWh/yr; hence, it appears that an additional 10,000 MWh/yr would be required. Additional electric power is already available in the 400 Area and could be easily supplied to a new building near FMEF (Sandberg 1998). The total fuel oil requirement for emergency generator testing during operations might also be higher than current site storage, but shortfalls could be met through additional procurements by normal contractual means. Table 4–219 reflects estimates of the additional annual resources required for operation of the proposed surplus plutonium disposition facilities. Available site resources and possible additional operational requirements are also presented.

Table 4–219. Maximum Annual Additional Site Infrastructure Requirements for Operations in 400 Area at Hanford

Resource	Facility Requirement				Availability[b]	Additional Requirement
	Pit Conversion	Immobilization[a]	MOX	Total		
Transportation						
Roads (km)	0	0	0	0	420	0
Railroads (km)	0	0	0	0	204	0

4.26.2 INEEL

For INEEL, the maximum impacts on environmental resources would be experienced if Alternative 7A, 7B, or 8 were implemented. Under these alternatives, the pit conversion and MOX facilities would be located at INEEL. These alternatives would require the maximum ground disturbance at INEEL, thereby maximizing the potential impacts on related resources such as geology and soils, ecological, and cultural. These alternatives would also require the most water and place the maximum strain on infrastructure at the site. None of the other alternatives evaluated in this SPD EIS include facilities being built at INEEL.

4.26.2.1 Geology and Soils

4.26.2.1.1 Construction

Construction of the pit conversion facility in FPF and the MOX facility in a new building at INEEL would have negligible impacts on the geologic and soils resources. In the *Storage and Disposition Final PEIS*, hazards of the large-scale geologic conditions at INEEL were analyzed in detail. The analysis determined that these conditions pose an acceptable risk to the proposed long-term storage facilities. That decision is not revisited in this SPD EIS. More detailed descriptions of impacts of the potential geologic hazards at INEEL are included in the *Storage and Disposition Final PEIS* (DOE 1996a: 4-148–4-150).

The soils at INEEL are considered acceptable for standard construction techniques. Within INEEL, economically viable sand, gravel, and pumice resources have been identified. New construction could increase the use of sand and gravel; however, large volumes of these materials are present, and the impact should be negligible. No soils at INEEL are currently classified as prime farmland.

4.26.2.1.2 Operations

Operation of the pit conversion facility in FPF and the MOX facility in a new building at INEEL would have no impact on the geologic or soils resources.

4.26.2.2 Water Resources

4.26.2.2.1 Construction

There would be no withdrawals of surface water for the proposed construction of the pit conversion and MOX facilities at INEEL (UC 1998l, 1998m). Thus, there would be no impact on the water availability to any downstream users. All wastewater during construction would be treated in approved facilities designed to meet NPDES permit limitations and be discharged to evaporation and percolation ponds, or would be available for recycling. In either case, no impact on surface water quality would be expected from construction activities.

It is estimated that proposed construction activities would use a maximum of about 20 million l/yr (5.3 million gal/yr) of water. The maximum estimated groundwater usage for construction of these facilities, when added to current usage at INTEC, would represent about 29 percent of the INTEC groundwater capacity. This withdrawal volume would have no impact on groundwater availability to other users in the area. There would be no impacts on groundwater availability, and the withdrawals would be within DOE's groundwater allotment. All wastewater flows would be treated in evaporation and percolation ponds, or would be available for recycling. The *Storage and Disposition Final PEIS* concluded there would be no impacts on groundwater quality from these activities, and no new data have been developed to require that this conclusion be revised (DOE 1996a: 4-686).

The potential site is not an area historically prone to flooding, but it could be in the floodplain if the Mackay Dam failed. The *Storage and Disposition Final PEIS* concluded that this flood would exceed either the 100- or 500-year floods. This dam failure would produce the probable maximum flood. The PEIS concluded the facility would be designed to withstand such flooding (DOE 1996a:3-115, 4-686). Therefore, the facility should neither affect nor be affected by flooding. Established construction techniques would be used to control soil erosion during construction. No long-term impacts would be expected from soil erosion during construction of this facility.

Proven construction techniques would be used to minimize soil erosion impacts during construction. Due to the success of these techniques, there would be no long-term impact on water quality due to soil erosion from the construction of this facility.

4.26.2.2.2 Operations

Surface water would not be used for operation of the proposed pit conversion or MOX facilities at INEEL, and there would be no impact on the availability of surface water to downstream users (UC 1998l, 1998m). All process and sanitary wastewater would be discharged to evaporation and percolation ponds with no surface discharge, or would be treated in approved facilities designed to meet NPDES permit limitations (Abbott, Crockett, and Moor 1997:9). Therefore, no impact on surface water quality would be expected from these activities.

Current estimates of the water that would be needed during operation of the pit conversion and MOX facilities at INEEL are much lower than was assumed in the *Storage and Disposition Final PEIS*. The maximum estimated annual water usage for these facilities at INEEL is 92 million l (24.3 million gal) (UC 1998l, 1998m). This represents about 60 percent of the INTEC groundwater capacity when added to current usage.

This reduced usage estimate would not change the analysis or conclusions of the *Storage and Disposition Final PEIS*. Because it was determined that there was no impact on water availability at the higher rate, there would be no impact at this lower usage rate (DOE 1996a: 4-685).

As stated in the construction section above, there would be no direct discharge of wastewater to the groundwater aquifer, and no impact on groundwater quality would be expected from these activities. This finding is consistent with the conclusions of the *Storage and Disposition Final PEIS* (DOE 1996a: 4-685).

4.26.2.3 Ecological Resources

Ecological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. However, habitat disturbance would be minimal; the land area required for construction activities is small in relation to regionally available habitat, and construction would take place in previously disturbed or developed areas. Operational impacts would also be minimal because facility emissions to the environment would be processed in accordance with applicable permitting procedures. Therefore, impacts on nonsensitive and sensitive habitats, plant and animal species, and the overall biodiversity of the candidate site would be minimal.

4.26.2.3.1 Construction

Nonsensitive Habitat. Siting the pit conversion facility and MOX facilities at INEEL would disturb 13 ha (32 acres) of land inside the INTEC-protected area adjacent to FPF. Some of this land (4.7 ha [12 acres]) would be used temporarily during the 5-year construction and startup phases for the MOX facility (UC 1998m). Although an additional 2 ha (4.9 acres) of land would be required for construction of the pit conversion facility, this land was disturbed during construction of FPF (UC 1998l). Animal species that are adapted to disturbed industrial areas, such as small mammals (e.g., mice, rabbits, ground squirrels), birds (e.g., sparrows, finches), and reptiles (e.g., lizards) would be affected. Some of the less-mobile species within the construction zone could perish during land-clearing activities and from increased vehicular traffic. Furthermore, activities and noise associated with construction could cause larger mammals and birds to relocate to similar habitat in the area. Depending on the populations presently in those areas, the ecosystem dynamics could be altered, adding stress if food or shelter were limited. Prior to construction, the proposed site would be surveyed for nests of migratory birds in accordance with the Migratory Bird Treaty Act. There would be no impacts on aquatic habitat from surface water consumption because water required for construction would be drawn from groundwater sources (Abbott, Crockett, and Moor 1997:15; DOE 1996a: 4-693; UC 1998l, 1998m).

Sensitive Habitat. Construction would have no impact on wetlands or critical habitat because there are none on the proposed site. It is also unlikely that any threatened, endangered, or other special status species at INEEL would be affected because none have been sighted within the immediate environs of FPF (Abbott, Crockett, and Moor 1997:15; Werner 1997:WAG3 Report Summary). In the surrounding INTEC area, however, there could be peregrine falcon, bald eagle, ferruginous hawk, black tern, burrowing owl, white-faced ibis, loggerhead shrike, northern goshawk, trumpeter swan, pygmy rabbit, Townsend's western big-eared bat, long-eared and small-footed myotis, and northern sagebrush lizard. Preconstruction surveys and consultations with the U.S. Fish and Wildlife Service (USFWS) and the equivalent State agency would be conducted to ensure that impacts on sensitive species living in the vicinity of FPF are negligible, and that appropriate mitigation actions are implemented as needed.

4.26.2.3.2 Operations

Nonsensitive Habitat. Activities associated with operation of the surplus plutonium disposition facilities could impact wildlife in the area due to noise and human presence. As a result, animal species could leave the area and take up residence in similar habitat nearby, thus changing the ecosystem dynamics and adding stress to the habitat and its occupants. However, impacts associated with airborne releases of criteria pollutants, hazardous and toxic air pollutants, and radionuclides would be unlikely because scrubbers and filters would be used (UC 1998l, 1998m). Aquatic resources should not be affected because groundwater would be used and liquid effluents would be sampled, treated, and disposed of in accordance with approved permits and procedures (UC 1998l, 1998m).

Sensitive Habitat. Operational impacts on wetlands or other sensitive habitats would be unlikely because airborne and aqueous effluents would be controlled and permitted. It is also unlikely that any federally listed, threatened, or endangered species would be affected, although Idaho State–classified special-status species could be affected by noise or human activity during operations, as discussed for construction.

4.26.2.4 Cultural and Paleontological Resources

Prehistoric, historic, Native American, and paleontological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. The land area required for construction activities is fairly small, however, and any such resource disturbance would be minimized by confinement of the construction to previously disturbed or developed areas. Impacts of operations would be negligible because facility operations and security would not restrict access to nearby prehistoric, historic, Native American, and paleontological resources. Continued compliance monitoring, before and after construction, would also help to limit or preclude impacts on these resources.

4.26.2.4.1 Construction

Siting the pit conversion and MOX facilities at INEEL would disturb about 13 ha (32 acres) of land inside the INTEC protected area adjacent to FPF. Some of this land (4.7 ha [12 acres]) would be used temporarily during the 5-year construction and startup phases for the MOX facility (UC 1998m). Although an additional 2 ha (4.9 acres) of land would be required for construction of the pit conversion facility, this land was previously disturbed during construction of FPF (UC 1998l).

Archaeological surveys have identified six prehistoric resources within the vicinity of the proposed construction area, but none are potentially eligible for nomination to the National Register. The surveys also identified two historic resources, a homestead and nearby trash dump, that may be eligible for nomination. Also, a historic building survey being conducted within INTEC is likely to identify structures potentially eligible for nomination to the National Register on the basis of relevance to the Cold War Era (Abbott, Crockett, and Moor 1997:16). Direct impacts of the proposed construction would be unlikely; however, consistent with the *INEL Management Plan for Cultural Resources*, surveys and monitoring would be conducted to ensure against impacts on National Register–eligible resources (Miller 1995).

Specific Native American resources have not been identified within the proposed construction area; however, resources important to the Shoshone and Bannock Tribes may be present in the vicinity. Direct consultations with the tribes would be conducted, consistent with a working agreement with DOE and the tribes, to ensure that there are no direct construction-related impacts (Abbott, Crockett, and Moor 1997:16). Paleontological resources are well documented within INEEL. No known resources have been reported within the proposed construction area; however, monitoring of construction excavations would be performed to ensure that no significant paleontological resources, if discovered, would be affected.

Indirect construction impacts on prehistoric, historic, or paleontological resources would be unlikely. There is, however, a potential for impacts on nearby Native American cultural resources. To avoid such impacts, consultations with the Shoshone and Bannock Tribes would be conducted prior to and during construction. Inadvertent discoveries of cultural resources will be handled in accordance with 36 CFR 800.11 (historic properties) or 43 CFR 10.4 (Native American human remains, funerary objects, objects of cultural patrimony, and sacred objects).

4.26.2.4.2 Operations

The proposed surplus plutonium disposition facilities should have no direct impacts on prehistoric, historic, or paleontological resources. However, operations-related noise and traffic could directly affect nearby Native American cultural resources (if identified in preconstruction consultations). To avoid such impacts, consultations with the Shoshone and Bannock Tribes would be conducted prior to operations.

There should also be no indirect impacts of operations on prehistoric, historic, or paleontological resources. However, any Native American resources in the vicinity of the proposed facility locations could experience indirect impacts such as access restrictions. Consultations with the Shoshone and Bannock Tribes would be conducted to avoid impacts of this nature.

4.26.2.5 Land Use and Visual Resources

Land resources (land use and visual resources) could be affected by construction and operation of the proposed surplus plutonium disposition facilities. The land-use impact analysis focused on the net land area affected, its relationship to conforming and nonconforming land uses, current growth trends and land values, and other socioeconomic factors pertaining to land use. Land-use impacts would vary from site to site depending on existing facility land-use configurations, adjoining land uses, and other environmental and containment factors. The visual resource impact analysis emphasized changes in the existing landscape character that could result from the proposed action. The visual resource assessment was based on the VRM methodology.

4.26.2.5.1 Construction

Land area requirements at INEEL under Alternatives 7A, 7B, or 8 would include sufficient land for the modification of FPF to house the pit conversion facility and for construction of the MOX facility adjacent to FPF at INTEC (UC 1998l, 1998m). Table 4–220 provides an estimate of the total footprint area required, in terms of newly disturbed land, for construction and operation of the proposed surplus plutonium disposition facilities. The land required for the construction of facilities at INTEC for any of the INEEL alternatives would be about 13 ha (32 acres). This includes approximately 6.5 ha (16 acres) of new building footprints, new parking lots, and security areas that would remain in use throughout operations.

Table 4–220. Maximum New Facility and Construction Area Requirements at INEEL

Land Requirement	Pit Conversion (Existing)	MOX (New)
Construction area[a] (ha)	2	4.7
New operational area (ha)	0.5	6

[a] For uses such as construction laydown, construction worker parking, and waste storage.
Source: UC 1998l, 1998m.

The remaining 6.7 ha (17 acres) would be needed temporarily during construction for laydown, temporary storage, and parking. Construction areas would not be used after the facilities became operational. A number

of these construction areas exist at INTEC. Land area requirements for Alternatives 7A, 7B, or 8 would not be major, and no permanent loss of land would result from construction and operation of the proposed surplus plutonium disposition facilities at INEEL.

4.26.2.5.2 Operations

The pit conversion facility activities would be in FPF, which is within the INTEC area (UC 1998l). FPF is an existing, structurally complete building that has not been used. Most of the support buildings required for operation of the pit conversion facility exist in INTEC. The MOX facility would be constructed within the existing INTEC area (UC 1998m). Operation of the pit conversion and MOX facilities would conform to existing and future land uses as described in the *INEEL Comprehensive Facilities and Land Use Plan* (DOE 1997f). Land within INTEC is currently disturbed and designated for waste-processing operations. Other INEEL land uses or special-status lands at INEEL would not be affected by facility operations. There would be no impact on Native American Treaty land-use rights from any of the proposed INEEL alternatives.

The appearance of the modified FPF and new facilities that may be required at INTEC would remain consistent with its industrialized landscape character and current VRM Class 4 designation. In height and size, the proposed facilities would be similar to existing buildings at INTEC (UC 1998l, 1998m). Construction and operation of the facilities would not effect a change in any natural features of visual interest in the area. The nearest sensitive viewpoint is Big Southern Butte National Natural Landmark, 20 km (12 mi) south of INTEC.

4.26.2.6 Infrastructure

4.26.2.6.1 Construction

Existing INEEL infrastructure would be capable of supporting the construction requirements for the proposed surplus plutonium disposition facilities included under Alternative 7A, 7B, or 8. Construction would require only a fraction of the available resources and thus would not jeopardize the resources required to operate the site. Only 2.3 km (1.4 mi) of road would be required for construction deliveries and access to new and temporary facilities (UC 1998l, 1998m); this would not have a major impact. The total requirement for fuel oil during construction might be higher than currently available storage, but the majority of fuel oil usage would be associated with construction vehicle usage; therefore, storage would not be limiting. Table 4–221 reflects estimates of additional annual infrastructure requirements for construction of the proposed surplus plutonium disposition facilities. Site resource availability and possible additional resource requirements are also presented.

4.26.2.6.2 Operations

Resources needed for operations under Alternative 7A, 7B, or 8 are well within INEEL capacity. The total fuel oil requirement for emergency generator testing during operations might be higher than current site storage, but shortfalls could be met through additional procurements by normal contractual means. Table 4–222 reflects estimates of additional annual resources required for operations of the proposed surplus plutonium disposition facilities. Available site resources and possible additional operational requirements are also presented.

4.26.3 Pantex

For Pantex, the maximum impacts on environmental resources would be experienced if Alternative 9A, 9B, or 10 were implemented. Under these alternatives, the pit conversion and MOX facilities would be located at Pantex. These alternatives would require the maximum ground disturbance at Pantex, thereby maximizing

Table 4–221. Maximum Annual Additional Site Infrastructure Requirements for Construction in INTEC at INEEL

Resource	Facility Requirement			Availability[a]	Additional Requirement

the potential impacts on related resources such as geology and soils, ecological, and cultural. These alternatives would also require the most water and place the maximum strain on infrastructure at the site. All the other Pantex alternatives evaluated in this SPD EIS would require less ground disturbance, so none would result in greater impacts than those associated with Alternative 9A, 9B, or 10.

Next Section

4.26.3.1 Geology and Soils

4.26.3.1.1 Construction

Construction of the pit conversion and the MOX facilities at Pantex would have no impact on the geologic and soils resources. In the *Storage and Disposition Final PEIS*, hazards of the large-scale geologic conditions at Pantex were analyzed in detail. The analysis determined that these conditions pose an acceptable risk to the proposed long-term storage facilities. That decision is not revisited in this SPD EIS. More detailed descriptions of impacts of the potential geologic hazards at Pantex are included in the *Storage and Disposition Final PEIS* (DOE 1996a: 4-204–4-206).

The soils at Pantex are considered acceptable for standard construction techniques. No economically viable geologic resources have been identified at Pantex. Pantex is underlain by soils of the Pullman-Randall association. The Pullman soil is classified as prime farmland. Pantex is exempt from the Farmland Protection Policy Act (FPPA) under Section 1540(c)(4) (7 U.S.C. Section 4201) because the acquisition of Pantex property occurred prior to the effective date of the act, June 22, 1982 (DOE 1996a:3-148).

4.26.3.1.2 Operations

Operation of the pit conversion and MOX facilities at Pantex would have no impact on the geologic and soils resources.

4.26.3.2 Water Resources

4.26.3.2.1 Construction

Surface water would not be used for the construction of the proposed pit conversion or MOX facilities at Pantex (UC 1998k, 1998n). Thus, there would be no impact on water availability for downstream users. The *Storage and Disposition Final PEIS* determined that wastewater would be discharged to the Zone 12 wastewater treatment plant, with discharge to the playa lakes, or be available for recycling, and that there would be no impact from these discharges (DOE 1996a: 4-397). No new data have been developed to require revision of these findings. As a result, no water quality impacts are expected.

The *Storage and Disposition Final PEIS* concluded that Pantex would neither affect nor be affected by flooding. For further information on this, consult the *Storage and Disposition Final PEIS* (DOE 1996a:3-498).

According to estimates, during construction the pit conversion and MOX facilities would use a maximum of about 28 million l/yr (7.4 million gal/yr) of water (UC 1998k, 1998n). When added to current usage on the site, this represents about 23 percent of the groundwater capacity. Pantex water use has decreased during the period from 1991 to 1995 by 231 million l (61 million gal) (M&H 1996:4-33, 9-8). The 28 million l/yr (7.4 million gal/yr) of water estimated to be used for construction of the pit conversion and MOX facilities would not increase water use above 1991 levels. The additional water use would be 0.1 percent of the 23.6 billion l (6.2 billion gal) of water pumped from the Carson County well fields by the city of Amarillo in 1995, and 0.03 percent of the 101 billion l (27 billion gal) of water applied for irrigation in Carson County in 1995. The amount of water required is relatively small in comparison with the available water resources, so there would be no impacts on groundwater capacity.

Although the expected drawdowns caused by withdrawing water required for this alternative are small, the overall decline in the groundwater level in the Ogallala aquifer near Amarillo is of concern. To mitigate some

of the effects from pumping groundwater from the Ogallala aquifer, the city of Amarillo could supply treated wastewater from the Hollywood Road Wastewater Treatment Plant for nonpotable uses at Pantex.

The *Storage and Disposition Final PEIS* concluded that the facility would not have any impact on groundwater quality (DOE 1996a:4-686, 4-687). There are no new data available to indicate that this conclusion should be revisited. Therefore, no impact on groundwater quality would be expected.

4.26.3.2.2 Operations

There would be no impacts to the surface water resources from the proposed operation of the pit conversion and MOX fuel facilities at Pantex because surface water would not be used for the operation of these facilities (UC 1998k, 1998n). The impact on surface water would be similar to that expected from the construction activities described above. No impacts on water availability or quality would be expected.

Current estimates indicate the pit conversion and MOX facilities would require a maximum of about 91 million l (24 million gal) per year (UC 1998k, 1998n). Pantex water use has decreased during the period from 1991 to 1995 by 231 million l (61 million gal) (M&H 1996:4-33, 9-8). The 91 million l/yr (24 million gal/yr) of water estimated to be used by the pit conversion and MOX facilities would not increase water use above 1991 levels. The additional water use would be 0.4 percent of the 23.6 billion l (6.2 billion gal) of water pumped from the Carson County well fields by the city of Amarillo in 1995, and 0.09 percent of the 101 billion l (27 billion gal) of water applied for irrigation in Carson County in 1995. The amount of water required is relatively small in comparison with the available water resources, so there would be no impacts on groundwater capacity.

Although the expected drawdowns caused by withdrawing water required for this alternative are small, the overall decline in the groundwater level in the Ogallala aquifer near Amarillo is of concern. To mitigate some of the effects from pumping groundwater from the Ogallala aquifer, the city of Amarillo could supply treated wastewater from the Hollywood Road Wastewater Treatment Plant for nonpotable uses at Pantex.

The *Storage and Disposition Final PEIS* concluded that the facility would not have any impact on groundwater quality (DOE 1996a:4-686, 4-687). There are no new data available to indicate that this conclusion should be revisited. Therefore, no impact on groundwater quality would be expected.

4.26.3.3 Ecological Resources

Ecological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. However, habitat disturbance would be minimal; the land area required for construction activities is small in relation to regionally available habitat, and construction would take place in previously disturbed or developed areas. Operational impacts would also be minimal because facility emissions to the environment would be processed in accordance with applicable permitting procedures. Therefore, impacts on nonsensitive and sensitive habitats, plant and animal species, and the overall biodiversity of the candidate site would be minimal.

4.26.3.3.1 Construction

Nonsensitive Habitat. Siting the pit conversion and MOX facilities in new buildings in Zone 4 at Pantex would disturb about 16 ha (39 acres). Some of this land (4.7 ha [12 acres]) would be used only temporarily during the 5-year construction and startup phases for the MOX facility (UC 1998n). Previously disturbed areas in Zone 4 would be used for construction laydown for the pit conversion facility (2 ha [4.9 acres]) (UC 1998k). Zone 4 at Pantex contains sufficient land area to accommodate the new building footprints. Thus, there should

be no direct impacts on nonsensitive terrestrial or aquatic habitats. Animal species inhabiting areas surrounding Zone 4 could be affected by the increased noise associated with construction activities, and the additional vehicular traffic could result in higher mortality for individual members of local animal populations. Prior to construction, the proposed sites would be surveyed for nests of migratory birds in accordance with the Migratory Bird Treaty Act. There would be no impacts on aquatic habitat from surface water consumption because water required for construction would be drawn from groundwater sources (UC 1998k, 1998n).

Sensitive Habitat. Although portions of Playas 1, 2, and 3 are within 1.6 km (1 mi) of the proposed pit conversion and MOX facilities, no wetlands should be directly affected by construction actions, which would be limited to developed areas of Zone 4 at Pantex. No critical habitat for any threatened or endangered species exists at Pantex; however, three special-status species (ferruginous hawk, western burrowing owl, and Texas horned lizard) might be found within the area surrounding Zone 4 (M&H 1997:22). Preconstruction surveys and consultations with USFWS and the equivalent State agency would be conducted to ensure that impacts on sensitive species living in the vicinity of Zone 4 are negligible, and that appropriate mitigation actions are implemented as needed.

4.26.3.3.2 Operations

Nonsensitive Habitat. Noise disturbance would probably be the most significant impact of routine operation of the proposed facilities on local wildlife populations. Disturbed individual members of local populations could migrate to adjacent areas of similar habitat. However, impacts associated with airborne releases of criteria pollutants, hazardous and toxic air pollutants, and radionuclides would be unlikely because scrubbers and filters would be used (UC 1998k, 1998n). Impacts on aquatic habitats should be limited because all liquid, nonhazardous sanitary wastes would be sampled, treated, and disposed of in accordance with approved permits and procedures (UC 1998k, 1998n).

Sensitive Habitat. Operational impacts on wetlands or other sensitive habitats would be unlikely because airborne and aqueous effluents would be controlled and permitted. It is also unlikely that any federally listed threatened or endangered species would be affected, although Texas State–classified special status-species could be affected by noise or human activity during operations, as discussed for construction.

4.26.3.4 Cultural and Paleontological Resources

Prehistoric, historic, Native American, and paleontological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. The land area required for construction activities is fairly small, however, and any such resource disturbance would be minimized by confinement of much of the construction to previously disturbed or developed areas. Impacts of operations would be negligible because facility operations and security would restrict access to nearby prehistoric, historic, Native American, and paleontological resources. Continued compliance monitoring, before and after construction, would also help to limit or preclude impacts on these resources.

4.26.3.4.1 Construction

Siting the pit conversion and MOX facilities in new buildings in Zone 4 at Pantex would disturb about 16 ha (39 acres). Some of this area would be used only temporarily during the 5-year construction and startup phases for the MOX facility (4.7 ha [12 acres]) (UC 1998n). Previously disturbed areas in Zone 4 would be used for construction laydown for the pit conversion facility (2 ha [4.9 acres]) (UC 1998k). Zone 4 at Pantex contains enough land area to accommodate the new buildings.

Surveys for prehistoric and historic archaeological resources have covered about 50 percent of the Pantex land area. As a consequence, two sites have been determined eligible for nomination to the National Register by the Texas State Historic Preservation Officer and the Advisory Council on Historic Preservation. Neither is in the vicinity of the proposed construction area. Further, the Texas State Historic Preservation Officer and the Advisory Council have determined that additional surveys are not required at Pantex (M&H 1997:26-27). Thus, there should be no impact on archaeological resources associated with the proposed construction.

Historic building surveys and recordings have been completed for World War II Era facilities remaining at Pantex and similar surveys are under way for the Cold War Era. Under the terms of a programmatic agreement among DOE, the Texas State Historic Preservation Officer, and the Advisory Council, all potential impacts on modifications of Pantex structures having historic potential require internal review and mitigation by DOE. No direct impacts on historic structures would result from the proposed construction (DOE 1996b, M&H 1997:27).

No known Native American resources have been, or are likely to be, identified at Pantex. Consultations (see Chapter 5 for discussion) would be initiated with appropriate American Indian Tribal Government on publication of this SPD EIS to address any concerns associated with the actions evaluated therein. No Native American resources should be directly impacted by the proposed construction (M&H 1997:27). No paleontological resources have been identified in Zone 4; thus, there should also be no direct impacts on such resources.

Given the absence of significant cultural or paleontological resources in the construction area and its environs, there should be no indirect impacts associated with the proposed construction. Inadvertent discoveries of cultural resources will be handled in accordance with 36 CFR 800.11 (historic properties) or 43 CFR 10.4 (Native American human remains, funerary objects, objects of cultural patrimony, and sacred objects).

4.26.3.4.2 Operations

Given to the absence of significant cultural or paleontological resources in the vicinity of the proposed surplus plutonium disposition facilities, there should be no direct or indirect impacts of plutonium disposition facility operations.

4.26.3.5 Land Use and Visual Resources

Land resources (land use and visual resources) could be affected by construction and operation of the proposed surplus plutonium disposition facilities. The land-use impact analysis focused on the net land area affected, its relationship to conforming and nonconforming land uses, current growth trends and land values, and other socioeconomic factors pertaining to land use. Land-use impacts would vary from site to site depending on existing facility land-use configurations, adjoining land uses, and other environmental and containment factors. The visual resource impact analysis emphasized changes in the existing landscape character that could result from the proposed action. The visual resource assessment was based on the VRM methodology.

4.26.3.5.1 Construction

Land area requirements at Pantex under Alternative 9A, 9B, or 10 would include sufficient land for the construction of the pit conversion and MOX facilities in Zone 4 (UC 1998k, 1998n). Table 4–223 provides an estimate of the total footprint area required, in terms of newly disturbed land, for construction and operation of the proposed surplus plutonium disposition facilities. The land required for the construction of facilities

Table 4–223. Maximum New Facility and Construction Area Requirements at Pantex

Land Requirement	Pit Conversion (New)	MOX (New)
Construction area[a] (ha)	2	4.7
New operational area (ha)	2.9	6

[a] For uses such as construction laydown, construction worker parking, and waste storage.
Source: UC 1998k, 1998n.

in Zone 4 for any of the Pantex alternatives would be about 16 ha (39 acres). This includes 8.9 ha (22 acres) of new building footprints, new parking lots, and security areas that would remain in use throughout operations.

The remaining 6.7 ha (17 acres) would be needed temporarily during construction for laydown, temporary storage, and parking. Construction areas would not be used after the facilities became operational. Land area requirements for Alternative 9A, 9B, or 10 would not be major, and no permanent loss of land would result from construction and operation of the surplus plutonium disposition facilities at Pantex.

4.26.3.5.2 Operations

The pit conversion and MOX facilities would be new buildings in Zone 4 at Pantex. Land within Zone 4 is currently disturbed and designated as industrial to support existing pit disassembly operations. Operation of the pit conversion and MOX facilities would conform to existing and future land uses as described in the *Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (DOE 1996b:4-24, 4-25). About 0.4 km (0.2 mi) to the east of Zone 4 is the Playa 1 Management Unit. Neither this protected land management area nor any other special-status lands at Pantex would be affected by facility operations. There would also be no impact on Native American Treaty land-use rights from any of the Pantex alternatives.

The appearance of the new facilities within Zone 4 would remain consistent with the zone's industrialized landscape character and VRM Class 5 designation. In height and size, the proposed facilities would be similar to buildings in other industrialized areas of the site (UC 1998k, 1998n). Construction and operation of the facilities would not effect a significant change in any natural features of visual interest in the area. The nearest sensitive viewpoint is the intersection of U.S. Route 60 and FM Road 2373, 2.4 km (1.5 mi) away.

4.26.3.6 Infrastructure

4.26.3.6.1 Construction

Existing Pantex infrastructure would be capable of supporting the construction requirements for the proposed surplus plutonium disposition facilities under Alternative 9A, 9B, or 10. Construction would require only a fraction of the available resources and thus would not jeopardize the resources required to operate the site. Only 4.1 km (2.6 mi) of road would be required for construction deliveries and access to new and temporary facilities; this would not have a major impact. The total requirement for fuel oil during construction might be higher than current available storage, but the majority of fuel oil usage would be connected to construction vehicle usage; therefore, storage would not be limiting. Table 4–224 reflects estimates of additional annual infrastructure requirements for construction of the proposed surplus plutonium disposition facilities. Site resource availability and possible additional resource requirements are also presented.

Table 4–224. Maximum Annual Additional Site Infrastructure Requirements for Construction in Zone 4 at Pantex

Resource	Facility Requirement			Availability[a]	Additional Requirement
	Pit Conversion	MOX	Total		
Transportation					
Roads (km)	3.1	1.0	4.1	76	4.1
Railroads (km)	0	0	0	27	0
Electricity

4.26.3.6.2 Operations

Resources needed for operations under Alternative 9A, 9B, or 10 are well within Pantex capacity. The total fuel oil requirement for emergency generator testing during operations might be higher than current site storage, but shortfalls could be met through additional procurements by normal contractual means. Table 4–225 reflects estimates of additional annual resources required for operation of the proposed surplus plutonium disposition facilities. Available site resources and possible additional operational requirements are also presented.

4.26.4 SRS

For SRS, the maximum impacts on environmental resources would be experienced if Alternative 3 were implemented. Under Alternative 3A, all the proposed surplus plutonium disposition facilities would be located in newly constructed buildings on the site. This alternative would require the maximum ground disturbance, thereby maximizing the potential impacts on related resources such as geology and soils, ecological, and cultural. Under Alternative 3B, the immobilization facility would be located in Building 221–F. This alternative would require the maximum water use. All the other SRS alternatives evaluated in this SPD EIS would require less new ground to be broken and less utility usage, so none would result in greater impacts than those associated with Alternative 3.

4.26.4.1 Geology and Soils

4.26.4.1.1 Construction

Construction of all the facilities in new buildings at SRS would have a negligible impact on the geologic and soils resources. In the *Storage and Disposition Final PEIS*, hazards of the large-scale geologic conditions at

Table 4–225. Maximum Annual Additional Site Infrastructure Requirements for Operations in Zone 4 at Pantex

SRS were analyzed in detail. The analysis determined that these conditions pose an acceptable risk to the proposed long-term storage facilities. That decision is not revisited in this SPD EIS. More detailed descriptions of impacts of the potential geologic hazards at SRS are included in the *Storage and Disposition Final PEIS* (DOE 1996a: 4-309–4-311).

The soils at SRS are considered acceptable for standard construction techniques. No economically viable geologic resources have been identified at SRS. No soils at SRS are currently classified as prime farmlands.

4.26.4.1.2 Operations

Operation of all the facilities in new buildings at SRS would have no impact on the geologic and soils resources.

4.26.4.2 Water Resources

4.26.4.2.1 Construction

Surface water would not be used in the construction of proposed surplus plutonium disposition facilities at SRS (UC 1998e, 1998f, 1998g, 1998h, 1998i, 1998j). Thus, there would be no impact on the surface water availability to downstream users.

All wastewater would be treated in the sitewide treatment system, which has sufficient hydraulic and organic capacity to treat the flows expected from these activities. No impacts on surface water quality would be expected from the discharge of these flows to the treatment system and to the receiving stream (Sessions 1997).

The maximum estimated annual average water usage for constructing all the proposed surplus plutonium disposition facilities at SRS would be 98 million l (25.6 million gal) (UC 1998e, 1998f, 1998g, 1998h, 1998i, 1998j). Current water usage in F-Area is 374 million l/yr (98.8 million gal/yr). When added to current usage,

the total construction requirement represents 30 percent of the F-Area groundwater capacity. No impact on water availability would be anticipated.

Wastewater would not be directly discharged to the groundwater aquifer (Sessions 1997:11); it would be treated in the Central Sanitary Wastewater Treatment Facility and subsequently discharged to surface water. Thus, no adverse impacts on groundwater quality are anticipated.

4.26.4.2.2 Operations

Surface water would not be used in the operation of these proposed surplus plutonium disposition facilities at SRS (UC 1998e, 1998f, 1998g, 1998h, 1998i, 1998j). No impact on surface water availability to downstream users would be expected. The Central Sanitary Wastewater Treatment Facility has sufficient capacity to treat the wastewater flows from these activities. Because the plant is only loaded at about 30 percent of its design capacity, it would be able to treat these flows adequately to meet NPDES permit limitations. Thus, no impacts on surface water quality would be expected (Sessions 1997).

The maximum annual average water usage for operating these facilities has been estimated at 138 million l (36.5 million gal) (UC 1998e, 1998f, 1998g, 1998h, 1998i, 1998j). When added to current water usage, the total requirement represents about 32 percent of the F-Area groundwater capacity. The water treatment system has an approved capacity to service this volume of water. Therefore, no impacts on water availability would be expected. There would be no direct discharge of waste to the groundwater aquifer. Therefore, no impacts on groundwater would be expected.

4.26.4.3 Ecological Resources

Ecological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. However, habitat disturbance would be minimal; land area required for construction activities is small in relation to regionally available habitat, and construction would take place largely in previously disturbed or developed areas. Operational impacts would also be minimal because facility emissions to the environment would be processed in accordance with applicable permitting procedures. Therefore, impacts on nonsensitive and sensitive habitats, plant and animal species, and the overall biodiversity of the candidate site would be minimal.

4.26.4.3.1 Construction

Nonsensitive Habitat. Siting the three proposed surplus plutonium disposition facilities in new buildings at SRS would disturb a total of about 31 ha (77 acres) of land adjacent to APSF, which is currently being constructed in F-Area (UC 1998e, 1998f, 1998g, 1998h). Some of this land (12 ha [30 acres]) would be used temporarily during the 3-year construction phase for the immobilization facility, and some (4.7 ha [12 acres]) during the 5-year construction and startup phases for the MOX facility (UC 1998f, 1998g, 1998h). Previously disturbed areas in F-Area would be used for construction laydown for the pit conversion facility (2 ha [4.9 acres]) (UC 1998e). Thus, there should be no direct impacts on nonsensitive terrestrial or aquatic habitats. Animal species inhabiting areas surrounding F-Area could be disturbed by the increased noise associated with construction activities, and the additional vehicular traffic could result in higher mortality for individual members of local animal populations. Prior to construction, the proposed sites would be surveyed for nests of migratory birds in accordance with the Migratory Bird Treaty Act. There would be no impacts on aquatic habitat from surface water consumption because water required for construction would be drawn from groundwater sources (UC 1998e, 1998f, 1998g, 1998h).

Sensitive Habitat. Wetlands associated with floodplains, streams, and impoundments should not be directly impacted by construction activities. No critical habitat for any threatened or endangered species exists on SRS. However, the bald eagle, red-cockaded woodpecker, wood stork, American alligator, smooth purple coneflower, and Oconee azalea might occur near F-Area (DOE 1995c:3-37, DOE 1996a:3-245). Preconstruction surveys and consultations with USFWS and the equivalent State agency would be conducted to ensure that impacts on sensitive species living in the vicinity of F-Area are negligible, and that appropriate mitigation actions are implemented as needed.

4.26.4.3.2 Operations

Nonsensitive Habitat. Noise disturbance would probably be the most significant impact of routine operation of the three facilities on local wildlife populations. Disturbed individual members of local populations could migrate to adjacent areas of similar habitat. However, impacts associated with airborne releases of criteria pollutants, hazardous and toxic air pollutants, and radionuclides would be unlikely because scrubbers and filters will be used (UC 1998e, 1998f, 1998g, 1998h). Impacts on aquatic habitats should be limited because all liquid, nonhazardous sanitary wastes would be sampled, treated, and disposed of in accordance with approved permits and procedures (UC 1998e, 1998f, 1998g, 1998h).

Sensitive Habitat. Operational impacts on wetlands or other sensitive habitats would be unlikely because airborne and aqueous effluents would be controlled and permitted. It is also unlikely that any federally listed threatened or endangered species would be affected, although South Carolina State–classified special status-species could be affected by noise or human activity during operations, as discussed for construction.

4.26.4.4 Cultural and Paleontological Resources

Prehistoric, historic, Native American, and paleontological resources could be impacted by construction and operation of the proposed surplus plutonium disposition facilities. The land area required for construction activities is fairly small, however, and any such resource disturbance would be minimized as much of the construction would take place in previously disturbed or developed areas. Impacts of operations would be negligible because facility operations and security would restrict access to nearby prehistoric, historic, Native American, and paleontological resources. Continued compliance monitoring, before and after construction, would also help to limit or preclude impacts on these resources.

4.26.4.4.1 Construction

Siting all facilities in new buildings at SRS would disturb a total of about 31 ha (77 acres) of land adjacent to APSF, which is currently being constructed in F-Area (UC 1998e, 1998f, 1998g, 1998h). Some of this land (12 ha [30 acres]) would be used temporarily during the 3-year construction phase for the immobilization facility, and some (4.7 ha [12 acres]) during the 5-year construction and startup phases for the MOX facility (UC 1998f, 1998g, 1998h). Previously disturbed areas in F-Area would be used for construction laydown for the pit conversion facility (2 ha [4.9 acres]) (UC 1998e).

Not all areas within the proposed construction area have been completely surveyed for cultural resources, and this area has a high potential to yield subsurface deposits (SRARP 1997:1, 5). Based on previous archaeological investigations, four archaeological sites have been recorded in or near the proposed construction areas (SRARP 1997). One of these sites (38AK546), located along the edge of the proposed construction impact area, has been recommended to the South Carolina State Historic Preservation Officer as eligible for nomination to the National Register (SRARP 1997:3–5; Cabak, Sassaman, and Gillam 1996). Potential direct impacts on 38AK546 and other archaeological sites that may exist in unsurveyed areas of the construction area could be mitigated through either avoidance or data recovery following additional survey and testing.

Mitigation would require South Carolina State Historic Preservation Officer's concurrence on National Register–eligibility determinations and plans for mitigation of potential adverse effect (SRARP 1997:5). All compliance activities would be conducted in accordance with the *Programmatic Memorandum of Agreement for the Savannah River Site* (SRARP 1989:179–188).

There should be no direct impacts on historic resources associated with the Cold War Era. A historical review of SRS was initiated in 1996 and will continue for several years. An assessment of two buildings (Buildings 217–F and 701–5F) located within the proposed construction area indicates neither structure meets the age nor architectural uniqueness criteria for eligibility to the National Register (Reed 1997). No Native American cultural sites or paleontological sites are known to exist within the proposed construction area. However, consultations (see Chapter 5 for discussion) would be initiated with appropriate American Indian Tribal Governments on publication of this SPD EIS to address any concerns associated with the actions evaluated therein.

No indirect impacts on prehistoric, historic, Native American, or paleontological resources would occur under this alternative. Inadvertent discoveries of cultural resources will be handled in accordance with 36 CFR 800.11 (historic properties) or 43 CFR 10.4 (Native American human remains, funerary objects, objects of cultural patrimony, and sacred objects).

4.26.4.4.2 Operations

There should be no direct impacts on prehistoric, historic, Native American, or paleontological resources associated with operation of the proposed surplus plutonium disposition facilities. Once the facilities were operational, no direct land disturbance or other action with impact potential would be conducted beyond the facility's perimeter fence.

There also should be no indirect impacts on prehistoric, historic, Native American, or paleontological resources associated with operation of the proposed surplus plutonium disposition facilities. Once the facilities were operational, access to, and the integrity of, resources beyond the direct impact area would not be affected.

4.26.4.5 Land Use and Visual Resources

Land resources (land use and visual resources) could be affected by construction and operation of the proposed surplus plutonium disposition facilities. The land-use impact analysis focused on the net land area affected, its relationship to conforming and nonconforming land uses, current growth trends and land values, and other socioeconomic factors pertaining to land use. Land-use impacts would vary from site to site depending on existing facility land-use configurations, adjoining land uses, and other environmental and containment factors. The visual resource impact analysis emphasized changes in the existing landscape character that could result from the proposed action. The visual resource assessment was based on the VRM methodology.

4.26.4.5.1 Construction

Land area requirements at SRS would include sufficient land for the construction of new facilities and the modification of APSF in F-Area to support the pit conversion, immobilization, and MOX facilities and the use of DWPF in S-Area (UC 1998e, 1998f, 1998g, 1998h). Table 4–226 provides an estimate for the total footprint area required, in terms of newly disturbed land, for construction and operation of the proposed surplus plutonium disposition facilities.

The land required for the construction of facilities in F-Area for Alternative 3A would be about 31 ha (77 acres). This includes 12 ha (30 acres) of new building footprints, new parking lots, and security areas that

Table 4–226. Maximum New Facility and Construction Area Requirements at SRS

Land Requirement	Pit Conversion (New)	Immobilization (New)	MOX (New)
Construction area[a] (ha)	2	12.4	4.7
New operational area (ha)	2.1	3.4	6

[a] For uses such as construction laydown, construction worker parking, and waste storage.
Source: UC 1998e, 1998f, 1998g, 1998h.

would remain in use throughout operations. The new facilities would occupy less than 0.02 percent of the 58,681 ha (145,000 acres) of available land designated for waste management facilities at SRS (DOE 1997g:4-20).

The remaining 19 ha (47 acres) would be needed temporarily during construction for laydown, temporary storage, and parking. Construction areas would not be used after the facilities became operational. A number of these construction areas exist within F-Area but are currently inactive. F-Area has ample space available for construction (UC 1998h). Land area requirements for Alternative 3A would not be major, and no permanent loss of land use would result from construction and operation of the proposed surplus plutonium disposition facilities at SRS.

4.26.4.5.2 Operations

All of the proposed surplus plutonium disposition facilities would be in new buildings adjacent to APSF in F-Area at SRS. Land within F-Area is currently disturbed and designated as industrial. Operation of the pit conversion, immobilization, and MOX facilities in F-Area would conform to existing heavy industrial land use and future land uses as described in the *Draft Site Development Plan* (DOE 1996f:7–9). Other SRS land uses or special-status lands would not be affected by facility operations. There would also be no impact on Native American Treaty land-use rights from Alternative 3A. Use of DWPF in S-Area would also be consistent with existing and future land uses as described in the *Draft Site Development Plan* (DOE 1996f:7–9).

The appearance of new facilities in and adjacent to F-Area would remain consistent with this area's industrialized landscape character and current VRM Class 5 designation. In height and size, the proposed facilities would be similar to existing buildings in F-Area. Facilities are generally not visible off the site because views are limited by rolling terrain and heavy vegetation. Construction and operation of the surplus plutonium disposition facilities would not effect a major change in any natural features of visual interest in the area. The nearest sensitive viewpoints are those on State Route 125 and SRS Road 1, 7 km (4.3 mi) and 8.5 km (5.3 km) away, respectively.

4.26.4.6 Infrastructure

4.26.4.6.1 Construction

Existing SRS infrastructure would be capable of supporting the construction requirements for the proposed surplus plutonium disposition facilities under Alternative 3B.[1] Construction would require only a fraction of the available resources and thus would not jeopardize the resources required to operate the site. Only 2.8 km (1.7 mi) of road would be required for construction deliveries and access to new and temporary facilities

[1] SRS infrastructure requirements for the construction of the proposed surplus plutonium disposition facilities under Alternative 3B are greater than those for Alternative 3A. Alternative 3B data is used for both construction and operations since the infrastructure requirements for operations are consistent in both alternatives.

(UC 1998e, 1998h); this would not have a major impact. Total construction requirements for fuel oil might be higher than currently available storage, but the majority of fuel oil usage would be connected to construction vehicle usage; therefore, storage would not be limiting. Table 4–227 reflects estimates of the additional annual infrastructure requirements for construction of the proposed surplus plutonium disposition facilities. Site resource availability and possible additional resource requirements are also presented.

Table 4–227. Maximum Annual Additional Site Infrastructure Requirements for Construction in F-Area at SRS

4.26.4.6.2 Operations

Resources needed for operations under Alternative 3B[2] are well within SRS capacity. The total fuel oil requirement for emergency generator testing during operations might be higher than current site storage, but shortfalls could be met through additional procurements by normal contractual means. Table 4–228 reflects estimates of additional annual resources required for operation of the proposed surplus plutonium disposition facilities. Available site resources and possible additional operational requirements are also presented.

[2] SRS infrastructure requirements for the construction of the proposed surplus plutonium disposition facilities under Alternative 3B are greater than those for Alternative 3A. Alternative 3B data is used for both construction and operations since the infrastructure requirements for operations are consistent in both alternatives.

Next Section

4.27 LEAD ASSEMBLY ALTERNATIVES

Five sites have been proposed for domestic fabrication of lead assemblies. Those sites are LLNL, LANL, and three of the four candidate sites for the proposed surplus plutonium disposition activities: Hanford, INEEL (the ANL–W facilities are being considered), and SRS. Pantex was not included as a candidate site for lead assembly fabrication because it does not currently have any plutonium processing facilities. After irradiation in a domestic, commercial LWR, the lead assemblies would be examined at a postirradiation examination facility. Locations include ANL–W, Oak Ridge National Laboratory (ORNL), or commercial examination facilities.

4.27.1 ANL–W

4.27.1.1 Air Quality and Noise

Potential air quality impacts of modification of facilities for lead assembly fabrication at ANL–W would not be major. Emissions from modification would result from welding and vehicle emissions from moving employees, equipment, and wastes. All modification activities would be inside existing buildings. Air pollutant concentrations from these modification activities would result in little increase in air pollutant concentrations at the site boundary.

Outdoor noise sources during modification would be limited to employee vehicles and truck traffic. Traffic associated with modification of these facilities would be a small fraction of the existing traffic associated with activities at ANL–W and would result in little or no increase in traffic noise levels along roads to the site.

Operational air quality impacts would result from emissions from emergency diesel generators, employee vehicles, and trucks moving materials and wastes. Emissions from heating these existing buildings would not change. The change in vehicular traffic would be small because most of the operations employees are expected to be existing employees, and that number is small in comparison to current employment at ANL–W and INEEL. Incremental air pollutant concentrations (e.g., carbon monoxide or nitrogen dioxide) for the site from operation of the lead assembly facility would be smaller than the levels shown in Table 4–131, and the concentrations at the site boundary would continue to meet ambient air quality standards. Radiological emissions are expected to be minor with the MEI receiving an additional dose of less than 0.001 mrem/yr. The overall site would be expected to remain within the 10-mrem/yr NESHAP limit.

Noise sources during operation would include employee vehicles and trucks and may include new ventilation equipment. Traffic noise associated with operating these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Traffic associated with operating these facilities would be a small fraction of the existing traffic associated with activities at ANL–W and should result in little or no increase in traffic noise levels along roads to the site. Noise from ventilation equipment would be similar to noise from existing ventilation equipment.

4.27.1.2 Waste Management

Table 4–229 compares the waste generated during modification of facilities for lead assembly fabrication at ANL–W with the existing treatment, storage, and disposal capacity for the various waste types. LLW would be generated during modification of contaminated areas of FMF and ZPPR, although no TRU, mixed, or hazardous waste is expected to be generated. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at INEEL or at other DOE sites or commercial facilities. For this SPD EIS, it is assumed that waste would be treated, stored, and disposed of in accordance with current site practices.

Table 4–229. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at ANL–W

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
LLW	18	<1	<1	<1
Nonhazardous				
Liquid	37	NA	NA	1
Solid	11	NA	NA	<1

[a] See definitions in Appendix F.8.
[b] Treatment, storage, and disposal capacities are compared with estimated additional waste generation assuming a 2-year modification period.
Key: ANL–W, Argonne National Laboratory–West; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated and stored on the site); TRU, transuranic.

LLW would be packaged, certified, and accumulated at the modification site before transfer for treatment and disposal in existing ANL–W and INEEL facilities. A total of 36 m^3 (47 yd^3) of LLW would be generated over the modification period. LLW generation during modification of facilities for lead assembly fabrication is estimated to be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) treatment capacity of WERF, less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity of RWMC, and less than 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of RWMC. Using the 6,264-m^3/ha (3,316-yd^3/acre) disposal land usage factor for RWMC published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 36-m^3 (47 yd^3) of waste would require less than 0.1 ha (0.25 acre) of disposal space. Therefore, impacts of the management of this additional LLW at ANL–W and INEEL should not be major.

Nonhazardous solid waste generated during modification of facilities for lead assembly fabrication would be packaged in conformance with standard industrial practice and would be disposed of in the onsite Central Facilities Area landfill complex, or shipped to offsite facilities for recycling. Nonhazardous solid waste generation during modification of facilities for lead assembly fabrication is estimated to be less than 1 percent of the 48,000-m^3 (62,800-yd^3) capacity of the Central Facilities Area landfill complex. The additional waste load generated during the modification period should not have a major impact on the nonhazardous solid waste management system at ANL–W and INEEL.

To be conservative, it was assumed that all nonhazardous liquid waste generated during modification of facilities for lead assembly fabrication would be managed at the ANL–W sewage treatment facility. Nonhazardous liquid waste generation during modification of these facilities is estimated to be 1 percent of the 6,057-m^3/yr (7,923-yd^3/yr) capacity of the ANL–W sewage treatment facility. Therefore, management of these wastes at ANL–W should not have a major impact on the nonhazardous liquid waste treatment system during the modification period.

Table 4–230 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from lead assembly fabrication at ANL–W. No HLW would be generated by lead assembly fabrication.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at INEEL or at other DOE sites or commerical facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate the shipment of contact-handled TRU waste from surplus plutonium disposition facilities

Table 4–230. Potential Waste Management Impacts of Operation of Lead Assembly Facility at ANL–W

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b] Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	41	1	<1	<1 of WIPP
LLW	200	<1	1	1
Mixed LLW	1	<1	<1	NA
Hazardous	<1	<1	<1	NA
Nonhazardous				
Liquid	1,600	NA	NA	26[d]
Solid	1,300	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional waste generation on an annual basis. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year operation period.
[c] Includes mixed TRU waste. Facilities would not generate remotely handled TRU waste.
[d] Percent of the capacity of the ANL–W sewage treatment facility.
Key: ANL–W, Argonne National Laboratory–West; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at INEEL are described in the *DOE Programmatic Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management Programs Final EIS* (DOE 1995a).

TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the facilities for lead assembly fabrication. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned Waste Characterization Facility at INEEL.

TRU waste generated by lead assembly fabrication at ANL–W is estimated to be 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. If all the TRU waste were to be stored at INEEL, this would be less than 1 percent of the 177,300 m^3 (231,900 yd^3) storage capacity available at RWMC. Impacts of the management of additional quantities of TRU waste at ANL–W and INEEL should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the lead assembly fabrication facility before transfer for treatment, storage, and disposal in existing ANL–W or INEEL facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated during the 3-year operation period. LLW generated during lead assembly fabrication is estimated to be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) treatment capacity of WERF, 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity of RWMC, and 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of RWMC. Using the 6,264-m^3/ha (3,316-yd^3/acre) disposal land usage factor for RWMC published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3)

of waste would require 0.11 ha (0.27 acre) of disposal space at RWMC. Therefore, impacts of the management of this additional LLW at ANL–W and INEEL should not be major.

Mixed LLW would be stabilized, packaged, and stored for treatment and disposal in a manner consistent with the site treatment plan. At INEEL, mixed LLW is currently treated on the site with some waste shipped to Envirocare of Utah for disposal. INEEL is planning a new facility for onsite disposal of mixed LLW. Mixed LLW generated by lead assembly fabrication is estimated to be less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project and less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity of RWMC. Therefore, the management of this additional waste at ANL–W and INEEL should not have a major impact on the mixed LLW management system.

Any hazardous waste generated during lead assembly fabrication at ANL–W would be packaged for storage and treatment at a combination of onsite and offsite facilities, with disposal at offsite commercial facilities. Assuming that all hazardous waste is managed at INEEL, hazardous waste generated by lead assembly fabrication is estimated to be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) capacity of WERF and less than 1 percent of the 1,600-m^3 (2,090-yd^3) capacity of the hazardous waste storage buildings. Therefore, the management of these additional hazardous wastes at ANL–W and INEEL should not have a major impact on the hazardous waste management system.

If all the TRU waste and mixed LLW generated by lead assembly fabrication at ANL–W is processed in the planned Advanced Mixed Waste Treatment Project, this additional waste would be 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) capacity of the facility. If all TRU waste, LLW, and mixed LLW generated by lead assembly fabrication is stored at RWMC, this additional waste would be 1 percent of the 112,400-m^3 (147,000-yd^3) capacity of the facility. If all LLW and hazardous waste generated by lead assembly fabrication is treated at WERF, this additional waste would be less than 1 percent of the 49,610-m^3 (64,890-yd^3) capacity of the facility.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site for disposal in the Bonneville County Landfill. This additional waste load should not have a major impact on the nonhazardous solid waste management systems at ANL–W and INEEL.

Nonhazardous wastewater generated by lead assembly fabrication would be treated, if necessary, before being discharged to the ANL–W sewage treatment facility. Nonhazardous liquid waste generated by lead assembly fabrication is estimated to be 26 percent of the 6,057-m^3/yr (7,923-yd^3/yr) capacity of the ANL–W sewage treatment facility. Therefore, management of nonhazardous liquid waste at ANL–W should not have a major impact on the wastewater treatment system.

4.27.1.3 Infrastructure

Site infrastructure includes those utilities and resources required to support modification and operation of the facilities for the proposed lead assembly program. Proposed activities would use existing facilities, therefore, all required utility connections are in existence. See Table 3–50 for current infrastructure characteristics at ANL–W. To support the lead assembly fabrication, annual electricity requirements at ANL–W are estimated to increase by 720 MWh. Current annual electrical usage at ANL–W is 4,200 MWh, with a site capacity of 7,000 MWh. Additional annual fuel requirements are estimated to be 49,200 l (13,000 gal) of diesel fuel for heating and 4,600 l (1,215 gal) of diesel oil for emergency generators. Fuel is procured on the site on an as-needed basis. Annual total water usage for sanitary and nonsanitary needs are estimated to be 1.6 million l (423,000 gal). No surface water requirements are expected for the facility. Current annual water usage at

ANL–W is 1.5 million l (396,000 gal), while the current capacity is 15 million l (4 million gal). Even though the amount of water needed at the site would effectively double, it would still be less than 25 percent of the water available. Thus, there would not be any major impacts on infrastructure should the decision be made to conduct the proposed lead test assembly program at ANL–W (O'Connor et al. 1998a).

4.27.1.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from modification of existing facilities for lead assembly fabrication at ANL–W. Moreover, doses to construction workers should not exceed the normally low levels attributable to routine occupancy. Nonetheless, construction workers would be monitored (badged) as appropriate, to help ensure that doses are maintained as low as is reasonably achievable.

Table 4–231 reflects the potential radiological impacts of normal operations on three individual receptor groups at ANL–W: the population living within 80 km (50 mi) in the year 2005, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected LCF risks to these groups from annual operation of the lead assembly facility. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Table 4–231. Potential Radiological Impacts on the Public of Operation of Lead Assembly Facility at ANL–W

Population within 80 km for year 2005	
Dose (person-rem/yr)	0.011
Percent of natural background[a]	1.2×10^{-5}
Associated latent fatal cancers	5.5×10^{-6}
Maximally exposed individual	
Annual dose (mrem/yr)	9.4×10^{-4}
Percent of natural background[a]	2.6×10^{-4}
Associated latent fatal cancer risk	4.7×10^{-10}
Average exposed individual within 80 km[b]	
Annual dose (mrem/yr)	4.4×10^{-5}
Associated latent fatal cancer risk	2.2×10^{-11}

[a] The annual natural background radiation level at INEEL is 361 mrem for the average individual; the population within 80 km (50 mi) in 2005 would receive 90,600 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of INEEL in 2005 (251,500).

Key: ANL–W, Argonne National Laboratory–West.
Source: Appendix J.

Given incident-free operation of the lead assembly facility, the total population dose in the year 2005 would be 0.011 person-rem. The corresponding number of LCFs in the population around ANL–W from annual operation of the facility would be 5.5×10^{-6}. The total dose to the maximally exposed member of the public from annual operation would be 9.4×10^{-4} mrem; this corresponds to an LCF risk of 4.7×10^{-10}. The impacts on the average individual would be lower.

Doses to involved workers from normal operations are given in Table 4–232; these workers are defined as those directly associated with lead assembly fabrication activities. Under the proposed action, the annual average dose to lead assembly facility workers would be an estimated 500 mrem. The annual dose received by the total involved workforce for this facility would be 28 person-rem, which corresponds to 0.011 LCF.

Table 4–232. Potential Radiological Impacts on Involved Workers of Operation of Lead Assembly Facility at ANL–W

Number of badged workers	55
Annual total dose (person-rem/yr)	28
Associated latent fatal cancers	0.011
Annual average worker dose (mrem/yr)	500
Associated latent fatal cancer risk	2.0×10^{-4}

Key: ANL–W, Argonne National Laboratory–West.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998a.

Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or operation activities. However, concentrations would be within the regulated exposure limits.

4.27.1.5 Facility Accidents

Given the estimated 1,517 person-days of construction labor and standard industrial accident rates, about 0.63 cases of nonfatal occupational injury or illness and 8.8×10^{-4} fatality would be expected. DOE-required industrial safety programs would be in place to reduce the risks.

The potential consequences of postulated bounding facility accidents from lead assembly fabrication activities at ANL–W are presented in Table 4–233. The most severe consequences of a design basis accident would be associated with a nuclear criticality. Radiological consequences of the criticality for the MEI would include a dose of 4.9×10^{-3} rem, corresponding to an LCF probability of 2.5×10^{-6}. Among the general population off the site, an estimated 1.6×10^{-4} LCF could occur as a result of a criticality. The frequency of this accident is estimated to be between 1 in 10,000 and 1 in 1,000,000 per year. This accident would also be expected to be more severe than any accident associated with postirradiation examination activities that could be conducted at ANL–W (see Section 4.27.6.3).

Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is a hypothetical individual working on the site but not involved in the proposed action, and assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be the highest during the nuclear criticality. The consequences of such an accident would include an LCF probability of 3.1×10^{-5}.

Given total facility collapse as a result of the beyond-design-basis earthquake, the radiological effects from the proposed activities would be 3.9×10^{-1} LCF in the population residing within 80 km (50 mi) of ANL–W. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

Table 4–233. Accident Impacts of Lead Assembly Fabrication at ANL–W

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	7.7×10^{-2}	3.1×10^{-5}	4.9×10^{-3}	2.5×10^{-6}	3.4×10^{-1}	1.6×10^{-4}
Design basis earthquake	Unlikely	1.7×10^{-4}	6.8×10^{-8}	7.7×10^{-6}	3.9×10^{-9}	2.7×10^{-3}	1.4×10^{-6}
Design basis fire	Unlikely	7.4×10^{-5}	2.9×10^{-8}	3.3×10^{-6}	1.7×10^{-9}	1.2×10^{-3}	5.9×10^{-7}
Design basis explosion	Extremely unlikely	1.2×10^{-3}	4.8×10^{-7}	5.4×10^{-5}	2.7×10^{-8}	1.9×10^{-2}	9.6×10^{-6}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	7.4×10^{1}	3.0×10^{-2}	2.8	1.4×10^{-3}	7.9×10^{2}	3.9×10^{-1}
Beyond-evaluation-basis fire	Beyond extremely unlikely	1.7×10^{-1}	6.6×10^{-5}	6.2×10^{-3}	3.1×10^{-6}	1.8	8.7×10^{-4}

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

Key: ANL–W, Argonne National Laboratory–West.

No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

4.27.1.6 Transportation

Plutonium dioxide would be shipped from LANL to lead assembly fabrication facilities at ANL–W. These facilities would also receive uranium dioxide and other material needed to assemble MOX fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 30 shipments of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 80,000 km (50,000 mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public, 10.3 person-rem. Accordingly, incident-free transportation of radioactive material would result in 5.9×10^{-4} LCF among transportation workers and 5.2×10^{-3} LCF in the total affected population over the duration of the transportation activities. (LCFs associated with radiological releases were estimated by multiplying the occupational (worker) dose by 4.0×10^{-4} cancer per person-rem of exposure, and the public accident and accident-free dose by 5.0×10^{-4} cancer per person-rem of exposure [ICRP 1991].) The estimated number of nonradiological fatalities from vehicular emissions would be 2.3×10^{-4}.

Impacts of Accidents During Ground Transportation. Estimates of the total ground transportation accident risks follow: a radiological dose to the population of 6.3 person-rem, resulting in a total population risk of 3.2×10^{-3} LCF; and traffic accidents resulting in 9.2×10^{-4} traffic fatality.

4.27.1.7 Other Resource Areas

Other resource areas include geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and socioeconomics. Impacts on these resource areas are primarily related to the construction of new buildings and the number of persons employed to support the activities. Because a relatively small number of largely existing personnel are expected to perform the lead assembly fabrication in existing buildings (i.e., no new buildings would be constructed and no additional land disturbed), little or no impacts are expected to any of these resource areas.

4.27.1.8 Environmental Justice

As demonstrated throughout the analyses presented in this section, the lead assembly fabrication activities at ANL–W would pose no significant health risks to the public. The expected number of LCFs as a result of the radiation released from these activities in the general population residing within 80 km (50 mi) of ANL–W would be 5.5×10^{-6}; thus, no additional LCFs would be expected (see Table 4–231). Transportation related to these activities would not be expected to result in any LCFs either (see Section 4.27.1.6). The number of transportation-related fatalities in the total population along the shipping routes would be expected to increase by 8.4×10^{-3} due to radiological impacts, by 2.3×10^{-4} due to emissions, and by 9.2×10^{-4} as a result of traffic accidents; thus, no transportation-related fatalities would be expected (see Section 4.27.1.6). Risks posed by the implementation of the ANL–W alternative for lead assembly fabrication would be negligible regardless of the racial or ethnic composition, or the economic status of the population. Therefore, the lead assembly fabrication activities at ANL–W would have no significant impacts on minority or low-income populations.

4.27.2 Hanford

4.27.2.1 Air Quality and Noise

Potential air quality impacts of modification of facilities for lead assembly fabrication at Hanford would not be major. Emissions from modification would result from welding and vehicle emissions from moving employees, equipment, and wastes. All modification activities would be inside existing buildings. Air pollutant concentrations from these modification activities would result in little increase in air pollutant concentrations at the site boundary. However, occasional exceedances of the PM_{10} and total suspended particulate standards would likely continue from natural sources.

Outdoor noise sources during modification would be limited to employee vehicles and truck traffic. Traffic associated with modification of these facilities would be a small fraction of the existing traffic associated with activities at Hanford and would result in little or no increase in traffic noise levels along roads to the site.

Operational air quality impacts would result from emissions from emergency diesel generators, employee vehicles, and trucks moving materials and wastes. Emissions from heating these existing buildings would not change. The change in vehicular traffic would be small because most of the operations employees are expected to be existing employees, and that number is small in comparison to current employment at Hanford. Incremental air pollutant concentrations (e.g., carbon monoxide or nitrogen dioxide) for the site from operation of the lead assembly facility would be smaller than the levels shown in Table 4–97, and the concentrations at the site boundary would continue to meet ambient air quality standards. However, occasional exceedances of the PM_{10} and total suspended particulate standards would likely continue from natural sources. Radiological emissions are expected to be minor with the MEI receiving an additional dose of less than 0.001 mrem/yr. The overall site would be expected to remain within the 10-mrem/yr NESHAP limit.

Noise sources during operation would include employee vehicles and trucks and may include new ventilation equipment. Traffic noise associated with operating these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Traffic noise associated with operating these facilities would be a small fraction of the existing traffic associated with activities at Hanford and should result in little or no increase in traffic noise levels along roads to the site. Noise from ventilation equipment would be similar to noise from existing ventilation equipment.

4.27.2.2 Waste Management

Table 4–234 compares the waste generated during modification of facilities for lead assembly fabrication at Hanford with the existing treatment, storage, and disposal capacity for the various waste types. No TRU waste, LLW, mixed LLW, or hazardous waste would be generated during modification. This SPD EIS also assumes that nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices.

Table 4–234. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at Hanford

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b] Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
Nonhazardous				
Liquid	15	<1	NA	<1
Solid	50	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment, storage, and disposal capacities are compared with estimated additional waste generation assuming a 2-year modification period.
Key: NA, not applicable (i.e., it is assumed that the majority of the nonhazardous solid waste would be treated and disposed of off the site by the construction contractor).

Nonhazardous solid waste generated during modification of facilities for lead assembly fabrication would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal. The additional waste load generated during the modification period should not have a major impact on the nonhazardous solid waste management system at Hanford.

To be conservative, it was assumed that all nonhazardous liquid waste generated during modification of facilities for lead assembly fabrication would be discharged to the sewer system in the 400 Area. Nonhazardous liquid waste generation during modification of these facilities is estimated to be less than 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer and less than 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility.

Therefore, management of these wastes at Hanford should not have a major impact on the nonhazardous liquid waste treatment system during the modification period.

Table 4–235 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from lead assembly fabrication activities at Hanford. No HLW would be generated during lead assembly fabrication.

Table 4–235. Potential Waste Management Impacts of Operation of Lead Assembly Facility at Hanford

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	41	2	1	<1 of WIPP
LLW	200	NA	NA	<1
Mixed LLW	1	<1	<1	<1
Hazardous	<1	NA	NA	NA
Nonhazardous				
Liquid	1,600	1[d]	NA	1[e]
Solid	1,300	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional waste generation annually. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year operation period.
[c] Includes mixed TRU waste. Facilities would not generate remotely handled TRU waste.
[d] Percent of the capacity of 400 Area sanitary sewer.
[e] Percent of the capacity of WPPSS Sewage Treatment Facility.
Key: LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant; WPPSS, Washington Public Power Supply System.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at Hanford or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts on treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS*, which is being prepared by the DOE Richland Operations Office (DOE 1997c).

TRU wastes would be packaged and certified to WIPP waste acceptance criteria at the lead assembly fabrication facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generated by lead assembly fabrication is estimated to be 2 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. If all of the TRU waste had to be stored on the site, this would be 1 percent of the 17,000-m^3 (2,220-yd^3) storage capacity available at Hanford. Therefore, impacts of the management of additional quantities of TRU waste at Hanford should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the lead assembly fabrication facility before transfer for disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generated by lead assembly fabrication is estimated to be less than 1 percent of the 1,740,000-m^3 (2,280,000-yd^3) capacity of the LLW Burial Grounds and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.2 ha (0.49 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW would be packaged and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Mixed LLW generated by lead assembly fabrication is estimated to be less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility, less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) planned disposal capacity of the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

If all TRU waste and mixed LLW generated by lead assembly fabrication were processed in the Waste Receiving and Processing Facility, this additional waste would be 2 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the facility, and therefore should not have a major impact on this facility.

The small quantity of hazardous waste generated during operations would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. The additional waste load generated during the operation period should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent offsite for recycling. The remaining solid sanitary waste would be sent for disposal in the Richland Sanitary Landfill. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

To be conservative, it was assumed that all nonhazardous wastewater generated by lead assembly fabrication at Hanford would be managed in the 400 Area. Nonhazardous wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer system, which connects to the WPPSS Sewage Treatment Facility. Nonhazardous liquid waste generated by lead assembly fabrication is estimated to be 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer and 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, management of additional nonhazardous liquid waste at Hanford should not have a major impact on the wastewater treatment system.

4.27.2.3 Infrastructure

Site infrastructure includes those utilities and resources required to support modification and operation of the facilities for the proposed lead assembly program. Proposed activities would use the existing space at the Fuel

Assembly Area, appended to FMEF, in Hanford's 400 Area; therefore, all utility connections are in existence. See Table 3–6 for additional information on the infrastructure characteristics at FMEF. To support lead assembly fabrication, annual electricity requirements are calculated to increase by 1,230 MWh; this includes 514 MWh for heating. Current annual electrical usage at FMEF is 7,300 MWh, with a capacity of 61,000 MWh. An estimated 4,600 l (1,215 gal) of diesel oil for emergency generators is also required. Fuel is procured on the site on an as-needed basis. Annual total water usage for sanitary and nonsanitary needs are estimated to be 1.6 million l (423,000 gal). Current water usage is 41.7 million l (11 million gal), while capacity is 400 million l (105 million gal). There would not be any major impacts on infrastructure should the decision be made to conduct the proposed lead assembly program at the Fuel Assembly Area at FMEF (Mecca 1997; O'Connor et al. 1998b:24).

4.27.2.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from modification of existing facilities for lead assembly fabrication at Hanford. Moreover, doses to construction workers should not exceed the normally low levels attributable to routine occupancy (Antonio 1998). Nonetheless, construction workers may be monitored (badged) as a precautionary measure.

Table 4–236 reflects the potential radiological impacts of normal operations on three individual receptor groups at Hanford: the population living within 80 km (50 mi) in the year 2005, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected LCF risks to these groups from annual operation of the lead assembly facility. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Table 4–236. Potential Radiological Impacts on the Public of Operation of Lead Assembly Facility at Hanford

Population within 80 km for year 2005	
Dose (person-rem/yr)	0.025
Percent of natural background[a]	2.3×10^{-5}
Associated latent fatal cancers	1.2×10^{-5}
Maximally exposed individual	
Annual dose (mrem/yr)	3.4×10^{-4}
Percent of natural background[a]	1.1×10^{-4}
Associated latent fatal cancer risk	1.7×10^{-10}
Average exposed individual within 80 km[b]	
Annual dose (mrem/yr)	7.0×10^{-5}
Associated latent fatal cancer risk	3.5×10^{-11}

[a] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km (50 mi) in 2005 would receive 107,400 person-rem.
[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Hanford in 2005 (358,100).
Source: Appendix J.

Given incident-free operation of the lead assembly facility, the total population dose in the year 2005 would be 0.025 person-rem. The corresponding number of LCFs in the population around Hanford from annual operation of the facility would be 1.2×10^{-5}. The total dose to the maximally exposed member of the public from annual operation would be 3.4×10^{-4} mrem; this corresponds to an LCF risk of 1.7×10^{-10}. The impacts on the average individual would be lower.

Doses to involved workers from normal operations are given in Table 4–237; these workers are defined as those directly associated with lead assembly fabrication activities. Under the proposed action, the annual average dose to lead assembly facility workers would be an estimated 500 mrem. The annual dose received by the total involved workforce for this facility would be 28 person-rem, which corresponds to 0.011 LCF. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–237. Potential Radiological Impacts on Involved Workers of Operation of Lead Assembly Facility at Hanford

Number of badged workers	55
Annual total dose (person-rem/yr)	28
Associated latent fatal cancers	0.011
Annual average worker dose (mrem/yr)	500
Associated latent fatal cancer risk	2.0×10^{-4}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998b.

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or operation activities. However, concentrations would be within the regulated exposure limits.

4.27.2.5 Facility Accidents

No major modifications would be required for any of the facilities proposed for lead assembly fabrication. The potential for accidents during construction would thus be minimal.

The potential consequences of postulated bounding facility accidents from lead assembly fabrication activities at Hanford is presented in Table 4–238. The source terms are identical to those for lead assembly activities at ANL–W; the different consequences are attributable to differences in stack height, meteorology, site boundary distance, and population.

The most severe consequences of a design basis accident would be associated with a nuclear criticality. Bounding radiological consequences for the MEI would result in a dose of 3.4×10^{-3} rem, corresponding to an LCF probability of 1.7×10^{-6}. Consequences of the criticality for the general population in the environs of Hanford would include an estimated 2.7×10^{-3} LCF. The frequency of such an accident is estimated to be between 1 in 10,000 and 1 in 1,000,000 per year.

Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be the highest for the criticality accident. The consequences of such an accident would include an LCF probability of 1.3×10^{-5}.

The radiological effects from total collapse of FMEF for lead assembly fabrication in the beyond-design-basis earthquake would be approximately 2.8 LCFs in the population residing within 80 km (50 mi) of Hanford. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of

Table 4–238. Accident Impacts of Lead Assembly Fabrication at Hanford

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	3.3×10^{-2}	1.3×10^{-5}	3.4×10^{-3}	1.7×10^{-6}	5.4	2.7×10^{-3}
Design basis earthquake	Unlikely	3.5×10^{-5}	1.4×10^{-8}	5.2×10^{-6}	2.6×10^{-9}	1.7×10^{-2}	8.5×10^{-6}
Design basis fire	Unlikely	1.5×10^{-5}	6.0×10^{-9}	2.3×10^{-6}	1.1×10^{-9}	7.4×10^{-3}	3.7×10^{-6}
Design basis explosion	Extremely unlikely	2.4×10^{-4}	9.8×10^{-8}	3.7×10^{-5}	1.8×10^{-8}	1.2×10^{-1}	5.9×10^{-5}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	7.1×10^{1}	2.8×10^{-2}	2.7	1.3×10^{-3}	6.5×10^{3}	2.8
Beyond-design- basis fire	Beyond extremely unlikely	1.6×10^{-1}	6.3×10^{-5}	5.9×10^{-3}	3.0×10^{-6}	1.4×10^{1}	6.2×10^{-3}

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

4.27.2.6 Transportation

Plutonium dioxide would be shipped from LANL to lead assembly fabrication facilities at Hanford. These facilities would also receive uranium dioxide and other material needed to assemble MOX fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 30 shipments

of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 89,000 km (55,000 mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public, 10.3 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.9×10^{-4} LCF among transportation workers and 5.2×10^{-3} LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 2.5×10^{-4}.

Impacts of Accidents During Ground Transportation. Estimates of the total ground transportation accident follow: a radiological dose to the population of 6.5 person-rem, resulting in a total population risk of 3.2×10^{-3} LCF; and traffic accidents resulting in 1.0×10^{-3} traffic fatality.

4.27.2.7 Other Resource Areas

Other resource areas include geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and socioeconomics. Impacts on these resource areas are primarily related to the construction of new buildings and the number of persons employed to support the activities. Because a relatively small number of largely existing personnel are expected to perform the lead assembly fabrication in existing buildings (i.e., no new buildings would be constructed and no additional land disturbed), little or no impacts are expected to any of these resource areas.

4.27.2.8 Environmental Justice

As demonstrated throughout the analyses presented in this section, the lead assembly fabrication activities at Hanford would pose no significant health risks to the public. The expected number of LCFs as a result of the radiation released from these activities in the general population residing within 80 km (50 mi) of Hanford would be 1.2×10^{-5}; thus, no additional LCFs would be expected (see Table 4–236). Transportation related to these activities would not be expected to result in any LCFs either. The number of transportation-related fatalities in the total population along the shipping routes would be expected to increase by 8.4×10^{-3} due to radiological impacts, by 2.5×10^{-4} due to emissions, and by 1.0×10^{-3} as a result of traffic accidents; thus, no transportation-related fatalities would be expected (see Section 4.27.2.6). Risks posed by the implementation of the Hanford alternative for lead assembly fabrication would be negligible regardless of the racial or ethnic composition, or the economic status of the population. Therefore, the lead assembly fabrication activities at Hanford would have no significant impacts on minority or low-income populations.

4.27.3 LLNL

4.27.3.1 Air Quality and Noise

Potential air quality impacts of modification of facilities for lead assembly fabrication at LLNL would not be major. Emissions from modification would result from welding and vehicle emissions from moving employees, equipment, and wastes. All modification activities would be inside existing buildings. Air pollutant concentrations from these modification activities would result in little increase in air pollutant concentrations at the site boundary.

Outdoor noise sources during modification would be limited to employee vehicles and truck traffic. Traffic associated with modification of these facilities would be a small fraction of the existing traffic associated with activities at LLNL and would result in little or no increase in traffic noise levels along roads to the site.

Next Section

Operational air quality impacts would result from emissions from emergency diesel generators, employee vehicles, and trucks moving materials and wastes. Emissions from heating these existing buildings would not change. The change in vehicular traffic would be small because most of the operations employees are expected to be existing employees, and that number is small in comparison to current employment at LLNL. Incremental air pollutant concentrations (e.g., carbon monoxide or nitrogen dioxide) for the site from operation of the lead assembly facility would be small. Estimated maximum concentrations of criteria air pollutants at the site boundary from testing of the emergency generators are less than 0.2 percent of the applicable standards. The estimated maximum 8-hr concentration of hydrocarbons at the site boundary from process sources is less than 0.007 percent of the threshold limit value for ethylene glycol and will not be of concern. The concentrations at the site boundary would continue to meet ambient air quality standards except possibly for ozone. Radiological emissions are expected to be minor with the MEI receiving an additional dose of less that 0.1 mrem/yr. The overall site would be expected to remain within the 10-mrem/yr NESHAP limit.

Section 176(c) of the 1990 Clean Air Act amendments requires that all Federal actions conform with the applicable State implementation plan. EPA has implemented rules that establish the criteria and procedures governing the determination of conformity for all Federal actions in nonattainment and maintenance areas. Although the area in which LLNL is located is not currently designated as nonattainment for any air pollutants (EPA 1997d; EPA 1998), EPA has recently proposed to redesignate the San Francisco Bay Area as nonattainment for ozone (EPA 1997e). Therefore, proposed actions at this site may need to be evaluated for applicability of the conformity regulations. Total direct and indirect emissions from the No Action Alternative or the lead assembly fabrication alternative result in little or no change in emissions from LLNL. Therefore, the requirement for a conformity determination is not applicable to the No Action Alternative or the lead assembly fabrication alternative and no further analysis of conformity at LLNL is required related to alternatives considered in this SPD EIS.

Noise sources during operation would include employee vehicles and trucks and may include new ventilation equipment. Traffic noise associated with operating these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Traffic associated with operating these facilities would be a small fraction of the existing traffic associated with activities at LLNL and should result in little or no increase in traffic noise levels along roads to the site. Noise from ventilation equipment should be similar to noise from existing ventilation equipment.

4.27.3.2 Waste Management

Table 4–239 compares the waste generated during modification of facilities for lead assembly fabrication at LLNL with the existing treatment, storage, and disposal capacity for the various waste types. No TRU waste, LLW, mixed LLW, or hazardous waste would be generated during modification. This SPD EIS also assumes that nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices.

Nonhazardous solid waste generated during modification of facilities for lead assembly fabrication would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal. The additional waste load generated during the modification period should not have a major impact on the nonhazardous solid waste management system at LLNL.

To be conservative, it was assumed that all nonhazardous liquid waste generated during modification of facilities for lead assembly fabrication would be discharged to the LLNL sanitary sewer system. Nonhazardous liquid waste generation during modification of these facilities is estimated to be less than 1 percent of the 2,763,271-m^3/yr (3,614,358-yd^3/yr) capacity of the LLNL sanitary sewer. Therefore, management of these wastes at LLNL should not have a major impact on the nonhazardous liquid waste treatment system during the modification period.

Table 4–239. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at LLNL

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
Nonhazardous				
Liquid	17	<1	NA	NA
Solid	12	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment, storage, and disposal capacities are compared with estimated additional waste generation assuming a 2-year modification period.
Key: LLNL, Lawrence Livermore National Laboratory; NA, not applicable (i.e., it is assumed that the majority of the nonhazardous solid waste would be treated and disposed of off the site by the construction contractor).

Table 4–240 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from the conduct of lead assembly fabrication activities at LLNL. No HLW would be generated during lead assembly fabrication.

Table 4–240. Potential Waste Management Impacts of the Conduct of Lead Assembly Fabrication Activities at LLNL

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	41	NA	4	<1 of WIPP
LLW	200	26	13	<1 of NTS
Mixed LLW	1	<1	<1	NA
Hazardous	<1	<1	<1	NA
Nonhazardous				
Liquid	1,600	<1	NA	NA
Solid	1,300	NA	NA	NA

[a] See waste type definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional waste generation annually. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
Key: LLNL, Lawrence Livermore National Laboratory; LLW, low-level waste; NTS, Nevada Test Site; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at LLNL or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate the shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed that TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment and storage of radioactive, hazardous, and mixed wastes at LLNL are described in the *Final EIS for Continued Operation of LLNL and SNL-Livermore* (DOE 1992:vol. I).

TRU wastes would be packaged and certified to WIPP waste acceptance criteria at the lead assembly fabrication facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LLNL facilities.

A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. If all of the TRU waste were stored on the site, this would be 51 percent of the 257 m^3 (336 yd^3) of contact-handled TRU waste currently in storage at LLNL and 4 percent of the 3,335 m^3 (4,362 yrd^3) of onsite storage capacity. Assuming that the waste were stored in 208-l (55-gal) drums that can be stacked two high and adding a 50 percent factor for aisle space, a storage area of about 189 m^2 (226 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at LLNL should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the lead assembly fabrication facility before transfer for treatment and storage in existing onsite facilities. LLW generated during lead assembly fabrication is estimated to be 26 percent of the 771-m^3/yr (1,008-yd^3/yr) capacity of the LLW size reduction facility. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. This would be 13 percent of the 5,255 m^3 (6,874 yd^3) of onsite storage capacity, and would not require LLNL to build additional storage capacity, because this waste would be shipped to a disposal facility on a routine basis. If additional storage space were required, and assuming that the waste were stored in 208-l (55-gal) drums that can be stacked two high and adding a 50 percent factor for aisle space, a storage area of about 1,000 m^2 (1,196 yd^2) would be required. Impacts of the storage of additional quantities of LLW on 0.1 ha (0.25 acre) of land at LLNL should not be major.

LLW would be disposed of at NTS or a similar facility off the site. The additional LLW from lead assembly fabrication at LLNL would be 4 percent of the 20,000 m^3 (26,000 yd^3) of LLW disposed of at NTS in 1995 and less than 1 percent of the 500,000-m^3 (650,000-yd^3) disposal capacity at NTS. Using the 6,085-m^3/ha (3,221-yd^3/acre) disposal land usage factor for NTS published in the *Final Storage and Disposition Final PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.12 ha (0.30 acre) of disposal space at NTS or a similar facility. Therefore, impacts of the management of this additional LLW at the disposal site should not be major. Impacts of disposal of LLW at NTS are described in the *Final EIS for the NTS and Off-Site Locations in the State of Nevada* (DOE 1996c).

The small quantity of mixed LLW would be packaged and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for LLNL. Mixed LLW disposal would occur off the site. Mixed LLW generation for these activities is estimated to be less than 1 percent of the 1,000-m^3/yr (1,310-yd^3/yr) capacity of the Building 513 and 514 waste treatment facilities. Over the operating period of the lead assembly fabrication activities, the 4 m^3 (5.2 yd^3) of mixed LLW generated would be less than 1 percent of the 2,825 m^3 (3,695 yd^3) of onsite storage capacity. Therefore, the management of this additional waste at LLNL should not have a major impact on the mixed LLW management system.

The small quantity of hazardous waste generated during operations (<1 m^3/yr [<1.3 yd^3/yr]) would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. Hazardous waste generated by lead assembly fabrication activities is estimated to be less than 1 percent of the 1,000 m^3/yr (1,310 yd^3/yr) capacity of the Building 513 and 514 waste treatment facilities, and less than 1 percent of the 2,825 m^3 (3,695 yd^3) of hazardous waste storage capacity. Because

the additional waste load is very small, the waste generated during the operation period should not have a major impact on the LLNL hazardous waste management system.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site for disposal in the Vasco Road Landfill. This additional waste load should not have a major impact on the nonhazardous solid waste management system at LLNL.

Nonhazardous wastewater would be treated, if necessary, before being discharged to the sanitary sewer system. After monitoring to ensure that the wastewater meets discharge limits, sanitary wastewaters from lead assembly fabrication, along with other sanitary wastewaters from LLNL and Sandia National Laboratories, Livermore (SNL-Livermore), would be routed to the City of Livermore Water Reclamation Plant. Nonhazardous liquid waste generated by these activities is estimated to be less than 1 percent of the existing annual site waste generation and less than 1 percent of the 2,763,271-m^3/yr (3,614,358-yd^3/yr) capacity of the LLNL sanitary sewer, and therefore should not have a major impact on the LLNL and City of Livermore sanitary wastewater treatment systems.

4.27.3.3 Infrastructure

Site infrastructure includes those utilities and resources required to support modification to and operations of the facilities for the proposed lead test assembly program. Proposed activities will use existing facilities on the Livermore Site at LLNL; therefore, all required utility connections are in existence. See Table 3–52 for current infrastructure characteristics at the Livermore Site. To support lead assembly fabrication, annual electricity requirements are estimated to increase by 720 MWh. Current annual electrical usage at the Livermore Site is 296,000 MWh. Natural gas requirements for heating are 55,200 m^3/yr (72,200 yd^3/yr). Current natural gas usage for the Livermore Site is 13 million m^3/yr (17 million yd^3/yr) . An estimated 4,600 l (1,215 gal) of diesel oil for emergency generators is also required. Annual liquid fuel usage at the Livermore Site is 1.3 million l (343,000 gal). Annual total water usage for sanitary and nonsanitary needs are estimated to be 1.6 million l (423,000 gal). Current annual water usage is 873 million l (231 million gal). There would not be any major impacts on infrastructure should the decision be made to conduct the proposed lead test assembly program at the Livermore Site at LLNL (DOE 1996a:4-333-337; O'Connor et al. 1998c:24).

4.27.3.4 *Human Health Risk*

Radiological Impacts. No radiological risk would be incurred by members of the public from modification of existing facilities for lead assembly fabrication at LLNL. Moreover, doses to construction workers should not exceed the normally low levels attributable to routine occupancy. Nonetheless, construction workers would be monitored (badged) as appropriate, to help ensure that doses are maintained as low as is reasonably achievable.

Table 4–241 reflects the potential radiological impacts of normal operations on three individual receptor groups at LLNL: the population living within 80 km (50 mi) in the year 2005, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected LCF risks to these groups from annual operation of the lead assembly facility. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Given incident-free operation of the lead assembly facility, the total population dose in the year 2005 would be 1.1 person-rem. The corresponding number of LCFs in the population around LLNL from annual operation of the facility would be 5.5×10^{-4}. The total dose to the maximally exposed member of the public from annual

Table 4–241. Potential Radiological Impacts on the Public of Operation of Lead Assembly Facility at LLNL

Population within 80 km for year 2005	
Dose (person-rem/yr)	1.1
Percent of natural background[a]	4.7×10^{-5}
Associated latent fatal cancers	5.5×10^{-4}
Maximally exposed individual	
Annual dose (mrem/yr)	0.064
Percent of natural background[a]	0.021
Associated latent fatal cancer risk	3.2×10^{-8}
Average exposed individual within 80 km[b]	
Annual dose (mrem/yr)	1.4×10^{-4}
Associated latent fatal cancer risk	7.1×10^{-11}

[a] The annual natural background radiation level at LLNL is 300 mrem for the average individual; the population within 80 km (50 mi) in 2005 would receive 2,323,000 person-rem.
[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of LLNL in 2005 (7,742,000).

Key: LLNL, Lawrence Livermore National Laboratory.
Source: Appendix J.

operation would be 0.064 mrem; this corresponds to an LCF risk of 3.2×10^{-8}. The impacts on the average individual would be lower.

Doses to involved workers from normal operations are given in Table 4–242; these workers are defined as those directly associated with lead assembly fabrication activities. Under the proposed action, the annual average dose to lead assembly facility workers would be an estimated 500 mrem. The annual dose received by the total involved workforce for this facility would be 28 person-rem, which corresponds to 0.011 LCF. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–242. Potential Radiological Impacts on Involved Workers of Operation of Lead Assembly Facility at LLNL

Number of badged workers	55
Annual total dose (person-rem/yr)	28
Associated latent fatal cancers	0.011
Annual average worker dose (mrem/yr)	500
Associated latent fatal cancer risk	2.0×10^{-4}

Key: LLNL, Lawrence Livermore National Laboratory.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998c.

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or operation activities. However, concentrations would be within the regulated exposure limits.

4.27.3.5 Facility Accidents

Given the estimated 2,060 person-days of construction labor and standard industrial accident rates, about 0.85 cases of nonfatal occupational injury or illness and 1.2×10^{-3} fatality would be expected. DOE-required industrial safety programs would be in place to reduce the risks.

The potential consequences of postulated bounding facility accidents from lead assembly fabrication activities at LLNL are presented in Table 4–243. The source terms are identical to those for lead assembly activities at ANL–W; the different consequences are attributable to differences in stack height, meteorology, site boundary distance, and population.

Table 4–243. Accident Impacts of Lead Assembly Fabrication at LLNL

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	5.3×10^{-1}	2.1×10^{-4}	5.3×10^{-1}	2.7×10^{-4}	6.4×10^{1}	3.1×10^{-2}
Design basis earthquake	Unlikely	1.3×10^{-3}	5.3×10^{-7}	1.7×10^{-3}	8.5×10^{-7}	2.8×10^{-1}	1.5×10^{-4}
Design basis fire	Unlikely	5.7×10^{-4}	2.3×10^{-7}	7.4×10^{-4}	3.7×10^{-7}	1.2×10^{-1}	6.3×10^{-5}
Design basis explosion	Extremely unlikely	9.3×10^{-3}	3.7×10^{-6}	1.2×10^{-2}	6.0×10^{-6}	1.9	1.0×10^{-3}
Beyond-design-basis fire	Beyond extremely unlikely	1.1	4.3×10^{-4}	1.1	5.3×10^{-4}	1.7×10^{2}	9.3×10^{-2}

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

Key: LLNL, Lawrence Livermore National Laboratory.

Note: A beyond-design-basis earthquake scenario was not evaluated for Building 332 at LLNL because extensive analyses of the seismic hazard at the site and the response of the building to those hazards indicate that the scenario is beyond the range of "reasonably foreseeable." Current estimates are that the frequency of collapse is about 1×10^{-7} per year or less (Murray 1998).

The most severe consequences of a design basis accident would be associated with a nuclear criticality. Bounding radiological consequences for the MEI would result in a dose of 0.53 rem, corresponding to an LCF probability of 2.7×10^{-4}. Consequences of the criticality for the population in the environs of LLNL would include an estimated 3.1×10^{-2} LCF. The frequency of such an accident is estimated to be between 1 in 10,000 and 1 in 1,000,000 per year.

Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be the highest for the criticality accident. The consequences of such an accident would include an LCF probability of 2.1×10^{-4}.

Extensive analyses have been performed on the seismic hazard at the LLNL site and the response of the Plutonium Facility, Building 332, to those hazards. The geology and seismology studies have characterized the nature and magnitude of the seismic threat to LLNL and indicate there is no physiographic basis for postulating earthquake magnitudes or ground accelerations greater than Richter magnitude 6.9g or 1.1g, respectively. Building 332, Increment III, has been designed and/or evaluated against earthquakes and ground accelerations of these magnitudes and found to be adequate. Significantly greater magnitude events and ground acceleration levels would be required before any potential collapse of Increment III would be expected. Based on the current LLNL hazard curve and various estimates of the fragility curves for collapse of Increment III, the frequency of collapse is on the order of 1×10^{-7} per year or less (Murray 1998). Thus, the frequency is considered sufficiently low that evaluation of consequences due to a beyond-design-basis earthquake is unnecessary.

No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident

4.27.3.6 Transportation

Plutonium dioxide would be shipped from LANL to lead assembly fabrication facilities at LLNL. These facilities would also receive uranium dioxide and other material needed to assemble MOX fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 30 shipments of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 73,000 km (45,000 mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public, 10.3 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.9×10^{-4} LCF among transportation workers and 5.2×10^{-3} LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 3.0×10^{-4}.

Impacts of Accidents During Ground Transportation. Estimates of the total ground transportation accident risks are as follows: a radiological dose to the population of 6.8 person-rem, resulting in a total population risk of 3.4×10^{-3} LCF; and traffic accidents resulting in 9.1×10^{-4} traffic fatality.

4.27.3.7 Other Resource Areas

Other resource areas include geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and socioeconomics. Impacts on these resource areas are primarily related to the construction of new buildings and the number of persons employed to support the activities. Because a relatively small number of largely existing personnel are expected to perform the lead

assembly fabrication in existing buildings (i.e., no new buildings would be constructed and no additional land disturbed), little or no impacts are expected to any of these resource areas.

4.27.3.8 Environmental Justice

As demonstrated throughout the analyses presented in this section, the lead assembly fabrication activities at LLNL would pose no significant health risks to the public. The expected number of LCFs as a result of the radiation released from these activities in the general population residing within 80 km (50 mi) of LLNL would be 5.5×10^{-4}; thus, no additional LCFs would be expected (see Table 4–241). Transportation related to these activities would not be expected to result in any LCFs either. The number of transportation-related fatalities in the total population along the shipping routes would be expected to increase by 8.6×10^{-3} due to radiological impacts, by 3.0×10^{-4} due to emissions, and by 9.1×10^{-4} as a result of traffic accidents; thus, no transportation-related fatalities would be expected (see Section 4.27.3.6). Risks posed by the implementation of the LLNL alternative for lead assembly fabrication would be negligible regardless of the racial or ethnic composition, or the economic status of the population. Therefore, the lead assembly fabrication activities at LLNL would have no significant impacts on minority or low-income populations.

4.27.4 LANL

4.27.4.1 Air Quality and Noise

Potential air quality impacts of modification of facilities for lead assembly fabrication at LANL would not be major. Emissions from modification would result from welding and vehicle emissions from moving employees, equipment, and wastes. All modification activities would be inside existing buildings. Air pollutant concentrations from these modification activities would result in little increase in air pollutant concentrations at the site boundary.

Outdoor noise sources during modification would be limited to employee vehicles and truck traffic. Traffic associated with modification of these facilities would be a small fraction of the existing traffic associated with activities at LANL and would result in little or no increase in traffic noise levels along roads to the site.

Operational air quality impacts would result from emissions from emergency diesel generators, employee vehicles, and trucks moving materials and wastes. Emissions from heating these existing buildings would not change. The change in vehicular traffic would be small because most of the operations employees are expected to be existing employees, and that number is small in comparison to current employment at LANL. Incremental air pollutant concentrations (e.g., carbon monoxide or nitrogen dioxide) for the site from operation of the lead assembly facility would be small. Estimated maximum concentrations of criteria air pollutants at the site boundary from testing of the emergency generators are less than 1 percent of the applicable standards. The estimated maximum 8-hr concentration of hydrocarbons at the site boundary from process sources is less than 0.02 percent of the threshold limit value for ethylene glycol and will not be of concern. The concentrations at the site boundary would continue to meet ambient air quality standards. Radiological emissions are expected to be minor with the MEI receiving an additional dose of less than 0.01 mrem/yr. The overall site would be expected to remain within the 10-mrem/yr NESHAP limit.

Noise sources during operation would include employee vehicles and trucks and may include new ventilation equipment. Traffic noise associated with operating these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Traffic associated with operating these facilities would be a small fraction of the existing traffic associated with activities at LANL and should result in little or no increase in traffic noise levels along roads to the site. Noise from ventilation equipment would be similar to noise from existing ventilation equipment.

4.27.4.2 Waste Management

Table 4–244 compares the waste generated during modification of facilities for lead assembly fabrication at LANL with the existing treatment, storage, and disposal capacity for the various waste types. TRU waste and LLW would be generated during modification of contaminated areas of the glovebox line in Building PF–4, although no mixed waste or hazardous wastes would be generated.

Table 4–244. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at LANL

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU	3	<1	<1	<1 of WIPP
LLW	3	NA	1	<1
Nonhazardous, liquid	10	<1	NA	<1

[a] See definitions in Appendix F.8.

[b] Treatment, storage, and disposal capacities are compared with estimated additional waste generation assuming a 2-year modification period.

Key: LANL, Los Alamos National Laboratory; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated or stored on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at LLNL or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate the shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices.

TRU wastes would be packaged and certified to WIPP waste acceptance criteria at the modification site. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LANL facilities.

TRU waste generated during modification of Building PF–4 is estimated to be less than 1 percent of the 1,080-m^3/yr (1,413-yd^3/yr) TRU waste volume reduction capacity. A total of 5 m^3 (6.5 yd^3) of TRU waste would be generated over the modification period. If all of the TRU waste were to be stored on the site, this would be less than 1 percent of the 24,355-m^3 (31,856-yd^3) storage capacity available at LANL. Therefore, impacts of the management of additional quantities of TRU waste at LANL should not be major. In addition, the TRU waste generated during modification of Building PF–4 would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building PF–4 would be packaged, certified, and accumulated at the facility before transfer for treatment, storage, and disposal in existing onsite facilities. A total of 5 m^3 (6.5 yd^3) of LLW would be generated over the modification period. LLW generated by modification of facilities for lead assembly fabrication is estimated to be 1 percent of the 663-m^3 (867-yd^3) LLW storage capacity and less than 1 percent of the 252,500-m^3 (330,270-yd^3) capacity of the Technical Area–54 (TA–54) LLW disposal area. Using the 12,562-m^3/ha (6,649-yd^3/acre) disposal land usage factor for LANL published in the *Stockpile*

Stewardship and Management PEIS (DOE 1996g:H-9), 5 m^3 (6.5 yd^3) of waste would require less than 0.1 ha (0.25 acre) of disposal space at LANL. Therefore, impacts of the management of this additional LLW at LANL should not be major.

To be conservative, it was assumed that all nonhazardous liquid waste generated during modification of facilities for lead assembly fabrication would be discharged to the LANL sanitary wastewater treatment plant. Nonhazardous liquid waste generation during modification of these facilities is estimated to be less than 1 percent of the 1,060,063-m^3/yr (1,386,562-yd^3/yr) capacity of the sanitary wastewater treatment plant and less than 1 percent of the 567,750-m^3/yr (742,617-d^3/yr) capacity of the sanitary drain fields. Therefore, management of these wastes at LANL should not have a major impact on the nonhazardous liquid waste treatment system during the modification period.

Table 4–245 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from lead assembly fabrication activities at LANL. No HLW would be generated during lead assembly fabrication.

Table 4–245. Potential Waste Management Impacts of Operation of Lead Assembly Facility at LANL

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	41	4	1	<1 of WIPP
LLW	200	NA	106	<1
Mixed LLW	1	NA	1	NA
Hazardous	<1	NA	<1	NA
Nonhazardous				
Liquid	1,600	<1[d]	NA	<1[e]
Solid	1,300	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional waste generation annually. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
[d] Percent of the capacity of sanitary wastewater treatment plant.
[e] Percent of the capacity of sanitary tile fields.
Key: LANL, Los Alamos National Laboratory; LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at LANL or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, it is assumed that TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate the shipment of contact-handled TRU waste form surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of waste at LANL will be evaluated in the *Draft LANL Site-Wide EIS*, which is being prepared by the DOE Albuquerque Operations Office (DOE 1995d).

TRU wastes would be packaged and certified to WIPP waste acceptance criteria at the lead assembly fabrication facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LANL facilities.

TRU waste generated by lead assembly fabrication is estimated to be 4 percent of the 1,080-m^3/yr (1,413 yd^3/yr) TRU waste volume reduction capacity. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. If all of the TRU waste were to be stored on the site, this would be 1 percent of the 24,355-m^3 (31,856-yd^3) storage capacity available at LANL. Therefore, impacts of the management of additional quantities of TRU waste at LANL should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the lead assembly fabrication facility before transfer for disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generated by lead assembly fabrication is estimated to be 106 percent of the 663-m^3 (867-yd^3) LLW storage capacity and less than 1 percent of the 252,000-m^3 (329,600-yd^3) capacity of the TA–54 LLW disposal area. Because the waste would be sent for disposal on a regular basis, storage should not be a problem. Using the 12,562-m^3/ha (6,649-yd^3/acre) disposal land usage factor for LANL published in the *Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management* (SSM PEIS) (DOE 1996g:H-9), 700 m^3 (916 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at LANL. Thus, impacts of the management of this additional LLW at LANL should not be major.

The small quantity of mixed LLW would be packaged and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for LANL. Mixed LLW generation at the lead assembly fabrication facility is estimated to be 1 percent of the 583-m^3 (763-yd^3) mixed LLW storage capacity. Therefore, the management of this additional waste at LANL should not have a major impact on the mixed LLW management system.

The small quantity of hazardous waste generated during operations would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. Hazardous waste generated by lead assembly fabrication facilities is estimated to be less than 1 percent of the 1,864 m^3 (2,438 yd^3) of hazardous waste storage capacity. The additional waste load generated during the operation period should not have a major impact on the LANL hazardous waste management system.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent for disposal in the Los Alamos County Landfill. This additional waste load should not have a major impact on the nonhazardous solid waste management system at LANL.

Nonhazardous wastewater would be treated, if necessary, before being discharged to the sanitary sewer system. Nonhazardous liquid waste generated by lead assembly fabrication is estimated to be less than 1 percent of the 1,060,063-m^3/yr (1,386,562-yd^3/yr) capacity of the sanitary wastewater treatment plant and less than 1 percent of the 567,750-m^3/yr (742,617-yd^3/yr) capacity of the sanitary drain fields. Therefore, management of additional nonhazardous liquid waste at LANL should not have a major impact on the wastewater treatment system.

4.27.4.3 Infrastructure

Site infrastructure includes those utilities and resources required to support modification and operation of the facilities for the proposed lead assembly program. Proposed activities would use existing facilities, therefore, utility connections are in existence. See Table 3–58 for additional information on the infrastructure characteristics at LANL. To support lead assembly fabrication, annual electricity requirements are calculated to increase by 720 MWh. Current annual electrical usage at LANL is 381,000 MWh, with a site capacity of 500,000 MWh. Additional annual natural gas requirements for heating are 55,200 m^3/yr (72,200 yd^3/yr). Current natural gas usage at LANL is 43.4 million m^3/yr (56.8 million yd^3/yr), with a site capacity of 103.4 million m^3/yr (135.2 million yd^3/yr). An estimated 4,600 l (1,215 gal) of diesel oil for emergency generators is also required. Fuel is procured on the site on an as-needed basis. Annual total groundwater usage for sanitary and nonsanitary needs are estimated to be 1.6 million l (423,000 gal). Current annual water usage is 5.5 million l (1.5 million gal), while the current capacity is 6.8 million l (1.8 million gal). DOE also owns a contract for 1.5 million l/yr (396,000 gal/yr) of San Juan-Chama water (DOE 1996a:3-317). If the lead assembly facilities were located at LANL, these water rights may need to be exercised. There would not be any other major impacts to infrastructure should the decision be made to conduct the proposed lead test assembly program at LANL (DOE 1997h:3-53, 3-60; O'Connor et al. 1998d).

4.27.4.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from modification of existing facilities for lead assembly fabrication at LANL. As shown in Table 4–246, additional doses (above the normally low levels attributable to routine occupancy) to construction workers are expected from modification activities. Construction worker exposures would be limited to ensure that doses are maintained ALARA and would be monitored (badged) as appropriate.

Table 4–246. Potential Radiological Impacts on Construction Workers of Lead Assembly Facility at LANL

Number of badged workers	15
Annual total dose (person-rem/yr)	5.7
Associated latent fatal cancers[a]	2.3×10^{-3}
Annual average worker dose (mrem/yr)	383
Associated latent fatal cancer risk	1.5×10^{-4}

[a] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Key: LANL, Los Alamos National Laboratory.

Note: If the worker is a LANL radiation worker, the whole body dose limit is 5,000 mrem/yr (DOE 1995e), with a DOE administrative control level of 2,000 mrem/yr. If the worker is a contractor (i.e., LANL site "visitor"), the whole body dose limit is 100 mrem/yr (DOE 1993) because the worker would be considered a member of the public. In either case, an effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: ICRP 1991; NAS 1990; O'Connor et al. 1998d.

Table 4–247 reflects the potential radiological impacts of normal operations on three individual receptor groups at LANL: the population living within 80 km (50 mi) in the year 2005, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected LCF risks to these groups from annual operation of the lead assembly facility. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Table 4–247. Potential Radiological Impacts on the Public of Operation of Lead Assembly Facility at LANL

Population within 80 km for year 2005	
Dose (person-rem/yr)	0.025
Percent of natural background[a]	2.4×10^{-5}
Associated latent fatal cancers	1.2×10^{-5}
Maximally exposed individual	
Annual dose (mrem/yr)	9.0×10^{-3}
Percent of natural background[a]	2.6×10^{-3}
Associated latent fatal cancer risk	4.5×10^{-9}
Average exposed individual within 80 km[b]	
Annual dose (mrem/yr)	8.5×10^{-5}
Associated latent fatal cancer risk	4.3×10^{-11}

[a] The annual natural background radiation level at LANL is 349 mrem for the average individual; the population within 80 km (50 mi) in 2005 would receive 102,200 person-rem.
[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of LANL in 2005 (292,700).
Key: LANL, Los Alamos National Laboratory.
Source: Appendix J.

Given incident-free operation of the lead assembly facility, the total population dose in the year 2005 would be 0.025 person-rem. The corresponding number of LCFs in the population around LANL from annual operation of the facility would be 1.2×10^{-5}. The total dose to the maximally exposed member of the public from annual operation would be 9.0×10^{-3} mrem; this corresponds to an LCF risk of 4.5×10^{-9}. The impacts on the average individual would be lower.

Doses to involved workers from normal operations are given in Table 4–248; these workers are defined as those directly associated with lead assembly fabrication activities. Under the proposed action, the annual average dose to lead assembly facility workers would be an estimated 500 mrem. The annual dose received by the total involved workforce for this facility would be 28 person-rem, which corresponds to 0.011 LCF.

Table 4–248. Potential Radiological Impacts on Involved Workers of Operation of Lead Assembly Facility at LANL

Number of badged workers	55
Annual total dose (person-rem/yr)	28
Associated latent fatal cancers	0.011
Annual average worker dose (mrem/yr)	500
Associated latent fatal cancer risk	2.0×10^{-4}

Key: LANL, Los Alamos National Laboratory.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved with operations will be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program will ensure that doses will be reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998d.

Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or operation activities. However, concentrations would be within the regulated exposure limits.

4.27.4.5 Facility Accidents

The only change in employment resources that would be required for lead assembly fabrication at LANL would be increased labor hours to modify the existing glovebox line and related equipment. Given the estimated 594 person-days of construction labor and standard industrial accident rates, about 0.25 cases of nonfatal occupational injury or illness and 3.5×10^{-4} fatality would be expected.

The potential consequences of postulated bounding facility accidents from lead assembly operations at LANL are presented in Table 4–249. The source terms are identical to those for lead assembly operations at ANL–W; the different consequences are attributable to differences in stack height, meteorology, site boundary distance, and population.

Table 4–249. Accident Impacts of Lead Assembly Fabrication at LANL

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	6.5×10^{-2}	2.6×10^{-5}	2.8×10^{-2}	1.4×10^{-5}	6.6	3.2×10^{-3}
Design basis earthquake	Unlikely	1.1×10^{-4}	4.3×10^{-8}	4.1×10^{-5}	2.1×10^{-8}	1.4×10^{-2}	6.8×10^{-6}
Design basis fire	Unlikely	4.7×10^{-5}	1.9×10^{-8}	1.8×10^{-5}	9.0×10^{-9}	5.9×10^{-3}	2.9×10^{-6}
Design basis explosion	Extremely unlikely	7.6×10^{-4}	3.0×10^{-7}	2.9×10^{-4}	1.5×10^{-7}	9.5×10^{-2}	4.8×10^{-5}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	5.1×10^{1}	2.1×10^{-2}	1.4×10^{1}	7.1×10^{-3}	4.2×10^{3}	2.1
Beyond-design-basis fire	Beyond extremely unlikely	1.1×10^{-1}	4.6×10^{-5}	3.1×10^{-2}	1.6×10^{-5}	9.2	4.6×10^{-3}

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

Key: LANL, Los Alamos National Laboratory.

The most severe consequences of a design basis accident would be associated with a nuclear criticality. Bounding radiological consequences for the MEI would result in a dose of 2.8×10^{-2} rem, corresponding to an LCF probability of 1.4×10^{-5}. Consequences of the criticality for the general population in the environs of LANL would include an estimated 3.2×10^{-3} LCF. The frequency of such an accident is estimated to be between 1 in 10,000 and 1 in 1,000,000 per year.

Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer,

and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be the highest for the criticality accident. The consequences of such an accident would include an LCF probability of 2.6×10^{-5}.

The radiological effects from total collapse of the lead assembly fabrication facility at LANL in the beyond-design-basis earthquake would be approximately 2.1 LCFs in the population residing within 80 km (50 mi) of LANL. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

4.27.4.6 Transportation

Plutonium dioxide would already be at LANL so no shipping would be required for this material. These facilities would receive uranium dioxide and other material needed to assemble MOX fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 20 shipments of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 55,000 km (34,000 mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public, 10.3 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.9×10^{-4} LCF among transportation workers and 5.1×10^{-3} LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 1.5×10^{-4}.

Impacts of Accidents During Ground Transportation. Estimates of the total ground transportation accident risks follow: a radiological dose to the population of 6.2 person-rem, resulting in a total population risk of 3.1×10^{-3} LCF; and traffic accidents resulting in 6.7×10^{-4} traffic fatality.

4.27.4.7 Other Resource Areas

Other resource areas include geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and socioeconomics. Impacts on these resource areas are primarily related to the construction of new buildings and the number of persons employed to support the activities. Because a relatively small number of largely existing personnel are expected to perform the lead

assembly fabrication in existing buildings (i.e., no new buildings would be constructed and no additional land disturbed), little or no impacts are expected to any of these resource areas.

4.27.4.8 Environmental Justice

As demonstrated throughout the analyses presented in this section, the lead assembly fabrication activities at LANL would pose no significant health risks to the public. The expected number of LCFs as a result of the radiation released from these activities in the general population residing within 80 km (50 mi) of LANL would be 1.2×10^{-5}; thus, no additional LCFs would be expected (see Table 4–247). Transportation related to these activities would not be expected to result in any LCFs either. The number of transportation-related fatalities in the total population along the shipping routes would be expected to increase by 8.3×10^{-3} due to radiological impacts, by 1.5×10^{-4} due to emissions, and by 6.7×10^{-4} as a result of traffic accidents; thus, no transportation-related fatalities would be expected (see Section 4.27.4.6). Risks posed by the implementation of the LANL alternative for lead assembly fabrication would be negligible regardless of the racial or ethnic composition, or the economic status of the population. Therefore, the lead assembly fabrication activities at LANL would have no significant impacts on minority or low-income populations.

4.27.5 SRS

4.27.5.1 Air Quality and Noise

Potential air quality impacts of modification of facilities for lead assembly fabrication at SRS would not be major. Emissions from modification would result from welding and vehicle emissions from moving employees, equipment, and wastes. All modification activities would be inside existing buildings. Air pollutant concentrations from these modification activities would result in little increase in air pollutant concentrations at the site boundary.

Outdoor noise sources during modification would be limited to employee vehicles and truck traffic. Traffic associated with modification of these facilities would be a small fraction of the existing traffic associated with activities at SRS and should result in little or no increase in traffic noise levels along roads to the site.

Operational air quality impacts would result from emissions from emergency diesel generators, employee vehicles, and trucks moving materials and wastes. Emissions from heating these existing buildings would not change. The change in vehicular traffic would be small because most of the operations employees are expected to be existing employees, and that number is small in comparison to current employment at SRS. Incremental air pollutant concentrations (e.g., carbon monoxide or nitrogen dioxide) for the site from operation of the lead assembly fabrication facility would be smaller than the levels shown in Table 4–79, and the concentrations at the site boundary would continue to meet ambient air quality standards. Radiological emissions are expected to be minor with the MEI receiving an additional dose of less than 0.0001 mrem/yr. The overall site would be expected to remain within the 10-mrem/yr NESHAP limit.

Noise sources during operation would include employee vehicles and trucks and may include new ventilation equipment. Traffic noise associated with operating these facilities would occur on the site and along offsite local and regional transportation routes used to bring materials and workers to the site. Traffic associated with operating these facilities would be a small fraction of the existing traffic associated with activities at SRS and should result in little or no increase in traffic noise levels along roads to the site. Noise from ventilation equipment should be similar to noise from existing ventilation equipment.

Next Section

4.27.5.2 Waste Management

Table 4–250 compares the waste generated during modification of facilities for lead assembly fabrication at SRS with the existing treatment, storage, and disposal capacity for the various waste types. No TRU waste, LLW, or mixed LLW would be generated during modification. For this SPD EIS, it is assumed that hazardous and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices.

Table 4–250. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
Hazardous	1	NA	NA	NA
Nonhazardous				
Liquid	2,350	2[c]	NA	<1[d]
Solid	19	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment, storage, and disposal capacities are compared with estimated additional waste generation assuming a 2-year modification period.
[c] Percent of the capacity of H-Area sanitary sewer.
[d] Percent of the capacity of Central Sanitary Wastewater Treatment Facility.
Key: NA, not applicable (i.e., it is assumed that the majority of the hazardous and nonhazardous solid waste would be treated and disposed of off the site by the construction contractor).

Hazardous waste generated during modification of facilities for lead assembly fabrication would be typical of those generated during construction of an industrial facility. Any hazardous waste generated during modification would be packaged in DOT-approved containers and shipped off the site to permitted commercial recycling, treatment, and disposal facilities. The additional waste load generated during the modification period should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste generated during modification of facilities for lead assembly fabrication would be packaged in conformance with standard industrial practice and shipped to offsite commercial facilities for recycling or disposal. The additional waste load generated during the modification period should not have a major impact on the SRS nonhazardous solid waste management system.

To be conservative, it was assumed that all nonhazardous liquid waste generated during modification of facilities for lead assembly fabrication would be managed at the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generation during modification of these facilities is estimated to be 2 percent of the 136,274-m^3/yr (178,246-yd^3/yr) capacity of the H-Area sanitary sewer and less than 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of these wastes at SRS should not have a major impact on the nonhazardous liquid waste treatment system during the modification period.

Table 4–251 compares the existing site treatment, storage, and disposal capacities with the expected waste generation rates from lead assembly fabrication at SRS. No HLW would be generated during lead assembly fabrication.

Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of at SRS or at other DOE sites or commercial facilities. According to the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and

Table 4–251. Potential Waste Management Impacts of Operation of Lead Assembly Facility at SRS

Waste Type[a]	Estimated Additional Waste Generation (m^3/yr)	Estimated Additional Waste Generation as a Percent of[b]		
		Characterization or Treatment Capacity	Storage Capacity	Disposal Capacity
TRU[c]	41	2	<1	<1 of WIPP
LLW	200	1	NA	2
Mixed LLW	1	<1	<1	NA
Hazardous	<1	<1	<1	NA
Nonhazardous				
Liquid	1,600	1[d]	NA	<1[e]
Solid	1,300	NA	NA	NA

[a] See definitions in Appendix F.8.
[b] Treatment capacities, and the disposal capacity for nonhazardous liquid waste, are compared with estimated additional waste generation annually. All other storage and disposal capacities are compared with total estimated additional waste generation assuming a 3-year operation period.
[c] Includes mixed TRU waste. Facilities are not expected to generate remotely handled TRU waste.
[d] Percent of the capacity of H-Area sanitary sewer.
[e] Percent of the capacity of Central Sanitary Wastewater Treatment Facility.
Key: LLW, low-level waste; NA, not applicable (i.e., the majority of this waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

shipped to WIPP for disposal. Current schedules for shipment of TRU waste to WIPP would accommodate the shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997b:17). Therefore, it is assumed the TRU waste would be stored on the site until 2016. This SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995c).

TRU wastes would be treated, packaged and certified to WIPP waste acceptance criteria at the lead assembly fabrication facilities. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generated by lead assembly fabrication is estimated to be 2 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. If all of the TRU waste were stored on the site, this would be less than 1 percent of the 34,400 m^3 (45,000 yd^3) of storage capacity available at the TRU Waste Storage Pads. Therefore, impacts of the management of additional quantities of TRU waste at SRS should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and less than 1 percent of the current 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW would be packaged, certified, and accumulated at the lead assembly fabrication facilities before transfer for treatment and disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generated by lead assembly fabrication is estimated to be 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility (CIF) and 2 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687-m^3/ha (4,598-yd^3/acre)

disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generated by lead assembly fabrication is estimated to be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of CIF, and less than 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste would be packaged at the generating facility for treatment and disposal at a combination of onsite and offsite facilities. Assuming that all hazardous waste is managed on the site, hazardous waste generated by lead assembly fabrication is estimated to be less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of CIF, and less than 1 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system. If all LLW, mixed LLW, and hazardous waste generated by lead assembly fabrication activities is treated in CIF, this additional waste would be only 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of CIF.

Nonhazardous solid waste would be packaged and transported in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent to a non-DOE disposal facility. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

To be conservative, it was assumed that all nonhazardous wastewater would be managed in H-Area. Nonhazardous wastewater would be treated, if necessary, before being discharged to the H-Area sanitary sewer system, which connects to the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generated by lead assembly fabrication is estimated to be 1 percent of the 136,274-m^3/yr (178,246-yd^3/yr) capacity of the H-Area sanitary sewer and less than 1 percent of the 1.03-million-m^3/yr (1.35-million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, management of nonhazardous liquid waste at SRS should not have a major impact on the wastewater treatment system.

4.27.5.3 Infrastructure

Site infrastructure includes those utilities and resources required to support modification and operation of the facilities for the proposed lead assembly program in Building 221–H. Proposed activities would use existing facilities, therefore, utility connections are in existence. See Table 3–64 for additional information on the infrastructure characteristics of Building 221–H. To support lead assembly fabrication, annual electricity requirements are estimated to increase by 720 MWh. Current annual electrical usage at Building 221–H is 120,000 MWh, with a current annual capacity is 500,000 MWh. An additional annual coal requirement for heating is estimated at 60 t (66 tons). An estimated 4,600 l (1,215 gal) of diesel oil for emergency generators is also required. Fuel is procured on the site on an as-needed basis. Annual total groundwater usage for sanitary and nonsanitary needs are estimated to be 1.6 million l (423,000 gal). Current annual water usage is 380 million l (100 million gal), while the current capacity is 1.5 billion l (396 million gal). There would not be any major impacts to infrastructure should the decision be made to conduct the proposed lead assembly program in Building 221–H (O'Connor et al. 1998e).

4.27.5.4 Human Health Risk

Radiological Impacts. No radiological risk would be incurred by members of the public from modification of existing facilities for lead assembly fabrication at SRS. Moreover, doses to construction workers should not exceed normally low levels attributable to routine occupancy. Nonetheless, construction workers would be monitored (badged) as appropriate, to help ensure that doses are maintained as low as is reasonably achievable.

Table 4–252 reflects potential radiological impacts of normal operations on three individual receptor groups at SRS: the population living within 80 km (50 mi) in the year 2005, the maximally exposed member of the public, and the average exposed member of the public. The table depicts the projected LCF risks to these groups from annual operation of the lead assembly facility. To put operational doses into perspective, comparisons with doses from natural background radiation are also provided in the table.

Table 4–252. Potential Radiological Impacts on the Public of Operation of Lead Assembly Facility at SRS

Population within 80 km for year 2005	
Dose (person-rem/yr)	6.6×10^{-3}
Percent of natural background[a]	3.0×10^{-6}
Associated latent fatal cancers	3.3×10^{-6}
Maximally exposed individual	
Annual dose (mrem/yr)	5.5×10^{-5}
Percent of natural background[a]	1.9×10^{-5}
Associated latent fatal cancer risk	2.8×10^{-11}
Average exposed individual within 80 km[b]	
Annual dose (mrem/yr)	8.8×10^{-6}
Associated latent fatal cancer risk	4.4×10^{-12}

[a] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2005 would receive 222,400 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of SRS in 2005 (754,000).

Source: Appendix J.

Given incident-free operation of the lead assembly facility, the total population dose in the year 2005 would be 6.6×10^{-3} person-rem. The corresponding number of LCFs in the population around SRS from annual operation of the facility would be 3.3×10^{-6}. The total dose to the maximally exposed member of the public from annual operation would be 5.5×10^{-5} mrem; this corresponds to an LCF risk of 2.8×10^{-11}. The impacts on the average individual would be lower.

Doses to involved workers from normal operations are given in Table 4–253; these workers are defined as those directly associated with lead assembly fabrication activities. Under the proposed action, the annual average dose to lead assembly facility workers would be an estimated 500 mrem. The annual dose received by the total involved workforce for this facility would be 28 person-rem, which corresponds to 0.011 LCF. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or operation activities. However, concentrations would be within the regulated exposure limits.

Table 4–253. Potential Radiological Impacts on Involved Workers of Operation of Lead Assembly Facility at SRS

Number of badged workers	55
Annual total dose (person-rem/yr)	28
Associated latent fatal cancers	0.011
Annual average worker dose (mrem/yr)	500
Associated latent fatal cancer risk	2.0×10^{-4}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998e.

4.27.5.5 Facility Accidents

The SRS lead assembly fabrication option would involve a total of 59,000 person-days of construction labor. Thus, given standard industrial accident rates, 24.3 cases of nonfatal occupational injury or illness and 0.034 fatality would be expected.

The potential consequences of postulated bounding facility accidents from lead assembly operations at SRS are presented in Table 4–254. The source terms are identical to those for lead assembly operations at ANL–W; the different consequences are attributable to differences in stack height, meteorology, site boundary distance, and population.

The most severe consequences of a design basis accident would be associated with a nuclear criticality. Bounding radiological consequences for the MEI would result in a dose of 9.3×10^{-4} rem, corresponding to an LCF probability of 4.6×10^{-7}. Consequences of the criticality for the general population in the environs of SRS would include an estimated 6.5×10^{-4} LCF. The frequency of such an accident is estimated to be between 1 in 10,000 and 1 in 1,000,000 per year.

Consistent with the analysis presented in the *Storage and Disposition Final PEIS*, the noninvolved worker is assumed to be 1,000 m (3,281 ft) from the location of the accident or at the site boundary, whichever is closer, and downwind from that location. For design basis accidents, the radiological consequences for this worker were estimated to be the highest for the criticality accident. The consequences of such an accident would include an LCF probability of 4.0×10^{-6}.

The radiological effects from total collapse of the lead assembly fabrication facility at SRS in the beyond-design-basis earthquake would be approximately 1.1 LCF in the population residing within 80 km (50 mi) of SRS. It should be emphasized that a seismic event of sufficient magnitude to collapse these facilities would likely cause the collapse of other DOE facilities, and would almost certainly cause widespread failure of homes, office buildings, and other structures in the surrounding area. The overall impact of such an event must therefore be seen in the context not only of the potential radiological impacts of these other facilities, but of hundreds, possibly thousands, of immediate fatalities from falling debris. The frequency of an earthquake of this magnitude is estimated to be between 1 in 100,000 and 1 in 10,000,000 per year.

No major consequences for the maximally exposed involved worker would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would be able to evacuate immediately or would not be affected by the events. Explosions could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality occurred, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the

Table 4–254. Accident Impacts of Lead Assembly Fabrication at SRS

Accident	Frequency (per year)	Dose to Noninvolved Worker (rem)[a]	Probability of Cancer Fatality Given Dose to Noninvolved Worker[b]	Dose at Site Boundary (rem)[a]	Probability of Cancer Fatality Given Dose at Site Boundary[b]	Population Dose Within 80 km (person-rem)[a]	Latent Cancer Fatalities Within 80 km[c]
Criticality	Extremely unlikely	1.0×10^{-2}	4.0×10^{-6}	9.3×10^{-4}	4.6×10^{-7}	1.3	6.5×10^{-4}
Design basis earthquake	Unlikely	7.8×10^{-6}	3.1×10^{-9}	1.3×10^{-6}	6.7×10^{-10}	5.6×10^{-3}	2.7×10^{-6}
Design basis fire	Unlikely	3.4×10^{-6}	1.3×10^{-9}	5.8×10^{-7}	2.9×10^{-10}	2.4×10^{-3}	1.2×10^{-6}
Design basis explosion	Extremely unlikely	5.5×10^{-5}	2.2×10^{-8}	9.5×10^{-6}	4.7×10^{-9}	3.9×10^{-2}	1.9×10^{-5}
Beyond-design-basis earthquake	Extremely unlikely to beyond extremely unlikely	2.6×10^{1}	1.0×10^{-2}	8.8×10^{-1}	4.4×10^{-4}	2.2×10^{3}	1.1

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

amount of shielding provided by the structures and equipment between the workers and accident. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

4.27.5.6 Transportation

Plutonium dioxide would be shipped from LANL to lead assembly fabrication facilities at SRS. These facilities would also receive uranium dioxide and other material needed to assemble MOX fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 20 shipments of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 84,000 km (52,000 mi).

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public, 10.2 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.9×10^{-4} LCF among transportation workers and 5.1×10^{-3} LCF in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 3.4×10^{-4}.

Impacts of Accidents During Ground Transportation. Estimates of the total ground transportation accident risks follow: a radiological dose to the population of 6.7 person-rem, resulting in a total population risk of 3.4×10^{-3} LCF; and traffic accidents resulting in 7.3×10^{-4} traffic fatality.

4.27.5.7 Other Resource Areas

Other resource areas include geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and socioeconomics. Impacts on these resource areas are primarily related to the construction of new buildings and the number of persons employed to support the activities. Because a relatively small number of largely existing personnel are expected to perform the lead assembly fabrication in existing buildings (i.e., no new buildings would be constructed and no additional land disturbed), little or no impacts are expected to any of these resource areas.

4.27.5.8 Environmental Justice

As demonstrated throughout the analyses presented in this section, the lead assembly fabrication activities at SRS would pose no significant health risks to the public. The expected number of LCFs as a result of the radiation released from these activities in the general population residing within 80 km (50 mi) of SRS would be 3.3×10^{-6}; thus, no additional LCFs would be expected (see Table 4–252). Transportation related to these activities would not be expected to result in any LCFs either. The number of transportation-related fatalities in the total population along the shipping routes would be expected to increase by 8.5×10^{-3} due to radiological impacts, by 3.4×10^{-4} due to emissions, and by 7.3×10^{-4} as a result of traffic accidents; thus, no transportation-related fatalities would be expected (see Section 4.27.5.6). Risks posed by the implementation of the SRS alternative for lead assembly fabrication would be negligible regardless of the racial or ethnic composition, or the economic status of the population. Therefore, the lead assembly fabrication activities at SRS would have no significant impacts on minority or low-income populations.

4.27.6 Postirradiation Examination

After the lead assemblies have been irradiated, they would be shipped to a postirradiation facility where they would be disassembled and examined. DOE facilities being considered for this work include ANL–W and ORNL. These two sites are currently the only sites that possess the capability to conduct postirradiation examination activities without major modifications to facility and processing capabilities. The only facility modification that might be needed to perform the work is to increase the size of the hot cell to receive a full-size fuel assembly.

4.27.6.1 Transportation

In order to support these activities, the spent MOX fuel assemblies would be shipped from the reactor site to the postirradiation examination facilities. Because it not known where the reactor would be located, it has been assumed that the fuel would be shipped 4,000 km (2,486 mi) to a postirradiation examination facility. Approximately eight shipments of radioactive materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be 32,000 km (20,000 mi). The transportation impacts for postirradiation examination have been included in the impacts presented in Sections 4.27.1 to 4.27.5.

Impacts of Incident-Free Transportation. The dose to transportation workers from all transportation activities related to postirradiation examination has been estimated at 1.5 person-rem; the dose the public, 10.2 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.8×10^{-4} LCF among transportation workers and 5.1×10^{-3} LCF in the total affected population over the

duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 8.3×10^{-5}.

Impacts of Accidents During Ground Transportation. The total ground transportation accident risks for shipping spent fuel assemblies to the postirradiation examination facility is estimated to be 0.0027 LCF from radiation and 2.5×10^{-4} traffic fatality.

4.27.6.2 ANL–W

Radiological Impacts. No radiological risk would be incurred by members of the public from the minor modification of the hot cell at the postirradiation examination facility at ANL–W. Moreover, doses to associated workers should not exceed the normally low levels attributable to routine occupancy. Nonetheless, workers would be monitored (badged) as appropriate, to help ensure that doses are maintained as low as is reasonably achievable.

There would be no radiological releases associated with the normal operation of the postirradiation examination facility at ANL–W; thus, there would be no radiological impacts incurred by the public from this facility.

Doses to involved workers from normal operations are given in Table 4–255; these workers are defined as those directly associated with postirradiation examination facility activities. Under the proposed action, the annual average dose to postirradiation examination facility workers is estimated to be 177 mrem. The annual dose received by the total involved workforce for this facility would be 1.8 person-rem, which corresponds to 7.1×10^{-4} LCF. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–255. Potential Radiological Impacts on Involved Workers of Operation of Postirradiation Examination Facility at ANL–W

Number of badged workers	10[a]
Total dose (person-rem/yr)	1.8
Associated latent fatal cancers	7.1×10^{-4}
Average worker dose (mrem/yr)	177
Associated latent fatal cancer risk	7.1×10^{-5}

[a] The maximum estimated dose to one of these workers is 347 mrem/yr.
Key: ANL–W, Argonne National Laboratory–West.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998a.

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or examination activities. However, concentrations would be within the regulated exposure limits.

Facility Accidents. The accident risks to the public, worker, and environment from postirradiation examination of spent light water reactor (LWR) fuel rods have been analyzed at a number of existing DOE and commercial facilities (PNL 1996). Spent fuel rods or assemblies are shipped from the reactor site to a postirradiation examination facility in heavy shielded casks. Fuel rods are typically removed from the fuel assemblies or bundles in deep, water-filled fuel storage basins and transferred via heavy, shielded casks. The rods are transferred from the casks to heavily shielded hot cells designed to protect the operators from the

intense gamma and neutron radiation. Accidents occurring in the hot cells due to fuel examination, including spills, fires, and handling accidents, would not result in unfiltered releases or serious worker exposures due to the multiple HEPA filters on the cell exhaust and the heavy construction and shielding of the cell. The most severe accident conceivable with these types of operations would be nuclear criticality. The amount of spent fuel necessary for an accident to be physically possible, however, would be at least one to two orders of magnitude greater than would normally be available during postirradiation examination. Such an accident could result in high, though probably not fatal, radiological exposures to hot cell workers. Noninvolved workers and members of the public would also be exposed to doses in the range of fractions of a millirem to a hundred millirem, depending on distance from the facility. For example, a criticality of 1×10^{19} fissions would result in increased probabilities of fatal cancer to the noninvolved worker and MEI of 3.1×10^{-5} and 2.5×10^{-6}, respectively. No LCFs would be expected in the general population as a result of the accident.

4.27.6.3 ORNL

Radiological Impacts. No radiological risk would be incurred by members of the public from the minor modification of the hot cell at the postirradiation examination facility at the Oak Ridge National Laboratory (ORNL). Moreover, doses to associated workers should not exceed the normally low levels attributable to routine occupancy. Nonetheless, workers would be monitored (badged) as appropriate, to help ensure that doses are maintained as low as is reasonably achievable.

There would be no radiological releases associated with the normal operation of the postirradiation examination facility at ORNL; there would be no radiological impacts incurred by the public from this facility.

Doses to involved workers from normal operations are given in Table 4–256; these workers are defined as those directly associated with postirradiation examination facility activities. Under the proposed action, the annual average dose to postirradiation examination facility workers is estimated to be 177 mrem. The annual dose received by the total involved workforce for this facility would be 1.8 person-rem, which corresponds to 7.1×10^{-4} LCF. Doses to individual workers would be kept to minimal levels by instituting badged monitoring, administrative limits, and ALARA programs (which would include worker rotations).

Table 4–256. Potential Radiological Impacts on Involved Workers of Operation of Postirradiation Examination Facility at ORNL

Number of badged workers	10[a]
Total dose (person-rem/yr)	1.8
Associated latent fatal cancers	7.1×10^{-4}
Average worker dose (mrem/yr)	177
Associated latent fatal cancer risk	7.1×10^{-5}

[a] The maximum estimated dose to one of these workers is 347 mrem/yr.
Key: ORNL, Oak Ridge National Laboratory.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995e). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: O'Connor et al. 1998f.

Hazardous Chemical Impacts. Limited hazardous chemical releases would be expected as a result of modification or examination activities. However, concentrations would be within the regulated exposure limits.

Facility Accidents. The impacts of accidents associated with postirradiation examination activities at ORNL are substantially equivalent to those associated with the same activities at ANL–W as discussed in Section 4.27.6.2.

Next Section

4.28 SUMMARY OF *STORAGE AND DISPOSITION PEIS* GENERIC REACTOR ANALYSIS

Section 4.3.5.2 of the *Storage and Disposition Final PEIS* provides an analysis of the Existing Light Water Reactor Alternative proposed in that document. This alternative is consistent with the MOX fuel fabrication alternatives proposed in this SPD EIS. Assemblies containing MOX fuel rods would replace some of the low-enriched uranium fuel assemblies in one or more existing domestic, commercial power reactors. The *Storage and Disposition Final PEIS* evaluated this alternative as the operation of a minimum of three reactors that could be located at the same or different sites, and presented the impacts in the context of a generic range of conditions that could exist at potential locations. Those impacts are summarized here, as they are used to present a complete picture of potential impacts of implementing the MOX fuel fabricating alternatives proposed in this SPD EIS.

The *Storage and Disposition Final PEIS* indicates that the only changes to an existing reactor site might be a small addition to the fuel receiving and storage buildings to properly handle MOX fuel. However, if this were required, it would be only a minor change to the plant profile and would be anticipated to use land area previously disturbed. Therefore, any new construction would be inconsequential. As a result, land use; visual, cultural, and paleontological resources; geology and soils; and site infrastructure would not be affected by any new construction or other activities related to MOX fuel use. Neither would there be any effect on air quality and noise, ecological and water resources, or socioeconomics.

Use of MOX fuel would not generate high-level or TRU waste, nor would it be expected to increase the amount or change the content of the waste generated. Although the radionuclide distribution in the waste would be somewhat different, the *Storage and Disposition Final PEIS* indicates that system modifications would not be expected to be required to comply with regulatory requirements. It also indicates that while there would be no additional waste generated as a result of using MOX fuel, more spent fuel would be generated as a result of the proposed disposition of surplus plutonium as MOX fuel. This was attributed to the assumed practice of removing the MOX fuel assemblies from the reactor as soon as the fuel had been irradiated enough to meet the Spent Fuel Standard, rather than leaving it in the reactor for the maximum length of time. The *Storage and Disposition Final PEIS* indicated that even so, there would be sufficient space at the reactor sites (in either spent fuel pools or dry storage) to store the additional spent fuel until it could be sent to a geologic repository pursuant to the Nuclear Waste Policy Act (NWPA).

During normal operation, there would be both radiological and hazardous chemical releases to the environment, and also direct in-plant exposures. However, the radiological doses and resulting fatal cancer risks to both the average and maximally exposed member of the public, and also to the population, would not be significantly different than operations with a uranium core. The *Storage and Disposition Final PEIS* predicts that the annual population dose would be less than 2.0 person-rem. Nonradiological chemical emissions, and consequently, hazardous chemical impacts, which were essentially zero, would not change as a result of using MOX fuel.

Doses to onsite workers from normal operations with a uranium core would range from 280 to 540 mrem/yr. Using MOX fuel could increase worker dose by 1.3 to 2.7 mrem/yr, to a range of 281 to 543 mrem/yr. Dose to the total site workforce could increase by 1.6 to 4.8 person-rem/yr, from a range of 327 to 1,190 person-rem/yr to 331 to 1,193 person-rem/yr.

The *Storage and Disposition Final PEIS* also evaluated the potential impacts from a set of postulated highly unlikely accidents with potentially severe consequences at a domestic, commercial power reactor using both uranium-only and MOX cores. In this evaluation, the *Storage and Disposition Final PEIS* cited a report by the National Academy of Sciences (NAS), *Management and Disposition of Excess Weapons Plutonium Reactor-Related Options* (NAS 1995). This NAS report indicates that the potential influences on safety of

the use of MOX fuel in LWRs[3] were extensively studied in the United States in the 1970s in the *Final Generic Environmental Impact Statement on the Use of Recycled Plutonium in Mixed Oxide Fuel in Light Water Cooled Reactors*, NUREG-0002 (NRC 1976). Regarding effects of MOX fuel on accident probabilities, the NAS report states, ". . . no important overall adverse impact of MOX use on the accident probabilities of the LWRs involved will occur; if there are adequate reactivity and thermal margins in the fuel, as licensing review should ensure, the main remaining determinants of accident probabilities will involve factors not related to fuel composition and hence unaffected by the use of MOX rather than low enriched uranium (LEU) fuel" (NAS 1995:352). Regarding the effects of MOX fuel on accident consequences, the report states, ". . . it seems unlikely that the switch from uranium-based fuel could worsen the consequences of a postulated (and very improbable) severe accident in a LWR by no more than 10 to 20 percent. The influence on the consequences of less severe accidents, which probably dominate the spectrum value of population exposure per reactor-year of operation would be even smaller, because less severe accidents are unlikely to mobilize any significant quantity of plutonium at all" (NAS 1995:355).

In the *Storage and Disposition Final PEIS*, the incremental effects of using MOX fuel in a commercial reactor in place of LEU fuel were derived from a quantitative analysis of several highly unlikely severe accident scenarios for MOX and LEU fuel. The analysis considers severe accidents where sufficient damage could occur to cause the release of plutonium or uranium. The consequences of these accident releases were found to be in the range of plus 8 to minus 7 percent,[4] compared with LEU fuel, depending on the accident release scenario. This analysis was based on existing commercial LWR probabilistic risk assessments of severe accidents, and the release scenarios were modeled assuming large population distributions near the LWRs and meteorological conditions for dispersal that lead to large doses, which are not necessarily reflective of specific or actual site conditions.

As discussed in Section 2.1.3, DOE is pursuing a contract for MOX fuel fabrication and irradiation services. As part of its Request for Proposals (RFP) for these services, DOE has requested that each offeror provide, as part of its proposal, environmental information specific to its proposed MOX facility design and the domestic, commercial reactors it proposes for irradiation of the MOX fuel. The SPD Final EIS will include environmental impact and accident analyses related to the specific reactors identified in response to the RFP.

[3] Light water reactor is the type of reactor used in the United States for power production. The domestic, commercial nuclear reactors referred to in this SPD EIS are LWRs.

[4] Accidents severe enough to cause a release of plutonium involve combinations of events that are highly unlikely. Estimates and analyses presented in the *Storage and Disposition Final PEIS* indicate a range of postulated LCFs of 1.3×10^{-2} to 7.3×10^{-3} (in the population within 80 km [50 mi] of the release point) with attendant risks of LCFs over 11 years of reactor operation of 0.012 and 0.010, respectively (and risks of LCFs over 17 years of reactor operation of 0.018 and 0.016, respectively). One of the accidents analyzed had a higher risk of LCFs, 0.098 over 11 years (0.15 over 17 years), but the number of postulated LCFs (5.9×10^{-3}) falls within the stated range of LCFs.

4.29 COMPARISON OF IMMOBILIZATION TECHNOLOGY IMPACTS

In order to provide a basis for evaluating alternative immobilization forms and technologies, the environmental impacts associated with operating the ceramic and glass can-in-canister immobilization facilities evaluated in this SPD EIS were compared with the corresponding environmental impacts associated with operating the homogenous ceramic immobilization and vitrification facilities evaluated in the *Storage and Disposition Final PEIS* (DOE 1996a).

Tables 4–257 through 4–265 present the comparable impacts for key environmental resources (e.g., air quality, waste management, human health risk, and resource requirements) at Hanford and SRS for the homogenous ceramic immobilization and vitrification facilities and the can-in-canister immobilization facilities. The impacts associated with facility accidents, intersite transportation and environmental justice are also discussed.

The comparison of impacts is based on immobilizing the full 50 t (55 tons) of surplus plutonium. The *Storage and Disposition Final PEIS* impact analyses are based on operating facilities that would convert the plutonium to an oxide in one new facility and immobilize it in a homogenous ceramic or glass form in another new facility. Impacts for a plutonium conversion facility are evaluated and itemized separately from the impacts for a ceramic immobilization or vitrification facility. In contrast, this SPD EIS considers the use of both new and existing facilities and is based on evaluating a collocated plutonium conversion and immobilization capability. To compare impacts, it was therefore necessary to combine the separate *Storage and Disposition Final PEIS* impact values, as appropriate, to establish a suitable standard of comparison.

4.29.1 Air Quality

Tables 4–257 and 4–258 present the potential emissions of federally regulated criteria pollutants for both the homogenous ceramic immobilization/vitrification facilities and the can-in-canister immobilization facilities. With the exception of sulfur dioxide in the ceramic can-in-canister process, all criteria pollutant emissions associated with either can-in-canister technology would be much lower. In terms of differences between the can-in-canister immobilized forms, pollutant levels attributed to the ceramic process would be slightly higher than those for the glass process, although both would be much lower than the regulatory limits.

Table 4–257. Estimated Concentrations of Air Pollutants ($\mu g/m^3$) of Immobilization Facilities During Operation at Hanford

4.29.2 Waste Management

As shown in Table 4–259, potential volumes of each waste type resulting from operation of the ceramic or glass can-in-canister technology would be considerably less than the waste volumes expected from either homogenous ceramic immobilization or vitrification technology evaluated in the *Storage and Disposition Final PEIS*. For example, operation of a can-in-canister facility using the ceramic process at Hanford or SRS is estimated to result in TRU waste volumes of 126 m^3/yr (165 yd^3/yr), compared with the 647 m^3/yr (846 yd^3/yr) of TRU waste estimated in the *Storage and Disposition Final PEIS* from operation of the homogenous ceramic immobilization facility. Factors contributing to the reduced waste levels associated with the can-in-canister facility would include the use of dry-feed preparation techniques, coordination with existing HLW vitrification operations, and the need for a smaller operating workforce. Waste volumes would not be expected to differ appreciably between the ceramic and glass can-in-canister processes.

4.29.3 Human Health Risk

Radiological Impacts. Tables 4–260 and 4–261 present the potential radiological exposure and cancer risk to the public from normal operation of the immobilization facilities. The potential risks to the public associated with either can-in-canister technology would be about the same as the homogenous technologies at Hanford, but lower at SRS. For example, operation of a can-in-canister facility using the ceramic process at Hanford or SRS is estimated to result in population doses of 1.6×10^{-2} or 4.9×10^{-3} person-rem/yr, respectively, compared with the population doses of 8.4×10^{-3} (at Hanford) or 6.6×10^{-2} (at SRS) person-rem/yr resulting from operation of the homogenous ceramic immobilization facility evaluated in the *Storage and Disposition Final PEIS*. These variations may be attributable to the incorporation of updated source terms, meteorology, population distribution, and other modeling variables in the analysis of the can-in-canister technologies. A comparison between the ceramic and glass can-in-canister technologies indicates operation of the ceramic process would result in slightly higher potential offsite impacts, regardless of whether it is located at Hanford or SRS. For example, the dose associated with operation of the can-in-canister facility at Hanford would result in a population dose of 1.6×10^{-2} person-rem/yr using the ceramic process and

1.5×10^{-2} person-rem/yr using the glass process; the same facility at SRS would result in a population dose of 4.9×10^{-3} person-rem/yr using the ceramic process, and a dose of 4.5×10^{-3} person-rem/yr using the glass process.

Table 4–262 presents the potential radiological exposure and cancer risk to involved workers at the homogenous ceramic immobilization/vitrification facilities evaluated in the *Storage and Disposition Final PEIS* and the can-in-canister immobilization facilities. The estimated average worker dose and associated cancer risk for the can-in-canister technologies are slightly higher than estimated in the *Storage and Disposition Final PEIS* for the homogenous technologies. In all cases, however, the average worker dose would be within the DOE design objective of 1,000 mrem/yr (DOE 1995e). Although the estimated average dose to an individual involved worker is higher for the can-in-canister approaches than for the homogenous approaches (e.g., 750 mrem/yr versus 512 mrem/yr), the total dose to all involved workers would be lower

from either can-in-canister technology (ranging from 193 to 218 person-rem/yr) than from either homogenous technology (ranging from 243 to 253 person-rem/yr) because fewer workers would be required. Potential radiological impacts on involved workers are not expected to differ appreciably between the ceramic and glass can-in-canister processes.

Hazardous Chemical Impacts. Tables 4–263 and 4–264 present the potential hazardous chemical impacts resulting from operation of the homogenous ceramic immobilization/vitrification facilities and can-in-canister immobilization facilities. Although some potential hazardous chemical impacts were determined for the homogenous technologies evaluated in the *Storage and Disposition Final PEIS*, none are expected for either the ceramic or glass can-in-canister technology because no hazardous chemical emissions would occur from operations.

4.29.4 Facility Accidents

Because of substantial differences between the *Storage and Disposition Final PEIS* and the SPD EIS in terms of the specific accident scenarios and supporting assumptions used in the determination of facility accident impacts, no basis for appropriately comparing between homogenous technology and can-in-canister technology accidents is available. However, comparison between the ceramic and glass can-in-canister processes indicates slightly higher impacts would be associated with the ceramic process. For example, a design basis earthquake at Hanford would result in 9.6×10^{-5} LCF in the general population using the ceramic process, and 8.4×10^{-5} LCF using the glass process. Similarly, a design basis earthquake in a new facility at SRS would result in 3.6×10^{-5} LCF in the general population using a ceramic process, and 3.1×10^{-5} LCF using a glass process.

4.29.5 Resource Requirements

As shown in Table 4–265, operation of the can-in-canister immobilization technologies would require substantially lower amounts of electricity, fuel, land area, and water than would the ceramic immobilization and vitrification technologies evaluated in the *Storage and Disposition Final PEIS*. Fewer workers would be required to operate the can-in-canister technologies, which in turn would result in lower socioeconomic impacts. Resource requirements would differ between the ceramic and glass can-in-canister processes in two areas: water requirements would be greater to support the ceramic process at Hanford (i.e., the ceramic process would require 44 million l/yr (12 million gal/yr), compared with 41 million l/yr (11 million gal/yr) for the glass process) and electricity requirements would be greater to support the ceramic process at either site (i.e., the ceramic process would require 16,000 or 14,000 MWh/yr at Hanford or SRS, respectively, compared with the 15,000 or 13,000 MWh/yr, respectively, required for the glass process).

Table 4–265. Estimated Resource Requirements for Operations at Hanford and SRS

	PEIS Homogenous Facilities		Can-in-Canister Immobilization Facilities					
			Hanford		SRS (New)		SRS (221–F)	
Resource	Ceramic Immobilization[a]	Vitrification[b]	Ceramic	Glass	Ceramic	Glass	Ceramic	Glass
Electricity (MWh/yr)	46,000	33,000	16,000	15,000	14,000	13,000	14,000	13,000

4.29.6 Intersite Transportation

The *Storage and Disposition Final PEIS* analysis assumes that canisters of plutonium immobilized with radionuclides would be transported to a Federal geologic repository via rail. Several canisters would be included in each shipment, and up to 64 shipments would be required from the homogenous ceramic immobilization/vitrification facility to the repository. Total potential fatalities were calculated based on both radiological and nonradiological risks to the public and workers for both routine and accident conditions. Intersite transportation associated with a homogenous ceramic immobilization/vitrification facility at Hanford were estimated to result in 0.96 and 0.98 total potential fatalities, respectively. Intersite transportation associated with those same facilities located at SRS were estimated to result in 1.40 and 1.43 total potential fatalities, respectively.

This SPD EIS analysis is consistent with the methodology used in the WM PEIS, which assumes that the immobilized canisters would be shipped by truck from the immobilization site to the repository. It also conservatively assumes that only one canister would be transported per truck shipment. The ceramic or glass can-in-canister facilities would require the production of an additional 210 or 340 canisters, respectively, over that expected for the DOE HLW vitrification program. Intersite transportation would result in 0.12 total potential fatalities in association with a glass can-in-canister facility at Hanford, and 0.21 total potential fatalities in association with a glass can-in-canister facility at SRS. Because the ceramic process would produce fewer canisters, it would correspondingly result in somewhat lower transportation impacts.

4.29.7 Environmental Justice

Evaluations of both the homogenous ceramic immobilization/vitrification technologies and can-in-canister technologies included routine facility operations and transportation as well as accidents. Generally, no LCFs would be expected to occur for normal operations or in the event of a design basis accident. For alternatives that include immobilization at Building 221–F, a design basis earthquake would be expected to result in 0.43 to 0.53 LCF among the general population. Depending on the weather conditions prevailing at the time of the earthquake, the expected impact could occur among any member of the general population residing within 80 km (50 mi) of the accident site. However, the probability of occurrence of a design basis earthquake is unlikely. Therefore, implementation of homogenous ceramic immobilization/vitrification technologies or can-in-canister technologies would pose no significant risk to the general population, nor would implementation of these technologies result in a significant risk of disproportionately high and adverse impacts on minority or low-income groups within the general population.

Next Section

4.30 INCREMENTAL IMPACTS OF REAPPORTIONING MATERIALS IN THE HYBRID APPROACH

Under the hybrid alternatives (Alternatives 2 through 10), it is possible that a small amount of the 33 t (36 tons) of surplus plutonium considered for disposition as MOX fuel would not meet fuel specifications, and thus would have to be added to the 17 t (19 tons) of surplus plutonium apportioned for immobilization. Because the immobilization and MOX facilities would be designed and constructed to process as much as 35 t (38 tons) and 50 t (55 tons), respectively, reapportionment of a small amount of material would not affect construction activities or schedules. However, such a shift in the material throughputs of each facility could slightly change their respective operating parameters. Thus, an analysis was conducted to evaluate the influence (per metric ton) of this shift on the environmental impacts presented for the hybrid alternatives in this SPD EIS—specifically, any operational incremental reduction of impacts attributable to the MOX facility and, conversely, the incremental increase in impacts attributable to the immobilization facility. In addition, a qualitative discussion of the incremental impacts of extending or shortening the operating period of the surplus plutonium disposition facilities is provided in Section 4.30.9.

4.30.1 Air Quality

The reapportionment of surplus plutonium from MOX fuel fabrication to immobilization would result in slight modifications in process emissions at each facility, as shown in Table 4–266. For the MOX facility, each metric ton of plutonium reallocated to the immobilization facility would result in a reduction in ethylene glycol emissions. As a result, the concentrations of this pollutant would decrease, but only by 29 one-millionths of the State standard at Hanford or 27 one-millionths of the State standard at SRS. For the immobilization facility, each additional metric ton of plutonium processed would result in increased carbon monoxide emissions. The concentrations of this pollutant would increase by only 10 one-millionths of the standard at Hanford and 5 one-millionths of the standard at SRS. No other process emissions would be associated with either facility. The pollutants associated with heating and cooling the facilities would not be affected because both facilities would continue to operate albeit at slightly higher or lower levels. See Appendix G for more details on the effects of these operations on air quality.

Table 4–266. Potential Incremental Changes in Emissions (kg/t) From Facility Operations

Pollutant	Incremental Reduction in MOX Facility Impacts[a]	Incremental Increase in Immobilization Facility Impacts[a]	Total Incremental Change
Carbon monoxide	NA	2,091	2,091
Ethylene glycol	303	NA	(303)

[a] Values are for the ceramic form of can-in-canister immobilization in FMEF at Hanford and a new facility at SRS.
Key: FMEF, Fuels and Materials Examination Facility; NA, not applicable.
Note: Values are per metric ton of surplus plutonium reapportioned from MOX fuel fabrication to immobilization.
Source: Appendix G.

4.30.2 Waste Management

Table 4–267 presents the incremental changes in annual operating waste volumes that would result from each metric ton of surplus plutonium reapportioned from MOX fuel fabrication to immobilization. This would result in slight annual reductions in the generation of TRU, LLW, mixed LLW, and hazardous wastes at the MOX facility. Although there would be associated slight increases in the generation of TRU and LLW at the immobilization facility, the incremental change from reapportioning each metric ton of plutonium would be a small net reduction in waste generation. However, such modifications in process throughput would not affect

Table 4–267. Potential Incremental Changes in Waste Generated (m^3/t) From Facility Operations

Waste Type[a]	Incremental Reduction in MOX Facility Impacts	Incremental Increase in Immobilization Facility Impacts	Total Incremental Change
TRU	13.9	9.4	(4.5)
LLW	10.3	6.1	(4.2)
Mixed LLW	0.61	0	(0.61)
Hazardous	<0.30	0	(<0.30)
Nonhazardous	NA[b]	NA[b]	NA[b]

[a] See definitions in Appendix F.8
[b] Generation of nonhazardous wastes (e.g., sanitary sewer, trash) are not considered a function of facility throughput.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.
Note: Values are per metric ton of surplus plutonium reapportioned from MOX fuel fabrication to immobilization.
Source: Appendix H.

either facility's generation of nonhazardous wastes, which is primarily a function of nonprocess activities such as facility air conditioning and sanitary systems.

4.30.3 Socioeconomics

Slight adjustments in the surplus plutonium material throughputs apportioned to either the MOX facility or immobilization facility would not be expected to affect the number of personnel needed to operate the facilities. Therefore, no change in socioeconomic impacts would be expected.

4.30.4 Human Health Risk

Table 4–268 presents the potential incremental radiological impacts on the public of reapportioning plutonium from the MOX facility to the immobilization facility. Because estimated radiological impacts would vary somewhat between sites and between the use of new or existing facilities, the analysis of a new MOX facility and a new immobilization facility at SRS is presented as a representative example of potential incremental changes to human health risk. In this example, the data clearly reflect the sensitivity of potential impacts to changes in material throughput. Each reapportioned metric ton of surplus plutonium would result in slight reductions in the doses and LCFs associated with normal operation of the MOX facility, and in contrasting increases in the doses and LCFs associated with normal operation of the immobilization facility. However, the total incremental change would equate to a net reduction in radiological impacts on the public.

4.30.5 Facility Accidents

Adjusting the amount of plutonium to be immobilized could influence accident impacts in two ways. One, increased throughput would increase the number of times a process would need to be repeated, therefore potentially increasing the chance of an accident occurring. Two, in some accident scenarios an increased amount of material at risk could increase the consequences. However, since the 50-t (55-ton) case was used to bound the accident analyses, the accident impacts reported under the individual immobilization alternatives would bound any incremental changes discussed here. See Appendix K for a more detailed description of assumptions and specific accident scenarios.

Table 4–268. Potential Incremental Changes in Radiological Impacts on the Public From Normal Operations[a]

Impact	Incremental Reduction in MOX Facility Impacts	Incremental Increase in Immobilization Facility Impacts[b]	Total Incremental Change
Population within 80 km for year 2010			
Dose (person-rem)	8.8×10^{-3}	7.9×10^{-4}	(8.0×10^{-3})
10-year latent fatal cancers	4.5×10^{-6}	3.9×10^{-7}	(4.2×10^{-6})
Maximally exposed individual			
Annual dose (mrem)	9.4×10^{-5}	7.9×10^{-6}	(8.6×10^{-5})
10-year latent fatal cancer risk	4.8×10^{-11}	3.9×10^{-12}	(4.5×10^{-11})
Average exposed individual within 80 km[c]			
Annual dose (mrem)	1.1×10^{-5}	1.0×10^{-6}	(1.0×10^{-5})
10-year latent fatal cancer risk	5.8×10^{-12}	5.2×10^{-13}	(5.2×10^{-12})

[a] SRS is presented as a representative site for purposes of analysis.
[b] Values are for the ceramic form of can-in-canister immobilization in a new facility.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of SRS in 2010 (785,400).
Note: Values are per metric ton of surplus plutonium reapportioned from MOX fuel fabrication to immobilization.
Source: Appendix J.

4.30.6 Transportation

The reapportionment of surplus plutonium from MOX fuel fabrication to immobilization would result in a slight decrease in the number of trips needed to transport uranium dioxide and MOX fuel rods from the MOX facility to a domestic commercial reactor. Conversely, it would increase the number of trips needed to transport additional canisters of immobilized plutonium from the HLW vitrification facility to the geologic repository. The incremental impacts of these changes would vary by site and SPD EIS collocation alternative because of the different travel routes and distances involved. Under any scenario, the radiological impacts from normal transportation of immobilized plutonium would not exceed those associated with Alternatives 12C or 12D. These alternatives entail the greatest distances for the transport of canisters given the disposition of all surplus plutonium through immobilization.

As more plutonium is sent to immobilization, the risks associated with radiological transportation accidents would generally become lower because there are fewer transportation requirements associated with immobilization. Any reduction in the amount of plutonium being sent to the MOX facility means there would be less depleted uranium required by the facility and less MOX fuel rods that would be shipped to a reactor for irradiation. Similarly, nonradiological transportation accident risks would also generally decrease as more plutonium is sent to immobilization, with the exception being under alternatives where the MOX facility would be collocated with the pit conversion facility at Pantex (Alternatives 9A, 9B, and 10). In these alternatives, the location of the majority of the surplus pits at Pantex, when collocated with the MOX facility, greatly reduces the distance that would need to be traveled under the hybrid alternatives. However, it needs to be recognized that the risks associated with transporting these materials to and from either disposition facility under any of the alternatives would be low.

4.30.7 *Environmental Justice*

Analysis in connection with this SPD EIS indicates that minority or low-income populations residing in the vicinity of the candidate sites would experience no significant impacts from either the MOX or immobilization facility under any of the disposition alternatives. Therefore, no significant impacts would be expected to result

from the reapportionment of plutonium throughputs during routine operations. Facility accidents would similarly not be expected to pose a significant risk (when probability is considered) to the general population, nor would they be expected to result in a significant risk of disproportionately high and adverse impacts to minority or low-income groups within the general population.

4.30.8 Other Resource Areas

Several resource areas (i.e., geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, and infrastructure) were determined to have minimal or no impacts from the disposition alternatives being considered, as discussed in Section 4.26. The reapportionment of plutonium throughputs from the MOX facility to the immobilization facility would not change the impacts on these resource areas.

4.30.9 Incremental Impacts of Extending or Shortening the Operating Period of Surplus Plutonium Disposition Facilities

Each of the disposition facilities is proposed to operate for only about 10 years. However, the operating life of the facilities may vary somewhat, depending on facility startup experiences and negotiations with other countries (e.g., Russia) regarding the pace of disposition. The operating period of the MOX facility could also be affected by the responses to the procurement, since the RFP allows offerors to recommend the length of operation needed to meet DOE's program goals. Slightly more or less material could be processed in any given year, potentially extending or shortening the operating period of any of the disposition facilities.

Some impacts occur only during surplus plutonium materials processing. For these resources, total impacts would not change even if the processing schedule was extended or shortened. This includes impacts to air quality for hazardous air pollutants, hazardous and radioactive waste management, human health risk, facility accidents during material processing, transportation impacts from material transport, and environmental justice. For example, if the operating period was extended by 1 year, the total dose and LCFs for the worker and the public would be expected to remain unchanged, even though the annual dose would be expected to decrease.

For other resources, impacts occur whenever the facility is operational regardless of whether material processing is occurring. These types of impacts are associated with activities, such as building heating, sanitary water use, and nonhazardous solid waste generation that would take place independent of the materials processing schedule. These include impacts to air quality for criteria air pollutants, nonhazardous waste management, socioeconomics, facility accidents not associated with material processing, transportation impacts from employee trips, and infrastructure. For example, air quality impacts from criteria pollutant emissions associated with building heating would continue as long as the facility is occupied. Likewise, impacts from nonhazardous waste management and impacts to infrastructure would occur as long as personnel continue to use potable water and generate nonhazardous waste. The impacts on these resource areas from extending or shortening the operating period are presented in Chapter 4 since this chapter largely presents impacts for these resources on an annual basis. Extending operations by 1 year would mean that impacts would continue at the level described in Chapter 4 for 1 year longer. Shortening operations by 1 year would mean that impacts would cease 1 year earlier.

4.31 DEACTIVATION AND STABILIZATION

DOE has anticipated the need for eventual deactivation of the proposed surplus plutonium disposition facilities. Process functions would be compartmentalized to allow isolation so that effective deactivation could be achieved. Protective coatings would be applied to concrete surfaces in the process areas to reduce the amount of contamination adsorbed into the concrete. Stainless steel cell and area liners would be provided to facilitate stabilization in selected areas where accumulation of radioactive contamination could increase personnel radiation exposure. Ventilation of operating and processing areas would minimize surface contamination from airborne contaminants. Process equipment would be designed to minimize areas where radioactive materials could accumulate. Operations would be conducted to minimize the spread of radioactive contamination.

When the missions have been completed and the facilities are no longer needed, deactivation and stabilization would be performed to reduce the risk of radiological exposure; reduce the need for and costs associated with long-term maintenance; and prepare the buildings for productive future use. At the end of the useful life of the facilities, DOE would evaluate options for decontamination and decommissioning (D&D). At that time, DOE would perform engineering evaluations, environmental studies, and further NEPA review to assess the consequences of different potential courses of action.

DOE anticipates that alternatives for disposition of the facilities would include:

- D&D and demolition of the structures and release of the site for unrestricted use
- D&D and demolition of the structures and restricted use of the site
- Partial D&D and retention of the structures for unrestricted use
- Partial D&D and retention of the structures for modified or restricted use

For the purposes of this SPD EIS, it is assumed that the equipment within the building would be deactivated and the facilities stabilized to a condition suitable for reuse. It is also assumed that this level of activity would take no more than 3 years to complete.

All feed materials, including any remaining plutonium metal, plutonium oxide, uranium oxide and chemicals, and process wastes, would be removed from the facilities to leave them in a low-cost condition for surveillance and maintenance. Usable items of equipment, instruments, and machine parts would be removed for reuse in other DOE facilities. After completion of the initial deactivation effort, the facilities would be monitored to ensure that contamination present in the facilities is contained and worker and public safety maintained. Deactivation and stabilization activities would be implemented in accordance with dismantlement work packages. Finally, a formal closeout would be conducted. Closeout activities would include inspection of support systems, such as heating, ventilation, and air conditioning (HVAC) and water systems, to ensure that they are in condition for reuse.

Next Section

4.32 CUMULATIVE IMPACTS

The projected incremental impacts of the operation of the proposed surplus plutonium disposition facilities were added to the impacts of other past, present, and reasonably foreseeable future actions at or near the candidate sites. These other site activities include baseline impacts presented in Chapter 3. A methodology for this cumulative impact assessment is presented in Appendix F.

Impacts of the following are considered in the cumulative impacts assessment:

- Current activities at or in the vicinity of candidate sites
- Operation of the proposed surplus plutonium disposition facilities
- Other onsite and offsite activities that are reasonably foreseeable and documented

Other activities that may be implemented in the foreseeable future at one or more of the surplus plutonium disposition candidate sites and included in the cumulative impact assessment are discussed in the following documents:

- *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (ROD issued)
- *Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement* (ROD issued)
- *Interim Management of Nuclear Materials at the Savannah River Site Final Environmental Impact Statement* (ROD issued)
- *Waste Isolation Pilot Plant Final Environmental Impact Statement* (ROD issued)
- *Tritium Supply and Recycling Final Programmatic Environmental Impact Statement* (ROD issued)
- *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (Final issued; ROD issued for TRU waste)
- *Department of Energy Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (ROD issued)
- *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (ROD issued)
- *Tank Waste Remediation System Final Environmental Impact Statement* (ROD issued)
- *Hanford Reach of the Columbia River Comprehensive River Conservation Study and Environmental Impact Statement* (Final issued)
- *Final Environmental Impact Statement for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapons Components* (ROD issued)
- *Final Environmental Impact Statement for Stockpile Stewardship and Management* (ROD issued)

- *Draft Environmental Impact Statement on Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site* (Draft issued)
- *Accelerator for Production of Tritium at Savannah River Site Environmental Impact Statement* (Draft issued)
- *Construction & Operation of a Tritium Extraction Facility at the Savannah River Site* (Draft issued)
- *Hanford Remedial Action and Comprehensive Land Use Plan Environmental Impact Statement* (Draft issued)

In addition to the actions listed in the above documents, DOE is also proposing a number of activities at some of the four candidate sites. For example, DOE recently proposed facilities for the treatment of mixed waste and HLW at INEEL (62 Federal Register 62025 and 62 Federal Register 49209). Such proposed facilities have the potential to affect cumulative impacts at INEEL by effects on air, soil, and water quality, by commitment of resources and use of land, and by effects on the public and workers from exposure to radiological and hazardous materials during normal operation and reasonably foreseeable accidents. Due to the preliminary nature of the proposed actions, no data are yet available, and therefore are not included in the cumulative impacts analysis. The SPD Final EIS will incorporate any additional data from those actions, as information becomes available.

The related programs included in the cumulative impact assessment and the four candidate sites potentially affected are identified in Table 4–269.

Tables included in the following sections combine No Action activities with reasonably foreseeable activities at each site under the heading "Other Site Activities." The impacts associated with the operation of the proposed surplus plutonium disposition facilities[5] are shown as "SPD EIS Maximum Impacts."

In addition to reasonably foreseeable site activities, non-Federal activities within the region of the candidate sites were considered in the cumulative impact analysis for selected resources. Because of the distances between the candidate sites and other existing and planned facilities, there is little opportunity for interactions of plant emissions in terms of impacts to air quality, water quality, or waste management. However, whenever possible, large source contributors have been evaluated for those impacts to human health risk and socioeconomics.

4.32.1 Hanford

For Hanford, the bounding alternative for this SPD EIS would be Alternative 2. Alternative 2 calls for the siting of all three proposed disposition facilities in the 400 Area with the pit conversion and immobilization facilities in FMEF and a new MOX facility located nearby.

4.32.1.1 Resource Requirements

Cumulative impacts on resource requirements at Hanford are presented in Table 4–270. Hanford would remain within its site capacity for its major resources, i.e., water, land, and power. If Alternative 2 were implemented, the proposed surplus plutonium disposition facilities would require 10 percent of the annual

[5] A bounding alternative was analyzed for each site. The bounding alternative is the alternative that involves the greatest amount of plutonium disposition construction and operation activity at the candidate site. For example, the bounding alternative for Hanford is Alternative 2—all facilities located at Hanford.

Table 4–269. Other Past, Present, and Reasonably Foreseeable Actions Included in the Cumulative Impact Assessment

Activities	Hanford	INEEL	Pantex	SRS

Table 4–270. Maximum Cumulative Resource Use and Impacts at Hanford—2007

Resource	Other Site Activities	Alternative 2 Maximum Impacts	Cumulative Total	Total Site Capacity
Site employment	14,840	1,014	15,854	NA
Electrical consumption (MWh/yr)	620,000	68,000	688,000	2,484,336
Water usage (million l/yr)	3,160	149	3,309	8,263
Developed land (ha)	9,279	15	9,294	143,200

Key: NA, not applicable.
Source: DOE 1995a, 1996e, 1997g.

electricity used on the site and 4.0 percent of the water; cumulatively, about 27 percent of the electricity, and 40 percent of the water would be required. The land used by these facilities would represent less than 1 percent of the developed land on the site; cumulatively, less than 6 percent of the land would be used. Impacts on resource requirements were evaluated for the year 2007 (the peak year) because that would be the first full year in which all three surplus plutonium disposition facilities operate simultaneously.

Nuclear facilities within an 80-km (50-mi) radius of Hanford include the WPPSS's WNP–2 nuclear reactor. Radiological impacts from the operation of the WNP–2 are minimal, but DOE has factored them into the analysis.

4.32.1.2 Air Quality

Cumulative impacts on air quality at Hanford are presented in Table 4–271. Hanford is currently in compliance with all Federal, State, and local regulations and guidelines, and would continue to remain in compliance even with consideration of the cumulative effects of all activities. The surplus plutonium disposition facilities' contributions to overall site concentration are extremely small.

Table 4–271. Maximum Cumulative Air Pollutant Concentrations at Hanford and Comparison With Standards or Guidelines

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a] ($\mu g/m^3$)	Alternative 2 Increment ($\mu g/m^3$)	Estimated Cumulative Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.53	34.6	0.35
	1 hour	40,000	3.29	51.6	0.13
Nitrogen dioxide	Annual	100	0.046	0.296	0.3
PM_{10}	Annual	50	0.0025	0.0204	0.041
	24 hours	150	0.0278	0.798	0.53
Sulfur dioxide	Annual	50	0.00222	1.63	3.1
	24 hours	260	0.0247	8.94	3.4
	3 hours	1,300	0.168	29.8	2.3

Other regulated pollutants					
Total suspended particulates	Annual	60	0.0025	0.0204	0.034
	24 hours	150	0.0278	0.798	0.53
Hazardous and other toxic compounds					
Ethylene glycol	24 hours	420	0.0406	0.0406	0.01

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.

4.32.1.3 Waste Management

Cumulative impacts on waste management at Hanford are presented in Table 4–272. Although a few cumulative waste volumes would be expected to exceed current storage capacities if the wastes were held in storage and not disposed, this is not likely. Current schedules for shipment of TRU waste to WIPP indicate that TRU waste generated by the surplus plutonium disposition facilities would need to be stored onsite until 2016 (DOE 1997b:17). However, since Hanford is expected to begin shipping its existing inventory of TRU waste to WIPP in 1999 (DOE 1997b:17), TRU waste generated by surplus plutonium disposition facilities could be stored in the space vacated by the waste shipped to WIPP. Likewise, it is unlikely that additional LLW storage capacity would be needed since this waste is routinely sent to onsite disposal. Additional mixed LLW storage and disposal capacity could be required, but would likely be augmented by offsite commercial capacity.

Table 4–272. Cumulative Impacts of Waste Management Activities at Hanford Over 15-Year Period From 2002–2016 (m^3)

Waste Type	Other Site Activities	Alternative 2 Maximum Impacts[a]	Cumulative Total	Site Capacity[b]		
				Treatment	Storage	Disposal
TRU	37,700	1,722	39,422	1,125,975	16,800	168,500[c]
LLW	129,000	2,240	131,240	2,047,050	23,988	1,970,000
Mixed LLW	37,500	44	37,544	2,376,975	24,466	14,200
Hazardous	13,000	414	13,414	NA	NA	NA
Nonhazardous						
Liquid	2,000,000	943,130	2,943,130	5,325,000	NA	5,325,000
Solid	645,000	30,094	675,094	NA	NA	NA

[a] Includes waste generated during lead assembly fabrication and postirradiation examination.
[b] Total 15-year capacity derived from Table 3–8.
[c] Current disposal capacity at WIPP.
Key: LLW, low-level waste; NA, not applicable (i.e., the majority of the waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

4.32.1.4 Human Health Risk

Cumulative impacts in terms of radiation exposure on the public and workers at Hanford are presented in Table 4–273. The number of LCFs in the general population from Hanford operations would be expected to increase from 0.05 to 0.10 if the proposed surplus plutonium disposition facilities were located there as described in Alternative 2. No additional LCFs would be expected as a result of these activities. Doses to the MEI are based on source location; summing the MEIs for each reasonably foreseeable and current activity would be both misleading and technically incorrect because the hypothetical MEI cannot be in a number of different locations simultaneously. However, to provide some comparative perspective, the hypothetical MEI for all reasonably foreseeable actions would receive an annual dose of 0.46 mrem which corresponds to an LCF risk from 15 years of site operations of 3.5×10^{-6}. The MEI for Alternative 2 would receive an additional 0.019 mrem per year, for a cumulative annual dose from all activities of 0.48 mrem and a corresponding risk of an LCF of 3.6×10^{-6}. The regulatory dose limits for individual members of the public are given in DOE Order 5400.5 (DOE 1993). As discussed in that order, the NESHAP dose limit from airborne emissions is 10 mrem/yr, as required by the Clean Air Act; the dose limit from drinking water is 4 mrem/yr, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 mrem/yr. Thus, the dose to the MEI would be expected to remain well within the regulatory dose limits. Workers on the site would be expected to see an increase in the number of LCFs due to radiation from normal site operations of 2.2, from about 10 to 12.2, if all of the proposed surplus plutonium dispositions activities were sited at Hanford.

Table 4–273. Maximum Cumulative Radiation Exposures and Impacts at Hanford

Impact	Population Dose Within 80 km[a]		Total Site Workforce	
	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Other site activities	120	0.06	25,000	10
Alternative 2	70	0.04	5,610	2.2
Cumulative	190	0.10	30,610	12.2

[a] Values are based on the total expected duration of all proposed disposition activities (includes construction, operation, and lead assembly).
Source: DOE 1995a, 1996e, 1997g.

4.32.1.5 Transportation

Transportation requirements associated with Alternative 2 at Hanford would include shipments to and from all three of the proposed surplus plutonium disposition facilities. It is estimated that the number of total shipments to and from Hanford would be 414,000 truck shipments during the same timeframe the surplus plutonium disposition facilities would be built and operated. Alternative 2 would add approximately 2,300 truck shipments to this estimate for a total of 416,300. The annual dose to the MEI from these shipments would be expected to increase from 1.68 mrem/yr to about 1.78 mrem/yr (DOE 1997g). This dose corresponds to an LCF risk from 15 years of transportation of 1.3×10^{-5}, which does not significantly increase the risk to the public.

4.32.2 INEEL

For INEEL, the bounding alternative for this SPD EIS would be Alternative 7A. Alternative 7A calls for the siting of the pit conversion facility in FPF and a new MOX facility to be located nearby.

4.32.2.1 Resource Requirements

Cumulative impacts on resource requirements at INEEL are presented in Table 4–274. INEEL would remain within its site capacity for all major resources. If Alternative 7A were implemented, the proposed surplus plutonium disposition facilities would require 8.4 percent of the annual electricity used on the site and about 1.5 percent of the water; cumulatively, about 81 percent of the electricity and 14 percent of the water would be required. The land used by these facilities would represent less than 1 percent of the developed land on the site; cumulatively, about 41 percent of the land would be used. Impacts on resource requirements were evaluated for the year 2007 because that would be the first full year in which both surplus plutonium disposition facilities operate simultaneously.

Table 4–274. Maximum Cumulative Resource Use and Impacts at INEEL—2007

Resource	Other Site Activities	Alternative 7A Maximum Impacts	Cumulative Total	Total Site Capacity
Site employment	7,250	750	8,000	NA
Electrical consumption (MWh/yr)	295,556	27,000	322,556	394,200
Water usage (million l/yr)	5,937	92	6,029	43,000
Developed land (ha)	9,328	13	9,341	230,000

Key: NA, not applicable.
Source: DOE 1995a, 1996h, 1997g.

4.32.2.2 Air Quality

Cumulative impacts on air quality at INEEL are presented in Table 4–275. INEEL is currently in compliance with all Federal, State, and local regulations and guidelines, and would continue to remain in compliance even with consideration of the cumulative effects of all activities. The surplus plutonium disposition facilities' contributions to overall site concentrations are extremely small.

4.32.2.3 Waste Management

Cumulative impacts on waste management at INEEL are presented in Table 4–276. It is unlikely that there would be major impacts to the waste management infrastructure at INEEL since sufficient capacity should exist to manage the wastes that could be generated by planned activities. In the case of storage capacity for

Table 4–275. Maximum Cumulative Air Pollutant Concentrations at INEEL and Comparison With Standards or Guidelines

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	Alternative 7A Concentration ($\mu g/m^3$)	Estimated Cumulative Concentration ($\mu g/m^3$)	Percent of Standard or Guideline

Ethylene glycol	24 hours	6,350	0.0197	0.0197	0.0031

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.

Table 4–276. Cumulative Impacts of Waste Management Activities at INEEL Over 15-Year Period From 2002–2016 (m^3)

	Other Site Activities	Alternative 7A Maximum Impacts[a]	Cumulative Total	Site Capacity[b]		
				Treatment	Storage	Disposal
TRU	1,125	783	1,908	722,723	158,772	168,500[c]
LLW	119,355	1,816	121,171	1,368,818	112,500	565,500
Mixed LLW	10,035	35	10,070	1,754,453	114,499	NA
Hazardous	15,450	112	15,562	744,150	NA	NA
Nonhazardous						
Liquid	30,000,000	713,894	30,713,894	48,000,000	NA	48,000,000
Solid	930,270	27,431	957,701	NA	NA	NA

[a] Includes waste generated during lead assembly fabrication and postirradiation examination.
[b] Total 15-year capacity derived from Table 3–20.
[c] Current disposal capacity at WIPP.
Key: LLW, low-level waste; NA, not applicable (i.e., the majority of the waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

LLW, if the wastes were held in storage and not disposed of, the total would exceed current storage capacity. However, this waste is routinely disposed of on the site so there should not be any problem.

4.32.2.4 Human Health Risk

Cumulative impacts in terms of radiation exposure on the public and workers at INEEL are presented in Table 4–277. The number of LCFs in the general population from INEEL site operations would be expected to increase from 0.06 to 0.07 if the proposed surplus plutonium disposition facilities were located there as described in Alternative 7A. Thus, no additional LCFs would be expected as a result of these activities. Doses to the MEI are based on source location; summing the MEIs for each reasonably foreseeable and current activity would be both misleading and technically incorrect because the hypothetical MEI cannot be in a number of different locations simultaneously. However, to provide some comparative perspective, the hypothetical MEI for all reasonably foreseeable actions would receive an annual dose of 0.72 mrem, which

Table 4–277. Maximum Cumulative Radiation Exposures and Impacts at INEEL

	Population Dose Within 80 km		Total Site Workforce	
	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Other site activities	127	0.064	8,985	3.6
Alternative 7A[a]	22	0.011	3,503	1.4
Cumulative	149	0.075	12,488	5

[a] Values are based on the total expected duration of all proposed disposition activities (includes construction, operation, and lead assembly).

Source: DOE 1995a, 1996h, 1997g.

corresponds to an LCF risk from 15 years of site operations of 5.4×10^{-6}. The MEI for Alternative 7A would receive an additional 0.016 mrem per year, for a cumulative annual dose from all activities of 0.74 mrem and a corresponding risk of an LCF of 5.5×10^{-6}. The regulatory dose limits for individual members of the public are given in DOE Order 5400.5 (DOE 1993). As discussed in that order, the dose limit from airborne emissions is 10 mrem/yr, as required by the Clean Air Act; the NESHAP dose limit from drinking water is 4 mrem/yr, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 mrem/yr. Thus, the dose to the MEI would be expected to remain well within the regulatory dose limits. Workers on the site would be expected to see an increase in the number of expected LCFs due to radiation from normal site operations of 1.4, from about 3.6 to 5, if the pit conversion and MOX facilities were sited at INEEL.

4.32.2.5 Transportation

Transportation requirements associated with Alternative 7A at INEEL would include shipments to and from the proposed pit conversion and MOX facilities. The number of total shipments to and from INEEL is estimated to be 35,746 truck shipments during the approximately 15-year timeframe the surplus plutonium disposition facilities would be built and operated. Alternative 7A would add approximately 2,500 truck shipments to this estimate for a total of 38,246. The annual dose to the MEI from these shipments would be expected to increase from 1.05 mrem per year to about 1.1 mrem per year (DOE 1997g). This dose corresponds to an LCF risk from 15 years of transportation of 8.3×10^{-6}, which does not significantly increase the risk to the public.

4.32.3 Pantex

For Pantex, the bounding alternative for this SPD EIS would be Alternative 9A. Alternative 9A calls for the siting of the new pit conversion and MOX facilities in Zone 4.

4.32.3.1 Resource Requirements

Cumulative impacts on resource requirements at Pantex are presented in Table 4–278. Pantex would remain within its site capacity for all major resources. The Ogallala aquifer would not be impacted. If Alternative 9A were implemented, the proposed surplus plutonium disposition facilities would require 13.2 percent of the annual electricity used on the site and about 6.8 percent of the water; cumulatively, this would require about 35 percent of the water and 50 percent of the electrical capacity. The land used by these facilities would represent one percent of the developed land on the site; cumulatively, about 23 percent of the land will be developed. Impacts on resource requirements were evaluated for the year 2007 because that would be the first full year in which both surplus plutonium disposition facilities operate simultaneously.

Table 4–278. Maximum Cumulative Resource Use and Impacts at Pantex—2007

Resource	Other Site Activities	Alternative 9A Maximum Impacts	Cumulative Total	Total Site Capacity
Site employment	1,750	750	2,500	NA
Electrical consumption (MWh/yr)	184,296	28,000	212,296	420,500
Water usage (million l/yr)	1,247	91	1,338	3,785
Developed land (ha)	1,489	16	1,505	6,475

Key: NA, not applicable.
Source: DOE 1995a, 1996a, 1996b.

4.32.3.2 Air Quality

Cumulative impacts on air quality at Pantex are presented in Table 4–279. Pantex is currently in compliance with all Federal, State, and local regulations and guidelines, and would continue to remain in compliance even with consideration of the cumulative effects of all activities. The surplus plutonium disposition facilities' contributions to overall site concentrations are extremely small.

Table 4–279. Maximum Cumulative Air Pollutant Concentrations at Pantex and Comparison With Standards or Guidelines

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	Alternative 9A Concentration ($\mu g/m^3$)	Estimated Cumulative Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.687	620	6.2
	1 hour	40,000	3.79	3000	7.5
Nitrogen dioxide	Annual	100	0.0725	2.02	2
PM_{10}	Annual	50	0.00514	8.8	18
	24 hours	150	0.056	89.5	60
Sulfur dioxide	Annual	50	0.00264	0.00264	0.0033
	24 hours	365	0.0314	0.0314	0.0066
	3 hours	1,300	0.137	0.137	0.011
	30 minutes	1,048	0.55	0.55	0.053
Other regulated pollutants

	1 hour	400	0.783	0.783[b]	0.12
Hazardous and other toxic compounds					
Ethylene glycol	24 hours	26	0.217	0.217	0.83
	1 hour	260	5.3	5.3	2

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Three- and 1-hr concentrations for total suspended particulates are not listed for existing sources in the source document. Only the contribution from sources associated with the alternative are presented.

4.32.3.3 Waste Management

Cumulative impacts on waste management at Pantex are presented in Table 4–280. It is likely that some additional TRU waste storage capacity would be needed at Pantex. Because there is not any TRU waste currently stored at Pantex, space for storage would be provided within the new surplus plutonium disposition

Table 4–280. Cumulative Impacts of Waste Management Activities at Pantex Over 15-Year Period From 2002–2016 (m^3)

Waste Type	Other Site Activities	Alternative 9A Maximum Impacts	Cumulative Total	Site Capacity[a]		
				Treatment	Storage	Disposal
TRU	0	640	640	NA	NA	168,500[b]
LLW	7,952	940	8,892	17,745	1,389	500,000[c]
Mixed LLW	420	30	450	16,335	1,047	NA
Hazardous	10,897	213	11,110	21,795	NA	NA
Nonhazardous						
Liquid	7,096,875	554,900	7,651,775	14,204,010	NA	14,204,010

Key: LLW, low-level waste; NTS, Nevada Test Site; TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

facility. It is unlikely that additional LLW storage capacity would be needed at Pantex because this waste is routinely sent to offsite disposal.

4.32.3.4 Human Health Risk

Cumulative impacts in terms of radiation exposure on the public and workers at Pantex are presented in Table 4–281. The number of LCFs in the general population from Pantex site operations would be expected to increase from 5.5×10^{-5} to 0.003 if the proposed surplus plutonium disposition facilities were located there, as described in Alternative 9A. Thus, no additional LCFs would be expected as a result of these activities. Doses to the MEI are based on source location; summing the MEIs for each reasonably foreseeable and current activity would be both misleading and technically incorrect because the hypothetical MEI cannot be in a number of different locations simultaneously. However, to provide some comparative perspective, the hypothetical MEI for all reasonably foreseeable actions would receive an annual dose of 2.2×10^{-3} mrem which corresponds to an LCF risk from 15 years of site operations of 1.7×10^{-8}. The MEI for Alternative 9A would receive an additional 0.068 mrem per year, for a cumulative annual dose from all activities of 0.070 mrem and a corresponding risk of an LCF would be 5.3×10^{-7}. The regulatory dose limits for individual members of the public are given in DOE Order 5400.5 (DOE 1993). As discussed in that order, the NESHAP dose limit from airborne emissions is 10 mrem/yr, as required by the Clean Air Act; the dose limit from drinking water is 4 mrem/yr, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 mrem/yr. Thus, the dose to the MEI would be expected to remain well within the regulatory limits. Workers on the site would be expected to see an increase in the number of expected LCFs due to radiation from normal site operations of 1.5, from about 0.2 to 1.7, if the pit conversion and MOX facilities were sited at Pantex.

4.32.3.5 Transportation

Transportation requirements associated with Alternative 9A at Pantex would include shipments to and from the proposed pit conversion and MOX facilities. It was estimated that the number of total shipments to and from Pantex would be 3,640 truck shipments during the approximately 15-year timeframe the surplus plutonium disposition facilities would be built and operated. Alternative 9A would add approximately 2,000 truck shipments to this estimate for a total of 5,640. The annual dose to the MEI from these shipments would be expected to increase from 0.97 mrem per year to about 1.3 mrem/yr (DOE 1997g). This dose

Table 4–281. Maximum Cumulative Radiation Exposures and Impacts at Pantex

	Population Dose Within 80 km		Total Site Workforce	
Impact	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Other site activities	0.11	5.5×10^{-5}	514	0.2
Alternative 9A[a]	5.8	0.0029	3,670	1.5
Cumulative	5.9	0.0030	4,184	1.7

[a] Values are based on the total expected duration of all proposed disposition activities (includes construction and operations).
Source: DOE 1995a, 1996a, 1996b.

corresponds to an LCF risk from 15 years of transportation of 9.8×10^{-6}, which does not significantly increase the risk to the public.

4.32.4 SRS

For SRS, the bounding alternative for this SPD EIS would be Alternative 3A or 3B. Alternative 3A calls for the siting of new pit conversion, immobilization, and MOX facilities near APSF in F-Area. Alternative 3B is identical to Alternative 3A with the exception of the immobilization facility being housed in Building 221–F. In some cases, the impacts associated with Alternative 3A would be greater than those of 3B and vice versa. For the purposes of this section, the greater of the two has been included in the tables.

4.32.4.1 Resource Requirements

Cumulative impacts on resource requirements at SRS are presented in Table 4–282. If Alternative 3 is implemented, the proposed surplus plutonium disposition facilities would require 1 percent of the annual electricity used on the site and about 1 percent of the water. The land used by these facilities would represent less than 1 percent of the developed land on the site; cumulatively, about 68 percent of the electricity, 130 percent of the water capacity, and 8 percent of the land would be used. Projected water requirements exceed current site capacity due to accelerator requirements. If the accelerator is built and operated, additional water would be drawn from the Savannah River to satisfy the demand. Without the accelerator requirements, resource requirements would be well within site capacities. Impacts on resource requirements were evaluated for the year 2007 because that would be the first full year in which all three surplus plutonium disposition facilities operate simultaneously.

Table 4–282. Maximum Cumulative Resource Use and Impacts at SRS—2007

Resource	Other Site Activities	Alternative 3 Maximum Impacts	Cumulative Total	Total Site Capacity
Site employment	11,200	1,022	12,222	NA
Electrical consumption (MWh/yr)	3,520,000[a]	38,000	3,558,000[a]	5,200,000
Water usage (million l/yr)	12,350[a]	143	12,493[a]	9,230[b]
Developed land (ha)	6,880	30	6,911	80,130

[a] Includes estimates for operation of an accelerator for tritium production at SRS.
[b] This capacity does not include the existing, separate infrastructure for withdrawals from the Savannah River.
Key: NA, not applicable.

Nuclear facilities within an 80-km (50-mi) radius of SRS include Georgia Power Company's Vogtle Electric Generating Plant across the river from SRS; Chem-Nuclear Services facility, a commercial low-level waste disposal facility just east of SRS; and Starmet CMI, Inc., located sourtheast of SRS, which processes uranium-contaminated metals. Radiological impacts from the operation of the Vogtle Electric Generating

Plant, a two-unit commercial nuclear power plant, are minimal, but DOE has factored them into the analysis. The South Carolina Department of Health and Environmental Control Annual Report (SCDHEC 1992) indicates that operation of the Chem-Nuclear Services facility and the Starmet CMI facility do not noticeably impact radiation levels in air or liquid pathways in the vicinity of SRS. Therefore, they are not included in this assessment.

The counties surrounding SRS have numerous existing and planned industrial facilities with permitted air emissions and discharges to surface waters. Because of the distances between SRS and the private industrial facilities, there is little opportunity for interactions of plant emissions, and no major cumulative impact on air or water quality.

4.32.4.2 Air Quality

Cumulative impacts on air quality at SRS are presented in Table 4–283. SRS is currently in compliance with all Federal, State, and local regulations and guidelines, and would continue to remain in compliance even with consideration of the cumulative effects of all activities. The surplus plutonium disposition facilities' contributions to overall site concentrations are extremely small.

Table 4–283. Maximum Cumulative Air Pollutant Concentrations at SRS and Comparison With Standards or Guidelines

Pollutant	Averaging Period	Most Stringent Standard or Guideline ($\mu g/m^3$)[a]	Alternative 3A Concentration ($\mu g/m^3$)	Estimated Cumulative Concentration ($\mu g/m^3$)	Percent of Standard or Guideline
Criteria pollutants					
Carbon monoxide	8 hours	10,000	0.341	64.3	0.64
	1 hour	40,000	1.29	280	0.7
Nitrogen dioxide	Annual	100	0.0412	9.34	9.3
PM_{10}	Annual	50	0.00262	4.14	8.3
	24 hours	150	0.0427	56.4	38
Sulfur dioxide	Annual	80	0.0796	15.2	19
	24 hours	365	1.09	220	60
	3 hours	1,300	2.88	965	74
Other regulated pollutants					
Total suspended particulates	Annual	75	0.00262	14.7	20
Hazardous and other *toxic compounds*					
Ethylene glycol	24 hours	650	0.0585	0.254	0.039

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.

4.32.4.3 Waste Management

Cumulative impacts on waste management at SRS are presented in Table 4–284. Additional mixed LLW storage capacity could be required, but would likely be augmented by offsite commercial capacity. Although the cumulative waste volume for hazardous waste exceeds the treatment and storage capacities, it is unlikely that there would be major impacts to the waste management infrastructure at SRS, since most hazardous waste is not held in long-term storage, and is treated and disposed of in offsite facilities. Treatment capacity for LLW could be exceeded; however, major impacts are unlikely since most LLW can be disposed of without treatment.

Table 4–284. Cumulative Impacts of Waste Management Activities at SRS Over 15-Year Period From 2002–2016 (m^3)

Waste Type	Other Site Activities	Alternative 3 Maximum Impacts[a]	Cumulative Total	Site Capacity[b]		
				Treatment	Storage	Disposal
TRU	19,665	1,872	21,537	25,800	34,400	168,500[c]
LLW	300,000	3,740	803,740	459,045	1,064	1,170,165
Mixed LLW	164,000	44	164,044	543,045	18,757	NA[d]
Hazardous	252,000	548	252,548	79,995	3,198	NA
Nonhazardous						
Liquid	6,341,550	855,400	7,196,950	15,450,000	NA	15,450,000
Solid	100,050	34,958	135,008	NA	NA	NA

[a] Includes waste generated during lead assembly fabrication.
[b] Total 15-year capacity derived from Table 3–44.
[c] Current disposal capacity at WIPP.
[d] Depending in part on decisions in the RODs for the WM PEIS, mixed LLW could be disposed of on the site or at another DOE site. (See Sections 3.5.8.8, 4.8.2.2, and Appendix F.8.)

Key: LLW, low-level waste; NA, not applicable (i.e., the majority of the waste is not routinely, treated, stored, or disposed of on the site); TRU, transuranic; WIPP, Waste Isolation Pilot Plant.
Source: DOE 1995b, 1995c, 1996a, 1996h, 1997g, 1997i, 1997j, 1998b.

4.32.4.4 Human Health Risk

Cumulative impacts in terms of radiation exposure on the public and workers at SRS are presented in Table 4–285. The number of LCFs in the general population from SRS operations would be expected to increase from 1.45 to 1.46 if the proposed surplus plutonium disposition facilities were located there, as described in Alternative 3B. Doses to the MEI are based on source location; summing the MEIs for each reasonably foreseeable and current activity would be both misleading and technically incorrect because the hypothetical MEI cannot be in a number of different locations simultaneously. However, to provide some comparative perspective, the hypothetical MEI for all reasonably foreseeable actions would receive an annual dose of 3.7 mrem (from atmospheric releases), which corresponds to an LCF risk from 15 years of site operations of 2.8×10^{-5}. The MEI for Alternative 3B would receive an additional 0.004 mrem per year, for a cumulative annual dose from all activities of 3.7 mrem, which, along with the corresponding risk of an LCF, would be unchanged when rounded. The regulatory dose limits for individual members of the public are given in DOE Order 5400.5 (DOE 1993). As discussed in that order, the NESHAP dose limit from airborne emissions is 10 mrem/yr, as required by the Clean Air Act; the dose limit from drinking water is 4 mrem/yr, as required by the Safe Drinking Water Act; and the dose limit from all pathways combined is 100 mrem/yr. Thus, the dose to the MEI would be expected to remain well within the regulatory dose limits. Workers on the site would be expected to see an increase in the number of expected LCFs due to radiation from normal site operations of 2.3, from about 7.6 to 9.9, if all of the proposed surplus plutonium dispositions activities were sited at SRS.

4.32.4.5 Transportation

Transportation requirements associated with Alternative 3 at SRS would include shipments to and from all three of the proposed surplus plutonium disposition facilities. The number of total shipments to and from SRS would be 239,790 truck shipments during the approximately 15-year timeframe the surplus plutonium disposition facilities would be built and operated. Alternative 3 would add approximately 2,500 truck shipments to this estimate for a total of 242,290. The annual dose to the MEI from these shipments would be

Table 4–285. Maximum Cumulative Radiation Exposures and Impacts at SRS

	Population Dose Within 80 km		Total Site Workforce	
Impact	**Dose (person-rem)**	**Number of Fatal Cancers**	**Dose (person-rem)**	**Number of Fatal Cancers**
Other site activities	2,900	1.5	19,000	7.6
Alternative 3B[a]	16	0.008	5,630	2.3
Cumulative	2,916	1.5	24,630	9.9

[a] Values are based on total expected duration of all proposed disposition activities (includes construction, operation, and lead assembly).

Source: DOE 1995b, 1995c, 1996a, 1996d, 1996h, 1997g, 1997i, 1997j, 1998b; NRC 1996.

expected to increase from 0.59 mrem per year to about 0.69 mrem per year (DOE 1997g). This dose corresponds to an LCF risk from 15 years of transportation of 5.2×10^{-6}, which does not significantly increase the risk to the public.

Next Section

4.33 IRREVERSIBLE AND IRRETRIEVABLE COMMITMENTS OF RESOURCES

This section describes the major irreversible and irretrievable commitments of resources associated with the maximum number of proposed surplus plutonium disposition facilities that could be located at each site under any of the alternatives described in Chapter 2. A commitment of resources is irreversible when its primary or secondary impacts limit the future options for a resource. An irretrievable commitment refers to the use or consumption of resources neither renewable nor recoverable for later use by future generations. This section discusses three major resource categories that are committed irreversibly or irretrievably to the proposed action and alternatives: land, materials, and energy. Values for each are shown in Tables 4–286 and 4–287.

Table 4–286. Irreversible and Irretrievable Commitments of Construction Resources for SPD EIS Facilities

Resource	Hanford (Alternative 2)	INEEL (Alternative 7)	Pantex (Alternative 9)	SRS (Alternative 3)
Electrical energy, (MWh)	50,000	7,400	7,400	64,000
Liquid fuel (l)	1,200,000	1,000,000	1,700,000	2,600,000
Concrete (m^3)	15,000	15,000	27,000	80,000
Steel (t)	3,600	5,000	3,400	23,000

4.33.1 Land Use

The land that might be used for plutonium disposition facilities could be returned, in the long term, to open space and other uses, if the buildings, roads, and other structures were removed, the area decontaminated, and the land revegetated. Alternatively, the land could be reused for some other industrial or DOE mission. Therefore, the commitment of the land for facilities is not necessarily irreversible.

4.33.2 Materials

The irreversible and irretrievable commitment of material resources during the entire life cycle of plutonium disposition activities using existing or new facilities includes construction materials that cannot be recovered or recycled, materials that are rendered radioactive but cannot be decontaminated, and materials consumed or reduced to unrecoverable forms of waste. For construction activities, a variety of common materials, such as wood, sand, gravel, plastics, or aluminum, in addition to those listed below, may be required. At this time, no unusual construction material requirements have been identified. Those construction resources would be generally irretrievably lost. None of these materials are in short supply, and all are readily available in the vicinity of each candidate DOE site. For operational activities, the commitment of materials made into equipment or used as feedstock cannot be recycled at the end of the project and are considered to be irretrievable. Although the use of such materials would be irretrievable, none are in short supply, and all are readily available in the vicinity of each candidate DOE site.

4.33.3 Energy

The irretrievable commitment of resources during construction and operation of the facilities would include the consumption of fossil fuels used to generate heat and electricity for each process. Energy would also be expended in the form of diesel fuel, gasoline, and oil, for construction equipment, and transportation vehicles. The plutonium and associated uranium feedstock materials used in the disposition process can be considered as energy sources irretrievable lost, if immobilized, or after being partially burned in a reactor as MOX fuel. Reactor burnup as MOX fuel would produce some useful electricity which would be a very small percentage of total U.S. electrical capacity and demand.

Table 4–287. Irreversible and Irretrievable Commitments of Operations Resources for SPD EIS Facilities

Resource	Hanford (Alternative 2)	INEEL (Alternative 7)	Pantex (Alternative 9)	SRS (Alternative 3)
Land (ha)	6.5	6.5	8.9	12
Electrical energy (MWh)	680,000	270,000	280,000	380,000
Liquid fuel (l)	1,100,000	810,000	810,000	1,100,000
Coal (t)	NA	37,000	NA	29,000
Natural gas (m^3)	NA	NA	22,000,000	NA
Hydrogen (m^3)	370,000	360,000	360,000	370,000
Nitrogen (m^3)	30,000	22,000	22,000	30,000
Oxygen (m^3)	6,640	4,040	4,040	6,640
Argon (m^3)	220,000	200,000	200,000	211,000
Chlorine (m^3)	620	630	620	600
Helium (m^3)	72,000	50,000	50,000	72,000
Sulfuric acid (kg)	5,700	4,600	4,700	960
Phosphoric acid (kg)	3,400	3,400	3,400	3,400
Oils and lubricants (kg)	30,000	16,000	16,000	30,000
Cleaning solvents (kg)	1,400	1,400	1,400	1,400
Polyphosphate (kg)	1,500	690	700	1,500
Polyelectrolyte (kg)	2,400	2,400	2,400	2,400
Liquid nitrogen (kg)	11,000	11,000	11,000	11,000
Sodium hypochlorite (kg)	570	NA	NA	570
Sodium hydroxide (kg)	760	760	760	760
Sodium nitrate (kg)	5,000	5,000	5,000	5,000
Stainless steel canisters (kg)	1,200,000	NA	NA	1,200,000
Ceramic precursor (kg)	310,000	NA	NA	310,000
Ceramic process lubricant (kg)	500	NA	NA	500
Carbon monoxide (m^3)	90,000	NA	NA	90,000
Carbon dioxide (m^3)	1,600,000	NA	NA	1,600,000
Aluminum sulfate (kg)	9,400	9,700	9,600	9,600
Bentonite (kg)	4,700	4,900	4,800	4,800
Glass frit (kg)	550,000	NA	NA	550,000
Ceramic binder (kg)	9,500	NA	NA	9,500
Ethylene glycol (kg)	3,000	3,000	3,000	3,000
Zinc stearate (kg)	3,000	3,000	3,000	3,000

Key: NA, not applicable.

4.33.4 Waste Minimization, Pollution Prevention, and Energy Conservation

4.33.4.1 Waste Minimization and Pollution Prevention

The *Pollution Prevention Act of 1990* and the *Hazardous and Solid Waste Amendments of 1984* required Federal agencies to develop and implement pollution prevention and waste minimization programs. NEPA's purpose, which is to promote efforts which will prevent or eliminate damage to the environment, is complemented by both acts. This relationship was further strengthened by Executive Order 12856 (Federal Compliance with Right to Know Laws and Pollution Prevention Requirements), 12873 (Federal Acquisition, Recycling, and Waste Prevention), and 12902 (Energy Efficiency and Water Consumption at Federal

Facilities), and a 1993 memorandum from the Council on Environmental Quality (CEQ 1993). The Council on Environmental Quality memorandum recommended that Federal agencies incorporated pollution prevention principles, techniques, and mechanisms in their NEPA planning and decision making processes (DOE 1996b:G-1).

Consistent with overall national policy, DOE programs are directed to incorporate pollution prevention into their planning and implementation activities. This includes reducing the quantity and toxicity of radioactive, hazardous, mixed, and sanitary waste generated; incorporating waste recycle and reuse into program planning and implementation; and conserving resources and energy (DOE 1996e:5-286).

DOE is responding to these initiatives by reducing the use of toxic chemicals; improving emergency planning, response, and accident notification; and encouraging the development and use of clean technologies. DOE's nuclear facilities have reduced the sizes of radiological control areas in order to reduce LLW. Other facilities have scrap metal segregation programs which reduce solid waste and allow useable material to be sold and recycled. DOE facilities also are replacing solvents and cleaners containing hazardous materials with less-toxic or nontoxic materials (DOE 1997j:6-3)

Although the surplus plutonium disposition facilities are still in the early stages of the engineering and design, the program would integrate pollution prevention practices that include waste stream minimization, source reduction and recycling, procurement processes that preferentially procure products made from recycled materials; inventory management, and technology transfer. The surplus plutonium disposition facility designs would minimize the size of radiologically controlled areas, thereby minimizing the generation of TRU waste and LLW. To the extent practicable, the facilities would not use solvents regulated by the Resource Conservation and Recovery Act, thereby minimizing the amount of hazardous and mixed waste generated. Wastewater would be recycled to the extent possible to minimize effluent discharge. Equipment would be installed as modules, so when there is a breakdown, a component, rather than a large piece of equipment, would be replaced. If possible, DOE would recycle materials rather than dispose of them. DOE would store such material for future use or sell these materials to other users or salvage vendors. Additionally, the DOE could burn nonrecyclable waste paper, cardboard and oil for energy recovery rather than disposing of it as waste.

4.33.4.2 Energy Conservation

Energy conservation and efficiency are also part of waste minimization and pollution prevention in terms of incorporating efficiencies into the design process. Energy conservation for each of the alternatives would be achieved primarily in three areas: process configuration, mechanical design, and electrical design. Energy conservation would be maximized by incorporating it into the process and facility design from the outset. Where possible, the process would be configured to conserve energy by using heat exchangers so the hot exit streams could heat cool incoming streams, which would conserve heating energy. Where cooling of process streams would be required, maximum use of cooling water would be employed, which would minimize the amount of refrigeration cooling to be used. Mechanical design would employ energy efficient compressors, pumps, and fans. Ductwork would be designed for minimum pressure drop. Facilities would employ energy-efficient insulation and reflective panels where appropriate. Air conditioning systems would make efficient use of outside air. Electrical design would employ energy efficient motors, actuators, and lighting. Accurate electrical power metering of each system would indicate the major power consumers and give warning of unusually high energy consumption. This would allow corrective measures to be taken promptly.

4.34 RELATIONSHIP BETWEEN LOCAL SHORT-TERM USES OF THE ENVIRONMENT AND THE MAINTENANCE AND ENHANCEMENT OF LONG-TERM PRODUCTIVITY

The use of land on any of the four DOE candidate sites under consideration for plutonium disposition activities would be short-term uses of the environment; on completion of the disposition activities, such land could be returned to other uses, including long-term productive uses.

Losses of the natural productivity of terrestrial and aquatic habitats due to construction and operation of new plutonium disposition facilities are possible at any of the DOE candidate locations. Land clearing and construction and operational activities could disperse wildlife and eliminate habitat on a short-term basis. Although some destruction would occur during and after construction, losses would be minimized by careful siting of facilities and incorporation of mitigation measures into all construction activities. In addition, consultation and coordination with State and Federal natural resource and wildlife agencies would occur prior to any site disturbances, in order to ensure that all potential sensitive species, candidate or listed, would be protected to the maximum extent possible.

There are no other activities under plutonium disposition that would affect long-term productivity of environmental resources at each site.

Next Section

Chapter 5
Environmental Regulations, Permits, and Consultations

5.1 LAWS, REGULATIONS, EXECUTIVE ORDERS, AND DOE ORDERS

The major laws, regulations, Executive orders, and other compliance actions that apply to surplus plutonium disposition activities depending on the various alternatives are identified in Tables 5–1 and 5–2. There are a number of Federal environmental statutes dealing with environmental protection, compliance, or consultation that affect compliance at every U.S. Department of Energy (DOE) location. In addition, certain environmental requirements have been delegated to State authorities for enforcement and implementation. It is DOE policy to conduct its operations in an environmentally safe manner in compliance with all applicable statutes, regulations, and standards. Although this chapter does not address pending legislation or future regulations, DOE recognizes that the regulatory environment is in transition, and subject to many changes, and that the construction, operation, and decommissioning of any surplus plutonium disposition facility must be conducted in compliance with all future regulations and standards.

The Atomic Energy Act (AEA) authorizes DOE to establish standards to protect health or minimize dangers to life or property for activities under DOE's jurisdiction. Through a series of DOE orders, an extensive system of standards and requirements has been established to ensure safe operation of facilities. DOE regulations are generally found in Title 10 of the Code of Federal Regulations (CFR). For purposes of this *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS), relevant regulations include 10 CFR 820, Procedural Rules for DOE Nuclear Activities; 10 CFR 830, Nuclear Safety Management; 10 CFR 834, Radiation Protection of the Public and the Environment (Draft); 10 CFR 835, Occupational Radiation Protection; 10 CFR 1021, Compliance with the National Environmental Policy Act; and 10 CFR 1022, Compliance with Floodplains/Wetlands Environmental Review Requirements. The DOE orders have been revised and reorganized to reduce duplication and eliminate obsolete provisions (though some older orders remain in effect during the transition). The new organization is by Series and is intended to include all DOE policies, manuals, requirements documents, notices, guides, and orders. Relevant series include Series 400, which deals with Work Process; and within this Series, DOE Order 420.1 addresses Facility Safety; 425.1 addresses Startup and Restart of Nuclear Facilities; 452.1A addresses Nuclear Explosive and Weapons Surety Programs; 452.2A addresses the Safety of Nuclear Explosives Operations; 452.4 addresses the Security and Control of Nuclear Explosives; 460.1A addresses Packaging and Transportation Safety; 470.1 addresses the Safeguards and Security Program; and 474.1 addresses the Control and Accountability of Nuclear Materials. In addition, DOE (older number) Series 5400 addresses environmental, safety, and health programs for DOE operations.

5.2 PERMITS

Permits are a means for the issuing agency to enforce applicable regulatory requirements. It is likely that new or modified permits will be needed before facilities for surplus plutonium disposition may be constructed or operated. Permits regulate many aspects of facility construction and operations, including the quality of construction, treatment and storage of hazardous waste, and discharges of effluents to the environment. These permits will be obtained from the appropriate Federal, State, and local agencies. Potentially applicable permits for Federal agencies are described in Table 5–1, and for State agencies in Table 5–2. Permits for constructing or operating facilities for surplus plutonium disposition would not be obtained or modified before a Record of Decision is issued on this SPD EIS.

5.3 CONSULTATIONS

Certain statutes and regulations require DOE to consider consultations with Federal, State, and local agencies and federally recognized Native American groups regarding the potential for alternatives for surplus plutonium disposition to disturb sensitive resources. The needed consultations must occur on a timely basis and are generally required before any land disturbance can begin. Most of these consultations are related to biotic resources, cultural resources, and Native American rights. The biotic resources consultations generally pertain to the potential for activities to disturb sensitive species or habitats. Cultural resources consultations relate to the potential for disruption of important cultural resources and archaeologic sites. Finally, Native American consultations are concerned with the potential for disturbance of ancestral Native American sites and the traditional practices of Native Americans. These and other consultations that may be required are listed in Table 5–3. DOE is in the process of initiating the required consultations at the sites and will report the status of these consultations in the SPD Final EIS.

5.3.1 Native American Tribal Government Consultations

Upon the publication of this SPD EIS, DOE representatives at the Amarillo, Idaho, Richland, and Savannah River Offices will initiate the government-to-government consultation process with federally recognized American Indian Tribal Governments for the proposed action and alternatives discussed herein. The consultations will be conducted consistent with the direction outlined in DOE Order 1230.2 *American Indian Tribal Government Policy*. A copy of this SPD EIS will be presented to each federally recognized tribe that has acknowledged potential concern for resources at the Hanford Site, Idaho National Engineering and Environmental Laboratory, Pantex Plant, and Savannah River Site during prior consultations initiated for compliance with the American Indian Religious Freedom Act (AIRFA) (P.L. 95-341) and the Native American Graves Protection and Repatriation Act (NAGPRA) (P.L. 101-601).

The consultation process will be initiated by the responsible DOE representative at each office through a formal letter identifying the potential actions at the DOE site accompanied by a copy of this SPD Draft EIS. The letter will request a response from each American Indian Tribal Government regarding concerns under AIRFA and NAGPRA. Among the areas of specific concern that may be identified by American Indian Tribal Governments are religious and sacred places and resources, Native American human remains, associated funerary objects, unassociated funerary objects, sacred objects, and cultural patrimony objects. Each response with be addressed by DOE through a consultation process acceptable to the specific American Indian Tribal Government including, but not limited to, government-to-government meetings, interviews, and site visits. It will be the intent of these consultations to identify all potential American Indian Tribal Government concerns associated with each action discussed in this SPD EIS and to consider the results of the consultation processes in the SPD Final EIS. The individual consultation processes for each site with each American Indian Tribal Government will be formally documented in the SPD Final EIS including a summary of the consultation processes along with copies of formal correspondence.

In the event of inadvertent discovery of potential important materials such as human remains, associated funerary objects, unassociated funerary objects, sacred objects, and cultural patrimony during construction and operation, another consultation process will be initiated. Each DOE site considered in this SPD EIS has plans and procedures which address inadvertent discoveries of cultural material. In each case, the ground disturbing activities would be immediately suspended upon recognition of human remains or potential cultural materials. DOE would be notified and qualified cultural resource specialists would evaluate the materials to determine potential Native American origin. If the remains or materials are determined to be of potential Native American origin and within the criteria of AIRFA and NAGPRA, DOE would immediately initiate an expedited formal consultation process with American Indian Tribal Governments with interest in the locations,

as determined during the SPD EIS consultation process described above. Based upon the results of the consultations, DOE would take appropriate action prior to resuming of ground disturbing activities.

5.3.2 Archaeological and Historical Resources Consultations

Each DOE site evaluated in this SPD EIS has cultural (archaeological and historical) resource management plans that prescribe consultation processes for activities which have the potential to adversely affect sites and properties eligible for nomination, or listed on, the National Register of Historic Places. The management plans have been developed consistent with archaeological and historical resource laws (see Table 5–1) as implemented under 36 CFR 800, *Procedures for the Protection of Historic and Cultural Properties.*

Upon the publication of this SPD Draft EIS, DOE representatives at the Amarillo, Idaho, Richland, and Savannah River Offices will initiate formal consultation with the State Historic Preservation Officers of Idaho, Texas, Washington and South Carolina, as appropriate under each site's Programmatic Agreement and management plan. The intent of each consultation will be to determine potential eligibility for nomination to the National Register of Historic Places of archaeological and historic resources which may be associated with the proposed actions and alternatives. Further consultations will be used to determine the potential for adverse effect to any resources determined to be eligible for nomination and any necessary actions required to mitigate potential adverse effects. The specific consultation processes will be conducted in compliance with site specific programmatic agreements among each DOE office, specific State Historic Preservation Offices, and the Advisory Council on Historic Preservation.

The consultation process will be initiated by the responsible DOE representative at each office through a formal letter to the appropriate State Historic Preservation Officer identifying the potential actions at the DOE site accompanied by a copy of this SPD Draft EIS and supporting cultural resource reports. The letter will request a consultation meeting, if necessary, to discuss specific concerns and information needs. A site visit may be appropriate for locations with identified resources. In all cases, the consultation process will conform to 36 CFR 800 requirements and programmatic agreements for the management of archaeological and historic resources and properties. Each consultation process will be documented in the SPD Final EIS, including a summary of the consultation processes along with copies of formal correspondence.

In the event that potential archaeological and historic materials are inadvertently discovered during construction and operation, another consultation process will be initiated. Each DOE site considered in this SPD EIS has plans and procedures that address inadvertent discoveries of cultural material. In each case, the ground-disturbing activities would be immediately suspended upon recognition of human remains or potential archaeological and historical materials. DOE would be notified and qualified cultural resource specialists would evaluate the materials to identify and evaluate their potential archaeological and historical value under 36 CFR 800. If the materials were determined to be potentially eligible for nomination to the National Register of Historic places, DOE would immediately initiate an expedited formal consultation process with the appropriate State Historic Preservation Officer, as appropriate under the programmatic agreement. Based on the results of the consultations, DOE would take appropriate action prior to resuming ground-disturbing activities to ensure mitigation of any adverse effect to resources determined eligible for nomination to the National Register of Historic Places.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders

Statute, Regulation, Executive Order	Citation	Potential Requirements
	Air Quality and Noise	
Clean Air Act of 1970 (CAA)	42 USC 7401 et seq.	Requires sources to meet standards and obtain permits to satisfy: National Ambient Air Quality Standards (NAAQS), State implementation plans, Standards of Performance for New Stationary Sources, National Emission Standards for Hazardous Air Pollutants (NESHAP), and Prevention of Significant Deterioration (PSD). Public radiological dose limits are outlined in paragraph II.1b of 40 CFR 61, subpart H, under the authority of this act.
National Ambient Air Quality Standards	42 USC 7409 et seq.; 40 CFR 50	Establishes primary and secondary ambient air quality standards governing SO_2, NO_2, CO, O_3, Pb, and PM_{10}.
Standards of Performance for New Stationary Sources	42 USC7411; 40 CFR 60	Establishes control/emission standards and recordkeeping requirements for new or modified sources specifically addressed by a standard.
National Emission Standards for Hazardous Air Pollutants	42 USC 7412; 40 CFR 61, 63	Establishes emission levels for carcinogenic or mutagenic pollutants or operation requirements; may require a preconstruction approval, depending on the process being considered and the level of emissions that will result from the new or modified source.
Prevention of Significant Deterioration	42 USC 7470 et seq.; 40 CFR 51.166	Establishes requirements for the State implementation plans for PSD programs. Applies to areas that are in compliance with NAAQS. Requires comprehensive preconstruction review and the application of Best Available Control Technology to major stationary sources (emissions of 100 tons per year [tons/yr]) and major modifications; requires a preconstruction review of air quality impacts and the issuance of a construction permit from the responsible State agency setting forth emission limitations to protect the PSD increment.
Determining conformity of Federal activities to State or Federal implementation plans	40 CFR 93	Requires Federal facilities to demonstrate compliance with State or Federal implementation plans for applicable actions in nonattainment areas.
Executive Order 12843, Procurement Requirements and Policies for Federal Agencies for Ozone-Depleting Substances	April 21, 1993	Requires Federal agencies to minimize procurement of ozone-depleting substances and conform their practices to comply with Title VI of CAA Amendments regarding stratospheric ozone protection and to recognize the increasingly limited availability of Class I substances until final phaseout.
Noise Control Act of 1972	42 USC 4901 et seq.	Requires facilities to maintain noise levels that do not jeopardize the health and safety of the public.
	Water Resources	
Clean Water Act (CWA)	33 USC 1251 et seq.	Requires EPA- or State-issued permits and compliance with provisions of permits regarding discharge of effluents to surface waters.
National Pollutant Discharge Elimination System (section 402 of CWA)	33 USC 1342	Requires permit to discharge effluents (pollutants) to surface waters and stormwaters; permit modifications are required if discharge effluents are altered.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders (Continued)

Statute, Regulation, Executive Order	Citation	Potential Requirements
	Water Resources (Continued)	
Wild and Scenic Rivers Act of 1968	16 USC 1271 et seq.	Requires consultation before construction of any new Federal project associated with a river designated as wild and scenic or under study in order to minimize and mitigate any adverse effects on the physical and biological properties of the river.
Safe Drinking Water Act of 1974	42 USC 300f et seq.; 40 CFR 141	Requires certification of any plant water treatment facility constructed on a site to ensure that the quality of public drinking water is protected and that maximum radioactive contaminant levels do not exceed 4 mrem dose equivalents.
Executive Order 11990, Protection of Wetlands	3 CFR 1977 Comp., p. 121	Requires Federal agencies to avoid the long- and short-term adverse impacts associated with the destruction or modification of wetlands.
Executive Order 11988, Floodplain Management	3 CFR 1977 Comp., p. 117	Directs Federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for any action undertaken in a floodplain and that floodplain impacts be avoided to the extent practical. Requires consultation if project impacts a floodplain.
Compliance with Floodplain/ Wetlands Environmental Review Requirements	10 CFR 1022	Requires DOE to comply with all applicable floodplain and wetlands environmental review requirements.
	Waste Management and Pollution Prevention	
Resource Conservation and Recovery Act, Hazardous and Solid Waste Amendments of 1984 (RCRA)	42 USC 6901 et seq.; PL 98-616	Requires notification and permits for operations involving hazardous waste treatment, storage, or disposal facilities; changes to site hazardous waste operations could require amendments to RCRA hazardous waste permits involving public hearings.
Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA); Superfund Amendments and Reauthorization Act of 1986	42 USC 9601 et seq.; PL 99-499	Requires cleanup and notification if there is a release or threatened release of a hazardous substance; requires DOE to enter into Interagency Agreements with EPA and State to control the cleanup of each DOE site on the NPL.
Nuclear Waste Policy Act of 1982	42 USC 10101–10270	Establishes a schedule for the siting, construction, and operation of geologic repositories that will provide a reasonable assurance that the public and the environment will be protected from the hazards posed by disposal of high-level radioactive waste and SNF; establishes the Federal responsibility and a Federal policy for the disposal of HLW and SNF; defines the relationship between Federal and State governments with respect to the disposal of HLW and SNF; and establishes a Nuclear Waste Fund.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders (Continued)

Statute, Regulation, Executive Order	Citation	Potential Requirements
Waste Management and Pollution Prevention (Continued)		
Pollution Prevention Act of 1990	42 USC 11001–11050	Establishes a national policy that pollution should be reduced at the source and requires a toxic chemical source reduction and recycling report for an owner or operator of a facility required to file an annual toxic chemical release form under section 313 of SARA.
Toxic Substances Control Act of 1976	15 USC 2601 et seq.	Requires compliance with inventory reporting and chemical control provisions of TSCA to protect the public from the risks of exposure to chemicals; TSCA imposes strict limitations on use and disposal of PCB-contaminated equipment.
Federal Facility Compliance Act of 1992	42 USC 6961	Waives sovereign immunity for Federal facilities under RCRA and requires DOE to develop plans and enter into agreements with States as to specific management actions for specific mixed waste streams.
Executive Order 12088, Federal Compliance with Pollution Control Standards	3 CFR 1978 Comp., p. 243	Requires Federal agency landlords to submit to OMB an annual plan for the control of environmental pollution and to consult with EPA and State agencies regarding the best techniques and methods.
Executive Order 12856, Federal Compliance with Right-To-Know Laws and Pollution Prevention Requirements	August 3, 1993	Requires Federal agencies to achieve 50 percent reduction of agency's total releases of toxic chemicals to the environment and offsite transfers, to prepare a written facility pollution prevention plan not later than 1995, and to publicly report toxic chemicals entering any waste stream from Federal facilities, including any releases to the environment, and to improve local emergency planning, response and accident notification.
Executive Order 12873, Federal Acquisition, Recycling, and Waste Prevention	October 20, 1993	Requires Federal agencies to develop affirmative procurement policies and establishes a shared responsibility between the system program manager and the recycling community to effect use of recycled items for procurement.
Executive Order 12580, Superfund Implementation	January 23, 1987	Delegates to the heads of Executive departments and agencies the responsibility for undertaking remedial actions for releases, or threatened releases that are not on the NPL and removal actions other than emergencies where the release is from any facility under the jurisdiction or control of Executive departments and agencies.
Biotic Resources		
Fish and Wildlife Coordination Act of 1958	16 USC 661 et seq.	Requires consultation on the possible effects on wildlife if there is construction, modification, or control of bodies of water in excess of 10 acres in surface area.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders (Continued)

Statute, Regulation, Executive Order	Citation	Potential Requirements
	Biotic Resources (Continued)	
Bald and Golden Eagle Protection Act of 1972	16 USC 668 et seq.	Requires consultations to determine if any protected birds are found to inhabit the area. If so, DOE must obtain a permit prior to moving any nests due to construction or operation of disposition facilities.
Migratory Bird Treaty Act of 1918	16 USC 703 et seq.	Requires consultation to determine if there are any impacts on migrating bird populations due to construction or operation of disposition facilities. If so, DOE will develop mitigation measures to avoid adverse effects.
Anadromous Fish Conservation Act of 1965	16 USC 757	Requires consultation to determine if there are any impacts on anadromous fish that spawn in fresh water or estuaries and migrate to ocean waters and on anadromous fishery resources that are subject to deplete from water resource development.
Wilderness Act of 1964	16 USC 1131 et seq.	Requires consultation with the Department of Commerce and the Department of Interior and minimize impact.
Wild Free-Roaming Horses and Burros Act of 1971	16 USC 1331 et seq.	Requires consultation with the Department of Interior and minimize impact.
Endangered Species Act of 1973	16 USC 1531 et seq.	Requires consultation to identify endangered or threatened species and their habitats, assess DOE impacts thereon, obtain necessary biological opinions and, if necessary, develop mitigation measures to reduce or eliminate adverse effects of construction or operation.
	Cultural Resources	
Antiquities Act of 1906	16 USC 431–433	Requires protection of historic, prehistoric, and paleontological objects in federal lands from appropriation, excavation, injury, and destruction without permission.
DOE American Indian Tribal Government Policy	DOE Order 1230.2	Establishes government-to-government protocols for DOE interactions with tribal governments.
National Historic Preservation Act of 1966	16 USC 470 et seq.	Requires consultation with the State Historic Preservation Office prior to construction to ensure that no historical properties will be affected.
Archaeological and Historical Preservation Act of 1974	16 USC 469 et seq.	Requires obtaining authorization for any disturbance of archaeological resources.
Archaeological Resources Protection Act of 1979	16 USC 470aa et seq.	Requires obtaining authorization for any excavation or removal of archaeological resources.
American Indian Religious Freedom Act of 1978	42 USC 1996	Requires consultation with local Native American Indian tribes prior to construction to ensure that their religious customs, traditions, and freedoms are preserved.
Native American Graves Protection and Repatriation Act of 1990	25 USC 3001	Requires consultation with local Native American Indian tribes prior to construction to guarantee that no Native American graves are disturbed.
Executive Order 13007, Indian Sacred Sites	May 24, 1996	Requires the protection and preservation of Native American religious practices.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders (Continued)

Statute, Regulation, Executive Order	Citation	Potential Requirements
	Cultural Resources (Continued)	
Executive Order 11593, Protection and Enhancement of the Cultural Environment	3 CFR 154, 1971–1975 Comp., p. 559	Requires the preservation of historic and archaeological data that may be lost during construction activities.
	Worker Safety and Health	
Occupational Safety and Health Act of 1970	5 USC 5108	Requires that agencies comply with all applicable worker safety and health legislation (including guidelines of 29 CFR 1960) and prepare, or have available, material safety data sheets.
Hazard Communication Standard	29 CFR 1910.1200	Ensures that workers are informed of, and trained to handle, all chemical hazards in the DOE workplace.
	Transportation	
Transportation regulations	49 CFR 171, 172, 173, 174, 176, 177, 397	Establishes standards for materials transportation including: packaging, marking and labeling, placarding, monitoring, routes, accident reporting, and manifesting. Includes requirements for transport by rail, air, and public highway.
Hazardous Materials Transportation Act of 1974	49 USC 1801 et seq.	Requires compliance with hazardous materials and waste transportation requirements.
Hazardous Materials Transportation Uniform Safety Act of 1990	49 USC 1801	Restricts shippers of highway route-controlled quantities of radioactive materials to use only permitted carriers.
Regulations of the International Atomic Energy Agency	IAEA Safety 6	Establishes standards for radioactive materials transportation.
International Maritime Organization Regulations	International Maritime Dangerous Goods Code, 1994	Requires segregation of radioactive materials packages from other dangerous goods and other aspects of stowage.
	Other	
Atomic Energy Act of 1954	42 USC 2011	Authorizes DOE to establish standards to protect health or minimize dangers to life or property for activities under DOE's jurisdiction.
Price Anderson Act	42 USC 2210	Allows DOE to indemnify its contractors if the contract involves the risk of public liability from a nuclear incident.
Nuclear Regulatory Commission	10 CFR 20, 70, 75	Establishes regulations for radioactive materials and the construction and operation of facilities that process and handle radioactive materials.
Department of Energy Orders	Parts 100–500	Establishes standards and requirements to ensure safe operation of facilities.
National Environmental Policy Act (NEPA)	42 USC 4321 et seq.	Requires Federal agency to prepare an environmental impact statement for any major Federal action with significant environmental impact.
Department of Energy NEPA Implementing Regulations	10 CFR 1021	Requires DOE to follow its own implementing regulations to ensure environmental quality.

Table 5–1. Federal Environmental Statutes, Regulations, and Executive Orders (Continued)

Statute, Regulation, Executive Order	Citation	Potential Requirements
	Other (Continued)	
Emergency Planning and Community Right-To-Know Act of 1986	42 USC 11001 et seq.	Requires the development of emergency response plans and reporting requirements for chemical spills and other emergency releases, and imposes right-to-know reporting requirements covering storage and use of chemicals that are reported on toxic chemical release forms.
Executive Order 11514, Protection and Enhancement of Environmental Quality	3 CFR 1966–1970 Comp., p. 902	Requires Federal agencies to demonstrate leadership in achieving the environmental quality goals of NEPA; provides for DOE consultation with appropriate Federal, State, and local agencies in carrying out their activities as they affect the environment.
Farmland Protection Policy Act of 1981	7 USC 4201 et seq.	Requires avoidance of any adverse effects to prime and unique farmlands.
Executive Order 12114, Environmental Affects Abroad of Major Federal Actions	January 4, 1979	Requires officials of Federal agencies having ultimate responsibility for authorizing and approving actions encompassed by this order to be informed of pertinent environmental considerations and to take such considerations into account, with other pertinent considerations of national policy in making decisions regarding such actions. While based on independent authority, this order furthers the purpose of NEPA.
Executive Order 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations	February 11, 1994	Requires Federal agencies to identify and address as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.
Executive Order 12656, Assignment of Emergency Preparedness Responsibilities	November 18, 1988	Assigns emergency preparedness responsibilities to Federal departments and agencies.

Table 5–2. State Environmental Statutes and Regulations

Legislation or Regulation	Citation	Potential Requirements
	HANFORD, WASHINGTON	
	Air Quality and Noise	
Washington Clean Air Act	Revised Code of Washington (RCW) Chapter 70.94	Provides for development of air pollution control and permitting regulations.
Washington Administrative Code of 1994	Title 173-400, 401, 406–490	Requires permitting of source, control of toxic air pollutants, radionuclides, and other pollutants.
Noise Control Act of 1974	RCW, Chapter 70.107	Provides for development of noise pollution control and permitting regulations.
Washington Administrative Code	Title 173-60	Establishes limits on environmental noise levels by zoning classifications.
	Water Resources	
Coastal Water Protection Act of 1971	RCW, Chapter 90.48	Requires water pollution control; applies to all waters of the State.
Chemical Contaminants and Water Quality	RCW, Chapter 70.142	Requires water pollution control.
Water Pollution Control Act	RCW, Chapter 90.48	Requires that a permit be obtained for any discharge to the soil column, and the quality of the groundwater in the vicinity be protected and not degraded
	Waste Management and Pollution Prevention	
Hazardous Waste Management Act	RCW, Chapter 70.105	Requires permits for various activities involving hazardous waste.
Nuclear Energy and Radiation	RCW, Chapter 70.98	Licenses and permits sources of radiation.
Radioactive Waste Storage and Transport Act of 1980	RCW, Chapter 70.99	Establishes various requirements for handling and storage of radioactive waste.
Radioactive Waste Act	RCW, Chapter 43.200	Establishes various requirements for handling and storage of radioactive waste.
	Biotic Resources	
Various Acts Concerning Fish and Game	RCW, Chapter 77	Requires consultation with responsible agency.
	Cultural Resources	
Archaeology and Historic Preservation	RCW, Chapter 43.51A	Required to follow rules designated to protect State cultural resources.
	Other	
Tri-Party Agreement	May 14, 1989	Establishes the applicability of RCRA and CERCLA and their amendments to Hanford. This is an agreement between DOE, EPA, and Washington State Department of Ecology.
	INEEL, IDAHO	
	Air Quality and Noise	
Idaho Environmental Protection and Health Act	ID Code, Title 39, Chapter 105, 107	Provides for development of air pollution control permitting regulations.

Table 5–2. State Environmental Statutes and Regulations (Continued)

Legislation or Regulation	Citation	Potential Requirements
	Air Quality and Noise (Continued)	
Rules for the Control of Air Pollution in Idaho	IDAPA 16, Title 1, Chapter 1, 000–729	Requires permitting of sources and control of toxic air pollutants and other pollutants.
	Water Resources	
Idaho Wastewater-Land Application Permit Regulations	ID Rules/Regs., Title 1, Chapter 17	Requires permit prior to construction or modification of a water discharge source.
Idaho Water Pollution Control Act	ID Code, Title 39, Chapter 36	Requires permit prior to construction or modification of a water discharge source.
Idaho Water Quality Standards	ID Rules/Regs., Title 1, Chapter 2	Requires permit prior to the construction or operation of a wastewater injection well.
Idaho Stream Channel Protection Act	ID Code, Title 42, Chapter 38	Requires permit prior to dredge or fill of any stream.
Idaho Lake Protection Act	ID Code, Section 58–142 et seq.	Requires permit prior to dredge or fill of any lake.
	Waste Management and Pollution Prevention	
Idaho Hazardous Waste Management Act	ID Code, Title 39, Chapter 44	Requires permit prior to construction or modification of a hazardous waste disposal facility.
Idaho Hazardous Waste Management Regulations	ID Rules/Regs., Title 1, Chapter 5	Requires permit prior to construction or modification of a hazardous waste disposal facility.
	Biotic Resources	
Various Acts Regarding Fish and Game	ID Code, Title 36	Requires consultation with responsible agency.
	Cultural Resources	
Idaho Historic Preservation Act	ID Code, Title 67, Chapter 46	Requires consultation with responsible local governing body.
	Other	
Spent Fuel Settlement Agreement (also known as the Batt Agreement)	October 16, 1995	Allows INEEL to receive spent nuclear fuel and establishes a schedule for removal of all spent fuel from the State.
Tribal Working Agreement	September 29, 1992	Requires consultation with Shoshone-Bannock tribes.
Federal Facility Agreement and Consent Order	December 9, 1991	Establishes a process for evaluating past potential releases to the environment at INEEL.
	PANTEX, TEXAS	
	Air Quality and Noise	
Texas Clean Air Act	382.017	Provides for the development of air pollution permitting regulations.
Texas Air Pollution Control Regulations	TX Admin Code, Title 30, Chapters 101–125	Requires permit prior to construction or modification of an air contaminant source and control of toxic air pollutants and other pollutants.
	Water Resources	
Texas Water Quality Standards	TX Admin. Code, Title 30, Chapters 305, 308–325	Requires permitting prior to any modification of waters of the State, including stream alteration for the construction of intakes, discharges, bridges, submarine utility crossings, etc. discharge source.
Texas Consolidated Permit Rules	TX Admin. Code, Title 30	Requires permit prior to construction or modification of a water discharge source.

Table 5–2. State Environmental Statutes and Regulations (Continued)

Legislation or Regulation	Citation	Potential Requirements
	Water Resources (Continued)	
Texas Water Quality Acts	TX Code, Title 30, Chapter 290	Requires permit prior to construction or modification of a water discharge source affecting a public water supply.
	Waste Management and Pollution Prevention	
Texas Solid Waste Management Regulations and Solid Waste Disposal Act	TX Admin. Code, Title 30, Chapters 305, 335; Statutes, Article 4477-7	Requires permit prior to construction or modification of a solid waste disposal facility.
	Biotic Resources	
Texas Parks and Wildlife Regulations	TX Parks and Wildlife Code, Chapters 67, 68, and 88	Requires permit by anyone who possesses, takes, or transports endangered, threatened, or protected plants or animals.
	Cultural Resources	
Antiquities Code of Texas	TX Natural Resource Code, Title 9, Chapter 191	Requires permit for the examination or excavation of sites and the collection or removal of objects of antiquity.
	SRS, South Carolina	
	Air Quality and Noise	
South Carolina Pollution Control Act	SC Code, Title 48, Chapter 1	Provides for the development of air pollution permitting regulations and air pollution control regulations.
South Carolina Air Pollution Control Regulations and Standards	Regulations 61 and 62	Requires permit prior to construction or modification of an air contaminant source and control of toxic air pollutants and other pollutants.
South Carolina Atomic Energy & Radiation Control Act	SC Code, Title 13, Chapter 7	Establishes standards for radioactive air emissions.
	Water Resources	
South Carolina Pollution Control Act	SC Code, Title 48, Chapter 1	Requires permit prior to construction or modification of a water discharge source.
South Carolina Water Quality Standards	SC Code, Title 61, Chapter 68	Requires permit required prior to construction or modification of a water discharge source.
South Carolina Safe Drinking Water Act	SC Code, Title 44, Chapter 55	Establishes drinking water standards.
	Waste Management and Pollution Prevention	
South Carolina Solid Waste Regulations	SC Code, Title 61, Chapter 60	Requires permit to store, collect, dispose, or transport solid wastes.
South Carolina Industrial Solid Waste Disposal Site Regulations	SC Code, Title 61, Chapter 66	Requires permit for industrial solid waste disposal systems.
South Carolina Hazardous Waste Management Act	SC Code, Title 44, Chapter 56	Requires permit to operate, construct, or modify a hazardous waste treatment, storage, or disposal facility.
South Carolina Solid Waste Management Act	SC Code, Title 44, Chapter 96	Establishes standards to treat, store, or dispose of solid waste.

Table 5–2. State Environmental Statutes and Regulations (Continued)

Legislation or Regulation	Citation	Potential Requirements
	Biotic Resources	
South Carolina Nongame and Endangered Species Conservation Act	SC Code, Title 50, Chapter 15	Requires consultation with Wildlife and Marine Resources Department and minimization of impact.
	Cultural Resources	
South Carolina Institute of Archaeology and Anthropology	SC Code, Title 60, Chapter 13-210	Requires consultation with State Historic Preservation Office and minimization of impact.

Table 5–3. Consultations

Basis for Consultation	Agency
Water Resources	
Wild and Scenic Rivers Act of 1968	USFWS, Bureau of Land Management, Forest Service, National Park Service
Biotic Resources	
Endangered Species Act of 1973	USFWS, National Marine Fisheries Service
Migratory Bird Treaty Act of 1918	USFWS
Bald and Golden Eagle Protection Act of 1972	USFWS
Fish and Wildlife Coordination Act of 1934	USFWS
Anadromous Fish Conservation Act of 1965	USFWS
Wilderness Act of 1964	Department of Commerce, Department of Interior
Wild Free-Roaming Horses and Burros Act of 1971	Department of Interior
Various Acts Concerning Fish and Game	Washington Department of Ecology
Various Acts Regarding Fish and Game	Idaho Department of Fish and Game
Texas Parks and Wildlife regulations	Texas Parks and Wildlife Department
South Carolina Nongame and Endangered Species Conservation Act	Wildlife and Marine Resources Department
Archaeological, Historical, and Cultural Resources	
National Historic Preservation Act of 1966	State Historic Preservation Office
American Indian Religious Freedom Act of 1978	Local Native American Indian Tribes
Native American Graves Protection and Repatriation Act of 1990	Local Native American Indian Tribes
Archaeology and Historic Preservation	Washington Office of Archaeology and Historic Preservation
Idaho Historic Preservation Act	Idaho Historic Preservation Commission
Tribal Working Agreement	Shoshone-Bannock Tribes
Antiquities Code of Texas	Texas State Historical Survey Committee
South Carolina Institute of Archaeology and Anthropology	State Historic Preservation Office

Key: USFWS, U.S. Fish and Wildlife Service.

Next Section

Chapter 6
Glossary

acute Extremely severe or intense for a limited time.

air pollutant Any substance borne through the air that can, in high enough concentrations, harm man, other animals, vegetation, or material.

Air Quality Control Region An area designated by a State or the U.S. Environmental Protection Agency for the attainment and maintenance of National Ambient Air Quality Standards.

ALARA See *as low as is reasonably achievable.*

alternative With reference to surplus plutonium disposition, a discrete sequence of disposition actions carried out in a dedicated group of facilities.

ambient air The atmosphere around people, plants, and structures.

Ambient Air Quality Standards Regulations prescribing the levels of airborne pollutants that may not be exceeded during a specified time in a defined area.

American Indian Religious Freedom Act of 1978 An act that protects and preserves for Native Americans their traditional religious rights, including the rights of access to religious sites, use and possession of sacred objects, and worship through traditional ceremonies and rites.

anadromous Migrating from salt water to fresh water to spawn.

Anadromous Fish Conservation Act An act seeking to enhance conservation and development of the anadromous fishery resources of the United States that are subject to depletion from water resources development.

aqueous process An operation involving chemicals dissolved in water.

aquifer A saturated geologic unit through which significant quantities of water can migrate under natural hydraulic gradients.

aquitard A less-permeable geologic unit in a stratigraphic sequence. Aquitards separate aquifers.

Archaeological Resources Protection Act of 1979 An act protecting cultural resources on federally owned lands. This act requires a permit for archaeological excavations or the removal of any archaeological resources on public or Native American lands. It also prohibits interstate or foreign trafficking in cultural resources taken in violation of State or local laws, and requires Federal agencies to develop plans for surveying lands under their control.

archaeological site Any location where humans have altered the terrain or discarded artifacts during prehistoric or historic times.

artifact An object produced or shaped by human beings and of archaeological or historical interest.

as low as is reasonably achievable An approach to radiation management and control by which exposures (individual and collective) of the workforce and the general public and releases of radioactive material to the environment are kept at levels as low as reasonable, taking into account social, technical, economic, practical, and public policy considerations.

Atomic Energy Act of 1954 An act setting up ". . . a program for Government control of the possession, use, and production of atomic energy and special nuclear material whether owned by the Government or others, so directed as to make the maximum contribution to the common defense and security and the national welfare, and to provide continued assurance of the Government's ability to enter into and enforce agreements with nations or groups of nations for the control of special nuclear materials and atomic weapons. . . ." (Section 3(c)).

attainment area An area considered to have air quality as good as or better than the National Ambient Air Quality Standards for a given pollutant. An area may be in attainment for one pollutant and nonattaining for others. See also *nonattainment area.*

background radiation Ionizing radiation present in the environment emanating from cosmic rays and natural sources in the Earth. Such radiation varies considerably with location.

badged (worker) A worker susceptible to exposure to radiation and thus equipped with an individual dosimeter.

Bald and Golden Eagle Protection Act An act making it unlawful to take, pursue, molest, or disturb the American bald eagle and golden eagle, their nests, or their eggs, anywhere in the United States.

basalt The most common volcanic rock, dark-gray to black in color, high in iron and magnesium, and low in silica. It is typically found in lava flows.

baseline A quantitative expression of conditions, costs, schedule, or technical progress that constitutes the standard against which to measure the performance of an effort.

basin Geologically, a circular or elliptical downwarp in whose center younger beds occur; topographically, a depression into which water from the surrounding area drains.

BEIR V A designation for the fifth in a series of committee reports from the National Research Council's Committee on the Biological Effects of Ionizing Radiation.

benthic Dwelling at the bottom of oceans, lakes, rivers, and other surface waters.

beyond-design-basis accident An accident generally with more severe impacts on onsite personnel and the public than a design basis accident, and an estimated probability of occurrence of less than 10^{-6} per year. This accident is used for estimating the impacts of a facility or process. See also *design basis accident.*

boiling water reactor A type of nuclear reactor in which fission heat is used to generate steam in the reactor to drive turbines and generate electricity.

calcareous Containing calcium carbonate (as, for example, calcite or limestone).

cancer The name given to a group of diseases characterized by uncontrolled cellular growth, with the cells having invasive characteristics such that the disease can be transferred from one organ to another.

Canadian Deuterium Uranium Reactor A Canadian nuclear reactor in which circulating heavy water (deuterium-rich water) is used to cool the reactor core and to moderate (reduce the energy of) the neutrons created in the core by the fission reactions.

can-in-canister An approach to plutonium immobilization wherein cans of either ceramic or glass forms containing plutonium are encapsulated within canisters of high-level-waste glass.

canyon A remotely operated, heavily shielded plutonium- or uranium-processing facility. A deep, steep-sided valley.

capable fault As defined in 10 CFR 100, Appendix A, III (g), "a fault which has exhibited one or more of the following characteristics: (1) movement at or near the ground surface at least once within the past 35,000 years or movement of a recurring nature within the past 500,000 years; (2) macro-seismicity instrumentally determined with records of sufficient precision to demonstrate a direct relationship with the fault; and (3) a structural relationship to a capable fault according to characteristics (1) or (2) . . . such that movement on one could be reasonably expected to be accompanied by movement on the other. Notwithstanding the foregoing . . . , structural association of a fault with geologic structural features which are geologically old (at least pre-Quarternary) . . . shall, in the absence of conflicting evidence, demonstrate that the fault is not a capable fault."

carbon dioxide A colorless, odorless, nonpoisonous gas that is a normal component of the ambient air and an expiration product of normal animal life.

carbon monoxide A colorless, odorless gas that is toxic if breathed in high concentrations over an extended period.

cask (for radioactive materials) A container that meets all applicable regulatory requirements for shipping spent nuclear fuel or high-level waste.

Cenozoic A geologic era dating from 65 million years ago to the present and characterized by the dominance of advanced mollusks and mammals.

ceramic Surplus plutonium and other materials mixed to form a porcelain end product.

cesium A silver-white alkali metal. A radioactive isotope of cesium, cesium 137, is a common fission product.

chronic Lasting for a long period or marked by frequent recurrence.

chronic exposure Low-level radiation exposure incurred over a long period due to residual contamination.

cladding An external layer of material applied directly to nuclear fuel or other material to provide protection from a chemically reactive environment, containment of radioactive products produced during irradiation of the composite, or structural support.

Clean Air Act An act mandating and providing for the enforcement of regulations to control air pollution from various sources.

Code of Federal Regulations A publication in codified form of all Federal regulations in force.

coliform bacteria The normally harmless bacteria that reside in the intestinal tract of human beings and other animals whose presence in water is an indicator that the water may be contaminated with untreated human and animal waste.

committed effective dose equivalent The predicted total effective dose equivalent to a tissue or organ over a 50-year period after the intake of a radionuclide into the body, exclusive of external dose contributions. The committed effective dose equivalent is the sum of the committed dose equivalents to the various tissues of the body, each multiplied by the appropriate weighting factor. It is expressed in units of rem or sievert.

Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (Superfund) An act providing the regulatory framework for the remediation of past contamination from hazardous waste. If a site meets the act's requirements for designation, it is ranked along with other Superfund sites on the National Priorities List. This ranking is the U.S. Environmental Protection Agency's way of determining the priority of sites for cleanup.

conceptual design Efforts to develop a project scope that will meet stipulated program needs; ensure project feasibility and attainable performance goals; develop project criteria and design parameters for all concerned engineering disciplines; and identify applicable codes and standards, quality assurance requirements, environmental studies, construction materials, space allowances, energy conservation features, health and safety safeguards, security requirements, and any essential features of the project.

confined aquifer A permeable geologic unit bounded above and below by aquitards and containing water at a pressure higher than atmospheric pressure.

conformity As defined in the Clean Air Act, "the nation's compliance with an implementation plan's purpose of eliminating or reducing the severity and number of violations of the National Ambient Air Quality Standards and achieving expeditious attainment of such standards. Activities in conformity will not (1) cause or contribute to any new violation of any standard in any area, (2) increase the frequency or severity of any existing violation of any standard in any area, or (3) delay timely attainment of any standard or any required interim emission reduction or other milestones in any area."

container The primary containment designed to meet the requirements of 10 CFR 60.

conversion An operation for changing material from one form, use, or purpose to another.

cosmic radiation Streams of highly penetrating, charged particles composed of protons, alpha particles, and a few heavier nuclei that bombard the earth from outer space.

credible accident An accident that has a probability of occurrence greater than or equal to one in a million years.

Cretaceous The geologic period making up the end of the Mesozoic era, dating from approximately 144 million to 66 million years ago.

criteria pollutants Common, widespread pollutants for which air quality standards have been established in accordance with the Clean Air Act. The U.S. Environmental Protection Agency developed these standards on the basis of its research into scientific knowledge about their health effects. Today, standards are in effect for six criteria pollutants: sulfur dioxide, carbon monoxide, particulate matter with aerodynamic diameters of less than or equal to 10 microns and less than or equal to 2.5 microns, nitrogen dioxide, ozone, and lead.

critical habitat As defined in the Endangered Species Act of 1973, "specific areas within the geographical area occupied by [an endangered or threatened] species . . . , essential to the conservation of the species and which may require special management considerations or protection; and specific areas outside the geographical area occupied by the species . . . that are essential for the conservation of the species."

criticality A state in which a self-sustaining nuclear chain reaction is achieved.

cultural resources Archaeological sites, architectural features, traditional-use areas, and Native American sacred sites.

cumulative impacts The incremental impact on the environment of an action in combination with other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal), private industry, or individual undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7.)

curie A unit of radioactivity equal to 37 billion disintegrations per second; also a quantity of any nuclide or mixture of nuclides having 1 curie of radioactivity.

deactivation A process for removing hazardous and radioactive materials and placing a facility in a safe and stable condition.

decay (radioactive) The decrease in the amount of any radioactive material with the passage of time, due to the spontaneous transformation of an unstable nuclide into a different nuclide or into a different energy state of the same nuclide. The emission of nuclear radiation (alpha, beta, or gamma) is part of the process.

day-night average sound level The 24-hour, A-weighted equivalent sound level expressed in decibels. A 10-decibel penalty is added to sound levels between 10:00 p.m. and 7:00 a.m. to account for increased annoyance due to noise during night hours.

decibel A logarithmic unit of sound measurement that describes the magnitude or particular quantity of sound pressure or power with respect to a standard reference value. In general, a sound doubles in loudness with every increase of 10 decibels.

decibel, A-weighted A unit of sound measurement that incorporates a metering characteristic and the "A" weighting specified by the the American National Standards Institute in S1.4–1983(R1994) to account for the frequency response of the human ear.

decommissioning Actions taken at the end of life of facility to make it suitable for reuse, including surveillance, maintenance, decontamination, and/or dismantlement.

decontamination The removal of radioactive or chemical contamination from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

depleted uranium Uranium whose content of the isotope uranium 235 is less than 0.7 percent, which is the uranium 235 content of naturally occurring uranium.

deposition In geology, the laying down of potential rock-forming materials—that is, sedimentation; in atmospheric transport, the settling out on ground and building surfaces of atmospheric aerosols and particles ("dry deposition") or their removal from the air to the ground by precipitation ("wet deposition" or "rainout").

derived concentration guide The concentration of a radionuclide in air or water which, under conditions of continuous exposure by one exposure mode (that is, ingestion of water or submersion in or inhalation of air) for 1 year, could cause a "reference man" to receive the more restrictive of two doses of that radionuclide: (1) an effective dose equivalent of 100 mrem, or (2) a dose equivalent of 5 rem to any tissues, including skin and the lens of the eye.

design basis For nuclear facilities, information that identifies the specific functions to be performed by a structure, system, or component and the specific values (or ranges of values) chosen as reference bounds for design. These values may reflect: (1) restraints derived from generally accepted, state-of-the-art practices for achieving functional goals; (2) requirements derived from analysis (calculation or experiment) of the effects of a postulated accident for which a structure, system, or component must meet its functional goals; or (3) requirements derived from Federal safety objectives, principles, goals, or requirements.

design basis accident For nuclear facilities, a postulated abnormal event used to establish the performance requirements of structures, systems, and components that are necessary to keep the facility in a safe shutdown condition indefinitely, or to prevent or mitigate the consequences of such an event, so as to ensure that the public and operating staff are not exposed to radiation in excess of appropriate guideline values. See also *beyond-design-basis accident.*

dewatering The removal of water. Saturated soils are "dewatered" to make construction of building foundations easier.

direct jobs The number of workers required at a site to implement an alternative.

dismantlement The process of taking apart a nuclear warhead and removing the subassemblies, components, and individual parts.

disposal The process of placing waste in a final repository.

disposition A process of use or disposal of materials that results in the remaining material being converted to a form that is substantially and inherently more proliferation resistant than the original form.

dissolution The chemical dispersal (dissolving) of a solid throughout a liquid medium.

dolomite A mineral composed of calcium magnesium carbonate; the chief constituent of the rock commonly called dolomite and of some kinds of marble.

dose The energy imparted to matter by ionizing radiation. The term encompasses absorbed dose, measurable in units of rem or gray, as well as dose equivalent, effective dose equivalent, committed dose equivalent, committed effective dose equivalent, and total dose equivalent, all measurable in rem or sievert (1 rem = 0.01 sievert).

dose commitment The dose an organ or tissue would receive during a specified period of time (for example, 50 to 100 years) as a result of intake (by ingestion or inhalation) of one or more radionuclides from a defined release, frequently over a year's time.

dose equivalent The product of the absorbed dose in rad or gray, the effect of this type of radiation on tissue, and a quality factor. Dose equivalent is expressed in units of rem or sievert, where 1 rem equals 0.01 sievert. The dose equivalent delivered to an organ, tissue, or the whole body will be the dose received from direct

exposure plus the 50-year committed dose equivalent received from the radionuclides taken into the body during a year.

drainage basin An aboveground area of the Earth's surface that supplies the water to a particular stream.

drawdown The height difference between the natural water level in an aquifer and the lower level caused by the withdrawal of groundwater.

drinking water standards The level of constituents or characteristics in a drinking water supply that cannot be exceeded legally.

ecology The study of the interrelationships of organisms and their environment.

ecosystem The biotic and abiotic components of a particular area (for example, a pond, a forest).

effective dose equivalent The summation of the products of the dose equivalent received by specified tissues of the body and a tissue-specific weighting factor. This sum is a risk-equivalent value that can be used to estimate the risk of health effects to the exposed individual. The tissue-specific weighting factor represents the fraction of the total health risk resulting from uniform whole-body irradiation that would be contributed by that particular tissue. The effective dose equivalent includes the committed effective dose equivalent from the internal deposition of radionuclides and the effective dose equivalent due to penetrating radiation from sources external to the body. It is expressed in units of rem or sievert.

effluent A gas or fluid discharged into the environment.

emission standards Legally enforceable limits on the quantities and kinds of air contaminants that can be emitted into the atmosphere.

endangered species As defined in the Endangered Species Act of 1973, "any species which is in danger of extinction throughout all or a significant part of its ranges."

Endangered Species Act of 1973 An act requiring Federal agencies, with the consultation and assistance of the Secretaries of the Interior and Commerce, to ensure that their actions will not likely jeopardize the continued existence of any endangered or threatened species or adversely affect the habitat of such species.

environment, safety, and health program A program encompassing those DOE requirements, activities, and functions in the conduct of all DOE and DOE-controlled operations concerned with: impacts on the biosphere; compliance with environmental laws, regulations, and standards controlling air, water, and soil pollution; reduction of risks to the well-being of both operating personnel and the general public to acceptably low levels; and adequate protection of property against accidental loss and damage. Typical activities and functions related to this program include, but are not limited to, environmental protection, occupational safety, fire protection, industrial hygiene, health physics, occupational medicine, process and facilities safety, nuclear safety, emergency preparedness, quality assurance, and radioactive and hazardous waste management.

environmental assessment A written environmental analysis prepared pursuant to the National Environmental Policy Act to determine whether a Federal action would significantly affect the environment and thus require preparation of a more detailed environmental impact statement. If the action does not significantly affect the environment, then a Finding of No Significant Impact is prepared.

environmental documentation Documents describing information and results of studies and evaluations required by the National Environmental Policy Act. This documentation includes a categorical exclusion, an environmental assessment, and an environmental impact statement.

environmental impact statement A document required of Federal agencies by the National Environmental Policy Act for major proposals or legislation that will or could significantly affect the environment. A tool for decisionmaking, it describes the positive and negative effects of the proposed and alternative actions.

environmental justice The fair treatment of people of all races, cultures, incomes, and educational levels with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment implies that no population of people should be forced to shoulder a disproportionate share of the negative environmental impacts of pollution or environmental hazards due to a lack of political or economic strength.

Eocene A geologic epoch early in the Cenozoic era, dating from approximately 54 to 38 million years ago.

ephemeral stream A stream that flows intermittently, typically only after periods of heavy precipitation.

epicenter The point on the Earth's surface directly above the focus of an earthquake.

equivalent sound (pressure) level The equivalent, steady sound level that, if continuous during a specified time period, would contain the same total energy as the actual time-varying sound. L_{eq} (1-h) and L_{eq} (24-h) are the 1-hour and 24-hour equivalent sound levels, respectively.

Farmland Protection Policy Act An act whose purpose is to reduce the conversion of farmland to nonagricultural uses as a result of Federal projects and programs. The Act requires that Federal agencies comply to the fullest extent possible with State and local government policies to preserve farmland. It includes a recommendation that evaluations and analyses of prospective farmland conversion impacts be made early in the planning process—before a site or design is selected—and that, where possible, agencies make such evaluations and analyses part of the National Environmental Policy Act process.

fault A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred. A normal fault occurs when the hanging wall has been depressed in relation to the footwall. A reverse fault occurs when the hanging wall has been raised in relation to the footwall. A thrust fault is a low-angle (dip less than about 30 degrees) reverse fault.

fauna Animals, especially those of a specific region, considered as a group. See also *flora.*

Finding of No Significant Impact A document from a Federal agency briefly presenting the reasons why an action, not otherwise excluded, will not have a significant effect on the human environment and will not require an environmental impact statement.

fissile A term referring to nuclear materials that are fissionable by slow (thermal) neutrons. Fissile materials include uranium 233 and 235 and plutonium 239. Materials such as uranium 238 and thorium 232, which can be converted into fissile materials, are called fertile materials. Thorium 232, uranium 238, and all plutonium isotopes are fissionable by fast but not slow neutrons; that is, they are fissionable but not fissile.

fission The splitting of a heavy atomic nucleus into at least two nuclei of lighter elements, accompanied by the release of energy and generally one or more neutrons. Fission can occur spontaneously or be induced by neutron bombardment.

fission products Nuclei formed by the fission or decay of heavy elements (primary fission products), many of which are radioactive.

fissionable material Material whose nuclei fission when bombarded by neutrons.

floodplain The lowlands adjoining inland and coastal waters and relatively flat areas, including, at a minimum, that area inundated by a 1-percent or greater-chance flood in any given year. The base floodplain is defined as the 100-year (1.0 percent) floodplain; the critical action floodplain, as the 500-year (0.2 percent) floodplain.

flora Plants, especially those of a specific region, considered as a group. See also *fauna.*

formation In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

fossil An impression or trace of an animal or plant of past geologic ages that has been preserved in the Earth's crust.

frit Finely ground glass used as feedstock for vitrification.

fugitive emissions Emissions to the atmosphere from pumps, valves, flanges, seals, and other process points not vented through a stack. Also included are emissions from area sources such as ponds, lagoons, landfills, piles of stored material, and exposed soil.

geologic repository (mined geologic repository) A repository meeting the specifications of the Nuclear Waste Policy Act, as amended, for the disposal of high-level nuclear waste and spent nuclear fuel. The waste is isolated by placement in a continuous, stable geologic formation at depths greater than 300 meters (984 feet).

geology The science that deals with the study of the materials, processes, environments, and history of the Earth, including the rocks and their formation and structure.

glass An amorphous material formed by the melting of silica.

glovebox An airtight box used to work with hazardous material. It is vented to a closed filtering system, and has gloves attached inside to protect the worker.

groundwater The supply of water found beneath the Earth's surface, usually in aquifers, which may supply wells and springs.

half-life (radiological) The time in which half the atoms of a radioactive substance decay to another nuclear form, varying for different radioisotopes from millionths of a second to billions of years.

hazardous material A material, including a hazardous substance as defined by 49 CFR 171.8, that poses a risk to health, safety, and property when transported or handled.

hazardous waste According to the Resource Conservation and Recovery Act, a solid waste that because of its characteristics may (1) cause or significantly contribute to an increase in mortality or an increase in serious irreversible or incapacitating reversible illness, or (2) pose a substantial hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed. Hazardous wastes appear on special U.S. Environmental Protection Agency lists and possess at least one of the following

characteristics: (1) ignitability, (2) corrosivity, (3) reactivity, or (4) toxicity. The term does not include source, special nuclear, or by-product material as defined by the Atomic Energy Act.

hazardous/toxic air pollutants Air pollutants known or suspected to cause serious health problems such as cancer, poisoning, or sickness, and possibly having immunological, neurological, reproductive, developmental, or respiratory effects.

high-efficiency particulate air filter A filter used to remove particulates from dry, gaseous effluent streams.

high-level waste The highly radioactive waste material that results from the reprocessing of spent nuclear fuel, including liquid waste produced directly in reprocessing and any solid waste derived from the liquid. Such waste contains a combination of transuranic elements and fission products in concentrations requiring permanent isolation.

highly enriched uranium Uranium enriched in the isotope uranium 235 to 20 percent or above, which thus becomes suitable for weapons use.

historic resources Archaeological sites, architectural structures, and objects dating from 1492 or later, after the arrival of the first Europeans to the Americas.

homogenous A term describing an approach to the immobilization of plutonium and other fission products (for example, high-level-waste glass) wherein such products are blended uniformly as a single waste form.

immobilization A process by which plutonium is converted to a chemically stable form for disposal.

incident-free risk The radiological or chemical impacts of packages aboard vehicles in normal transport. This includes the radiation or hazardous chemical exposure of specific population groups such as crew, passengers, and bystanders.

indirect jobs Jobs generated or lost in related industries within a regional economic area as a result of a change in direct employment.

infrastructure The basic facilities, services, and utilities needed for the functioning of an industrial facility or DOE site. Transportation and electrical systems are part of the infrastructure.

interbedded Occurring between beds (layers) or lying in a bed parallel to other beds of a different material.

interfluvial Occurring in the land area between two streams.

interim (permit) status Period during which treatment, storage, and disposal facilities subject to the Resource Conservation and Recovery Act are temporarily permitted to operate while awaiting the issuance or denial of a permanent permit.

interim storage Safe, secure storage supportive of continuing operations until long-term storage or disposition actions are implemented.

invertebrate An animal without vertebrae (a backbone).

ion exchange A physiochemical process that removes anions and cations, including radionuclides, from liquid streams (usually water) for the purpose of purification or decontamination.

ionizing radiation Radiation that can displace electrons from atoms or molecules, thereby producing ions.

isotope An atom of an element with a specific atomic number and atomic mass. Isotopes of the same element have the same number of protons (atomic number) but different numbers of neutrons (mass number).

land resources All of the terrestrial areas available for economic production, residential or recreational use, Government activities (such as military bases), or natural resources consumption. The patterns and densities of land use and the quality of visual resources are included in evaluations of land resources.

land use A characterization of land surface in terms of its potential utility for various activities.

landscape character The variety and intensity of the landscape features (land, water, vegetation, and structures) and the four basic elements (form, line, color, and texture) that distinguish an area from its immediate surroundings.

large release A release of radioactive material that would result in doses greater than 25 rem to the whole body or 300 rem to the thyroid at 1.6 kilometers (1 mile) from the control perimeter (security fence) of a facility.

latent fatalities Fatalities that occur within 30 years of acute and chronic environmental exposures to chemicals or radiation.

light water The common form of water: a molecule with two hydrogen atoms and one oxygen atom in which the hydrogen atom consists largely or completely of the normal hydrogen isotope (one proton).

light water reactor Either of two types of thermal reactors, a pressurized water reactor or a boiling water reactor, in which circulating light water is used to cool the reactor core and to moderate (reduce the energy of) the neutrons created in the core by the fission reactions. All commercially operating reactors in the United States and most commercial reactors worldwide are of this type.

low-enriched uranium Uranium enriched in the isotopic content of uranium 235 (greater than 0.7 percent but less than 20 percent of the total mass) for use as light water reactor fuel. Naturally occurring uranium contains only about 0.7 percent uranium 235, and almost all the rest is uranium 238.

low-level waste Waste that contains radioactivity and is not classified as high-level waste, transuranic waste, or spent nuclear fuel, or the tailings of wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Test specimens of fissionable materials irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the concentration of transuranics is less than 100 nanocuries per gram of waste.

mandatory standards Standards adopted by DOE that define the minimum requirements with which DOE and its contractors must comply. Standards may be classified as mandatory because of applicable Federal or State statutes or implementing requirements, or as a matter of DOE policy.

marsh An area of low-lying wetland dominated by grasslike plants.

maximally exposed individual A person who, hypothetically, could receive the maximum dose of radiation or hazardous chemicals.

megawatt A unit of power equal to 1 million watts. Megawatt-thermal is commonly used to define heat produced, while megawatt-electric defines electricity produced.

meteorology The science dealing with the atmosphere and its phenomena, especially as relating to weather.

migration The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

Migratory Bird Treaty Act An act making it unlawful, except in connection with permitted activities, to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird.

Miocene A geologic epoch of the Cenozoic era dating from 26 to 7 million years ago.

Mississippian (geologic) A period of the Paleozoic era in North America dating from 360 to 330 million years ago (following the Devonian period and preceding the Pennsylvanian period).

mitigation A series of actions implemented to ensure that projected impacts will result in no net loss of habitat value or wildlife populations. The purpose of these actions is to avoid, minimize, rectify, or compensate for any adverse environmental impact.

mixed low-level waste Low-level waste that contains hazardous components regulated under the Resource Conservation and Recovery Act.

mixed oxide A physical blend of uranium oxide and plutonium oxide.

mixed transuranic waste Transuranic waste that also contains hazardous components regulated under the Resource Conservation and Recovery Act.

mixed waste Waste that contains both hazardous and radioactive components.

Modified Mercalli Intensity A level of the perceived intensity of earthquake ground shaking on the modified Mercalli scale. The scale is a unitless expression of observed effects with 12 divisions, from I (not felt by people) to XII (nearly total damage).

National Ambient Air Quality Standards Air quality standards established by the U.S. Environmental Protection Agency for certain widespread "criteria" pollutants in accordance with the Clean Air Act, as amended. The "primary" standards are intended to protect the public health with an adequate margin of safety; the "secondary" standards, to protect the public welfare, including plant and animal life, visibility, and materials, from any known or anticipated adverse effects of a pollutant.

National Emission Standards for Hazardous Air Pollutants A set of national standards governing the emission of listed hazardous pollutants from specific classes or categories of new and existing sources.

National Environmental Policy Act of 1969 An act constituting the basic national charter for protection of the environment. The act calls for the preparation of an environmental impact statement for every major Federal action that may significantly affect the quality of the human or natural environment. Its main purpose is to provide environmental information to decisionmakers so that their actions are based on an understanding of the potential environmental consequences of a proposed action and the reasonable alternatives.

National Environmental Research Park An outdoor laboratory set aside for research into the environmental impacts of energy developments. Such parks were established by DOE to provide protected land areas for research and education in the environmental sciences and to demonstrate the environmental compatibility of energy technology development and use.

National Historic Preservation Act of 1966, as amended An act providing that property resources with significant national historic value be placed on the National Register of Historic Places. It does not require permits; rather, it mandates consultation with the proper agencies whenever it is determined that a proposed action might impact a historic property.

National Pollutant Discharge Elimination System A Federal permitting system controlling the discharge of effluents to surface waters of the United States and regulated through the Clean Water Act, as amended.

National Register of Historic Places A list of districts, sites, buildings, structures, and objects of prehistoric or historic local, State, or national significance. The list, maintained by the Secretary of the Interior, is expanded as authorized by Section 2(b) of the Historic Sites Act of 1935 (16 U.S.C. 462) and Section 101(a)(1)(A) of the National Historic Preservation Act of 1966, as amended.

Native American Graves and Repatriation Act of 1990 An act established to protect Native American graves and associated funerary objects. This act requires Federal agencies and museums to inventory human remains and associated funerary objects, to provide culturally affiliated tribes with the documented results of that inventory, and to return, on request, items in the inventory to the culturally affiliated tribes.

natural uranium Uranium in its pre-enriched state, having a uranium 235 concentration of approximately 0.7 percent.

nitrogen oxides The oxides of nitrogen, primarily nitrogen oxide and nitrogen dioxide, produced in the combustion of fossil fuels. Nitrogen dioxide emissions constitute an air pollution problem, as they contribute to acid deposition and the formation of atmospheric ozone.

noise Any sound that is undesirable because it interferes with speech and hearing, is intense enough to damage hearing, or is otherwise annoying (unwanted sound).

Noise Control Act of 1972 An act directing all Federal agencies to carry out programs in a manner that furthers the national policy of promoting an environment free from noise that jeopardizes health or welfare.

nonattainment area The U.S. Environmental Protection Agency's designation for an air quality control region (or portion thereof) in which ambient air concentrations of one or more "criteria" pollutants exceed National Ambient Air Quality Standards.

nonproliferation Preventing the spread of nuclear weapons, nuclear weapons materials, and nuclear weapons technology.

Nonproliferation Treaty A treaty aimed at controlling the spread of nuclear weapons technologies, limiting the number of nuclear weapons states, and pursuing, in good faith, effective measures relating to cessation of the nuclear arms race. The treaty does not invoke stockpile reductions by nuclear states, nor does it address actions of nuclear states relative to stockpile maintenance.

Notice of Intent A notice that an environmental impact statement will be prepared and considered. Prepared in accordance with 40 CFR 1508.22, the Notice of Intent describes the proposed action the agency is

considering, provides information on issues and potential impacts, and invites comments and suggestions on the scope of the environmental impact statement.

nuclear criticality See *criticality*.

nuclear facility A facility whose operations involve radioactive materials in such form and quantity as to pose a hazard to the employees or the public. Included are facilities that produce, process, or store radioactive liquid or solid waste, fissionable materials, or tritium; conduct separations operations; conduct irradiated materials inspection, fuel fabrication, decontamination, or recovery operations; or conduct fuel enrichment operations. Incidental operational use of radioactive materials (for example, as check sources, as radioactive sources, in x-ray machines) does not necessarily qualify that facility for designation as nuclear.

nuclear material A term encompassing (1) special nuclear material; (2) source material such as uranium or thorium or ores containing uranium or thorium; and (3) by-product material, which is any radioactive material made radioactive by exposure to the radiation incident to the process of producing or using special nuclear material.

nuclear power plant A facility that converts nuclear energy into electric power. Heat produced in a nuclear reactor is used to make steam, which drives a turbine connected to an electric generator.

nuclear reactor A device in which a fission chain reaction is maintained for the purpose of irradiating materials or producing heat for the generation of electricity.

nuclear weapon The general name given to any weapon in which the explosion results from the energy released by reactions (fission, fusion, or both) of atomic nuclei.

outfall The discharge point of a drain, sewer, or pipe into a body of water.

oxidation The combination of an element with oxygen wherein the element's atoms lose electrons and its positive charge (that is, valence) is correspondingly increased.

oxide A compound formed when an element (for example, plutonium) is bonded to oxygen.

ozone The triatomic form of oxygen that in the stratosphere protects the Earth from the Sun's ultraviolet rays, but at lower atmospheric levels is an air pollutant. Ozone is a major constituent of smog.

packaging For radioactive materials, a container consisting of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shock—all to ensure compliance with regulations of the U.S. Department of Transportation.

paleontology The study of plant and animal life that existed in former geologic times, particularly through the analysis of fossils.

Paleozoic The longest era of geologic time, dating from 570 million to 245 million years ago. Seed-bearing plants, amphibians, and reptiles first appeared in the Paleozoic era.

particulate matter Air pollutants, including dust, dirt, soot, smoke, and liquid droplets. Total suspended particulates were first used as the indicator of particulate concentrations. Current indicators are PM_{10} and $PM_{2.5}$ (PM for "particulate matter"), which include only those particles with aerodynamic diameters smaller

than or equal to 10 and 2.5 micrometers, respectively. The smaller particles are more responsible for adverse health effects because they penetrate farther into the respiratory tract.

perched groundwater A body of groundwater of small lateral dimensions separated from an underlying body of groundwater by an unsaturated zone.

person-rem The unit of the collective radiation dose commitment of a given population; the sum of the individual doses received by a population segment.

pH A numeric value that indicates the relative acidity or alkalinity of a substance on a scale of 0 to 14, with the neutral point at 7.0. Acid solutions have pH values lower than 7.0; basic (alkaline) solutions, values higher than 7.0.

phytoplankton Aquatic, free-floating, microscopic, photosynthetic organisms.

pit The core element of a nuclear weapon's "primary" or fission component.

pit cladding The material that encapsulates a pit, forming a hermetic seal around it.

playa A dry lake bed in a desert basin or a closed depression that seasonally contains water.

Pleistocene The geologic time of the earliest epoch of the Quaternary period, occurring approximately 11,000 to 2 million years ago and characterized by a succession of northern glaciations and the appearance of human beings.

Pliocene The geologic time of the latest epoch of the Tertiary period, occurring approximately 7 million to 2 million years ago and characterized by the appearance of distinctly modern animals.

plume The elongated pattern of contaminated air or water originating at a point source such as a smokestack or a hazardous waste disposal site.

plutonium A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially in a reactor by the bombardment of uranium with neutrons and is used in the production of nuclear weapons. Plutonium has 15 isotopes with mass numbers ranging from 232 to 246. Weapons-usable plutonium consists mainly of plutonium 239, which has a radiological half-life of 24,110 years. See also *half-life (radiological).*

potable water Water that is fit to drink.

pounds per square inch A measure of pressure. Atmospheric pressure is about 14.7 pounds per square inch.

power reactor–grade material Plutonium and highly enriched uranium in any of various forms (for example, metals, oxides) that can be used in commercial nuclear power reactors. Power reactor–grade plutonium contains plutonium 240 in concentrations higher than 19 percent.

precipitate To cause a solid substance to become separate from a solution.

prehistoric Predating written history; in North America, also predating contact with Europeans.

pressurized water reactor A nuclear power reactor that uses water under pressure as a coolant. The water boiled to generate steam is in a separate (secondary) system.

prevention of significant deterioration The designation for regulations established by the Clean Air Act to limit increases in "criteria" air pollutant concentrations above the baseline; also, actions consistent with those regulations.

Prevention of Significant Deterioration Class I, II, and III Areas A Clean Air Act classification of clean air areas in terms of the levels of increased pollution allowed. Very little increase in pollution is allowed in Class I areas, and progressively more in Classes II and III. National parks and wilderness areas receive mandatory Class I protection; all other areas start out as Class II. States can reclassify Class II areas up or down, subject to Federal requirements.

prime farmland Land with the best combination of physical and chemical characteristics (soil quality, growing season, and moisture supply) for economically producing high yields of food, feed, forage, fiber, and oilseed crops, with minimum inputs of fuel, fertilizer, pesticides, and labor without intolerable soil erosion (Farmland Protection Policy Act of 1981, 7 CFR 7, paragraph 658). Land classified as prime farmland includes cropland, pastureland, rangeland, and forest land, but not urban or built-up land or land covered with water. Prime farmlands are designated by the Soil Conservation Service.

probabilistic risk assessment A comprehensive, logical, and structured method for identifying and quantitatively evaluating the sequences and consequences of hypothetical accidents.

probable maximum flood Flood levels predicted for hydrological conditions that maximize the flow of surface waters.

process The act of extracting, separating, or purifying a substance by physical or chemical means.

programmatic environmental impact statement A document that evaluates the environmental impacts of Federal programs potentially affecting one or more sites. The document is prepared in accordance with Section 102(2)(C) of the National Environmental Policy Act.

proliferation The spread of nuclear, biological, and chemical capabilities and the weapons (for example, missiles) capable of delivering them.

protected area An area designated for the protection of material assets and typically encompassed by physical barriers, subject to access controls, surrounding material access areas, and meeting the standards of DOE 5632.1C, *Protection and Control of Safeguards and Security Interests.*

Quaternary The second geologic period of the Cenozoic era, lasting from 2 million years ago to the present and characterized by the appearance of human beings.

rad See *radiation absorbed dose.*

radiation The emitted particles or photons from the nuclei of radioactive atoms. Some elements are naturally radioactive; others are induced to become radioactive by bombardment in a reactor. Naturally occurring radiation is indistinguishable from induced radiation.

radiation absorbed dose The basic unit of absorbed radiation, equivalent to 0.01 joule per kilogram of absorbing material.

radioactive accident risk As described in the *Final Environmental Statement on the Transportation of Radioactive Material by Air and Other Modes* (NUREG–0170), the probability of an accident in which the release of radioactive material is likely to occur, and its consequences. The consequences are expressed in terms of the potential effects of the release of a specified quantity of dispersible radioactive material to the environment or the exposure resulting from damaged package shielding. The risk calculations incorporate accident rates and package release fraction estimates, both of which are functions of accident severity. Radiological accident risks are expressed in terms of the probabilities of early cancer fatalities and annual latent cancer fatalities.

radioactive waste Materials that are radioactive or are contaminated with radioactive materials, and for which use, reuse, or recovery are impractical.

radioactivity The spontaneous decay or disintegration of unstable atomic nuclei, accompanied by the emission of radiation.

radioisotopes Radioactive nuclides of the same element (that is, having the same number of protons in their nuclei) that differ in the number of neutrons.

radionuclide A radioactive element characterized according to its atomic mass and atomic number Radionuclides can be man-made or naturally occurring, can have a long life, and have potentially mutagenic or carcinogenic effects on the human body.

radon A gaseous radioactive element resulting from the radioactive decay of radium. Radon (atomic number 86) occurs naturally in the environment and can collect in enclosed, unventilated areas such as basements. Large concentrations of radon can cause lung cancer in humans.

Record of Decision A document providing a concise public record of DOE's decision on a proposed action for which an environmental impact statement was prepared. Prepared in accordance with 40 CFR 1505.2, the Record of Decision identifies the alternatives considered in reaching the decision, the environmentally preferable alternative, factors balanced by DOE in making the decision, whether all practicable means to avoid or minimize environmental harm have been adopted, and if not, why they have not.

region of influence A site-specific geographic area that includes the counties where approximately 90 percent of the site's current DOE and contractor employees reside.

regional economic area A geographic area consisting of an economic node and the surrounding, economically related counties, including the places of work and residences of the labor force. Regional economic areas are defined by the Bureau of Economic Analysis.

rem See *roentgen equivalent man.*

reprocessing The chemical separation of spent reactor fuel into uranium, transuranic elements, and fission products.

Resource Conservation and Recovery Act, as amended The Act that establishes a "cradle-to-grave" regulatory program for hazardous waste, including a system for managing such waste from its generation until its ultimate disposal.

rhyolite A volcanic rock rich in silica; the volcanic equivalent of granite.

Richter scale A logarithmic scale used to express the total amount of energy released by an earthquake. The scale has 10 divisions, from 1 (not felt by humans) to 10 (nearly total destruction).

riparian On or around rivers or streams.

risk A quantitative or qualitative expression of possible loss that takes into account both the probability that an event will cause harm and the consequences of that event.

risk assessment (chemical or radiological) The qualitative and quantitative evaluation performed to define the risk posed to human health or the environment by the presence, potential presence, or use of specific chemicals or radionuclides.

roentgen A unit of exposure to ionizing X- or gamma radiation equal to or producing 1 electrostatic unit of charge per cubic centimeter of air. It is approximately equal to 1 rad. See also *radiation absorbed dose.*

roentgen equivalent man The unit of biologically absorbed radiation, equal to the product of the absorbed dose, in rads, and a quality factor that accounts for the variation in biological effectiveness of different types of radiation.

runoff The portion of rainfall, melted snow, or irrigation water that flows across the ground surface and eventually enters streams.

Safe Drinking Water Act, as amended An act protecting the quality of public water supplies, water supply and distribution systems, and all sources of drinking water.

safe, secure trailer A specially designed semitrailer, pulled by a specially designed tractor, that is used for the safe, secure transportation of cargo containing nuclear weapons or special nuclear material.

safety analysis report A safety document providing a complete description and safety evaluation of a site; a design; normal and emergency facility operations; and potential accidents, predicted consequences of such accidents, and the means proposed to prevent such accidents or mitigate their consequences. A Safety Analysis Report is designated as final when it is based on final design information; otherwise, as preliminary.

safety document A document prepared specifically to ensure that the safety aspects of part or all of the activities conducted are formally and thoroughly analyzed, evaluated, and recorded. Examples include Technical Specifications, Safety Analysis Reports and addenda, and documented reports of special safety reviews and studies.

saltstone Concrete block formed by mixing the low-radioactivity fraction of high-level waste from the in-tank precipitation process with cement, ash, and slag.

sandstone A sedimentary rock composed mostly of sand-size particles cemented usually by calcite, silica, or iron oxide.

sanitary wastes Nonhazardous, nonradioactive liquid and solid wastes generated by normal housekeeping activities.

scintillation Minute flash of light caused when alpha, beta, or gamma rays strike certain phosphors.

scoping The solicitation of comments from interested persons, groups, and agencies at public meetings, in public workshops, in writing, electronically, or via fax to assist DOE in defining a proposed action, identifying alternatives, and developing preliminary issues to be addressed in an environmental impact statement.

security Controls instituted or actions taken to minimize the likelihood of unauthorized access to, or loss of custody of, a nuclear weapon or weapon system, and to ensure that the weapon can be recovered should unauthorized access or loss of custody occur.

seismic Pertaining to any earth vibration, especially that of an earthquake.

seismic zone An area defined by the Uniform Building Code (1991) on the basis of its susceptibility to damage as the result of earthquakes. The United States is divided into six zones distinguished as to the level of damage that can be expected: (1) Zone 0, no damage; (2) Zone 1, minor damage, corresponding to intensities V and VI of the Modified Mercalli Intensity scale); (3) Zone 2A, moderate damage, corresponding to intensity VII of the Mercalli scale (Eastern United States); (4) Zone 2B, slightly more damage than 2A (Western United States); (5) Zone 3, major damage, corresponding to intensity VII and higher of the Mercalli scale; and (6) Zone 4, areas within Zone 3 nearer certain major fault systems.

seismicity The frequency and distribution of earthquakes.

sensitivity level A basis for the characterization of a landscape that takes into account the visibility of specific features, the potential number of viewers, viewer interest in and concern for the landscape, and viewer attitudes toward proposed landscape changes.

severe accident An accident that would have more severe consequences than a design basis accident in terms of damage to a facility, offsite consequences, or both; an accident with a frequency rate of less than 10^{-6} per year.

sewage The total nonhazardous organic waste and wastewater generated by an industrial establishment or a community.

shale A type of easily split rock composed of layers of claylike, fine-grained sediments.

shielding Any material of obstruction (bulkheads, walls, or other structures) that absorbs radiation in order to protect personnel or equipment.

shutdown That condition in which a DOE reactor has ceased operation and DOE has declared officially that it does not intend to operate it further.

silt A sedimentary material consisting of fine mineral particles intermediate in size between sand and clay.

siltstone A fine-grained, elastic (fragmented) sedimentary rock whose particles range from 1/6 to 1/256 millimeter in diameter.

sinter To form a homogenous mass by heating without melting.

sitewide environmental impact statement A legal document prepared in accordance with the requirements of Section 102(2)(C) of the National Environmental Policy Act that reflects an evaluation of the environmental impacts of proposed Government actions at a large, multiple-facility site.

solid waste Discarded solid, liquid, semisolid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities. Solid waste does not include solid or dissolved materials in domestic sewage; industrial discharges subject to permit under the Clean Water Act; or source, special nuclear, or byproduct material as defined by the Atomic Energy Act.

source term The estimated quantities of radionuclides or chemical pollutants released to the environment.

special nuclear materials As defined in Section 11 of the Atomic Energy Act, "(1) plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material which the NRC determines to be special nuclear material, or (2) any material artificially enriched by any of the foregoing."

Spent Fuel Standard A term, coined by the National Academy of Sciences and modified by DOE, denoting the main objective of alternatives for the disposition of surplus weapons-usable plutonium: that such plutonium be made roughly as inaccessible and unattractive for weapons use as the much larger and growing stock of plutonium in civilian spent nuclear fuel.

spent nuclear fuel Fuel that has been withdrawn from a nuclear reactor following irradiation, and whose constituents have not been separated.

stabilization Treatment, packaging, and removal of hazardous and radioactive materials in such a manner as to ensure that a facility is safe and environmentally secure.

stabilize To convert a compound, mixture, or solution to a nonreactive form.

staging An interim storage or gathering of items pending their use, transportation, consumption, or other disposition.

standby That condition in which a reactor facility is neither operable nor declared excess, and as authorized in writing, is being kept in readiness for possible future operation.

State Historic Preservation Officer State officer charged with the identification and protection of prehistoric and historic resources in accordance with the National Historic Preservation Act.

steppe A semiarid, grass-covered, generally treeless plain.

steppe climate (semiarid climate) The type of climate in which precipitation is very slight but sufficient for the growth of short, sparse grass.

stored weapons standard A storage standard that invokes the high standards of security and accounting for the storage of intact nuclear weapons. Invocation of the standard for weapons-usable fissile materials implies maintenance thereof to the extent practical through the processes of dismantlement, storage, and disposition.

Superfund Amendments and Reauthorization Act of 1986 An environmental act that, in addition to certain freestanding provisions of law, extensively amends the Comprehensive Environmental Response, Compensation, and Liability Act (Superfund) and the Safe Drinking Water Act. The act's major goals are a stepped-up pace of cleanup, increased public participation, and more stringent and better-defined cleanup standards, emphasizing remedial actions. See also *Comprehensive Environmental Response, Compensation, and Liability Act of 1980; Safe Drinking Water Act, as amended.*

surface water Water on the Earth's surface, as distinguished from water in the ground (groundwater).

surplus fissile materials Weapons-usable fissile materials that have no identified programmatic use or do not fall into one of the categories of national security reserves.

Tertiary The first geologic period of the Cenozoic era, dating from 66 million to about 3 million years ago. During this period, mammals became the dominant life form.

threatened species As defined in the Endangered Species Act of 1973, "any species which is likely to become an endangered species within the foreseeable future throughout all or a significant portion of its range."

total effective dose equivalent The sum of the internal dose (committed effective dose equivalent) and the external dose (effective dose equivalent).

toxic air pollutants See *hazardous/toxic air pollutants.*

Toxic Substances Control Act of 1976 An act authorizing the U.S. Environmental Protection Agency to secure information on all new and existing chemical substances and to control any of these substances determined to cause an unreasonable risk to public health or the environment. This law requires that the health and environmental effects of all new chemicals be reviewed by the Agency before such chemicals are manufactured for commercial purposes.

transmissivity A measure of a water-bearing unit's capacity to transmit fluid, expressed as the product of the thickness and the average hydraulic conductivity of the unit. Also, the rate at which water is transmitted through a strip of an aquifer of a unit width under a unit hydraulic gradient at a prevailing temperature and pressure.

transuranic Of, relating to, or being any element whose atomic number is higher than that of uranium (that is, 92). All transuranic elements are produced artificially and are radioactive.

transuranic waste Waste containing more than 100 nanocuries per gram of alpha-emitting transuranic isotopes with half-lives greater than 20 years, except for (1) high-level waste; (2) waste that DOE has determined, with the concurrence of the U.S. Environmental Protection Agency, does not need the degree of isolation called for by 40 CFR 191; or (3) waste that the U.S. Nuclear Regulatory Commission has approved for disposal case by case in accordance with 10 CFR 61.

treatment An operation necessary to prepare material for storage, disposal, or transportation.

Triassic The first period of the Mesozoic era, dating from 245 to 208 million years ago.

tritium A radioactive isotope of the element hydrogen having two neutrons and one proton.

tritium recycling The recovery, purification, and reuse of tritium contained in tritium reservoirs within the nuclear weapons stockpile.

unconfined aquifer A permeable geologic unit having the following properties: a water-filled pore space (saturated), the capability to transmit significant quantities of water under ordinary differences in pressure, and an upper water boundary at atmospheric pressure.

uranium A heavy, silvery-white metallic element (atomic number: 92) with many radioactive isotopes. One isotope, uranium 235, is most commonly used as a fuel for nuclear fission; another, uranium 238, is transformed into fissionable plutonium 239 following its capture of a neutron in a nuclear reactor.

vadose zone A region in a porous medium in which the pore space is not filled with water (unsaturatured zone).

viewshed The extent of the area that may be viewed from a particular location. Viewsheds are generally bounded by topographic features such as hills or mountains.

Visual Resource Management A process devised by the Bureau of Land Management to assess analytically the aesthetic quality of a landscape, and consistent with the results of that analysis, to so design proposed activities as to minimize their visual impact on that landscape. The process consists of a rating of site visual quality followed by a measurement of the degree of contrast between proposed development activities and the existing landscape.

Visual Resource Management Class Any of the classifications of visual resources established through application of the Visual Resources Management process of the Bureau of Land Management. Five classifications are employed to define the different degrees of modification to landscape elements: Class 1, pristine areas, including designated wilderness and wild and scenic rivers; Class 2, areas with very limited land development activity, resulting in contrasts that are seen but do not attract attention; Class 3, areas in which contrasts caused by development activity are evident, but the natural landscape still dominates; Class 4, areas in which contrasts caused by human activities attract attention and are dominant features of the landscape in terms of scale, but repeat the contrasts of the characteristic landscape; Class 5, areas in which contrasts caused by cultural activities are such dominant features of the landscape that the natural landscape character no longer exists.

visual resources Natural and cultural features by which the appearance of a particular landscape is defined.

vitrification A process by which glass (for example, borosilicate glass) is used to encapsulate or immobilize radioactive wastes.

volatile organic compounds A broad range of organic compounds, often halogenated, that vaporize at rather low ambient temperatures. Examples include certain solvents, paint thinners, degreasers (for example, benzene), chloroform, and methyl alcohol.

waste A discardable residue of a manufacturing or purification process.

Waste Isolation Pilot Plant A facility in southeastern New Mexico that is being developed as the national disposal site for transuranic and mixed transuranic waste.

waste minimization and pollution prevention An action that economically avoids or reduces the generation of waste and pollution by means of source reduction, reduction in the toxicity of hazardous waste and pollution, improvement in energy use, and recycling. These actions are consistent with the general goal of minimizing present and future threats to human health, safety, and the environment.

waste package The waste, waste container, and any absorbent that are intended for disposal as a unit. In the case of surface-contaminated, damaged, leaking, or breached waste packages, any overpack is considered the waste container, and the original container is considered part of the waste.

wastewater Water originating from human sanitary water use (domestic wastewater) and from a variety of industrial processes (industrial wastewater).

water quality standards and criteria Limits on the concentrations of specific constituents or on the characteristics of water, often based on water use classifications (for example, drinking water, recreation, propagation of fish and aquatic life, agricultural and industrial use). Water quality standards are legally enforceable, whereas water quality criteria are nonenforceable recommendations based on biotic impacts.

water table The boundary between the unsaturated zone and the deeper, saturated zone. The upper surface of an unconfined aquifer.

weapons-grade material Plutonium or highly enriched uranium, in metallic form, that was manufactured for weapons application. Weapons-grade plutonium contains less than 7 percent plutonium 240.

weapons-usable material Plutonium or highly enriched uranium in forms (for example, metals, oxides) that can be readily converted for use in nuclear weapons. Weapons-grade, fuel-grade, and power reactor–grade plutonium are all weapons usable.

wetland Land areas exhibiting hydric soil conditions, saturated or inundated soil during some portion of the year, and plant species tolerant of such conditions.

whole-body dose Dose of radiation resulting from the uniform exposure of all organs and tissues in a human body. See also *effective dose equivalent.*

Wild and Scenic Rivers Act The Act that established the National Wild and Scenic Rivers System with a view to preserving and protecting the free-flowing condition of selected rivers having outstanding natural, cultural, or recreational features. For federally owned land within the boundaries of rivers in the system, certain activities that would have a direct and adverse effect on river values may be controlled.

zooplankton A collective term for nonphotosynthetic organisms present in plankton.

6M A container, resembling a 55-gallon stainless steel drum, that is used by the U.S. Department of Energy for the shipment of radioactive material. This container is one unit of a containment package that includes an inner impact absorber material (Type B packaging), which protects another inner container (usually Type 2R) in which the radioactive material is placed.

List of Preparers

Borghi, Louis C., *Ecological Resources*, SAIC
M.S., Ecology (1977), The Pennsylvania State University, State College, PA
B.A., Biology (1975), LaSalle University, Philadelphia, PA
Years of Experience: 20

Brin, Gerald L., *Plutonium Polishing*, SAIC
Indentured Apprenticeship Certification (1976), Denver, CO
Years of Experience: 30

Brown, Tracy L., *Crosscutting Functions*, SAIC
B.A., Environmental Engineering Science (1994), Dartmouth College, Hanover, NH
Years of Experience: 4

Collins, Michael G., *Land Use and Visual Resources*, SAIC
M.E.P., Master of Environmental Planning (1996), Arizona State University, Tempe, AZ
B.S., Urban Planning and Development (1990),
University of Southern California, Los Angeles, CA
Years of Experience: 6

Crede, Suzanne C., *Cumulative Impacts*, SAIC
M.A., Counseling and Guidance (1977), West Virginia University, Morgantown, WV
B.S., General Science and Safety Education (1976),
West Virginia University, Morgantown, WV
Years of Experience: 18

DeMoss, Gary M., *Transportation Accidents*, SAIC
M.A., Engineering Administration (1991),
Virginia Polytechnic Institute and State University, Blacksburg, VA
B.S., Mechanical Engineering (1981), University of Virginia, Charlottesville, VA
Years of Experience: 16

DiMarzio, John A., *Waste Management*, SAIC
M.S., Geology (1984), The George Washington University, Washington, DC
B.S., Geology (1981), University of Maryland, College Park, MD
Years of Experience: 14

Eichner, John M., *Deputy Project Manager*, SAIC
B.S., Accounting and Finance (1980), Syracuse University, Syracuse, NY
Years of Experience: 17

Everett, H. Christopher, *Facility Accidents*, SAIC
B.S., Physics (1985), Tufts University, Medford, MA
Years of Experience: 12

Ford, Dennis G., *Cumulative Impacts*, SAIC
Ph.D., Zoology (1972), SUNY College of Environmental Science
and Forestry at Syracuse University, Syracuse NY
B.A., Biology (1966), SUNY College of Arts, Geneseo, NY
Years of Experience: 32

Frost, Donna R., *Geology and Soils*, SAIC
M.S., Geology (1971), Iowa State University, Ames, IA
B.A., Psychology (1968), Iowa State University, Ames, IA
Years of Experience: 25

Frost, James C., *Water Resources*, SAIC
M.A., Business Administration (1973), Sangamon State University, Springfield, IL
B.A., Biology (1969), Blackburn University, Carlynville, IL
Years of Experience: 27

Gandee, Kitty B., *Impact Analysis*, SAIC
M.S., Nuclear Engineering (1978), Oregon State University, Corvallis, OR
M.L.S., Library Science (1975), University of Pittsburgh, Pittsburgh, PA
M.S., Materials Engineering (1974), University of Maryland, College Park, MD
B.S., Metallurgical Engineering (1972), Chen Kung University, Taiwan
Years of Experience: 20

Groome, Chadi D., *MOX Fuel Options*, SAIC
M.S., Environmental Engineering Sciences (1977), University of Florida, Gainesville, FL
B.S., Zoology (1973), Clemson University, Clemson, SC
Years of Experience: 18

Haley, Timothy A., *Transportation Analysis*, SAIC
B.S., Engineering, Nuclear Engineering (1989), University of Cincinnati, Cincinnati, OH
Years of Experience: 7

Hanson, Glen T, *Cultural Resources*, SAIC
M.A., Anthropology/Archaeology (1976), Arizona State University, Tempe, AZ
B.S., Anthropology (1971), Grand Valley State College, Allendale, MI
Years of Experience: 21

Hirrlinger, Diana N., *Crosscutting Functions/Quality Assurance*, SAIC
M.B.A., Marketing and Organizational Behavior (1987),
University of Maryland, College Park, MD
B.S., Conservation of Natural Resources (1980),
University of California, Berkeley, CA, 1980
Years of Experience: 17

Hoffman, Robert G., *Immobilization Options*, SAIC
B.S., Environmental Resource Management (1986),
The Pennsylvania State University, State College, PA
Years of Experience: 12

Jones, Marcus E., *EIS Document Manager*, Reactors Group, Office of Fissile Materials Disposition (MD-4), U.S. Department of Energy
M.S.E., Environmental Engineering (1986), University of Alabama, Tuscaloosa, AL
B.S., Biology (1980), University of Alabama, Tuscaloosa, AL
Years of Experience: 15

Lam, Ying, *Affected Environment*, SAIC
M.S., Environmental Science (1997), Indiana University, Bloomington, IN
M.P.A., Master of Public Affairs (1997), Indiana University, Bloomington, IN
B.S., Environmental Biology (1993), Jinan University, Guangzhu, China
Years of Experience: 1

Mahosky, Paul R., *Infrastructure*, SAIC
M.S.E., Engineering Management (1993),
The Catholic University of America, Washington, DC
B.S., Ocean Engineering (1983), United States Naval Academy, Annapolis, MD
Years of Experience: 14

Mancino, Frank P., *Comment Response Systems Manager*, SAIC
M.S., Natural Resources Management and Policy (1979),
University of Michigan, Ann Arbor, MI
B.S., Environmental Studies (1976), Florida International University, Miami, FL
Years of Experience: 20

Martin, James F., *Editor*, SAIC
M.S., Theoretical Linguistics (1969), Georgetown University, Washington, DC
B.S., Modern Languages (1959), Memphis State University, Memphis, TN
Years of Experience: 39

Martin, Karen L., *Impact Analysis*, SAIC
B.A., Conservation and Resource Development (1981),
University of Maryland, College Park, MD
Years of Experience: 16

Nemeth, Diane M., *Socioeconomics*, SAIC
M.S., Urban Planning (1978), Columbia University, New York, NY
B.A., Economics (1973), Miami University, Oxford, OH
Years of Experience: 24

Nulton, J. David, *Director, Reactor Group*, Office of Fissile Materials Disposition (MD-4), U.S. Department of Energy
M.S., Mechanical Engineering (1970), Stanford University, Stanford, CA
B.S., Mechanical Engineering (1968), Drexel University, Philadelphia, PA
Years of Experience: 29

Outlaw, Douglas A., *Facility Accidents*, SAIC
Ph.D., Nuclear Physics (1974), North Carolina State University, Raleigh, NC
M.S., Nuclear Physics (1970), North Carolina State University, Raleigh, NC
B.S., Physics (1969), North Carolina State University, Raleigh, NC
Years of Experience: 20

Papa, Patricia, E., *Socioeconomics*, SAIC
B.A., Journalism and Psychology (1966), Syracuse University, Syracuse, NY
Years of Experience: 15

Pietzyk, Sharon M., *Ecological Resources*, SAIC
M.S., Systems Management (1988), Univ. of Southern California, Los Angeles, CA
B.S., Biology (1981), James Madison University, Harrisonburg, VA
Years of Experience: 16

Rhone, Jacquelyn L., *Production*, SAIC
A.Sc., Radiological Health Technology (1972), Central Florida Community College, Ocala, FL
Years of Experience: 25

Sawyer, Cheri A., *Document Production Manager*, SAIC
B.S., Journalism (1977), University of Maryland, College Park, MD
Years of Experience: 20

Schlegel, Robert L., *Human Health Risk*, SAIC
Degree of Nuclear Engineer (1964), Columbia University, New York, NY
M.S., Nuclear Engineering (1961), Columbia University, New York, NY
B.S., Chemical Engineering (1959),
Massachusetts Institute of Technology, Cambridge, MA
Years of Experience: 35

Stevenson, G. Bert, *NEPA Compliance Officer*, Office of Fissile Materials Disposition (MD-4), U.S. Department of Energy
B.S., Physics (1963), Marshall University, Huntington, WV
Years of Experience: 34

Updike, Paul J., *Infrastructure, Impact Summary*, SAIC
M.A., International Affairs (1997), University of Pittsburgh, Pittsburgh, PA
B.S., Economics (1985), Clarion University, Clarion, PA
Years Experience: 9

Waldman, Gilbert H., *Human Health Risk*, SAIC
B.S., Nuclear Engineering (1991), University of Florida, Gainesville, FL
Years of Experience: 6

Werth, Robert H., *Air Quality and Noise*, SAIC
B.A., Physics (1973), Gordon College, Wenham, MA
Years of Experience: 24

Wherley, Patricia L., *EIS Project Manager*, SAIC
B.A., Geography (1980), The George Washington University, Washington, DC
Years of Experience: 21

Wilkinson, Matthew C., *Environmental Justice*, SAIC
M.A., Professional Studies; Soil and Water Conservation Engineering (1997), Cornell University, Ithaca, NY
B.S., Environmental Systems Technology (1995), Cornell University, Ithaca, NY
Years of Experience: 1

Williams, Alan K., *Aqueous Processing*, SAIC
B.A., Physical Science (1952), University of Northern Colorado, Greeley, CO
Years of Experience: 46

Williams, John W., *Environmental Justice*, SAIC
Ph.D., Physics (1972), New Mexico State University, Las Cruces, NM
M.S., Physics (1970), New Mexico State University, Las Cruces, NM
B.S., Mathematics (1962), North Texas State University, Denton, TX
Years of Experience: 22

Chapter 8
Distribution List

The U.S. Department of Energy is providing copies of the *Surplus Plutonium Disposition Draft Environmental Impact Statement* to Federal, State, and local elected and appointed government officials and agencies; Native American groups; and other organizations and individuals listed below. Copies will be distributed in bulk to some individuals and organizations for further distribution (e.g., the State single points of contact for the National Environmental Policy Act [NEPA]). Copies will be provided to other organizations and individuals on request.

ELECTED OFFICIALS

Federal-Elected Officials

- Senators and Representatives from the States of California, Georgia, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington
- Congressional Committees:
  - Senate: Committee on Appropriations; Committee on Armed Services; and Energy and Natural Resources Committee
  - House of Representatives: Committee on Appropriations; Committee on National Security

State-Elected Officials

- Governors from the States of California, Georgia, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington
- State Senators and Representatives from the States of California, Georgia, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington

Local-Elected Officials

- Mayors, council members, etc., from areas near the Hanford Site; Idaho National Engineering and Environmental Laboratory; Lawrence Livermore National Laboratory; Los Alamos National Laboratory; Pantex Plant; and Savannah River Site

APPOINTED OFFICIALS

Federal-Appointed Officials

- Agencies that are members of the Interagency Working Group for Plutonium Disposition—Arms Control and Disarmament Agency, Central Intelligence Agency, Council on Environmental Quality, Defense Nuclear Facilities Safety Board, Department of Defense, National Security Council, Nuclear Regulatory Commission, Office of Management and Budget, State Department, Environmental Protection Agency
- Other Federal agencies including: General Accounting Office, National Academy of Sciences, National Oceanic and Atmospheric Administration, National Science Foundation, U.S. Bureau of Indian Affairs, U.S. National Park Service

State-Appointed Officials

- NEPA single points of contact for the States of California, Georgia, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington
- State agencies including: Georgia Emergency Management Agency, South Carolina Nuclear Waste Program, Southern States Energy Board, State of Idaho's Idaho National Engineering and Environmental Laboratory Oversight Program, State of Texas' Division of Emergency Management, State of Texas' Office of the Attorney General, Texas

Natural Resources Conservation Commission, State of Texas' Department of Health, State of Washington's Department of Ecology, State of Washington's Energy Office

NATIVE AMERICAN GROUPS

Federally recognized Native American Indian Tribes from the States of California, Georgia, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington

DEPARTMENT OF ENERGY

Department of Energy Reading Rooms in the States of California, Idaho, New Mexico, Oregon, South Carolina, Texas, and Washington

ORGANIZATIONS AND INDIVIDUALS

Organizations and individuals who have requested copies of the *Surplus Plutonium Disposition Draft Environmental Impact Statement*

Voice: (202) 586–4600 or (800) 472–2756

Abstract: On May 22, 1997, DOE published a Notice of Intent (NOI) in the Federal Register (62 Federal Register 28009) announcing its decision to prepare an environmental impact statement (EIS) that would tier from the analysis and decisions reached in connection with the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic EIS (Storage and Disposition PEIS)*. DOE's disposition strategy allows for both the immobilization of surplus plutonium and its use as mixed oxide (MOX) fuel in existing domestic, commercial reactors. The disposition of surplus plutonium would also involve disposal of the immobilized plutonium and MOX fuel (as spent nuclear fuel) in a geologic repository.

The *Surplus Plutonium Disposition Environmental Impact Statement* analyzes alternatives that would use the immobilization approach (for some of the surplus plutonium) and the MOX fuel approach (for some of the surplus plutonium); alternatives that would immobilize all of the surplus plutonium; and the No Action Alternative. The alternatives include three disposition facilities that would be designed so that they could collectively accomplish disposition of up to 50 metric tons (55 tons) of surplus plutonium over their operating lives: 1. The pit disassembly and conversion facility would disassemble pits (a weapons component) and convert the recovered plutonium, as well as plutonium metal from other sources, into plutonium dioxide suitable for disposition. 2. The immobilization facility would include a collocated capability for converting nonpit plutonium materials into plutonium dioxide suitable for immobilization and would be located at either Hanford or SRS. DOE has identified SRS as the preferred site for an immobilization facility. 3. The MOX fuel fabrication facility would fabricate plutonium dioxide into MOX fuel.

Public Involvement: Comments on the SPD Draft EIS may be submitted: by mail to DOE, Office of Fissile Materials Disposition, c/o SPD EIS, P.O. Box 23786, Washington, DC 20026–3786; by calling DOE at 1–800–820–5156; or by sending a facsimile (fax) message to DOE at 1–800–820–5156. To ensure consideration in the SPD Final EIS, these comments should be submitted within 60 days after the U.S. Environmental Protection Agency Notice of Availability is published in the Federal Register. Comments received after the end of the comment period will be considered to the extent possible. Public meetings will be held on the dates and times specified in a DOE Federal Register notice and announced in local media. Comments on the SPD Draft EIS can also be submitted at these meetings. Preregistration for the public meetings is available by calling 1–800–820–5134 or by fax at 1–800–820–5156. Additional information can be obtained by calling the contacts listed above, or by visiting the Office of Fissile Materials Disposition web site at http://www.doe-md.com.

Appendix L
Evaluation of Human Health Effects from Transportation L–1

L.1 Introduction L–1
L.2 Scope of Assessment L–1
L.3 Packaging and Representative Shipment Configurations L–2
L.3.1 Packaging Overview L–2
L.3.1.1 Uranium Hexafluoride Packaging L–3
L.3.1.2 Uranium Dioxide Packaging L–3
L.3.1.3 Mixed Oxide Fuel Packaging L–3
L.3.1.4 Highly Enriched Uranium Packaging L–4
L.3.1.5 Plutonium Packaging L–4
L.3.1.6 Overview of Type B Containers L–4
L.3.2 Safe, Secure Transportation L–5
L.3.3 Ground Transportation Route Selection Process L–6
L.4 Methods for Calculating Transportation Risks L–7
L.5 Alternatives, Parameters, and Assumptions L–9
L.5.1 Transportation Alternatives L–9
L.5.2 Representative Routes and Populations L–11
L.5.3 Distance Traveled by Alternative L–11
L.5.4 Shipment External Dose Rates L–16
L.5.5 Health Risk Conversion Factors L–17
L.5.6 Accident Involvement Rates L–17
L.5.7 Container Accident Response Characteristics and Release Fractions L–17
L.6 Risk Analysis Results L–18
L.6.1 Per-Shipment Risk Factors L–18
L.6.2 Evaluation of Shipment Risks L–18
L.6.3 Maximally Exposed Individuals L–19
L.6.4 Waste Transportation L–21
L.6.5 Consequences of Sabotage or Terrorist Attack During Transportation L–23
L.7 Cumulative Impacts of Transportation L–24
L.7.1 Radiological Impacts L–24
L.7.2 Accident Impacts L–27
L.8 Uncertainty and Conservatism in Estimated Impacts L–27
L.8.1 Uncertainties in Material Inventory and Characterization L–28
L.8.2 Uncertainties in Containers, Shipment Capacities, and Number of Shipments L–28
L.8.3 Uncertainties in Route Determination L–29
L.8.4 Uncertainties in the Calculation of Radiation Doses L–29

Next Section

List of Acronyms

AEA	Atomic Energy Act of 1954
AECL	Atomic Energy of Canada Limited
AIRFA	American Indian Religious Freedom Act
ALARA	as low as is reasonably achievable
ANL–W	Argonne National Laboratory–West
APSF	Actinide Packaging and Storage Facility
AQCR	Air Quality Control Region
ARF	airborne release fraction
BEA	Bureau of Economic Analysis
BEIR–V	Report V of the Committee on the Biological Effects of Ionizing Radiations
BIO	Basis for Interim Operation
BLM	Bureau of Land Management
BWR	boiling water reactor
CAA	Clean Air Act
CANDU	Canadian Deuterium Uranium (reactors)
CEQ	Council on Environmental Quality
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
CFA	Central Facilities Area
CFR	Code of Federal Regulations
CPP	Chemical Processing Plant
CWA	Clean Water Act of 1972, 1987
D&D	decontamination and decommissioning
DBA	design-basis accident
DNFSB	Defense Nuclear Facilities Safety Board
DOC	U.S. Department of Commerce
DoD	U.S. Department of Defense
DOE	U.S. Department of Energy
DOL	U.S. Department of Labor
DOT	U.S. Department of Transportation
DR	damage ratio
DWPF	Defense Waste Processing Facility
EA	environmental assessment
EBR	Experimental Breeder Reactor (I or II)
EIS	environmental impact statement

EPA	U.S. Environmental Protection Agency
ES&H	environment, safety, and health
ETB	Engineering Test Bay
FAA	U.S. Federal Aviation Administration
FDP	fluorinel dissolution process
FEMA	Federal Emergency Management Agency
FFCA	Federal Facility Compliance Agreement
FFF	Uranium Fuel Fabrication Facility
FFTF	Fast Flux Test Facility
FI	field investigation
FM	Farm-to-Market (road)
FMF	Fuel Manufacturing Facility
FMEA	failure modes and effects analysis
FMEF	Fuels and Materials Examination Facility
FONSI	finding of no significant impact
FPF	Fuel Processing Facility
FPPA	Farmland Protection Policy Act
GDP	gaseous diffusion plant
GE	General Electric Company
GENII	Generation II, Hanford Environmental Radiation Dosimetry Software System
GPS	global positioning satellite
HE	high explosive
HEPA	high-efficiency particulate air (filter)
HEU	highly enriched uranium
HFEF	Hot Fuel Examination Facility
HIGHWAY	(computer code: distances and populations along U.S. highways)
HLW	high-level waste
HLWVF	high-level-waste vitrification facility
HWTPF	Hazardous Waste Treatment and Processing Facility
HYDOX	hydride oxidation
IAEA	International Atomic Energy Agency
ICPP	Idaho Chemical Processing Plant
ICRP	International Commission on Radiological Protection
ID DHW	Idaho Department of Health and Welfare
INEEL	Idaho National Engineering and Environmental Laboratory
INRAD	Intrinsic Radiation

INTEC	Idaho Nuclear Technology and Engineering Center
ISC3	Industrial Source Complex Model, Version 3
ISCST3	Industrial Source Complex Model, Short-Term, Version 3
LANL	Los Alamos National Laboratory
LCF	latent cancer fatality
LDR	Land Disposal Restrictions
LEU	low-enriched uranium
LLNL	Lawrence Livermore National Laboratory
LLW	low-level waste
LPF	leak path factor
LWR	light-water reactor
M&H	Mason & Hanger Corporation
MACCS2	Melcor Accident Consequence Code System (computer code)
MAR	material at risk
MEI	maximally exposed individual
MMI	Modified Mercalli Intensity
MOX	mixed oxide
NAAQS	National Ambient Air Quality Standards
NAGPRA	Native American Graves Protection and Repatriation Act
NCRP	National Council on Radiation Protection and Measurements
NDA	nondestructive analysis
NEPA	National Environmental Policy Act of 1969
NESHAP	National Emissions Standards for Hazardous Air Pollutants
NIOSH	National Institute of Occupational Safety and Health
NOAA	National Oceanic and Atmospheric Administration
NOI	Notice of Intent
NPDES	National Pollutant Discharge Elimination System
NPH	natural phenomena hazard
NPS	U.S. National Park Service
NRC	U.S. Nuclear Regulatory Commission
NRU	National Research Universal
NTS	Nevada Test Site
NWCF	New Waste Calcining Facility
NWS	National Weather Service

ORR	Oak Ridge Reservation
OSHA	Occupational Safety and Health Administration
ORNL	Oak Ridge National Laboratory
PBF	Power Burst Facility
PEIS	programmatic environmental impact statement
PFP	Plutonium Finishing Plant
PIE	postirradiation examination
$PM_{2.5}$	particulate matter with an aerodynamic diameter less than or equal to 2.5 microns
PM_{10}	particulate matter with an aerodynamic diameter less than or equal to 10 microns
PNNL	Pacific Northwest National Laboratory
PRA	probabilistic risk assessment
PSD	prevention of significant deterioration
PUREX	Plutonium-Uranium Extraction (Facility)
PWR	pressurized water reactor
R&D	research and development
RADTRAN4	(computer code: risks and consequences of radiological materials transport)
RAMOD	Radioactive Materials Research, Operations, and Demonstration
RCRA	Resource Conservation and Recovery Act, as amended
REA	regional economic area
RF	respirable fraction
RfC	reference concentration
RfD	reference dose
RFETS	Rocky Flats Environmental Technology Site
RIMS II	Regional Input-Output Modeling System II (computer code)
RISKIND	(computer code: risks and consequences of radiological materials transport)
ROD	Record of Decision
ROI	region of influence
RMF	Radiation Measurements Facility
RWMC	Radioactive Waste Management Complex
S/A	Similarity of Appearance (provision of Endangered Species Act)
SAR	safety analysis report
SARA	Superfund Amendments and Reauthorization Act of 1986
SCDHEC	South Carolina Department of Health and Environmental Control
SCE&G	South Carolina Electric & Gas Company
SCSHPO	South Carolina State Historic Preservation Officer
SDWA	Safe Drinking Water Act, as amended
SHPO	State Historic Preservation Officer

SMC	Specific Manufacturing Complex
SNF	spent nuclear fuel
SNM	special nuclear material
SPD	surplus plutonium disposition
SPD EIS	*Surplus Plutonium Disposition Environmental Impact Statement*
SPERT	Special Power Excursion Reactor Test
SRS	Savannah River Site
SST	safe, secure trailer
SWMU	solid waste management unit
SWP 1	Service Waste Percolation Pond 1
TA	Technical Area
TCE	trichloroethylene
TNRCC	Texas Natural Resource Conservation Commission
TPBAR-LTA	tritium-producing burnable absorber rod lead test assembly
TRU	transuranic
TRUPACT	TRU waste package transporter
TSCA	Toxic Substances Control Act
TSP	total suspended particulates
TWRS	tank waste remediation system
TWRS EIS	*Tank Waste Remediation System Final Environmental Impact Statement*
UC	Regents of the University of California
USACE	U.S. Army Corps of Engineers
USEC	United States Enrichment Corporation
USFWS	U.S. Fish and Wildlife Service
UV	ultraviolet
VOC	volatile organic compounds
VORTAC	Very High Frequency Omnidirection Radio Tactical Air Navigation Device
VRM	Visual Resource Management
WAG 3	Waste Area Grouping 3
WERF	Waste Experimental Reduction Facility
WIPP	Waste Isolation Pilot Plant
WM PEIS	*Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste*
WNP–2	Washington Nuclear Plant–2

WPPSS	Washington Public Power Supply System
WROC	Waste Reduction Operations Complex
WSRC	Westinghouse Savannah River Company
ZPPR	Zero Power Physics Reactor

Chemicals and Units of Measure

μCi	microcurie
μg	microgram
μm	micrometer (micron)
46°26'07"	46 degrees, 26 minutes, 7 seconds
Ci	curie
cm	centimeter
CO	carbon monoxide
CO_2	carbon dioxide
dB	decibel
dBA	decibel, A-weighted
ft	foot
ft^2	square foot
ft^3	cubic foot
g	gram
g	gravitational acceleration
gal	gallon
ha	hectare
hr	hour (in compound units)
in	inch
kg	kilogram
km	kilometer
km^2	square kilometers
kV	kilovolt
l	liter
lb	pound
m	meter
m^2	square meter
m^3	cubic meter
mg	milligram
mi	mile
min	minute
mph	miles per hour

mrem	millirem
MVA	megavolt-ampere
MW	megawatt
MWe	megawatt electric
MWh	megawatt-hour
N_2	nitrogen
nCi	nanocurie
NO_2	nitrogen dioxide
pCi	picocurie
person-rem	person-rem
$PM_{2.5}$	particulate matter less than or equal to 2.5 μm in diameter
PM_{10}	particulate matter less than or equal to 10 μm in diameter
rad	radiation absorbed dose
rem	roentgen equivalent man
s	second
SO_2	sulfur dioxide
t	metric ton
ton	short ton
UF_6	uranium hexafluoride
UO_2	uranium dioxide
yd	yard
yd^3	cubic yard
yr	year (in compound units)
°C	degrees Celsius (Centigrade)
°F	degrees Fahrenheit

Metric Conversion Chart

To Convert Into Metric			To Convert Out of Metric		
If You Know	**Multiply By**	**To Get**	**If You Know**	**Multiply By**	**To Get**
Length					
inches	2.54	centimeters	centimeters	0.3937	inches
feet	30.48	centimeters	centimeters	0.0328	feet
feet	0.3048	meters	meters	3.281	feet
yards	0.9144	meters	meters	1.0936	yards
miles	1.60934	kilometers	kilometers	0.6214	miles
Area					
sq. inches	6.4516	sq. centimeters	sq. centimeters	0.155	sq. inches
sq. feet	0.092903	sq. meters	sq. meters	10.7639	sq. feet
sq. yards	0.8361	sq. meters	sq. meters	1.196	sq. yards
acres	0.40469	hectares	hectares	2.471	acres
sq. miles	2.58999	sq. kilometers	sq. kilometers	0.3861	sq. miles
Volume					
fluid ounces	29.574	milliliters	milliliters	0.0338	fluid ounces
gallons	3.7854	liters	liters	0.26417	gallons
cubic feet	0.028317	cubic meters	cubic meters	35.315	cubic feet
cubic yards	0.76455	cubic meters	cubic meters	1.308	cubic yards
Weight					
ounces	28.3495	grams	grams	0.03527	ounces
pounds	0.45360	kilograms	kilograms	2.2046	pounds
short tons	0.90718	metric tons	metric tons	1.1023	short tons
Temperature					
Fahrenheit	Subtract 32 then multiply by 5/9ths	Celsius	Celsius	Multiply by 9/5ths, then add 32	Fahrenheit

Metric Prefixes

Prefix	Symbol	Multiplication Factor
exa-	E	$1\,000\,000\,000\,000\,000\,000 = 10^{18}$
peta-	P	$1\,000\,000\,000\,000\,000 = 10^{15}$
tera-	T	$1\,000\,000\,000\,000 = 10^{12}$
giga-	G	$1\,000\,000\,000 = 10^{9}$
mega-	M	$1\,000\,000 = 10^{6}$
kilo-	k	$1\,000 = 10^{3}$
hecto-	h	$100 = 10^{2}$
deka-	da	$10 = 10^{1}$
deci-	d	$0.1 = 10^{-1}$
centi-	c	$0.01 = 10^{-2}$
milli-	m	$0.001 = 10^{-3}$
micro-	μ	$0.000\,001 = 10^{-6}$
nano-	n	$0.000\,000\,001 = 10^{-9}$
pico-	p	$0.000\,000\,000\,001 = 10^{12}$

A.1 RECORD OF DECISION FOR THE STORAGE AND DISPOSITION OF WEAPONS-USABLE FISSILE MATERIALS FINAL PROGRAMMATIC ENVIRONMENTAL IMPACT STATEMENT

Responses: 18,620 Burden Hours: 64,310.

Abstract: The LESCP is being conducted in response to the legislative requirement in P.L. 103-382, Section 1501 to assess the implementation of Title I and related education reforms. The information will be used to examine changes—over a 3-year period—that are occurring in schools and classrooms. Teachers and teacher aides will complete a mail survey, and district Title I administrators, principals, school-based staff, and parents will be interviewed during on-site field work.

BILLING CODE 4000-01-P

DEPARTMENT OF ENERGY

Record of decision for the Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement

AGENCY: Department of Energy.

ACTION: Record of Decision.

SUMMARY: The Department of Energy (DOE) has decided to implement a program to provide for safe and secure storage of weapons-usable fissile materials (plutonium and highly enriched uranium [HEU]) and a strategy for the disposition of surplus weapons-usable plutonium, as specified in the Preferred Alternative in the Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement (S&D Final PEIS, DOE/EIS-0229, December 1996). The fundamental purpose of the program is to maintain a high standard of security and accounting for these materials while in storage, and to ensure that plutonium produced for nuclear weapons and declared excess to national security needs (now, or in the future) is never again used for nuclear weapons.

DOE will consolidate the storage of weapons-usable plutonium by upgrading and expanding existing and planned facilities at the Pantex Plant in Texas and the Savannah River Site (SRS) in South Carolina, and continue the storage of weapons-usable HEU at DOE's Y-12 Plant at the Oak Ridge Reservation (ORR) in Tennessee, in upgraded and, as HEU is dispositioned, consolidated facilities. After certain conditions are met, most plutonium now stored at the Rocky Flats Environmental Technology Site (RFETS) in Colorado will be moved to Pantex and SRS. Plutonium currently stored at the Hanford Site (Hanford), the Idaho National Engineering Laboratory (INEL), and the Los Alamos National Laboratory (LANL) will remain at those sites until disposition (or movement to lag storage at the disposition facilities).

DOE's strategy for disposition of surplus plutonium is to pursue an approach that allows immobilization of surplus plutonium in glass or ceramic material for disposal in a geologic repository pursuant to the Nuclear Waste Policy Act, and burning of some of the surplus plutonium as mixed oxide (MOX) fuel in existing, domestic, commercial reactors, with subsequent disposal of the spent fuel in a geologic repository pursuant to the Nuclear Waste Policy Act. DOE may also burn MOX fuel in Canadian Deuterium Uranium [CANDU] reactors in the event of an appropriate agreement among Russia, Canada, and the United States, as discussed below. The timing and extent to which either or both of these disposition approaches (immobilization or MOX) are ultimately deployed will depend upon the results of future technology development and demonstrations, follow-on (tiered) site-specific environmental review, contract negotiations, and detailed cost reviews, as well as nonproliferation considerations, and agreements with Russia and other nations. DOE's program will be subject to the highest standards of safeguards and security throughout all aspects of storage, transportation, and processing, and will include appropriate International Atomic Energy Agency verification.

Due to technology, complexity, timing, cost, and other factors that would be involved in purifying certain plutonium materials to make them suitable for potential use in MOX fuel, approximately 30 percent of the total quantity of plutonium (that has or may be declared surplus to defense needs) would require extensive purification to use in MOX fuel, and therefore will likely be immobilized. DOE will immobilize at least 8 metric tons (MT) of currently declared surplus plutonium materials that DOE has already determined are not suitable for use in MOX fuel. DOE reserves the option of using the immobilization approach for all of the surplus plutonium.

The exact locations for disposition facilities will be determined pursuant to a follow-on, site-specific disposition environmental impact statement (EIS) as well as cost, technical and nonproliferation studies. However, DOE has decided to narrow the field of candidate disposition sites. DOE has decided that a vitrification or immobilization facility (collocated with a plutonium conversion facility) will be located at either Hanford or SRS, that a potential MOX fuel fabrication facility will be located at Hanford, INEL, Pantex, or SRS (only one site), and that a "pit" disassembly and conversion facility will be located at Hanford, INEL, Pantex, or SRS (only one site). ("Pits" are weapons components containing plutonium.) The specific reactors, and their locations, that may be used to burn the MOX fuel will depend on contract negotiations, licensing, and environmental reviews. Because there are a number of technology variations that could be used for immobilization, DOE will also determine the specific immobilization technology based on the follow-on EIS, technology developments, cost information, and nonproliferation considerations. Based on current technological and cost information, DOE anticipates that the follow-on EIS will identify, as part of the proposed action, immobilizing a portion of the surplus plutonium using the "can-in-canister" technology at the Defense Waste Processing Facility (DWPF) at the Savannah River Site.

The use of MOX fuel in existing reactors would be undertaken in a manner that is consistent with the United States' policy objective on the irreversibility of the nuclear disarmament process and the United States' policy discouraging the civilian use of plutonium. To this end, implementing the MOX alternative would include government ownership and control of the MOX fuel fabrication facility at a DOE site, and use of the facility only for the surplus plutonium disposition program. There would be no reprocessing or subsequent reuse of spent MOX fuel. The MOX fuel would be used in a once-through fuel cycle in existing reactors, with appropriate arrangements, including contractual or licensing provisions, limiting use of MOX fuel to surplus plutonium disposition.

The Department of Energy also retains the option of using MOX fuel in Canadian Deuterium Uranium (CANDU) reactors in Canada in the event a multilateral agreement is negotiated among Russia, Canada, and the United States to use CANDU reactors for surplus United States' and Russian plutonium. DOE will engage in a test and demonstration program for CANDU MOX fuel as appropriate and consistent with future cooperative efforts with Russia and Canada.

These efforts will provide the basis and flexibility for the United States to initiate disposition efforts either multilaterally or bilaterally through negotiations with other nations, or unilaterally as an example to Russia and

other nations. Disposition of the surplus plutonium will serve as a nonproliferation and disarmament example, encourage similar actions by Russia and other nations, and foster multilateral or bilateral disposition efforts and agreements.

EFFECTIVE DATE: The decisions set forth in this Record of Decision (ROD) are effective upon issuance of this document, in accordance with DOE's National Environmental Policy Act (NEPA) Implementing Procedures and Guidelines (10 CFR Part 1021) and the Council on Environmental Quality (CEQ) regulations implementing NEPA (40 CFR Parts 1500-1508).

ADDRESSES: Copies of the S&D Final PEIS, the Technical Summary Report For Long-Term Storage of Weapons-Usable Fissile Materials, the Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition, the Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition, and this ROD may be obtained by writing to the U.S. Department of Energy, Office of Fissile Materials Disposition, MD-4, 1000 Independence Avenue, SW., Washington, DC 20585, or by calling (202) 586-4513. The 56-page Summary of the S&D Final PEIS, the other documents noted above (other than the full PEIS), and this ROD are also available on the Fissile Materials Disposition World Wide Web Page at: http://web.fie.com/htdoc/fed/DOE/fsl/pub/menu/any/

FOR FURTHER INFORMATION CONTACT: For information on the storage and disposition of weapons-usable fissile materials program or this ROD contact: Mr. J. David Nulton, Director, NEPA Compliance and Outreach, Office of Fissile Materials Disposition (MD-4), U.S. Department of Energy, 1000 Independence Avenue, SW., Washington, DC 20585, telephone (202) 586-4513.

For information on the DOE NEPA process, contact: Carol M. Borgstrom, Director, Office of NEPA Policy and Assistance (EH-42), U.S. Department of Energy, 1000 Independence Ave., SW, Washington, DC 20585, telephone (202) 586-4600 or leave a message at (800) 472-2756.

SUPPLEMENTARY INFORMATION:

I. Background

The end of the Cold War has created a legacy of surplus weapons-usable fissile materials both in the United States and the former Soviet Union. Further agreements on disarmament may increase the surplus quantities of these materials. The global stockpiles of weapons-usable fissile materials pose a danger to national and international security in the form of potential proliferation of nuclear weapons and the potential for environmental, safety, and health consequences if the materials are not properly safeguarded and managed.

In September 1993, President Clinton issued a Nonproliferation and Export Control Policy in response to the growing threat of nuclear proliferation. Further, in January 1994, President Clinton and Russia's President Yeltsin issued a Joint Statement Between the United States and Russia on Nonproliferation of Weapons of Mass Destruction and the Means of Their Delivery. In accordance with these policies, the focus of the U.S. nonproliferation efforts in this regard is five-fold: (i) To secure nuclear materials in the former Soviet Union; (ii) to assure safe, secure, long-term storage and disposition of surplus weapons-usable fissile materials; (iii) to establish transparent and irreversible nuclear arms reductions; (iv) to strengthen the nuclear nonproliferation regime; and (v) to control nuclear exports. The policy also states that the United States will not encourage the civil use of plutonium and that the United States does not engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes.

To demonstrate the United States' commitment to these objectives, President Clinton announced on March 1, 1995, that approximately 200 metric tons of U.S.-origin weapons-usable fissile materials, of which 165 metric tons are HEU and 38 metric tons are weapons-grade plutonium, had been declared surplus to the United States' defense needs.[1] The safe and secure storage of weapons-usable plutonium and HEU, and the disposition of surplus weapons-usable plutonium, consistent with the Preferred Alternative in the S&D Final PEIS and the decisions described in section V of this ROD, are consistent with the President's nonproliferation policy.

[1] The Secretary of Energy's Openness Initiative announcement of February 6, 1996, announced that the United States has about 213 metric tons of surplus fissile materials, including the 200 metric tons the President announced in March, 1995. Of the 213 metric tons of surplus materials, the Openness Initiative announcement indicated that about 174.3 metric tons are HEU and about 38.2 metric tons are weapons-grade plutonium. Additional quantities of plutonium may be declared surplus in the future; therefore, the S&D Final PEIS analyzes the disposition of a nominal 50 metric tons of plutonium, as well as the storage of 89 metric tons of plutonium and 994 metric tons of HEU.

II. Decisions Made in This ROD

This ROD encompasses two categories of decisions: (1) The sites and facilities for storage of non-surplus weapons-usable plutonium and HEU, and storage of surplus plutonium and HEU pending disposition; and (2) the programmatic strategy for disposition of surplus weapons-usable plutonium. This ROD does not encompass the final selection of sites for plutonium disposition facilities, nor the extent to which the two plutonium disposition approaches (immobilization or MOX) will ultimately be implemented. Those decisions will be made pursuant to a follow-on EIS. However, DOE does announce in this ROD that the slate of candidate sites for plutonium disposition has been narrowed. This ROD does not include decisions about the disposition of surplus HEU, which were made in July 1996 in the separate ROD for the Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement, 61 FR 40619 (Aug. 5, 1996).[2]

III. NEPA Process

A. S&D Draft PEIS

On June 21, 1994, DOE published a Notice of Intent (NOI) in the Federal Register (59 FR 31985) to prepare a Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement (S&D PEIS), which was originally to address the storage and disposition of both plutonium and HEU. DOE subsequently concluded that a separate EIS on surplus HEU disposition would be appropriate. Accordingly, DOE published a notice in the Federal Register (60 FR 17344) on April 5, 1995, to inform the public of the proposed plan to prepare a separate EIS for the disposition of surplus HEU.

DOE published an implementation plan (IP) for the S&D PEIS in March 1995 (DOE/EIS-0229-IP). The IP recorded the issues identified during the scoping process, indicated how they would be addressed in the S&D PEIS, and provided guidance for the preparation of the S&D PEIS. DOE issued the Storage and Disposition of Weapons-Usable Fissile Materials Draft Programmatic Environmental Impact Statement (S&D Draft PEIS, DOE/EIS-0229-D) for public comment in February 1996. On March 8, 1996, both DOE and the Environmental Protection

[2] The material considered in the S&D Final PEIS, and covered by the decisions in this ROD, does not include spent nuclear fuel, irradiated targets, uranium-233, plutonium-238, plutonium residues of less than 50-percent plutonium by weight, or weapons program materials-in-use.

Agency (EPA) published Notices of Availability of the S&D Draft PEIS in the Federal Register (61 FR 9443 and 61 9450), announcing a public comment period from March 8 until May 7, 1996. In response to requests from the public, DOE on May 13, 1996 published another Notice in the Federal Register (61 FR 22038) announcing an extension of the comment period until June 7, 1996. Eight public meetings on the S&D Draft PEIS were held during March and April 1996 in Washington, DC and in the vicinity of the DOE sites under consideration for the proposed actions.

During the 92-day public comment period, the public was encouraged to provide comments via mail, toll-free fax, electronic bulletin board (Internet), and toll-free telephone recording device. By these means, DOE received 8,442 comments from 6,543 individuals and organizations for consideration. In addition, 250 oral comments were recorded from some of the 734 individuals who attended the eight public meetings. All of the comments received, and the Department's responses to them, are presented in Volume IV (the Comment Response Document) of the S&D Final PEIS. All of the comments were considered in preparation of the S&D Final PEIS, and in many cases resulted in changes to the document. The Notice of Availability for the S&D Final PEIS was published by EPA in the Federal Register on December 13, 1996 (61 FR 65572). DOE published its own Notice of Availability for the S&D Final PEIS in the Federal Register on December 19, 1996 (61 FR 67001).

B. Alternatives Considered

The S&D PEIS analyzes the reasonable action alternatives in addition to the Preferred Alternative and the No Action Alternative. The Preferred Alternative, which is described below in section V, Decisions, and which DOE has decided to implement, represents a combination of alternatives for both storage and disposition.

1. The Proposed Action

The proposed action, as described in the S&D PEIS, would involve the following actions for U.S. weapons-usable fissile materials:

- Storage—provide a long-term storage system (for up to 50 years) for nonsurplus plutonium and HEU that meets the Stored Weapons Standard [3] and applicable environmental, safety, and health standards while reducing storage and infrastructure costs.
- Storage Pending Disposition—provide storage that meets the Stored Weapons Standard for inventories of weapons-usable plutonium and HEU [4] that have been or may be declared surplus.
- Disposition—convert surplus plutonium and plutonium that may be declared surplus in the future to forms that meet the Spent Fuel Standard,[5] thereby providing evidence of irreversible disarmament and setting a model for proliferation resistance.

2. Long-Term Storage Alternatives and Related Activities

a. No Action. Under the No Action Alternative, all weapons-usable fissile materials would remain at existing storage sites. Maintenance at existing storage facilities would be done as required to ensure safe operation for the balance of the facility's useful life. Sites covered under the No Action Alternative included Hanford, INEL, Pantex, the ORR, SRS, RFETS, and LANL. Although there are no weapons-usable fissile materials within the scope of the S&D PEIS stored currently at Nevada Test Site (NTS), it was also analyzed under No Action to provide an environmental baseline against which impacts of the storage and disposition action alternatives were analyzed.

b. Upgrade at Multiple Sites. Under this alternative for storage, DOE would either modify certain existing facilities or build new facilities, depending on the site's ability to meet standards for nuclear material storage facilities, and would utilize existing site infrastructure to the extent possible. These modified or new facilities would be designed to operate for up to 50 years. Plutonium materials currently stored at Hanford, INEL, Pantex, and SRS would remain at those four sites (in upgraded or new facilities), and HEU would remain at ORR (in upgraded, consolidated facilities). This alternative does not apply to NTS because NTS does not currently store weapons-usable fissile materials.

A sub-alternative of relocating portions of the plutonium inventory (a total of 14.4 metric tons according to DOE's Openness Initiative announcements of December 7, 1993, and February 6, 1996, respectively) from RFETS and LANL to one or more of the four existing plutonium storage sites is analyzed. Storage of surplus materials without strategic reserve and weapons research and development (R&D) materials is also included as a sub-alternative. Within some of the five candidate storage sites under this alternative, there are also multiple storage options.

c. Consolidation of Plutonium. Under this alternative, plutonium materials at existing sites would be removed, and the entire DOE inventory of plutonium would be consolidated at one site, while the HEU inventory would remain at ORR. Again, Hanford, INEL, Pantex and SRS would be candidate sites for plutonium consolidation. In addition, NTS would be a candidate site for this alternative. Consolidation of plutonium at ORR would result in a situation in which inventories of plutonium and HEU were collocated at one site; this alternative was therefore analyzed as one option under the Collocation Alternative (see below). A sub-alternative to account for the separate storage of surplus materials without strategic reserve and weapons R&D materials was also included.

d. Collocation of Plutonium and Highly Enriched Uranium. Under the Collocation Alternative, the entire DOE inventory of plutonium and HEU would be consolidated and collocated at the same site. The six candidate sites would be Hanford, NTS, INEL, Pantex, ORR, and SRS. A sub-alternative for the separate storage of surplus materials without strategic reserve and weapons R&D materials was also included.

3. Plutonium Disposition Alternatives and Related Activities

The disposition technologies analyzed in the S&D PEIS were those that would convert surplus plutonium into a form that would meet the Spent Fuel Standard. For the purpose of environmental impact analyses of the various disposition alternatives, both generic and specific sites were used to provide perspective on these

[3] The "Stored Weapons Standard" for weapons-usable fissile materials storage was initially defined in Management and Disposition of Excess Weapons Plutonium, National Academy of Sciences, 1994. DOE defines the Stored Weapons Standard as follows: The high standards of security and accounting for the storage of intact nuclear weapons should be maintained, to the extent practical, for weapons-usable fissile materials throughout dismantlement, storage, and disposition.

[4] The S&D PEIS covers long-term storage of nonsurplus HEU and storage of surplus HEU pending disposition. Until storage decisions are implemented, surplus HEU that has not gone to disposition will continue to be stored pursuant to, and not to exceed the 10-year interim storage time period evaluated in, the Environmental Assessment for the Proposed Interim Storage of Enriched Uranium Above the Maximum Historical Storage Level at the Y-12 Plant, Oak Ridge, Tennessee (Y-12 EA) (DOE/EA-0929, September 1994) and Finding of No Significant Impact (FONSI).

[5] The "Spent Fuel Standard" for disposition was also initially defined in Management and Disposition of Excess Weapons Plutonium, National Academy of Sciences, 1994. DOE defines the Spent Fuel Standard as follows: The surplus weapons-usable plutonium should be made as inaccessible and unattractive for weapons use as the much larger and growing quantity of plutonium that exists in spent nuclear fuel from commercial power reactors.

alternatives. Under each alternative, there are various ways to implement the alternative. These "variants" (such as the can-in-canister[6] approach) are shown in Table 1 to provide a range of available options for consideration.

TABLE 1.—DESCRIPTION OF VARIANTS UNDER PLUTONIUM DISPOSITION ALTERNATIVES

Alternatives analyzed	Possible variants
• Deep Borehole Direct Disposition	• Arrangement of plutonium in different types of emplacement canisters.
• Deep Borehole Immobilized Disposition	• Emplacement of pellet-group mix.
	• Pumped emplacement of pellet-grout mix.
	• Plutonium concentration loading, size and shape of ceramic pellets.
• New Vitrification Facilities	• Collocated pit disassembly/conversion, plutonium conversion, and immobilization facilities.
	• Use of either Cs–137 from capsules or HLW as a radiation barrier.
	• Wet or dry feed preparation technologies.
	• An adjunct melter adjacent to the DWPF at SRS, in which borosilicate glass frit with plutonium (without highly radioactive radionuclides) is added to borosilicate glass containing HLW from the DWPF.
	• A can-in-canister approach at SRS in which cans of plutonium glass (without highly radioactive radionuclides) are plaed in DWPF canisters which are then filled with borosilicate glass containing HLW in the DWPF (see Appendix O of the Final PEIS).
	• A can-in-canister approach similar to above but using new facilities at sites other than SRS.
• New Ceramic Immobilization Facilities	• Collocated pit disassembly/plutonium conversion, and immobilization facilities.
	• Use of either Cs–137 from capsules or HLW as a radiation barrier.
	• Wet or dry feed preparation technologies.
	• A can-in-canister approach at SRS in which the plutonium is immobilized without highly radioactive radionuclides in a ceramic matrix and then placed in the DWPF canisters that are then filled with borosilicate glass containing HLW (See Appendix O of the Final PEIS).
	• A can-in-canister approach similar to above but using new facilities at sites other than SRS.
• Electrometallurgical Treatment (glass-bonded zeolite form)	• Immobilize plutonium into metal ingot form.
	• Locate at DOE sites other than ANL–W at INEL.
• Existing LWR With New MOX Facilities	• Pressurized or Boiling Water Reactors.
	• Different numbers of reactors.
	• European MOX fuel fabrication.
	• Modification/completion of existing facilities for MOX fabrication.
	• Collocated pit disassembly/conversion, plutonium conversion, and MOX facilities.
	• Reactors with different core management schemes (plutonium loadings, refueling intervals).
• Partially Completed LWR With New MOX Facilities	• Same as for existing LWR (except that MOX fuel would not be fabricated in Europe).
• Evolutionary LWR With New MOX Facilities	• Same as for partially completed LWR.
• Existing CANDU Reactor With New MOX Facilities	• Different numbers of reactors.
	• Modification/completion of existing facilities for MOX fabrication.
	• Collocated pit disassembly/conversion, plutonium conversion, and MOX facilities.
	• Reactors with different core management schemes (plutonium loadings, refueling intervals).

Note: ANL–W=Argonne National Laboratory-West; Cs–137=cesium-137; HLW=high-level waste; LWR=light water reactor

The first step in plutonium disposition is to remove the surplus plutonium from storage, then process this material in a pit disassembly/conversion facility (for pits) or in a plutonium conversion facility (for non-pit materials). The processing would convert the plutonium material into a form suitable for each of the disposition alternatives described in the following sections. The pit disassembly/conversion facility and the plutonium conversion facility would be built at a DOE site. The six candidate sites for long-term storage were evaluated for the potential environmental impacts of constructing and operating these facilities.

a. No Disposition Action. A "No Plutonium Disposition" action means disposition would not occur, and surplus plutonium-bearing weapon components (pits) and other forms, such as metal and oxide, would remain in storage in accordance with decisions on the long-term storage of weapons-usable fissile materials.

b. Deep Borehole Category. Under this category of alternatives, surplus weapons-usable plutonium would be disposed of in deep boreholes that would be drilled at least 4 kilometers (km) (2.5 miles [mi]) into ancient, geologically stable rock formations beneath the water table. The deep borehole would provide a geologic barrier against potential proliferation. A generic site was evaluated for the construction and operation of a borehole complex where the surplus plutonium would be prepared for emplacement in the borehole. This complex would consist of five major facilities: Processing; drilling; emplacing/sealing; waste management; and support (security, maintenance, and utilities).

(1) Direct Disposition (Borehole). Under the Direct Disposition Alternative, surplus plutonium would be removed from storage, processed as necessary, converted to a form suitable for emplacement, packaged, and placed in a deep borehole. The deep borehole would be sealed to isolate the

[6] In the can-in-canister variant, cans of plutonium in a glass or ceramic matrix would be placed in a canister. This canister would then be filled with borosilicate glass containing high-level radioactive waste (HLW) or highly radioactive material such as cesium. This variant, at an existing facility (the Defense Waste Processing Facility [DWPF] at SRS), is described in Appendix O of the S&D Final PEIS.

plutonium from the accessible environment. Long-term performance of the deep borehole would depend on the stability of the geologic system. A generic site was used for the borehole complex to analyze the environmental impact of this alternative.

(2) Immobilized Disposition (Borehole). Under the Immobilized Disposition Alternative, the surplus plutonium would be removed from storage, processed, and converted to a suitable form for shipment to a ceramic immobilization facility. The output of this facility would be spherical ceramic pellets containing plutonium, facilitating handling during transportation and emplacement. The ceramic pellets (about 2.54 centimeters [cm] [1 inch {in}] in diameter and containing 1 percent plutonium by weight) would then be placed in drums and shipped to the borehole complex. At the deep borehole site, the ceramic pellets would be mixed with non-plutonium ceramic pellets and fixed with grout during emplacement. The deep borehole would be sealed to isolate the plutonium from the accessible environment. Long-term performance of the deep borehole would depend on the stability of the geologic system.

Although a generic site was used for analyses of the borehole complex in this alternative, the ceramic immobilization facility would be built at a DOE site. Therefore, the six candidate sites for long-term storage were used to evaluate the environmental impacts of the borehole immobilization facility.

c. Immobilization Category. Under this category of alternatives, surplus plutonium would be immobilized to create a chemically stable form for disposal in a geologic repository pursuant to the Nuclear Waste Policy Act (NWPA).[7] The plutonium material would be mixed with or surrounded by high-level waste (HLW) or other radioactive isotopes and immobilized to create a radiation field that could serve as a proliferation deterrent, along with safeguards and security comparable to those of commercial spent nuclear fuel, thereby achieving the Spent Fuel Standard. All immobilized plutonium would be encased in stainless steel canisters and would remain in onsite vault-type storage until a geologic repository pursuant to the NWPA is operational.

(1) Vitrification. Under the Vitrification Alternative, surplus plutonium would be removed from storage, processed, packaged, and transported to the vitrification facility. In this facility, the plutonium would be mixed with glass frit and highly radioactive cesium-137 (Cs-137) or HLW to produce borosilicate glass logs (a slightly different process, using HLW, would be used for the can-in-canister variant, as discussed in Appendix O of the S&D Final PEIS). The Cs-137 isotope could come from the cesium chloride (CsCl) capsules currently stored at Hanford or from existing HLW if the site selected for vitrification already manages HLW. Each glass log produced from the vitrification facility would contain about 84 kilograms (kg) (185 pounds [lb]) of plutonium. The vitrification facility would be built at a DOE site. The six candidate sites for long-term storage were analyzed for this alternative.

(2) Ceramic Immobilization. Under the Ceramic Immobilization Alternative, surplus plutonium would be removed from storage, processed, packaged, and transported to a ceramic immobilization facility. In this facility, the plutonium would be mixed with nonradioactive ceramic materials and Cs-137 or HLW to produce ceramic disks (a slightly different process, using HLW, would be used for the can-in-canister variant, as discussed in Appendix O of the S&D Final PEIS). Each disk would be approximately 30 cm (12 in) in diameter and 10 cm (4 in) thick, and would contain approximately 4 kg (9 lb) of plutonium. The Cs-137 or HLW would be provided as previously described. The ceramic immobilization facility would be built at a DOE site. The six candidate sites for long-term storage were analyzed for this alternative.

(3) Electrometallurgical Treatment. Under the Electrometallurgical Treatment Alternative, surplus plutonium would be removed from storage, processed, packaged, and transported to new or modified facilities for electrometallurgical treatment. This process could immobilize surplus fissile materials into a glass-bonded zeolite (GBZ) form. With the GBZ material, the plutonium would be in the form of a stable, leach-resistant mineral that is incorporated in durable glass materials.[8] Existing electrometallurgical facilities at INEL were used as a representative site for analysis of potential environmental impacts.

d. Reactor Category. Under the reactor alternatives considered in the S&D PEIS, DOE would fabricate surplus plutonium into MOX fuel for use in reactors. The irradiated MOX fuel would reduce the proliferation risks of the plutonium material, and the reactors would also generate electricity. MOX fuel would be used in a once-through fuel cycle, with no reprocessing or subsequent reuse of spent fuel. The spent nuclear fuel generated by the reactors would then be sent to a geologic repository pursuant to the NWPA.

Because the United States does not have a MOX fuel fabrication facility or capability, a new dedicated MOX fuel fabrication facility would be built at a DOE or commercial site.[9] The surplus plutonium from storage would be processed, converted to plutonium dioxide (PuO_2), and transferred to the MOX fuel fabrication facility. In this facility, PuO_2 and uranium dioxide (UO_2) (from existing domestic sources) would be blended and fabricated into MOX pellets, loaded into fuel rods, and assembled into fuel bundles suitable for use in the reactor alternatives under consideration.

(1) Existing Light Water Reactors. Under the Existing Light Water Reactor (LWR) Alternative, the MOX fuel containing surplus plutonium would be fabricated and transported to existing commercial LWRs in the United States, where the MOX fuel would be used instead of conventional UO_2 fuel. The LWRs employed for domestic electric power generation are pressurized water reactors (PWRs) and boiling water reactors (BWRs). Both types of reactors use the heat produced from nuclear fission reactions to generate steam that drives turbines and generates electricity. Three to five reactor units would be needed.[10]

[7] Also referred to as a permanent, or HLW repository. Pursuant to the Nuclear Waste Policy Act, DOE is currently characterizing the Yucca Mountain Site in Nevada as a potential repository for spent nuclear fuel and HLW. Legislative clarification, or a determination by the Nuclear Regulatory Commission that the immobilized plutonium should be isolated as HLW, may be required before the material could be placed in Yucca Mountain should DOE and the President recommend, and Congress approve, its operation. No Resource Conservation and Recovery Act (RCRA) wastes would be immobilized unless the immobilization would constitute adequate treatment under RCRA. The immobilized product would be consistent with the repository's waste acceptance criteria.

[8] In May 1996, the Department issued a Finding of No Significant Impact (FONSI) (61 Fed. Reg. 25647) and decision to proceed with the limited demonstration of the electrometallurgical treatment process at Argonne National Laboratory-West (ANL-W) at INEL for processing up to 125 spent fuel assemblies from the Experimental Breeder Reactor II (100 drivers and 25 blanket assemblies). Although this alternative could be conducted at other DOE sites, ANL-W is described in the S&D PEIS as the representative site for analysis.

[9] Although a generic commercial site was evaluated in the S&D PEIS, it is not part of the Preferred Alternative or the decisions in this ROD.

[10] It is possible that an existing LWR can be configured to produce tritium, consume plutonium as fuel, and generate revenue through the production of electricity. This configuration is called a multipurpose reactor. Environmental

(2) Partially Completed Light Water Reactors. Under the Partially Completed LWR Alternative, commercial LWRs on which construction has been halted would be completed. The completed reactors would use MOX fuel containing surplus plutonium. The characteristics of these LWRs would be the same as those of the existing LWRs discussed in the Existing LWR Alternative. The Bellefonte Nuclear Plant located along the west bank of the Tennessee River in Alabama was used as a representative site for the environmental analysis of this alternative. Two reactor units (such as those at the Bellefonte Nuclear Plant) would be needed to implement this alternative.

(3) Evolutionary Light Water Reactors. The evolutionary LWRs are improved versions of existing commercial LWRs. Two design approaches were considered in the S&D PEIS. The first is a large PWR or BWR similar to the size of the existing PWR and BWR. The second is a small PWR approximately one-half the size of the large PWR. Two large or four small evolutionary LWRs would be needed to implement this alternative.

Under each design approach for this alternative, evolutionary LWRs would be built at a DOE site. Therefore, the six candidate sites for long-term storage were used to evaluate the environmental impacts of this alternative.

(4) Canadian Deuterium Uranium Reactor. Under the CANDU Reactor Alternative, the MOX fuel containing surplus plutonium would be fabricated in a U.S. facility, then transported for use in one or more commercial heavy water reactors in Canada. The Ontario Hydro Bruce-A Nuclear Generating Station identified by the Government of Canada was used as a representative site for evaluation of this alternative. This station is located on Lake Huron about 300 km (186 mi) northeast of Detroit, Michigan. Environmental analysis of domestic activities up to the U.S./Canadian border is presented in the S&D PEIS. The use of CANDU reactors would be subject to the policies, regulations, and approval of the Federal and Provincial Canadian Governments. Pursuant to Section 123 of the Atomic Energy Act, any export of MOX fuel from the United States to Canada must be made under the agreement for cooperation between the two countries. Spent fuel generated by a CANDU reactor would be disposed under the Canadian spent fuel program.

C. Preferred Alternative

The S&D Final PEIS presented the Department's Preferred Alternative for both storage and disposition. DOE has decided to implement the Preferred Alternative as described in the S&D Final PEIS. Thus, the Preferred Alternative is described in Section V of this ROD, Decisions.

D. Environmental Impacts

Chapter 4 and the appendices of the S&D Final PEIS analyzed the potential environmental impacts of the storage and disposition alternatives in detail. The S&D Final PEIS also evaluated the maximum site impacts that would result at Hanford, INEL, Pantex, and SRS from combining the Preferred Alternative for storage with the Preferred Alternative for disposition. Consistent with the Preferred Alternative, Hanford, INEL, Pantex, and SRS are each a possible location for all or some plutonium disposition activities. The siting, construction, and operation of disposition facilities will be covered in a separate, follow-on EIS. The S&D Final PEIS described the total life cycle impacts that would result from the Preferred Alternative at the DOE sites identified for potential placement of the disposition facilities.

Based on analyses in the S&D Final PEIS, the areas where impacts might be significant are as follows:

- The use of groundwater at the Pantex Plant for storage and disposition facilities could contribute to the overall declining water levels of the Ogallala Aquifer. The projected No Action Alternative water usage at Pantex in the year 2005 reflects a reduction from current usage due to planned downsizing over the next few years. The Preferred Alternative would require a 72-percent increase in the projected No Action Alternative water use; the total amount (428 million liters per year) is considerably less than what is currently being withdrawn (836 million liters per year) at Pantex.
- A set of postulated accidents was used for each plutonium disposition alternative over the life of the campaign to obtain potential radiological impacts at the four DOE sites where disposition facilities could be built. The PEIS analyzes the risk of latent cancer fatalities (reflecting the probability of accident occurrence and the latent cancer fatalities potentially caused by the accident) for accidents that have low probabilities of occurrence and severe consequences, as well as those that have higher probabilities and low consequences. For potential severe accidents, the risk of latent cancer fatalities to the population located within 80 kilometers (50 miles) of the accident for the "front-end" disposition process campaign would range from 4.5×10^{-16} (that is, approximately 1 chance in 2 quadrillion) to 1.7×10^{-4} (approximately 1 chance in 6,000) for the pit disassembly/conversion facility, and from 1.5×10^{-16} to 1.3×10^{-4} for the plutonium conversion facility. This risk would range from 2.8×10^{-14} to 1.8×10^{-5} for the vitrification facility, from 7.0×10^{-16} to 1.9×10^{-7} for the ceramic immobilization facility, and from 4.6×10^{-16} to 4.3×10^{-4} for the MOX fuel fabrication facility. To estimate the change in risk associated with using MOX fuel instead of uranium fuel in existing LWRs, the severe accident scenarios assumed a large population distribution near a generic existing LWR and extreme meteorological conditions for dispersal, leading to large doses that were not necessarily reflective of actual site conditions. The resultant change in risk of cancer fatalities to a generic population located within 80 km (50 mi) of the severe accidents was estimated to range from -2.0×10^{-4} to 3.0×10^{-5} per year [11], reflecting a postulated risk of using MOX fuel that ranges from seven percent lower to eight percent higher than the risk of using uranium fuel. Under the Preferred Alternative, the estimated risk of cancer fatalities under severe accident conditions using MOX fuel in existing LWRs ranges from 0.01 to 0.098 for an 11-year campaign.
- Under the Preferred Alternative, HEU would continue to be stored at the Y-12 Plant at ORR in existing facilities that would be upgraded to meet requirements for withstanding natural phenomena, including earthquakes and tornadoes. This upgrade would reduce the expected risk for the design basis accidents analyzed in the Y-12 EA (for example, Building 9212) by approximately 80 percent, resulting in a latent cancer fatality risk of 7.4×10^{-6} (approximately 7 in a million) to the maximally exposed individual, 5.7×10^{-8} (approximately 6 in 100

analysis of the multipurpose reactor is included in Chapter 4 of the Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling (TSR PEIS) (DOE/EIS-0161, October 1995) and Appendix N of the S&D PEIS. In the TSR PEIS ROD (December 1995), the multipurpose reactor was preserved as an option for future consideration. The Fast Flux Test Facility (FFTF) at Hanford has been under consideration for tritium production, and could also use surplus plutonium as reactor fuel if it were shown to be useful for tritium production. This ROD does not preclude use of the FFTF for tritium production or the potential use of surplus plutonium as fuel for the FFTF.

[11] Accidents severe enough to cause a release of plutonium involved combinations of events that are highly unlikely. Estimates and analyses presented in Chapter 4 and summarized in Table 2.5-3 of the PEIS indicate a range of latent cancer fatalities of 5,900 to 7,300 and a risk of 0.016 to 0.15 of a fatality in the population for the 17-year campaign analyzed under the Existing LWR Alternative.

million) to a non-involved worker, and 5.1×10^{-7} (approximately 5 in 10 million) to the 80-km offsite population.

• Under the Preferred Alternative, safe, secure storage would continue for materials at Hanford, INEL, and ORR, pending disposition. Therefore, there would be no transportation impact at these sites until disposition. The storage transportation impact would come from movement of the RFETS materials to Pantex and SRS. If, following the EIS for construction and operation of plutonium disposition facilities, potential plutonium disposition activities were added to Hanford, INEL, Pantex, and SRS, the estimated total health effects for the life of the project from transportation of surplus plutonium (including transportation of those materials from RFETS to Pantex and SRS) would range from 0.193 fatalities for transportation to Pantex, to 1.87 fatalities for transportation to SRS (primarily from normal expected traffic accidents, not from radiological releases). In addition to the disposition activities at DOE sites, there would be transportation of the MOX fuel from the DOE fuel fabrication site to existing LWRs. The location of the LWRs and the destination of the MOX fuel could be either the eastern or western United States. For 4,000 km (2,486 mi) of such transportation, there could be up to an additional 3.61 potential fatalities (primarily from normal expected traffic accidents, not from radiological releases) for the life of the campaign, assuming 100 percent of the surplus plutonium would be used in commercial reactors. The actual amount would be smaller, and therefore potential fatalities would be lower, under the Preferred Alternative.

• At Hanford, INEL, Pantex, and SRS the Preferred Alternative would slightly increase regional employment and income. At RFETS, phaseout of plutonium storage would result in the loss of approximately 2,200 direct jobs. Compared to the total employment in the area, the loss of these jobs and the impacts to the regional economy would not be severe.

DOE has fully considered all of the environmental analyses in the S&D Final PEIS in reaching the decisions set forth in Section V, below.

E. Avoidance/Minimization of Environmental Harm

For the long-term storage of fissile material, there are four sites (Hanford, NTS, INEL, and LANL) where the Preferred Alternative is "no action"; that is, no plutonium would be stored at NTS, and at Hanford, INEL, and LANL, DOE would continue storage at existing facilities, using proven nuclear materials safeguards and security procedures, until disposition. These existing facilities would be maintained to ensure their safe operation and compliance with applicable environmental, safety and health requirements. At RFETS, the Preferred Alternative is to phase out storage of weapons-usable fissile materials, thus mitigating environmental impacts at RFETS. There are three sites (Pantex, ORR, and SRS) where the Preferred Alternative is to upgrade existing and planned new facilities. Site-specific mitigation measures for storage at these sites have been described in the S&D Final PEIS, and are summarized as follows:

• At Pantex, to alleviate the effects from using groundwater from the Ogallala Aquifer, the city of Amarillo is considering supplying treated wastewater to Pantex from the Hollywood Road Wastewater Treatment Plant for industrial use; the Department will use such treated wastewater to the extent possible. Radiation doses to individual workers will be kept low by maintaining comprehensive badged monitoring and programs to keep worker exposures "as low as reasonably achievable" (ALARA).

• At ORR, radiation doses to individual workers will be kept low by maintaining comprehensive badged monitoring and ALARA programs, including worker rotations. Upgrades for HEU storage to meet performance requirements will include seismic structural modifications as documented in Natural Phenomena Upgrade of the Downsized/Consolidated Oak Ridge Uranium/Lithium Plant Facilities. These modifications will reduce the risk of accidents to workers and the public.

• At SRS, to minimize soil erosion impacts during construction, storm water management and erosion control measures will be employed. Mitigation measures for potential Native American resources will be identified through consultation with the potentially affected tribes. Radiation doses to individual workers will be kept low by maintaining comprehensive badged monitoring and ALARA programs including worker rotations. The modified Actinide Packaging and Storage Facility (APSF) will be designed and operated in accordance with contemporary DOE Orders and regulations to reduce risks to workers and the public.

From a nonproliferation standpoint, the highest standards for safeguards and security will be employed during transportation, storage, and disposition. With respect to transportation, DOE will coordinate the transport of plutonium and HEU with State officials, consistent with current policy. Although the actual routes will be classified, they will be selected to circumvent populated areas, maximize the use of interstate highways, and avoid bad weather. DOE will continue to coordinate emergency preparedness plans and responses with involved states through a liaison program. The packaging, vehicles, and transport procedures being used are specifically designed and tested to prevent a radiological release under all credible accident scenarios.

For the Preferred Alternative for disposition, site-specific mitigation measures will be addressed in the follow-on, site-specific EIS. In the Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives, measures are proposed to reduce the possibility of the theft or loss of material. For both immobilization and MOX fuel fabrication, bulk processing is the point in the disposition process when the material is most vulnerable to covert attempts to steal or divert it. A variety of opportunities for improving safeguards, some of which are already implemented at large, modern facilities, include near real-time accounting, increased automation in the process design, and improved containment and surveillance.

The security risks posed by transportation can be reduced by minimizing the amount of transportation required (for example, putting the plutonium processing and MOX fabrication operations at the same site), minimizing the number of sites to which material has to be shipped, and minimizing the distance between those sites.

F. Environmentally Preferable Alternatives

The environmental analyses in Chapter 4 of the S&D Final PEIS indicate that the environmentally preferable alternative (the alternative with the lowest environmental impacts over the 50 years considered in the PEIS) for storage of weapons-usable fissile materials would be the Preferred Alternative, which consists of No Action at Hanford, NTS, INEL, and LANL pending disposition, phaseout of storage at RFETS, and upgrades that would ultimately reduce environmental vulnerabilities at ORR, SRS, and Pantex.

For disposition of surplus plutonium, the environmentally preferable alternative would be the No Disposition Action alternative, because the

plutonium would remain in storage in accordance with decisions on the long-term storage of weapons-usable fissile materials, and there would be no new Federal actions that could impact the environment. For normal operations, analyses show that immobilization would be somewhat preferable to the existing LWR and preferred alternatives, although these alternatives, with the exception of waste generated, would be essentially environmentally comparable.[12]

Severe facility accident considerations indicate that immobilization options would be environmentally preferable to the existing reactor and preferred alternatives, although the likelihood of occurrence of severe accidents and the risk to the public are expected to be fairly low. Although No Disposition Action would be environmentally preferable, it would not satisfy the purpose and need for the Proposed Action, because the stockpile of surplus plutonium would not be reduced, and the Nonproliferation and Export Control Policy would not be implemented.

The hybrid approach (pursuing both reactors/MOX and immobilization) is being chosen over immobilization alone because of the increased flexibility it will provide by ensuring that plutonium disposition can be initiated promptly should one of the approaches ultimately fail or be delayed. Establishing the means for expeditious plutonium disposition will also help provide the basis for an international cooperative effort that can result in reciprocal, irreversible plutonium disposition actions by Russia. (See discussion in sections IV and V, below.)

IV. Non-Environmental Considerations

A. Technical Summary Reports

To assist in the preparation of this ROD, DOE's Office of Fissile Materials Disposition prepared and in July 1996 issued a *Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition and a Technical Summary Report for Long-Term Storage of Weapons-Usable Fissile Materials.* These Technical Summary Reports (TSRs) summarize technical, cost, and schedule data for the storage and disposition alternatives that are considered in the S&D PEIS. After receiving comments on each of the TSRs, DOE issued revised versions of the reports in October and November, 1996, respectively.

1. Storage Technical Summary Report

This report provides technical, cost and schedule information for long-term storage alternatives analyzed in the S&D PEIS. The cost information for each alternative is presented in constant 1996 dollars and also discounted or present value dollars. It identifies both capital costs and life cycle costs. The following costs are in 1996 dollars.

The cost analyses show that the combination (preferred) alternative for the storage of plutonium would provide advantages to the Department with respect to implementing disposition technologies and would be the least expensive compared to other storage alternatives. The cost of the combination (preferred) alternative would be approximately $30 million in investment and $360 million in operating costs from inception until disposition occurs. The cost of the upgrade at multiple sites alternative would be approximately $380 million in investment and $3.2 billion in operating costs for 50 years. The costs for the consolidation alternative could range from approximately $40 million to $360 million in investment and $600 million to $1.1 billion for operating costs for 50 years, depending on the extent to which existing facilities and capabilities can be shared with other programs at the sites.

The schedule analysis shows that the upgraded storage facilities for plutonium under the combination (preferred) alternative could be operational by 2004 at Pantex (Zone 12), and by 2001 at SRS. The upgrade for the storage of HEU could be completed by 2004 (or earlier). RFETS pits could be received at Pantex beginning in 1997 in Zone 4 on a temporary basis until Zone 12 upgrades are completed. The other analyzed alternatives (upgrade and consolidation) would require about six years to complete.

2. Disposition Technical Summary Report

This report provides technical viability, cost, and schedule information for plutonium disposition alternatives and variants analyzed in the S&D PEIS. The variants analyzed in the report are based on pre-conceptual design information in most cases.

a. Technical Viability Estimates. The report indicates that each of the alternatives appears to be technically viable, although each is currently at a different level of technical maturity. There is high confidence that the technologies are sufficiently mature to allow procurement and/or construction of facilities and equipment to meet plutonium disposition technical requirements and to begin disposition in about a decade.[13]

Reactor Alternatives—Light water reactors (LWRs) can be readily converted to enable the use of MOX fuels. Many European LWRs currently operate on MOX fuel cycles. Although some technical risks exist, they are all amenable to engineering resolution. Sufficient existing domestic reactor capacity exists, unless significant delays occur in the disposition mission. CANDU reactors appear to be capable of operating on MOX fuel cycles, but this has never been demonstrated on any industrial scale. Therefore, additional development would be required to achieve the level of maturity for the CANDU reactors that exists for light water reactors. Partially complete and evolutionary LWRs would involve increased technical risk relative to existing LWRs, as well as the need to complete or build (and license) new reactor facilities. The spent MOX fuel waste form that results from reactor disposition of surplus plutonium will have to satisfy waste acceptance criteria for the geologic repository.

Immobilization Alternatives—All vitrification alternatives require additional research and development prior to implementation of immobilization of weapons-usable plutonium. However, a growing experience base exists relating to the vitrification of high-level waste. These existing technologies can be adapted to the plutonium disposition mission, though different equipment designs and glass formulations will generally be necessary due to criticality considerations and chemical differences between plutonium and HLW that may affect the stability of the glass matrix. Vitrification and ceramic immobilization alternatives are similar with regard to the technical maturity of incorporating plutonium in their respective matrices. The technical viability of electrometallurgical treatment has not yet been established for the plutonium disposition mission. The experimental data base for this alternative is limited, and critical questions on waste form performance are not yet resolved. This alternative is considered practical only if the underlying technology is further

[12] The potential risk of latent cancer fatality for a maximally exposed individual of the public from lifetime accident-free operation under the various alternatives are: 1.2×10^{-9} to 1.2×10^{-7} for boreholes, 1.2×10^{-9} to 1.2×10^{-7} for immobilization (vitrification or ceramic immobilization), 1.3×10^{-6} to 2.6×10^{-6} for existing LWRs, and 9.0×10^{-7} to 1.7×10^{-6} for the Preferred Alternative.

[13] Actual timing would depend on technical demonstrations, follow-on site-specific environmental review, detailed cost estimates, and international agreements.

developed for spent nuclear fuels.[14] All of the immobilization alternatives will require qualification (to meet acceptance criteria) of the waste form for the geologic repository, and may require legislative clarification or NRC rulemaking.

Deep Borehole Alternatives—Uncertainties for the deep borehole alternatives relate to selecting and qualifying a site; additional legislation and regulations, or legislative and regulatory clarification, may be required. The front-end feed processing operations for the deep borehole alternatives are much simpler than for other alternatives because no highly radioactive materials are processed, thus avoiding the need for remote handling operations. Emplacement technologies are comprised of largely low-technology operations which would be adaptations from existing hardware and processes used in the oil and gas industry.

Hybrid Approaches—Two hybrid approaches that combine technologies were considered as illustrative examples, using existing LWR or CANDU reactors in conjunction with a can-in-canister (immobilization) approach. Hybrids provide insurance against technical or institutional hurdles which could arise for a single technology approach for disposition. If any significant roadblock is encountered in any one area of a hybrid, it would be possible to simply divert the feed material to the more viable technology. In the case of a single technology, such roadblocks would be more problematic.

b. Cost Estimates. The following discussion is in constant 1996 dollars unless otherwise stated.

(1) Investment Costs.

• The investment costs for existing reactor variants tends to be about $1 billion; completing or building new reactors increases the investment cost to between $2 billion and $6 billion.

• The investment cost for the immobilization alternatives ranges from approximately $0.6 billion for the can-in-canister variants to approximately $2 billion for new greenfield variants.[15]

• Hybrid alternatives (combining both immobilization and reactor alternatives) require approximately $200 million additional investment over the existing light water reactor stand-alone alternatives.

• Investment costs for the deep borehole alternatives range from about $1.1 billion for direct emplacement to about $1.4 billion for immobilized emplacement.

• Alternatives that utilize existing facilities for plutonium processing, immobilization, or fuel fabrication would realize significant investment cost savings over building new facilities for the same function.

• Large uncertainties in the cost estimates exist, relating to both engineering and institutional factors.

• A significant fraction of the investment cost for an alternative/variant is related to the front-end facilities for the extraction of the plutonium from pits and other plutonium-bearing materials and for other functions that are common to all alternatives.

(2) Life Cycle Costs.

• The life cycle costs for hybrid alternatives are similar to the stand-alone reactor alternatives. For the existing LWR/immobilization hybrid alternative (preferred alternative), the cost is $260 million higher than the stand-alone reactor alternative; for the CANDU/immobilization hybrid alternative, the cost is $70 million higher.

• The combined investment and net operating costs for MOX fuel are higher than for commercial uranium fuel; thus, the cost of MOX fuel cannot compete economically with low-enriched uranium fuel for LWRs or natural uranium fuel for CANDU reactors.

• The can-in-canister approaches are the most attractive variants for immobilization based on cost considerations.

• The deep borehole alternatives are more expensive than the can-in-canister and existing reactor alternatives. The immobilized borehole alternative life cycle cost is $1 billion greater than that for the direct emplacement alternative ($3.6 billion vs. $2.6 billion).

• Large uncertainties in the cost estimates exist, relating to engineering, regulatory, and policy considerations.

c. Schedule Estimates. The key conclusions of the Disposition Technical Summary Report with respect to schedules are as follows:

• Significant schedule uncertainties exist, relating to both engineering and institutional factors.

• Opportunities for compressing or expanding schedules exist.

(1) Reactor Alternatives. • The rate at which MOX fuel is consumed in reactors will depend on the rate that MOX fuel is provided and fabricated, and the rate that plutonium oxide is provided to the MOX fuel fabrication facility.

• The time to attain production scale operation in existing LWRs and CANDU reactors could be about 8–12 years, depending on the need for and source of test assemblies that might be required.

• The time to complete the disposition mission is a function of the number of reactors committed to the mission, among other factors. For the variants considered, the time to complete varies from about 24 to 31 years.

(2) Immobilization Alternatives.

• The time to start the disposition mission ranges from 7 to 13 years, depending on the technology used and whether existing facilities are used.

• The operating campaign for the immobilization alternatives at full-scale operation would be about 10 years; it is possible to compress or expand the operating schedule by several years, if desired, by resizing the immobilization facility designs selected for analysis in this study. The overall mission duration (including research and development, construction, and operation) is expected to be about 18 to 24 years.

• Potential delays for start-up of the immobilization alternatives involve completing process development and demonstration, and qualifying the waste form for a geologic repository.

(3) Deep Borehole Alternatives. • The time to start-up is expected to be 10 years.

• The operating duration of the mission would be about 10 years, although completing all burial operations at the borehole site in 3 years is possible. Therefore, the overall mission duration is estimated to be 20 years with accelerated emplacement reducing the duration by about 7 years.

• The schedule for the deep borehole alternatives would depend in part on selecting and qualifying a site, and obtaining legislative and regulatory clarification as well as any necessary permits.

(4) Hybrid Approaches. • In general, the schedule data that apply to the component technologies apply to the hybrid alternatives as well.

• Confidence in an early start-up and an earlier completion can both be improved with a hybrid approach, relative to stand-alone alternatives.

• Hybrid alternatives provide an inherent back-up technology approach to enhance confidence in attaining schedule goals.

[14] A recent study by the National Research Council concludes that the electrometallurgical treatment technology is not sufficiently mature to provide a reliable basis for timely plutonium disposition. "An Evaluation of the Electrometallurgical Approach for Treatment of Excess Weapons Plutonium" (National Academy Press, Washington, D.C., 1996).

[15] "Greenfield" means a variant involving a new facility, with no existing plutonium-handling infrastructure.

B. Nonproliferation Assessment

To assist in the development of this ROD, DOE's Office of Arms Control and Nonproliferation, with support from the Office of Fissile Materials Disposition, prepared a report, Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives. The report was issued in draft form in October 1996, and following a public comment period, was issued in final form in January 1997. It analyzes the nonproliferation and arms reduction implications of the alternatives for storage of plutonium and HEU, and disposition of excess plutonium. It is based in part on a Proliferation Vulnerability Red Team Report prepared for the Office of Fissile Materials Disposition by Sandia National Laboratory. The assessment describes the benefits and risks associated with each option. Some of the "options" and "alternatives" discussed in the Nonproliferation Assessment are listed as "variants" (such as can-in-canister) in the S&D Final PEIS. The key conclusions of the report, as presented in its Executive Summary, are reproduced below.

1. Storage. • Each of the options under consideration for storage of U.S. weapons-usable fissile materials has the potential to support U.S. nonproliferation and arms reduction goals, if implemented appropriately.

• Each of the storage options could provide high levels of security to prevent theft of nuclear materials, and could provide access to excess materials for international monitoring.

• Making excess plutonium and HEU available for bilateral U.S.-Russian monitoring and International Atomic Energy Agency (IAEA) safeguards, while protecting proliferation-sensitive information, would help demonstrate the U.S. commitment never to return this material to nuclear weapons, providing substantial arms reduction and nonproliferation benefits in the near-term.

2. Disposition of U.S. Excess Plutonium

a. In General. • Each of the options for disposition of excess weapons plutonium that meets the Spent Fuel Standard would, if implemented appropriately, offer major nonproliferation and arms reduction benefits compared to leaving the material in storage in directly weapons-usable form. Taking into account the likely impact on Russian disposition activities, the no-action alternative appears to be by far the least desirable of the plutonium disposition options from a nonproliferation and arms reduction perspective.

• Carrying out disposition of excess U.S. weapons plutonium, using options that ensured effective nonproliferation controls and resulted in forms meeting the Spent Fuel Standard, would:

• reduce the likelihood that current arms reductions would be reversed, by significantly increasing the difficulty, cost, and observability of returning this plutonium to weapons;

• increase international confidence in the arms reduction process, strengthening political support for the nonproliferation regime and providing a base for additional arms reductions, if desired;

• reduce long-term proliferation risks posed by this material by further helping to ensure that weapons-usable material does not fall into the hands of rogue states or terrorist groups; and

• lay the essential foundation for parallel disposition of excess Russian plutonium, reducing the risks that Russia might threaten U.S. security by rebuilding its Cold War nuclear weapons arsenal, or that this material might be stolen for use by potential proliferators.

• Choosing the "no-action alternative" of leaving U.S. excess plutonium in storage in weapons-usable form indefinitely, rather than carrying out disposition:

• would represent a clear reversal of the U.S. position seeking to reduce excess stockpiles of weapons-usable materials worldwide;

• would make it impossible to achieve disposition of Russian excess plutonium;

• could undermine international political support for nonproliferation efforts by leaving open the question of whether the United States was maintaining an option for rapid reversal of current arms reductions; and

• could undermine progress in nuclear arms reductions.

• The benefits of placing U.S. excess plutonium under international monitoring and then transforming it into forms that met the Spent Fuel Standard would be greatly increased, and the risks of these steps significantly decreased, if Russia took comparable steps with its own excess plutonium on a parallel track. The two countries need not use the same plutonium disposition technologies, however.

• As the 1994 NAS committee report [16] concluded, options for disposition of U.S. excess weapons plutonium will provide maximum nonproliferation and arms control benefits if they:

• minimize the time during which the excess plutonium is stored in forms readily usable for nuclear weapons;

• preserve material safeguards and security during the disposition process, seeking to maintain to the extent possible the same high standards of security and accounting applied to stored nuclear weapons (the Stored Weapons Standard);

• result in a form from which the plutonium would be as inaccessible and unattractive for weapons use as the larger and growing quantity of plutonium in commercial spent fuel (the Spent Fuel Standard).

• In order to achieve the benefits of plutonium disposition as rapidly as possible, and to minimize the risks and negative signals resulting from leaving the excess plutonium in storage, it is important for disposition options to begin, and to complete the mission as soon as practicable taking into account nonproliferation, environment, safety, and health, and economic constraints. Timing should be a key criterion in judging disposition options. Beginning the disposition quickly is particularly important to establishing the credibility of the process, domestically and internationally.

• Each of the options under consideration for plutonium disposition has its own advantages and disadvantages with respect to nonproliferation and arms control, but none is clearly superior to the others.

• Each of the options under consideration for plutonium disposition can potentially provide high levels of security and safeguards for nuclear materials during the disposition process, mitigating the risk of theft of nuclear materials.

• Each of the options under consideration for plutonium disposition can potentially provide for effective international monitoring of the disposition process.

• Plutonium disposition can only reduce, not eliminate, the security risks posed by the existence of excess plutonium, and will involve some risks of its own:

• Because all plutonium disposition options would take decades to complete, disposition is not a near-term solution to the problem of nuclear theft and smuggling. While disposition will make a long-term contribution, the near-term problem must be addressed through programs to improve security and safeguarding for nuclear materials, and to ensure adequate police, customs, and intelligence capabilities to interdict nuclear smuggling.

[16] See footnote 3, above.

Next Section

• All plutonium disposition options under consideration would involve processing and transport of plutonium, which will involve more risk of theft in the short term than if the material had remained in heavily guarded storage, in return for the long-term benefit of converting the material to more proliferation-resistant forms.

• Both the United States and Russia will still retain substantial stockpiles of nuclear weapons and weapons-usable fissile materials even after disposition of the fissile materials currently considered excess is complete. These weapons and materials will continue to pose a security challenge regardless of what is done with excess plutonium.

• None of the disposition options under consideration would make it impossible to recover the plutonium for use in nuclear weapons, or make it impossible to use other plutonium to rebuild a nuclear arsenal. Therefore, disposition will only reduce, not eliminate, the risk of reversal of current nuclear arms reductions.

• A U.S. decision to choose reactor alternatives for plutonium disposition could offer additional arguments and justifications to those advocating plutonium reprocessing and recycle in other countries. This could increase the proliferation risk if it in fact led to significant additional separation and handling of weapons-usable plutonium. On the other hand, if appropriately implemented, plutonium disposition might also offer an opportunity to develop improved procedures and technologies for protecting and safeguarding plutonium, which could reduce proliferation risks and would strengthen U.S. efforts to reduce the stockpiles of separated plutonium in other countries.

• Large-scale bulk processing of plutonium, including processes to convert plutonium pits to oxide and prepare other forms for disposition, as well as fuel fabrication or immobilization processes, represents the stage of the disposition process when material is most vulnerable to covert theft by insiders or covert diversion by the host state. Such bulk processing is required for all options, however; in particular, initial processing of plutonium pits and other forms is among the most proliferation-sensitive stages of the disposition process, but is largely common to all the options. More information about the specific process designs is needed to determine whether there are significant differences between the various immobilization and reactor options in the overall difficulty of providing effective assurance against theft or diversion during the different types of bulk processing involved, and if so, which approach is superior in this respect.

• Transport of plutonium is the point in the disposition process when the material is most vulnerable to overt armed attacks designed to steal plutonium. With sufficient resources devoted to security, however, high levels of protection against such overt attacks can be provided. International, and particularly overseas, shipments would involve greater transportation concerns than domestic shipments.[17]

b. Conclusions Relating to Specific Disposition Options.

• The reactor options, homogeneous immobilization[18] options, and deep borehole immobilized emplacement option can all meet the Spent Fuel Standard. The can-in-canister options are being refined to increase the resistance to separation of the plutonium cans from the surrounding glass, with the goal of meeting the Spent Fuel Standard. The deep borehole direct emplacement option substantially exceeds the Spent Fuel Standard with respect to recovery by sub-national groups, but could be more accessible and attractive for recovery by the host state than spent fuel.

• The reactor options have some advantage over the immobilization options with respect to perceived irreversibility, in that the plutonium would be converted from weapons-grade to reactor-grade, even though it is possible to produce nuclear weapons with both weapons and reactor-grade plutonium. The immobilization and deep borehole options have some advantage over the reactor options in avoiding the perception that they could potentially encourage additional separation and civilian use of plutonium, which itself poses proliferation risks.

• Options that result in accountable "items" (for purposes of international safeguards) whose plutonium content can be accurately measured (such as fuel assemblies or immobilized cans without fission products in the "can-in-canister" option) offer some advantage in accounting to ensure that the output plutonium matches the input plutonium from the process. Other options (such as homogeneous immobilization or immobilized emplacement in deep boreholes) would require greater reliance on containment and surveillance to provide assurance that no material was stolen or diverted—but in some cases could involve simpler processing, easing the task of providing such assurance.

• The principal uncertainty with respect to using excess weapons plutonium as MOX in U.S. LWRs relates to the potential difficulty of gaining political and regulatory approvals for the various operations required.

• Compared to the LWR option, the CANDU option would involve more transport and more safeguarding issues at the reactor sites themselves (because of the small size of the CANDU fuel bundles and the on-line refueling of the CANDU reactors). Demonstrating the use of MOX in CANDU reactors by carrying out this option for excess weapons plutonium disposition could somewhat detract from U.S. efforts to convince nations operating CANDU reactors in regions of proliferation concern not to pursue MOX fuel cycles, but these nations are likely to base their fuel cycle decisions primarily on factors independent of disposition of this material. Disposing of excess weapons plutonium in another country long identified with disarmament could have significant symbolic advantages, particularly if carried out in parallel with Russia. Disposition of Russian plutonium in CANDU reactors, however, would require resolving additional transportation issues and additional questions relating to the likely Russian desire for compensation for the energy value of the plutonium.

• The immobilization options have the potential to be implemented more quickly than the reactor options. They face somewhat less political uncertainty but somewhat more technical uncertainty than the reactor options.

• The likelihood of very long delays in gaining approval for siting and construction of deep borehole sites represents a very serious arms reduction and nonproliferation disadvantage of the borehole option, in either of its variants. While the deep borehole direct-emplacement option requires substantially less bulk processing than the other disposition options, that option may not meet the Spent Fuel Standard for retrievability by the host state, as mentioned above. Any potential

[17] International shipments would be involved (from the United States to Canada) if the CANDU option were pursued as a result of international agreements among the U.S., Canada, and Russia. Overseas shipments would be involved if European MOX fuel fabrication were utilized in the interim before a domestic MOX fabrication facility were completed. The Preferred Alternative and the decisions in this ROD do not involve European MOX fuel fabrication.

[18] The term "homogeneous immobilization" refers to mixing of solutions of plutonium and either HLW or cesium in liquid form, followed by solidification of the mixture in either glass or ceramic matrices. This contrasts with the "can-in-canister" variant, in which the plutonium and HLW or cesium materials are never actually mixed together.

advantage from the reduced processing is small compared to the large timing uncertainty and the potential retrievability disadvantage.

• Similarly, the electrometallurgical treatment option, because it is less developed than the other immobilization options, involves more uncertainty in when it could be implemented, which represents a significant arms reduction and nonproliferation disadvantage. It does not appear to have major compensating advantages compared to the other immobilization options.

• The "can-in-canister" immobilization options have a timing advantage over the homogeneous immobilization options, in that, by potentially relying on existing facilities, they could begin several years sooner. As noted above, however, modified systems intended to allow this option to meet the Spent Fuel Standard are still being designed.

C. Comments on the S&D Final PEIS

After issuing the Final PEIS, DOE received approximately 100 letters from organizations and individuals commenting on the alternatives addressed in the PEIS. Many of these letters expressed opposition to the MOX fuel approach for surplus plutonium disposition. The major concern raised in these letters was the contention that the use of MOX fuel is associated with proliferation risk as well as additional delays, costs, and safety and environmental risks. One of these letters was from a coalition of 14 national organizations recommending that the Department decide to utilize immobilization for the disposition of all surplus plutonium and that MOX be retained for use, if at all, only as an "insurance policy" if immobilization should prove infeasible. Several of those 14 organizations also wrote separately making similar points. Conversely, many of the letters provided comments in support of the use of MOX fuel and/or a dual path, while a few expressed opposition to the immobilization alternatives.

Seven of the letters received suggested the use of disposition approaches that were not analyzed in the PEIS. Three of these approaches (dropping plutonium into volcanoes, burying it in the sea at the base of a volcano, and storing it in large granite or marble structures) are similar to options that were either considered (but found to be unreasonable) in a screening process that preceded the PEIS, or were addressed in the PEIS Comment Response Document. These approaches were considered to be potentially damaging to the environment, among other things, and were therefore dismissed as unreasonable. Three other alternatives (plasma technology, binding and neutralizing plutonium with a new organic material, and use in rocket engines) recommended in these letters would require a substantial amount of development and could not be accomplished in the same time frame as alternatives analyzed in the PEIS. One commentor suggested adding the plutonium to the radioactive sludge being stored at Hanford for eventual disposal. The Department views this as unreasonable because of delays and increased costs that would be incurred in the program to manage the wastes in the Hanford tanks. One commentor was opposed to the utilization of Hanford's Fuels and Materials Examination Facility for MOX fuel fabrication and the Fast Flux Test Facility for MOX fuel burning.

All of the issues raised in these letters are covered in the body of the Final PEIS, in the Comment Response Document, the Summary Report of the Screening Process (DOE/MD-0002, March 19, 1995), the Technical Summary Report for Surplus Weapons-Usable Plutonium Disposition, or the Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives, which have each been considered in reaching this ROD.

The Department's decision for surplus plutonium disposition is to pursue both the existing LWR (MOX fuel) and immobilization approaches. DOE recognizes that the estimated life-cycle cost of immobilization alone would be less than that of the hybrid approach (pursuing both), but the additional expense would be warranted by the increased flexibility should one of the approaches ultimately fail, and the increased ability to influence Russian plutonium disposition actions. (The lowest cost approach would be the No Disposition Action alternative; however, as noted in section III.F, above, that option would not satisfy the purpose and need for this program.) DOE also recognizes that analyses in the PEIS indicated that, for normal operation, the environmental and health impacts would be somewhat lower for immobilization, although, with the exception of waste generation, impacts for the preferred, immobilization, and existing LWR (MOX) alternatives would be essentially comparable (see prior discussion).

Potential latent cancer fatalities for members of the public under the MOX approach would be significantly higher than under the immobilization approach only under highly unlikely facility accident scenarios; the risk (taking into account accident probabilities) to the public of latent cancer fatalities from accidents would be fairly low for both approaches.

From the nonproliferation standpoint, results of the Nonproliferation and Arms Control Assessment of Weapons-Usable Fissile Material Storage and Plutonium Disposition Alternatives (see section IV.B) indicated that each of the options under consideration for plutonium disposition has its own advantages and disadvantages, and each can potentially provide high levels of security and safeguards for nuclear materials during the disposition process, mitigating the risk of theft of nuclear materials. Initial processing of plutonium pits and other forms is among the most proliferation-sensitive stages of the disposition process, but is largely common to all the options. Although the Assessment also concluded that none of the approaches is clearly superior to the others, both the Nonproliferation Assessment and a letter from the Secretary of Energy Advisory Board Task Force on the Nonproliferation and Arms Control Implications of Weapons-Usable Fissile Materials Disposition Alternatives (included as Appendix B to the Nonproliferation Assessment) concluded that the hybrid approach (both reactors/MOX and immobilization) is preferable because of uncertainties in each approach and because it would minimize potential delays should problems develop with either approach. Numerous comment letters have made similar points.

One such letter was received from five individuals who were the U.S. participants on the U.S.-Russian Independent Scientific Commission on Disposition of Excess Weapons Plutonium. This letter supported the dual-track approach on the grounds that "ruling out reactors and thus depending solely on vitrification as the only approach to plutonium disposition that might be implementable anytime soon, would have far bigger nonproliferation liabilities then would the two-track approach." These commentors argued that designating only immobilization as the preferred approach, with MOX as a back-up, would have essentially all the nonproliferation and arms reduction liabilities of a one-track approach, which would weaken the U.S. position and have severe consequences for the likely success of programs to carry out permanent disposition of weapons plutonium in Russia, and therefore jeopardize the success of programs to

carry out U.S. disposition. These commentors stated that without the dual-track approach, the U.S. will lose any leverage it might have over the conditions and safeguards accompanying the use of Russian plutonium in their reactors. They also pointed out that pursuing both the MOX option and immobilization in the U.S. may be the best way to convince Russia, which currently favors converting its own plutonium to MOX fuel, of the value of immobilization for a portion of its excess plutonium. These commentors argued that the dual-track approach would not undermine U.S. nonproliferation policy, would not increase the risk of nuclear theft and terrorism, and would not lead to a new domestic plutonium recycle industry since it would not significantly affect the huge economic barriers to using MOX fuel on a commercial basis.

Two commentors expressed opposition to plutonium recycling (reprocessing), citing the Final Generic Environmental Statement on the Use of Recycle Plutonium in Mixed Oxide Fuel in Light Water Cooled Reactors (GESMO), NUREG–0002, which was issued by the NRC in 1976, and President Carter's decision to ban plutonium recycling. DOE notes that plutonium recycling is not part of the plutonium disposition program or the decisions in this ROD; on the contrary, this ROD includes conditions on the use of MOX fuel that are intended to prevent the use of recycled plutonium.

The use of MOX fuel in existing reactors would be undertaken in a manner that is consistent with the United States' policy objective on the irreversibility of the nuclear disarmament process and the United States' policy discouraging the use of plutonium for civil purposes. To this end, implementing the MOX alternative would include government ownership and control of the MOX fuel fabrication facility at a DOE site, and use of the facility only for the surplus plutonium disposition program. There would be no reprocessing or subsequent reuse of spent MOX fuel. The MOX fuel would be used in a once-through fuel cycle in existing reactors, with appropriate arrangements, including contractual or licensing provisions, limiting use of MOX fuel to surplus plutonium disposition.

One commentor, who opposed MOX fuel use, urged DOE not to use European MOX fuel fabrication capability if the MOX approach is pursued. In this ROD, DOE has not decided to use European MOX fuel fabrication.

V. Decisions

A. Storage of Weapons-Usable Fissile Materials

Consistent with the Preferred Alternative in the S&D Final PEIS, the Department has decided to reduce, over time, the number of locations where the various forms of plutonium are stored, through a combination of storage alternatives in conjunction with a combination of disposition alternatives. DOE will begin implementing this decision by moving surplus plutonium from RFETS as soon as possible, transporting the pits to Pantex beginning in 1997, and non-pit plutonium materials to SRS upon completion of the expanded Actinide Packing and Storage Facility (APSF), anticipated in 2001. Over time, DOE will store this plutonium in upgraded facilities at Pantex and in the expanded APSF. Surplus and non-surplus HEU will be stored in upgraded facilities at ORR. Storage facilities for the surplus HEU will also be modified, as needed, to accommodate international inspection requirements consistent with the President's Nonproliferation and Export Control Policy. Accordingly, DOE has decided to pursue the following actions for storage:

- Phase out storage of all weapons-usable plutonium at RFETS beginning in 1997; move pits to Pantex, and non-pit materials to SRS upon completion of the expanded APSF. At Pantex, DOE will repackage pits from RFETS in Zone 12, then place them in existing storage facilities in Zone 4, pending completion of facility upgrades in Zone 12. At SRS, DOE will expand the planned new APSF, and move separated and stabilized non-pit plutonium materials from RFETS to the expanded APSF upon completion. The small number of pits currently at RFETS that are not in shippable form will be placed in a shippable condition in accordance with existing procedures prior to shipment to Pantex. Additionally, some pits and non-pit plutonium materials from RFETS could be used at SRS, LANL, and Lawrence Livermore National Laboratory (LLNL) for tests and demonstrations of aspects of disposition technologies (see disposition decision, below). All non-pit weapons-usable plutonium materials currently stored at RFETS are surplus.

The Department's decision to remove plutonium from RFETS is based on the cleanup agreement among DOE, EPA, and the State of Colorado for RFETS, the proximity of RFETS to the Denver metropolitan area, and the fact that some of the RFETS plutonium is currently stored in buildings 371 and 376, two of the most vulnerable facilities as defined by and identified in DOE's Plutonium Working Group Report on Environmental, Safety, and Health Vulnerabilities Associated With the Department's Plutonium Storage (DOE/EH–0414, November, 1994).

- Upgrade storage facilities at Zone 12 South (to be completed by 2004) at Pantex to store those surplus pits currently stored at Pantex, and surplus pits from RFETS, pending disposition. Storage facilities at Zone 4 will continue to be used for these pits prior to completion of the upgrade.
- In accordance with the preferred alternative in the Final Programmatic Environmental Impact Statement for Stockpile Stewardship and Management (Stockpile Stewardship and Management PEIS), store Strategic Reserve pits at Pantex in other upgraded facilities in Zone 12.

The Department's decision to consolidate pit storage at Pantex places the pits at a central location where most of the pits already reside and where the expertise and infrastructure are already in place to accommodate pit storage.[19] Pantex has more than 40 years of experience with the handling of pits. Zone 12 facilities would be modified for long-term storage of the Pantex plutonium inventory and the small number of pits transferred from RFETS and SRS for a modest cost (about $10 million capital cost). Pursuant to the Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components (DOE/EIS–0225), DOE is proposing to continue nuclear weapons stockpile management operations and related activities at the Pantex Plant, including interim storage of up to 20,000 pits.[20] Consequently, the storage of surplus pits at Pantex would offer the opportunity to share trained people and other resources, and a decreased cost could be realized over other sites without similar experience. Using the Pantex Plant for pit storage would also involve the lowest cost and the least new construction relative to other sites.

- Expand the planned APSF at SRS (Upgrade Alternative) to store those surplus, non-pit plutonium materials currently at SRS and surplus non-pit plutonium materials from RFETS, pending disposition (see disposition decision, below). DOE analyzed the

[19] A small number of research and development pits located at RFETS that have been and will continue to be packaged and returned to LANL and LLNL are outside the scope of the S&D PEIS and this ROD.

[20] The pits that are to be moved to Pantex pursuant to this ROD fall within the 20,000 pit limit.

potential impacts of constructing and operating the APSF in the Final Environmental Impact Statement, Interim Management of Nuclear Materials (DOE/EIS-0220) and announced the decision to build the facility in the associated ROD (60 FR 65300, December 19, 1995). DOE, pursuant to the decisions announced here to store surplus non-pit plutonium at SRS, will likely design and build the APSF and the expanded space to accommodate the RFETS material as one building,[21] which DOE plans to complete in 2001. The RFETS surplus non-pit plutonium materials[22] will be moved to SRS after stabilization is performed at RFETS under corrective actions in response to Defense Nuclear Facilities Safety Board Recommendation 94-1; and after the material is packaged in DOE-approved storage and shipping containers pursuant to existing procedures. The surplus plutonium already on-site at SRS and the movement of separated and stabilized non-pit plutonium from RFETS would result in the storage of a maximum of 10 metric tons of surplus plutonium in the new, expanded APSF at SRS. In addition, shipment of the non-pit plutonium from RFETS to SRS, after stabilization, would only be implemented if the subsequent ROD for a plutonium disposition site (see Section V.B., below) calls for immobilization of plutonium at SRS. Placement of surplus, non-pit plutonium materials in a new storage facility at SRS will allow utilization of existing expertise and plutonium handling capabilities in a location where disposition activities could occur (see disposition decision, below). The decision to store non-pit plutonium from RFETS at SRS places most non-pit material at a plutonium-competent site with the most modern, state-of-the-art storage and processing facilities, and at a site with the only remaining large-scale chemical separation and processing capability in the DOE complex.[23] Pits currently located at SRS will be moved to Pantex for storage consistent with the Preferred Alternative in the Stockpile Stewardship and Management PEIS. There are no strategic non-pit materials currently located at SRS.

- Continue current storage (No Action) of surplus plutonium at Hanford and INEL, pending disposition (or movement to lag storage[24] at disposition facilities when selected).[25] This action will allow surplus plutonium to remain at the sites with existing expertise and plutonium handling capabilities, and where potential disposition activities could occur (see disposition decision, below). There are no non-surplus weapons-usable plutonium materials currently stored at either site.
- Continue current storage (No Action) of plutonium at LANL, pending disposition (or movement to lag storage at the disposition facilities). This plutonium will be stored in stabilized form with the non-surplus plutonium in the upgraded Nuclear Material Storage Facility pursuant to the No Action alternative for the site.
- Take No Action at the NTS. DOE will not introduce plutonium to sites that do not currently have plutonium in storage.
- Upgrade storage facilities at the Y-12 Plant (Y-12) (to be completed by 2004 or earlier) at ORR to store non-surplus HEU and surplus HEU pending disposition. Existing storage facilities at Y-12 will be modified to meet natural phenomena requirements, as documented in Natural Phenomena Upgrade of the Downsized/Consolidated Oak Ridge Uranium/Lithium Plant Facilities (Y/EN-5080, 1994). Storage facilities will be consolidated, and the storage footprint will be reduced, as surplus HEU is dispositioned and blended to low-enriched uranium, pursuant to the ROD for the Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement (61 FR 40619, August 5, 1996). Consistent with the Preferred Alternative in the Stockpile Stewardship and Management PEIS, HEU strategic reserves will be stored at the Y-12 Plant.

B. Plutonium Disposition

Consistent with the Preferred Alternative in the S&D Final PEIS, DOE has decided to pursue a strategy for plutonium disposition that allows for immobilization of surplus weapons plutonium in glass or ceramic forms and burning of the surplus plutonium as mixed oxide fuel (MOX) in existing reactors. The decision to pursue disposition of the surplus plutonium using these approaches is supported by the analyses in the Disposition Technical Summary Report (section IV.A.2 above) and the Nonproliferation Assessment (section IV.B above), as well as the S&D Final PEIS. The results of additional technology development and demonstrations, site-specific environmental review, detailed cost proposals, nonproliferation considerations, and negotiations with Russia and other nations will ultimately determine the timing and extent to which MOX as well as immobilization is deployed. These efforts will provide the basis and flexibility for the United States to initiate disposition efforts either multilaterally or bilaterally through negotiations with other nations, or unilaterally as an example to Russia and other nations.

Pursuant to this decision, the United States policy not to encourage the civil use of plutonium and, accordingly, not to itself engage in plutonium reprocessing for either nuclear power or nuclear explosive purposes, does not change. Although under this decision some plutonium may ultimately be burned in existing reactors, extensive measures will be pursued (see below) to ensure that federal support for this unique disposition mission does not encourage other civil uses of plutonium or plutonium reprocessing. The United States will maintain its commitments regarding the use of plutonium in civil nuclear programs in western Europe and Japan.

The Disposition Technical Summary Report (section IV.A.2 above) concluded that the lowest cost option for plutonium disposition would be immobilization using the can-in-canister variant and existing facilities to the maximum extent possible, with a net life-cycle cost of about $1.8 billion. The Disposition Technical Summary Report also estimated that the net life-cycle cost of the hybrid immobilization/MOX approach would be about $2.2 billion. The additional expense of pursuing the hybrid approach would be warranted by

[21] Building the APSF in this way, rather than as originally configured plus an expansion, will not increase the potential impacts of constructing and operating the facility beyond those analyzed in the S&D Final PEIS in conjunction with the analyses in the Final Environmental Impact Statement, Interim Management of Nuclear Materials.

[22] This decision does not include residues at RFETS that are less than 50-percent plutonium by weight, or scrub alloys. The management and disposition of those materials has been or is being considered in separate NEPA reviews. See Environmental Assessment for Solid Residue Treatment, Repackaging, and Storage (DOE/EA-1120, April 1996); Notice of Intent to Prepare an EIS on the Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site (61 FR 58866, November 19, 1996).

[23] SRS is one of the preferred candidate sites for plutonium disposition facilities, including the potential for the early start of disposition by immobilization using the can-in-canister option at the DWPF.

[24] Lag storage is temporary storage at the applicable disposition facility.

[25] Lawrence Livermore National Laboratory (LLNL) currently stores 0.3 metric tons of plutonium, which are primarily research and development and operational feedstock materials not surplus to government needs. Adequate storage facilities for this material currently exist at LLNL, where it will be stored and used for research and development activities. None of the plutonium stored at LLNL falls within the scope of the disposition alternatives in the S&D Final PEIS or the disposition decisions in this ROD.

the increased flexibility it would provide, as noted in the Nonproliferation Assessment, to ensure that plutonium disposition could be initiated promptly should one of the approaches ultimately fail or be delayed. Establishing the means for expeditious plutonium disposition will also help provide the basis for an international cooperative effort that can result in reciprocal, irreversible plutonium disposition actions by Russia. This disposition strategy signals a strong U.S. commitment to reducing its stockpile of surplus plutonium, thereby effectively meeting the purpose of and need for the Proposed Action.

To accomplish the plutonium disposition mission, DOE will use, to the extent practical, new as well as modified existing buildings and facilities for portions of the disposition mission. DOE will analyze and compare existing and new buildings and facilities, and technology variations, in a subsequent, site-specific EIS. In addition, all disposition facilities will be designed or modified, as needed, to accommodate international inspection requirements consistent with the President's Nonproliferation and Export Control Policy. Accordingly, DOE has decided to pursue the following strategy and supporting actions for plutonium disposition:

- Immobilize plutonium materials using vitrification or ceramic immobilization at either Hanford or SRS, in new or existing facilities. Immobilization could be used for pure or impure forms of plutonium. In the subsequent EIS (referenced above), DOE anticipates that the preferred alternative for vitrification or ceramic immobilization will include the can-in-canister variant, utilizing the existing HLW and the DWPF at SRS (see below). Alternatively, new immobilization facilities could be built at Hanford or SRS. The immobilized material would be disposed of in a geologic repository. Pursuant to appropriate NEPA review, DOE will continue the research and development leading to the demonstration of the can-in-canister variant at the DWPF using surplus plutonium and the development of vitrification and ceramic formulations.
- Convert surplus plutonium materials into mixed oxide (MOX) fuel for use in existing reactors. Pure surplus plutonium materials including pits, pure metal, and oxides could be converted without extensive processing into MOX fuel for use in existing commercial reactors. Other, already separated forms of surplus plutonium would require additional purification. (This purification would not involve reprocessing of spent nuclear fuel.) The Government-produced MOX fuel (from plutonium declared surplus to defense needs) would be used in existing LWRs with a once-through fuel cycle, with no reprocessing or subsequent reuse of the spent fuel. In addition, DOE will explore appropriate contractual limits to ensure that any reactor license modification for use of the MOX fuel is limited to governmental purposes involving the disposition of surplus, weapons-usable plutonium, so as to discourage general civil use of plutonium-based fuel. The spent MOX fuel would be disposed of in a geologic repository. If partially completed LWRs were to be completed by other parties, they would be considered for this mission. The MOX fuel would be fabricated in a domestic, government-owned facility at one of four DOE sites (SRS, Hanford, INEL, or Pantex).

The Department reserves as an option the potential use of some MOX fuel in CANDU reactors in Canada in the event that a multilateral agreement to deploy this option is negotiated among Russia, Canada, and the United States. DOE will engage in a test and demonstration program for CANDU MOX fuel consistent with ongoing and potential future cooperative efforts with Russia and Canada.

The test and demonstration activities could occur at LANL and at sites in Canada, potentially beginning in 1997, and will be based on appropriate NEPA review. Fabrication of MOX fuel for CANDU reactors would occur in a DOE facility, as would be true in the case of domestic LWRs. Strict security and safeguards would be employed in the fabrication and transport of MOX fuel to CANDU reactors, as well as domestic reactors. Whether, and the extent to which, the CANDU option is implemented will depend on multi-national agreements and the results of the test and demonstration activities.

Due to technology, complexity, timing, cost, and other factors that would be involved in purifying certain plutonium materials to make them suitable for potential use in MOX fuel, approximately 30 percent of the total quantity of plutonium that has been or may be declared surplus to defense needs would require extensive purification for use in MOX fuel, and therefore will likely be immobilized. Of the plutonium that is currently surplus, DOE will immobilize at least 8 metric tons that it has determined are not suitable for use in MOX fuel.[26] DOE reserves the option of using the immobilization approach for all of the surplus plutonium.

The timing and extent to which either option is ultimately utilized will depend on the results of international agreements, future technology development and demonstrations, site-specific environmental review, detailed cost proposals, and negotiations with Russia and other nations. In the event both technologies are utilized, because the time required for plutonium disposition using reactors would be longer than that for immobilization, it is probable that some surplus plutonium would be immobilized initially, prior to completion of reactor irradiation for other surplus plutonium.

Implementation of this strategy will involve some or all of the following supporting actions:

- Construct and operate a plutonium vitrification facility or ceramic immobilization facility at either Hanford or SRS. DOE will analyze alternative locations at these two sites for constructing new buildings or using modified existing buildings in subsequent, site-specific NEPA review. SRS has existing facilities (the DWPF) and infrastructure to support an immobilization mission, and at Hanford, DOE has proposed constructing and operating immobilization facilities for the wastes in Hanford tanks.[27] DOE will not create new infrastructure for immobilizing plutonium with HLW or cesium at INEL, NTS, ORR, or Pantex. Due to the substantial timing and cost advantages associated with the can-in-canister option, as discussed in the Technical Summary Report For Surplus Weapons-Usable Plutonium Disposition and summarized in section IV.A.2, above, DOE anticipates that the proposed action for immobilization in the follow-on plutonium disposition EIS will include the use of the can-in-canister option at the DWPF at SRS for immobilizing a portion of the surplus, non-pit plutonium material.[28]

[26] The S&D Final PEIS, for purposes of analysis of impacts of the preferred alternative (using both reactors and immobilization), assumed that about 30 percent (approximately 17 MT) of the surplus plutonium materials might be immobilized because they are impure. DOE's decision here that immobilization will be used for at least 8 MT currently located at SRS and RFETS is based on DOE's current assessment that that quantity of material is so low in quality that its purification for use in MOX fuel would not be cost-effective. This decision does not preclude immobilizing all of the surplus plutonium, but it does preclude using the MOX/reactor approach for all of the material.

[27] See Final Environmental Impact Statement for the Tank Waste Remediation System, Hanford Site, Richland, Washington (DOE/EIS-0189, August 1996); ROD expected early in 1997.

[28] DOE expects to issue a Notice of Intent to prepare the follow-on EIS shortly following this ROD. Reasonable alternatives for the proposed

• Construct and operate a plutonium conversion facility for non-pit plutonium materials at either Hanford or SRS. DOE will collocate the plutonium conversion facility with the vitrification or ceramic immobilization facility discussed above. In subsequent, site-specific NEPA review, DOE will analyze alternative locations at Hanford and SRS for constructing new buildings or using modified existing buildings for the plutonium conversion facility.

• Construct and operate a pit disassembly/conversion facility at Hanford, INEL, Pantex, or SRS (only one site). DOE will not introduce plutonium to sites that do not currently have plutonium in storage. Therefore, two sites analyzed in the S&D PEIS, NTS and ORR, will not be considered further for plutonium disposition activities. DOE will analyze alternative locations at Hanford, INEL, Pantex, and SRS for constructing new buildings or using modified existing buildings in subsequent, site-specific NEPA review. Based on appropriate NEPA review, DOE anticipates demonstrating the Advanced Recovery and Integrated Extraction System (ARIES) concept at LANL for pit disassembly/conversion beginning in fiscal year 1997.

• Construct and operate a domestic, government-owned, limited-purpose MOX fuel fabrication facility at Hanford, INEL, Pantex, or SRS (only one site). As noted above, NTS and ORR will not be considered further for plutonium disposition activities. In follow-on NEPA review, DOE will analyze alternative locations at Hanford, INEL, Pantex, and SRS, for constructing new buildings or using modified existing buildings. The MOX fuel fabrication facility will serve only the limited mission of fabricating MOX fuel from plutonium declared surplus to U.S. defense needs, with shut-down and decontamination and decommissioning of the facility upon completion of this mission.[29]

DOE's program for surplus plutonium disposition will be subject to the highest standards of safeguards and security for storage, transportation, and processing (particularly during operations that involve the greatest proliferation vulnerability, such as during MOX fuel preparation and transportation), and will include International Atomic Energy Agency verification as appropriate. Transportation of all plutonium-bearing materials under this program, including the transportation of prepared MOX fuel to reactors, will be accomplished using the DOE Transportation Safeguards Division's "Safe Secure Transports" (SSTs), which affords these materials the same level of transportation safety, security, and safeguards as is used for nuclear weapons.

Pursuant to appropriate NEPA review(s), DOE will continue research and development and engage in further testing and demonstrations of plutonium disposition technologies which may include: dissolution of small quantities of plutonium in both glass and ceramic formulation; experiments with immobilization equipment and systems; fabrication of MOX fuel pellets for demonstrations of reactor irradiation at INEL; mechanical milling and mixing of plutonium and uranium feed; and testing of shipping and storage containers for certification, in addition to the testing and demonstrations previously described for the can-in-canister immobilization variant, the ARIES system, and other plutonium processes.

DOE has decided not to pursue several disposition alternatives that were evaluated in the S&D PEIS: two deep borehole alternatives, electrometallurgical treatment, evolutionary reactors, and partially-completed reactors (unless they were completed by others, in which case they would qualify as existing reactors). Although the deep borehole options are technically attractive, the institutional uncertainties associated with siting of borehole facilities make timely implementation of this alternative unlikely. To implement the borehole alternatives, new legislation and regulations, or clarification of existing regulations, may be necessary. DOE has decided not to pursue the electrometallurgical treatment option for immobilization because its technology is less mature than vitrification or ceramic immobilization.[30] DOE has decided not to pursue evolutionary reactors or partially-completed reactors because they offer no advantages over existing reactors for plutonium disposition and would involve higher costs, greater regulatory uncertainties, higher environmental impacts from construction, and less timely commencement of disposition actions.

VI. Conclusion

DOE has decided to implement a program to provide for safe and secure storage of weapons-usable fissile materials and for disposition of weapons-usable plutonium that is declared excess to national security needs (now or in the future), as specified in the Preferred Alternative in the S&D Final PEIS. DOE will consolidate the storage of weapons-usable plutonium by upgrading and expanding existing facilities at the Pantex Plant in Texas and SRS in South Carolina, continuing storage of surplus plutonium currently onsite at Hanford, LANL, and INEL pending disposition, and continuing storage of weapons-usable HEU at DOE's Y-12 Plant in Tennessee, in upgraded and, as surplus HEU is down-blended under the ROD for Disposition of Surplus Highly Enriched Uranium Final Environmental Impact Statement, consolidated facilities. DOE will provide for disposition of surplus plutonium by pursuing a strategy that allows: (1) Immobilization of surplus plutonium for disposal in a repository pursuant to the Nuclear Waste Policy Act, and (2) fabrication of surplus plutonium into MOX fuel, for use in existing domestic commercial reactors (and potentially CANDU reactors, depending on future agreements with Russia and Canada). The timing and extent to which each of these disposition technologies is deployed will depend upon the results of future technology development and demonstrations, site-specific environmental review, detailed cost proposals, and the results of negotiations with Russia, Canada, and other nations. This programmatic decision is effective upon being made public, in accordance with DOE's regulations implementing NEPA (10 CFR 1021.315). The goals of this program are to support U.S. nuclear weapons nonproliferation policy by reducing global stockpiles of excess fissile materials so that they may never be used in weapons again. This program will demonstrate the United States' commitment to its nonproliferation goals, as specified in the President's Nonproliferation and Export Control Policy of 1993, and provide an example for other nations, where stockpiles of surplus weapons-usable fissile materials may be less secure from potential theft or diversion than those in the United

action will be considered in the follow-on disposition EIS.

[29] DOE supports external regulation of its facilities, and in the Report of Department of Energy Working Group on External Regulation (DOE/UF-0001, December 1996), DOE proposed to seek legislation that would generally require NRC licenses for new DOE facilities. Therefore, DOE anticipates seeking an NRC license for the MOX fuel fabrication facility, which would be limited to a license to fabricate MOX fuel from plutonium declared surplus to defense needs. DOE may also seek legislation that would by statute limit the MOX fuel fabrication facility to disposition of surplus plutonium.

[30] An evaluation by the National Research Council in a recent report (see footnote 12, above) concluded that the electrometallurgical treatment process is not sufficiently mature to provide a reliable basis for timely plutonium disposition.

States, to encourage them to take similar actions.

The decision process reflected in this Notice complies with the requirements of the National Environmental Policy Act (42 U.S.C. §4321 et seq.) and its implementing regulations at 40 CFR Parts 1500–1508 and 10 CFR Part 1021.

Issued in Washington, D.C., January 14, 1997.

Hazel R. O'Leary,

Secretary.

BILLING CODE 6450–01–P

Energy Information Administration

Agency Information Collection Activities: Proposed Collection; Comment Request

SUMMARY: The Energy Information Administration (EIA) is soliciting comments concerning the proposed three-year extension of existing form DOE–887, "Department of Energy Customer Surveys."

DATES: Written comments must be submitted on or before March 24, 1997. If you anticipate that you will be submitting comments, but find it difficult to do so within the period of time allowed by this notice, you should advise the contact listed below of your intention to do so as soon as possible.

ADDRESSES: Send comments to Herbert T. Miller, Office of Statistical Standards, EI–73, Forrestal Building, U.S. Department of Energy, Washington, D.C. 20585, (Phone 202–426–1103, FAX 202–426–1081, or e-mail hmiller@eia.doe.gov).

FOR FURTHER INFORMATION: Requests for additional information should be directed to Herbert Miller at the address listed above.

SUPPLEMENTARY INFORMATION:

I. Background
II. Current Actions
III. Request for Comments

I. Background

In order to fulfill its responsibilities under the Federal Energy Administration Act of 1974 (Pub. L. No. 93–275) and the Department of Energy Organization Act (Pub. L. No. 95–91), the Energy Information Administration is obliged to carry out a central, comprehensive, and unified energy data and information program. As part of this program, EIA collects, evaluates, assembles, analyzes, and disseminates data and information related to energy resource reserves, production, demand, and technology, and related economic and statistical information relevant to the adequacy of energy resources to meet demands in the near and longer term future for the Nation's economic and social needs.

The Energy Information Administration, as part of its continuing effort to reduce paperwork and respondent burden (required by the Paperwork Reduction Act of 1995 (Pub. L. 104–13)), conducts a presurvey consultation program to provide the general public and other Federal agencies with an opportunity to comment on proposed and/or continuing reporting forms. This program helps to ensure that requested data can be provided in the desired format, reporting burden is minimized, reporting forms are clearly understood, and the impact of collection requirements on respondents can be properly assessed. Also, EIA will later seek approval by the Office of Management and Budget (OMB) for the collections under Section 3507(h) of the Paperwork Reduction Act of 1995 (Pub. L. No. 104–13, Title 44, U.S.C. Chapter 35).

On September 11, 1993, the President signed Executive Order No. 12862 aimed at "* * * ensuring the Federal government provides the highest quality service possible to the American people." The Order discusses surveys as a means for determining the kinds and qualities of service desired by Federal Government customers and for determining satisfaction levels for existing services. These voluntary customer surveys will be used to ascertain customer satisfaction with the Department of Energy in terms of services and products. Respondents will be individuals and organizations that are the recipients of the Department's services and products. Previous customer surveys have provided useful information to the Department for assessing how well the Department is delivering its services and products and for making improvements. The results are used internally and summaries are provided to the Office of Management and Budget on an annual basis, and are used to satisfy the requirements and the spirit of Executive Order No. 12862.

II. Current Actions

The request to OMB will be for a three-year extension of the expiration date of approval for DOE to conduct customer surveys. During the past clearance cycle, over 20 customer surveys have been conducted by telephone and mail. (Examples of previously conducted customer surveys are available upon request.) Our planned activities in the next 3 fiscal years reflect our increased emphasis on and expansion of these activities, including an increased use of electronic means for obtaining customer input (CD–ROM and World Wide Web).

III. Request for Comments

Prospective respondents and other interested parties should comment on the actions discussed in item II. The following guidelines are provided to assist in the preparation of responses.

General Issues

A. Is the proposed collection of information necessary, taking into account its accuracy, adequacy, and reliability, and the agency's ability to process the information it collects in a useful and timely fashion?

B. What enhancements can EIA make to the quality, utility, and clarity of the information to be collected?

As a Potential Respondent

A. Average public reporting burden for a customer survey is estimated to be .25 hours per response (8,333 respondents per year x 15 minutes per response = 2,083 hours annually). Burden includes the total time, effort, or financial resources expended to generate, maintain, retain, or disclose or provide the information including: (1) reviewing instructions; (2) developing, acquiring, installing, and utilizing technology and systems for the purposes of collecting, validating, verifying, processing, maintaining, disclosing and providing information; (3) adjusting the existing ways to comply with any previously applicable instructions and requirements; (4) training personnel to respond to a collection of information; (5) searching data sources; (6) completing and reviewing the collection of information; and (7) transmitting, or otherwise disclosing the information.

Please comment on (1) the accuracy of our estimate and (2) how the agency could minimize the burden of the collection of information, including the use of automated collection techniques or other forms of information technology.

B. EIA estimates that respondents will incur no additional costs for reporting other than the hours required to complete the collection. What is the estimated (1) total dollar amount annualized for capital and start-up costs and (2) recurring annual dollar amount of operation and maintenance and purchase of services costs associated with this data collection? The estimates should take into account the costs associated with generating, maintaining, and disclosing or providing the information.

A.2 NOTICE OF INTENT - SURPLUS PLUTONIUM DISPOSITION ENVIRONMENTAL IMPACT STATEMENT

collection on the respondents, including through the use of information technology.

Dated: May 16, 1997.

Gloria Parker,

Director, Information Resources Management Group.

Office of Management

Type of Review: New.
Title: Department of Education Federal Cash Award Certification Statement and Department of Education Federal Cash Quarterly Confirmation Statement.
Frequency: Annually.
Affected Public: Business or other for-profit; Not for Profit institutions; Federal Government; State, Local or Tribal Government, SEAs or LEAs.
Annual Reporting and Recordkeeping Hour Burden:
Responses: 12,000.
Burden Hours: 38,160.
Abstract: The collection of the Federal Cash Award Statement is necessary for the Agency to monitor cash advanced to grantees and to obtain expenditure information for each grant from grantees. Information collection is used to report total outlays to the Office of Management and Budget and the Department of the Treasury and is used to project the Federal government's and the Department's financial condition. This information collection also enables the Department to provide Treasury with outlay information to facilitate Treasury's estimation of future borrowing requirements. Respondents include over 12,000 State, local, college, university, proprietary school and non-profit grantees who draw funds from the Department.

The collection of Federal cash quarterly confirmation statement enables grantees to identify discrepancies in grant authorizations, and funds drawn and funds refunded. Action is required only if a grantee's records do not agree with the information contained on the statement. This information will be used to help grantees report and initiate resolution of discrepancies. Respondents include over 12,000 State, local, college, university, proprietary school and non-profit grantees who draw funds from the Department.

Office of Special Education and Rehabilitative Services

Type of Review: New.
Title: Grantee Reporting Form.
Frequency: Annually.
Affected Public: Business or other for-profit; Not-for-profit institutions; State, local or Tribal Gov't, SEAs or LEAs.
Annual Reporting and Recordkeeping Hour Burden:
Responses: 165.
Burden Hours: 330.
Abstract: Rehabilitation Services Administration (RSA) training grants provide stipends to "RSA Scholars" in order to train skilled rehabilitation personnel. Grantees are required to "track" scholars, relative to the "payback" provision in the Rehabilitation Act. Data collection is reported annually to RSA in order to monitor performance and report progress to Congress.

BILLING CODE 4000-01-M

DEPARTMENT OF ENERGY

Surplus Plutonium Disposition Environmental Impact Statement

AGENCY: Department of Energy
ACTION: Notice of intent

SUMMARY: The Department of Energy (DOE) announces its intent to prepare an Environmental Impact Statement (EIS) pursuant to the National Environmental Policy Act (NEPA) on the disposition of United States' weapons-usable surplus plutonium. This EIS is tiered from the Storage and Disposition of Weapons-Usable Fissile Materials Programmatic Environmental Impact Statement (Storage and Disposition PEIS) (DOE/EIS-0229), issued in December 1996, and the associated Record of Decision (62 FR 3014), issued on January 14, 1997.

The EIS will examine reasonable alternatives and potential environmental impacts for the proposed siting, construction, and operation of three types of facilities for plutonium disposition. The first is a facility to disassemble and convert pits (a nuclear weapons component) into plutonium oxide suitable for disposition. As explained in the January 1997 Record of Decision, this pit disassembly and conversion facility will be located at either DOE's Hanford Site, Idaho National Engineering and Environmental Laboratory (INEEL), Pantex Plant, or Savannah River Site (SRS). The second is a facility to immobilize surplus plutonium in a glass or ceramic form for disposition in a geologic repository pursuant to the Nuclear Waste Policy Act. This second facility will be located at either Hanford or SRS, and include a collocated capability to convert non-pit plutonium materials into a form suitable for immobilization. The EIS will discuss various technologies for immobilization. The third type of facility would fabricate plutonium oxide into mixed oxide (MOX) fuel. The MOX fuel fabrication facility would be located at either Hanford, INEEL, Pantex or SRS. MOX fuel would be used in existing commercial light water reactors in the United States, with subsequent disposal of the spent fuel in accordance with the Nuclear Waste Policy Act. Some MOX fuel could also be used in Canadian deuterium uranium (CANDU) reactors depending upon negotiation of a future international agreement between Canada, Russia, and the United States. The EIS will also discuss decommissioning and decontamination (D&D) of the three facilities.

This Notice of Intent describes the Department's proposed action, solicits public input, and announces the schedule for the public scoping meetings.

DATES: Comments on the proposed scope of the Surplus Plutonium Disposition EIS (SPD EIS) are invited from the public. To ensure consideration in the draft EIS, written comments should be postmarked by July 18, 1997. Comments received after that date will be considered to the extent practicable. DOE will hold interactive scoping meetings near sites that may be affected by the proposed action to discuss issues and receive oral and written comments on the scope of the EIS. The locations, dates and times for these public meetings are included in the Supplementary Information section of this notice and will be announced by additional appropriate means.

ADDRESSES: Comments and questions concerning the plutonium disposition program can be submitted by calling (answering machine) or faxing them to the toll free number 1-800-820-5156, or by mailing them to: Bert Stevenson, NEPA Compliance Officer, Office of Fissile Materials Disposition, U.S. Department of Energy, Post Office Box 23786, Washington, DC 20026-3786.

Comments may also be submitted electronically by using the Office of Fissile Materials Disposition's web site. The address is http://web.fie.com/fedix/fisl.html.

FOR FURTHER INFORMATION CONTACT: For general information on the DOE NEPA process, please contact: Carol Borgstrom, Director, Office of NEPA Policy and Assistance, U.S. Department of Energy 1000, Independence Avenue, S.W., Washington, DC 20585, 202-586-4600 or 1-800-472-2756.

SUPPLEMENTARY INFORMATION:

Background

The Storage and Disposition Programmatic Environmental Impact Statement (PEIS) analyzed the potential environmental consequences of alternatives for the long-term storage (up to 50 years) of weapons-usable fissile materials and the disposition of surplus plutonium. Surplus plutonium for disposition refers to that weapons-usable plutonium that the President has declared surplus to national security needs, as well as such plutonium that may be declared surplus in the future. As stated in the Record of Decision for the Storage and Disposition PEIS, the Department decided to pursue a hybrid approach that allows immobilization of surplus plutonium in glass or ceramic form and burning of some of the surplus plutonium as MOX fuel in existing, commercial light water reactors in the United States (and potentially in Canadian Deuterium Uranium (CANDU) reactors in Canada depending on future international agreement). The Department decided that the extent to which either or both of these disposition approaches would ultimately be deployed would depend in part upon future NEPA review, although the Department committed to immobilize at least 8 metric tons (tonnes) of currently declared surplus plutonium and reserved the option of immobilizing all surplus weapons plutonium. In the Record of Decision for the Storage and Disposition PEIS, the Department further decided to: (1) locate the immobilization facility (collocated with a plutonium conversion facility) at either Hanford or SRS; (2) locate a potential MOX fuel fabrication facility at either Hanford, INEEL, Pantex, or SRS; (3) locate a pit disassembly and conversion facility at either Hanford, INEEL, Pantex, or SRS; and (4) determine the specific technology for immobilization based in part on this follow-on disposition EIS.

The processes, materials and technologies involved in surplus plutonium disposition are depicted in Figure 1.

BILLING CODE 6450-01-P

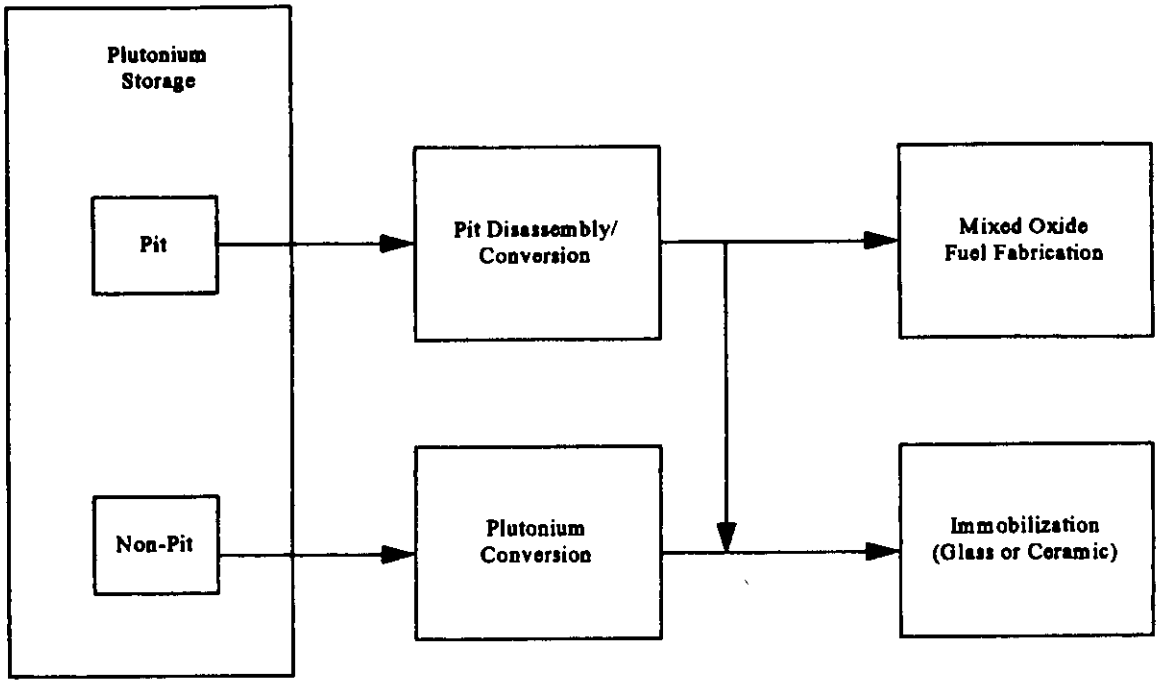

Figure 1. Plutonium Disposition Processes in DOE's Proposed Action

BILLING CODE 6450-01-C

Proposed Action

The Department proposes to determine whether to continue with both the immobilization and MOX approaches for surplus plutonium disposition and if so, to site, construct, and operate and ultimately D&D three types of facilities for plutonium disposition at one or more of four DOE sites, as follows:

- A collocated non-pit plutonium conversion and immobilization facility at either Hanford, near Richland, Washington, or SRS, near Aiken, South Carolina, with sub-alternatives for the technology and facilities used to form the immobilized plutonium.
- A pit disassembly/conversion facility at either Hanford; SRS; INEEL, near Idaho Falls, Idaho; or the Pantex Plant, near Amarillo, Texas.
- A MOX fuel fabrication facility at either Hanford, INEEL, Pantex, or SRS, with sub-alternatives for fabrication of Lead Test Assemblies for use in fuel qualification demonstrations.

Construction of these facilities would be on previously disturbed land and could include the modification of existing facilities where practicable, to reduce local environmental impacts, reduce costs, and shorten schedules. In the pit disassembly and conversion facility, the Department proposes to disassemble surplus pits and convert the plutonium in them to an unclassified oxide form suitable for disposition. The Department also proposes to convert most non-pit plutonium materials to plutonium oxide at the plutonium conversion facility, which will be collocated with the immobilization facility.

Plutonium Disposition Decisions

The Department expects to make the following decisions based upon the results of this EIS and other information and considerations:

- Whether to construct and operate collocated plutonium conversion and immobilization facilities, and if so, where (including selection of the specific immobilization technology).
- Whether to construct and operate a pit disassembly/conversion facility, and if so, where.
- Whether to construct and operate a MOX fuel fabrication facility, and if so, where (including selection of the site for fabrication of Lead Test Assemblies).

The exact extent to which the MOX approach would ultimately be deployed will depend on a number of factors, in addition to environmental impacts. These are likely to include cost, contract negotiations, and international agreements.

Alternatives

No Action

A No Action alternative will be analyzed (Alternative 1) in the SPD EIS. Implementation of the No Action alternative would mean that disposition would not occur, and surplus weapons-usable plutonium, including pits, metals and oxides, would remain in storage in accordance with the Storage and Disposition PEIS Record of Decision.

Plutonium Disposition Alternatives

The SPD EIS will analyze alternatives for the siting, construction and operation of the three facilities at various candidate sites as described in the Proposed Action. These facilities would be designed so that they could collectively disposition surplus plutonium (existing and future) over their operating lives. Although the exact quantity of plutonium that may be declared surplus over time is not known, for purposes of analysis a nominal 50 tonnes of surplus plutonium will be used for assessing the environmental impacts of plutonium disposition activities at the various candidate sites. Under alternatives involving the "hybrid" (immobilization and MOX) approach selected in the Storage and Disposition Record of Decision, the SPD EIS will analyze the same distribution of surplus plutonium that was analyzed in the Storage and Disposition PEIS, which is fabrication of pits and pure plutonium metal or oxide (approximately 33 tonnes) into MOX fuel, and immobilization of the remaining non-pit plutonium (approximately 17 tonnes). The Record of Decision on the Storage and Disposition PEIS states, "DOE will immobilize at least eight tonnes of currently declared surplus plutonium materials that DOE has already determined are not suitable for use in MOX fuel." Since the issuance of that decision, the Department has further determined that a total of about 17 tonnes of surplus plutonium is not suitable for use in MOX fuel without extensive processing. Thus, an alternative for fabricating all surplus plutonium into MOX fuel will not be analyzed. However, converting the full 50 tonnes of surplus plutonium into an immobilized form will be analyzed as a reasonable alternative.

Under each disposition approach, DOE could in principle locate one, two, or all three facilities at a candidate site. However, locating one facility at each of three sites would mean conducting disposition activities at three widely separated locations around the country. This would substantially increase transportation cost, unnecessarily increase exposure of workers and the public, and increase transportation risks, without any apparent compensating benefit. Therefore, the Department is proposing to consider only alternatives that locate two or more facilities at one site, with the possibility of one facility at a separate site. Further, certain combinations of facilities and sites are not being considered as reasonable alternatives, because they would also substantially increase transportation cost, unnecessarily increase exposure to workers and the public, and increase transportation risks, without any apparent compensating benefit.

Based on the above considerations and the candidate site selections in the Storage and Disposition Record of Decision, the following alternatives have been developed in addition to the No Action alternative. Table 1 summarizes the alternatives by site. Alternatives 2 through 10 (see Table 1) would involve immobilization of approximately 17 tonnes of low purity (non-pit) plutonium, and fabrication of approximately 33 tonnes of high purity plutonium (pits and plutonium metal) into MOX fuel. The differences among alternatives 2 through 10 are the locations of the proposed facilities. Alternatives 11 and 12 would involve immobilization of all 50 tonnes of plutonium at either Hanford or SRS.

The Department has identified existing facilities that can be modified for use in plutonium disposition at various candidate sites. A summary of the existing and new facilities (shown in the parentheses in Table 1) to be used in the SPD EIS analyses is given in Table 1, where FMEF is the Fuel and Materials Examination Facility, FPF is the Fuel Processing Facility, and DWPF is the Defense Waste Processing Facility.

Lead Test Assemblies

With respect to the MOX alternatives, the Department would qualify MOX fuel forms for use in existing commercial reactors. DOE will analyze two sub-alternatives for the fabrication of the lead test assemblies needed to qualify the fuel. In one sub-alternative, the lead test assemblies would be fabricated in the United States. Fabrication in the United States would involve constructing a pilot capability in conjunction with the fuel fabrication facility. Therefore, the potential sites include the candidate sites for the fuel fabrication facility (i.e., Hanford, INEEL, Pantex, and SRS). The pilot capability could also be located in an existing small facility at the Los Alamos National Laboratory (LANL). The

second alternative would be for fabrication in existing European facilities; three potential fabrication sites exist (Belgium, France, and the United Kingdom) that would allow fabrication of the Lead Test Assemblies sooner than with any facility under the United States alternative.

TABLE 1.—DISPOSITION ALTERNATIVES

	Alternative/Site/Disposition Facility			
Alt. No.	Pit disassembly	MOX plant	Plutonium conversion and immobilization	Amounts of plutonium
1	No Action			
2	Hanford (FMEF)	Hanford (FMEF)	Hanford (FMEF)	17t Immobilization / 33t MOX.
3	SRS (New)	SRS (New)	SRS (New, or Bldg 221F, and DWPF)	17t Immobilization / 33t MOX.
4	Pantex (New)	Hanford (FMEF)	Hanford (FMEF)	17t Immobilization / 33t MOX.
5	Pantex (New)	SRS (New)	SRS (New, or Bldg 221F, and DWPF)	17t Immobilization / 33t MOX.
6	Hanford (FMEF)	Hanford (FMEF)	SRS (New, or Bldg 221F, and DWPF)	17t Immobilization / 33t MOX.
7	INEEL (FPF)	INEEL (New)	SRS (New, or Bldg 221F, and DWPF)	17t Immobilization / 33t MOX.
8	INEEL (FPF)	INEEL (New)	Hanford (FMEF)	17t Immobilization / 33t MOX.
9	Pantex (New)	Pantex (New)	SRS (New, or Bldg 221F, and DWPF)	17t Immobilization / 33t MOX.
10	Pantex (New)	Pantex (New)	Hanford (FMEF)	17t Immobilization / 33t MOX.
11	Hanford (FMEF)	N/A	Hanford (FMEF)	50t Immobilization / 0t MOX.
12	SRS (New)	N/A	SRS (New, or Bldg 221F, and DWPF)	50t Immobilization / 0t MOX.

Immobilization Technology

The Record of Decision on the Storage and Disposition PEIS stated, "Because there are a number of technology variations that could be used for immobilization, DOE will also determine the specific immobilization technology based upon the follow-on EIS * * *" (i.e., the SPD EIS). The technologies to be considered are those identified as variants in the Storage and Disposition PEIS.

Preferred Alternative

For immobilization, the Department prefers to use the "can-in-canister" technology at the DWPF at SRS. Under the can-in-canister approach, cans containing plutonium in glass or ceramic form would be placed in DWPF canisters, which would be filled with borosilicate glass containing high-level waste.

Classified Information

The Department plans to prepare the SPD EIS as an unclassified document with a classified appendix. The classified information in the SPD EIS will not be available for public review. However, the classified information will be considered by DOE in reaching a decision on the disposition of surplus plutonium. DOE will provide as much information as possible in unclassified form to assist public understanding and comment.

Research and Development Activities

The Department recently announced its intent to prepare two environmental assessments (EAs) for proposed research and development activities that DOE would conduct prior to completion of the SPD EIS and ROD. One EA will analyze the potential environmental impacts of a proposed pit disassembly and conversion integrated systems test at LANL. In addition, to further the purposes of NEPA, this EA will describe other research and development activities currently on-going at various sites, including work related to immobilization and to MOX fuel fabrication. The other EA will be prepared for the proposed shipment of special MOX fuel to Canada for an experiment involving the use of United States and Russian fuel in a Canadian test reactor, for development of fuel for the CANDU reactors. This EA will analyze the prior and future fabrication and proposed shipment of the fuel pellets needed for the experiment.

Relationships With Other DOE NEPA Activities

In addition to the SPD EIS and the EAs discussed above, the Department is currently conducting NEPA reviews of other activities that have a potential relationship with the SPD EIS. They include:

1. *Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage and Disposal of Radioactive and Hazardous Waste* (DOE/EIS-0200D) (Draft issued: September 22, 1995; 60 FR 49264).

2. *Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site EIS* (Notice of Intent to Prepare an Environmental Impact Statement: November 19, 1996; 61 FR 58866).

Invitation To Comment

DOE invites comments on the scope of this EIS from all interested parties, including potentially affected Federal, State, and local agencies, and Indian tribes. Comments can be provided by any of the means listed in the Address Section of this notice and by providing oral and written comments at the scoping meetings.

The Department is requesting, by separate correspondence, that Federal agencies [1] desiring to be designated as cooperating agencies on the SPD EIS inform DOE by July 18, 1997.

Scoping Meetings

Public scoping meetings will be held near each site that may be affected by the proposed action. The interactive scoping meetings will provide the public with the opportunity to present comments, ask questions, and discuss concerns regarding plutonium disposition activities with DOE officials, and for the Department to receive oral and written comments on the scope of the EIS. Written and oral comments will be given equal weight in the scoping process. Input from the scoping meetings along with comments received by other means (phone, mail, fax, web-site) will be used by the Department in refining the scope of the EIS. The locations and dates for these public meetings are as shown below. All meetings will consist of two sessions (1:00 pm to 4:00 pm and 6:00 pm to 9:00 pm).

Advanced registration for the public meetings is requested but not required. Please call 1-800-820-5134 and leave your name and the location of the meeting(s) you plan to attend. This information will be used to determine the size and number of rooms needed for the meeting.

Scoping Meeting Format:

The Department intends to hold a plenary session at the beginning of each scoping meeting in which DOE officials will more fully explain the framework for the plutonium disposition program, the proposed action, preliminary alternatives for accomplishing the proposed action and public participation in the NEPA process. Following the plenary session, the Department intends to discuss relevant issues in more detail, answer questions, and receive comments. Each scoping meeting for the Surplus Plutonium Disposition EIS will have two sessions, with each session lasting approximately three to four hours.

Issued in Washington, DC this 16 day of May, 1997, for the United States Department of Energy.

Peter N. Brush,

Principal Deputy Assistant Secretary, Environment, Safety and Health.

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

[Docket No. RP97-165-003]

Alabama-Tennessee Natural Gas Company; Notice of Compliance Filing

May 16, 1997.

Take notice that on May 12, 1997, Alabama-Tennessee Natural Gas Company (Alabama-Tennessee) tendered for filing the tariff sheets listed in Appendix A to the filing, to be effective June 1, 1997.

Alabama-Tennessee states that the tariff sheets are submitted in compliance with Order No. 587 and the Commission's order issued on May 1, 1997 FERC ¶ 61,117).

Any person desiring to protest said filing should file a protest with the Federal Energy Regulatory Commission, 888 First Street, NE., Washington, DC 20426, in accordance with Section 385.211 of the Commission's Regulations. All such protests must be filed as provided in Section 154.210 of the Commission's Regulations. Protests will be considered by the Commission in determining appropriate action to be taken, but will not serve to make protestants parties to the proceedings. Copies of this filing are on file with the Commission and are available for public inspection.

Discovery Gas Transmission LLC; Notice of Site Visit

May 16, 1997.

On May 22, 1997, beginning at 9:30 a.m., the Office of Pipeline Regulation (OPR) staff will conduct a compliance inspection of the onshore facilities of the Discovery Gas Transmission LLC Pipeline Construction Project in Lafourche Parish, Louisiana, beginning at the Larose Gas Processing Plant site (off state highway 24) in Larose.

All parties may attend. Those planning to attend must provide their own transportation (an air boat is required for most of the pipeline route).

For further information, please contact Paul McKee at (202) 208-1088.

Warren C. Edmunds,

Acting Director, Office of Pipeline Regulation.

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

[Docket No. ER97-2846-000]

Florida Power Corporation; Notice of Filing

May 16, 1997.

Take notice that on May 5, 1997, Florida Power Corporation (Florida Power) filed an Application for an Order Approving Market-Based Rates for Sales Outside of Florida. In its Application, Florida Power requests authorization to engage in wholesale, bulk power sales outside of Florida at market-determined prices, including sales not involving Florida Power's generation or transmission. Florida Power requests an effective date of 60 days after this filing, or the date on which the Commission issues an order approving Florida Power's application for market-based rates, whichever is earlier.

Appendix B
CONTRACTOR NONDISCLOSURE STATEMENT

NEPA DISCLOSURE STATEMENT FOR PREPARATION OF EIS FOR DOE SURPLUS PLUTONIUM DISPOSITION

The Council on Environmental Quality (CEQ) Regulations at 40 CFR 1506.5(c), which have been adopted by the the U.S. Department of Energy (DOE) (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for purposes of this disclosure is defined in the March 23, 1981, guidance "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations," 46 FR 18026-18038 at Question 17a and b.

"Financial or other interest in the outcome of the project" includes "any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)." 46 FR 18026-18038 at 18031.

In accordance with these requirements, the offerer and any proposed subcontractors hereby certify as follows: (check either (a) or (b) to assure of your proposal).

(a) X Offerer and any proposed subcontractors have no financial or other interest in the outcome of the project.

(b) ___ Offerer and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

Appendix C
Adjunct Melter Vitrification Process

C.1 ADJUNCT MELTER AS AN IMMOBILIZATION TECHNOLOGY VARIANT

The adjunct melter vitrification process was identified in the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement (Storage and Disposition Final PEIS)* (DOE 1996) as a possible technology variant for immobilizing surplus plutonium. It is a homogenous immobilization approach similar to the new, stand-alone vitrification facility evaluated in the *Storage and Disposition Final PEIS*, except that the approach would use some existing facilities and infrastructure at the Savannah River Site (SRS).

In the adjunct melter approach, plutonium would be immobilized, using modified facilities in Building 221–F, into a borosilicate glass frit that would be temporarily stored in individual cans. This frit would be mixed in the new adjunct melter facility with high-level waste (HLW) supplied from the Defense Waste Processing Facility (DWPF). The blended feed would be melted and poured into DWPF canisters to produce a radiation field in the final product that would meet the Spent Fuel Standard (UC 1996).

C.2 EVALUATION OF IMMOBILIZATION TECHNOLOGY VARIANTS

The U.S. Department of Energy (DOE) examined six immobilization technology variants to determine the more promising variants for further development. The six variants were divided into two categories—the external radiation barrier approach and internal radiation barrier approach—as follows:

I. External barrier (Can-in-canister variants)	1. Ceramic immobilization in existing facilities 2. Glass immobilization in existing facilities
II. Internal barrier (Homogenous variants)	3. Vitrification in new, stand-alone facilities 4. Vitrification with an adjunct melter in existing (DWPF at SRS) and new facilities 5. Ceramic immobilization in new, stand-alone facilities 6. Electrometallurgical treatment in existing and new facilities

Nine evaluation criteria, similar to those used in the screening of alternatives for analysis in the *Storage and Disposition PEIS*, were used to qualitatively evaluate the six immobilization technology variants:

1. Resistance to theft and diversion by unauthorized parties
2. Resistance to retrieval, extraction, and reuse by host nation
3. Technical viability
4. Environmental, safety, and health compliance
5. Cost effectiveness
6. Timeliness
7. Fostering progress and cooperation with Russia and other countries
8. Public and institutional acceptance
9. Additional benefits

The evaluation concluded that the external barrier variants would be superior to the internal barrier variants in terms of timeliness, higher technical viability, much lower costs, and, to a lesser extent, slightly lower

environmental and health risks (UC 1997). As a result of this evaluation, the can-in-canister variants (1 and 2) were considered reasonable alternatives for analysis in the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS) and are compared with the homogenous vitrification and ceramic immobilization facilities (3 and 5) evaluated in the *Storage and Disposition PEIS*. DOE decided, in the Record of Decision for the *Storage and Disposition PEIS*, not to pursue the electrometallurgical treatment option (6) because its technology is less mature than vitrification or ceramic immobilization. Although use of the adjunct melter (4) may be viable from a technical standpoint, it would cost twice as much as the can-in-canister approach and would take 1 to 5 years longer to implement. Based on the relative sizes of the facilities, their use of existing facilities and infrastructure, and the processing steps associated with their operation, specific environmental impacts associated with the adjunct melter approach would be expected to result in environmental impacts ranging between those of the new facility (homogenous) variants and the two can-in-canister variants. The adjunct melter's lack of an environmental advantage combined with its timeliness, cost, and technical shortcomings make it less reasonable than the can-in-canister approach. Thus, it is not included as a reasonable alternative for detailed environmental analysis in the SPD EIS. For completeness, a description of the vitrification process using the adjunct melter with DWPF at SRS is provided below.

C.3 ADJUNCT MELTER VITRIFICATION PROCESS

A simplified flow diagram using a new adjunct melter at SRS is shown in Figure C–1. The disposition process would begin with the conversion of feed materials to plutonium oxide at Building 221–F. This oxide would be blended by a dry feed preparation process to prepare a consistent feedstock and fed into a melter along with glass frit to initiate the first stage of vitrification. The first-stage melter would dissolve the plutonium oxide into the borosilicate glass and convert the mixture to a frit containing about 10 percent plutonium by weight. The assumed nominal feed of plutonium over the life of the adjunct melter vitrification process would be 50 t (55 tons) over a 10-year period.

The plutonium glass frit would then be stored in small steel cans and transported as needed to the new adjunct melter facility adjacent to DWPF. Standard DWPF operations receive two main feedlines from the SRS HLW tank farms to be vitrified—a washed tank sludge and an aqueous HLW precipitate that contains highly radioactive cesium 137. In the adjunct melter process, some of the aqueous HLW precipitate would be diverted from the DWPF, via an interarea pipeline, to the adjunct melter facility. At the adjunct melter facility, the plutonium glass frit would be mixed with DWPF frit and the aqueous HLW precipitate in a melter feed tank, and slurry fed to the melter, producing a homogenous glass melt that would then be poured into DWPF canisters. The surplus plutonium contained in the canisters would be dissolved in the glass and uniformly integrated with fission products. The canisters would then be stored on the site awaiting final disposal at a geologic repository pursuant to the Nuclear Waste Policy Act.

Appendix D
Fast Flux Test Facility

D.1 BACKGROUND

During the public scoping period for the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS), the U.S. Department of Energy (DOE) received comments on the use of the Fast Flux Test Facility (FFTF) at the Hanford Site (Hanford) for the disposition of surplus plutonium.

FFTF is a 400-MW thermal reactor cooled by liquid sodium. It was built in 1978 to test plant equipment and mixed oxide (MOX) fuel for the U.S. Government's liquid metal reactor development program. After operating successfully from 1982 to 1992, FFTF was transitioned to a safe, standby condition. As part of the process of selecting plutonium disposition technologies for evaluation in the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement (Storage and Disposition Final PEIS)*, DOE considered FFTF because it was an existing facility that would not require the large commitment of time and money that a new reactor would require for implementation of the plutonium disposition mission. FFTF, however, was eliminated because it was in a standby status awaiting shutdown and because it could not satisfy the *Storage and Disposition Final PEIS* criterion of completing the disposition mission within 25 years using the historic FFTF plutonium enrichment specifications (DOE 1996).

D.2 RESTART EVALUATION

In December 1995, DOE issued a Record of Decision (ROD) to pursue a dual track for tritium supply based on the two most promising tritium supply alternatives analyzed in the *Final Programmatic Environmental Impact Statement for Tritium Supply and Recycling* (DOE 1995). The dual track alternatives consisted of (1) initiating the purchase of an existing commercial reactor (operating or partially complete) or irradiation services with an option to purchase the reactor for conversion to a defense facility, and (2) designing, building, and testing critical components of an accelerator system for tritium production. DOE's current plans are to select, by the end of 1998, one of these approaches for development as the primary source of tritium supply and to continue to study the other as a potential backup source. The ROD also noted that DOE would evaluate the potential restart and operation of FFTF to determine if it might have a role in meeting future tritium requirements. Accordingly, FFTF has been maintained in standby condition, pending results of the restart evaluation.

FFTF could be used as a dual-purpose reactor, producing tritium and consuming surplus plutonium as fuel. Such use of FFTF, however, would result in a slower plutonium disposition rate than using MOX fuel in commercial reactors.

A number of studies (Drell et al. 1996; PNNL 1997; Putnam, Hayes & Bartlett 1995) have been conducted to date to evaluate the technical feasibility, environmental and safety issues, cost, and schedule associated with the restart and operation of FFTF. The general conclusion was that it is technically feasible for FFTF to be restarted safely to meet commercial or equivalent standards in a relatively short time at a reasonable cost.

Before FFTF could begin to use surplus plutonium from pits or clean metal for the production of tritium, however, 3 to 4 years would be required to develop and test a higher plutonium enriched reactor fuel (the previous FFTF fuel had an enrichment of approximately 35 percent plutonium) and to establish a MOX fuel fabrication capability. Under these conditions, it would take at least 35 years to disposition the surplus weapons-grade plutonium that is suitable for use in reactors. The goal of completing the disposition mission within 25 years of project authorization could only be achieved if additional reactors were to be provided, or if immobilization were used for a portion of the fuel-usable surplus plutonium.

At the time the SPD EIS went to print, DOE had not proposed to use FFTF for tritium production. If DOE proposes to restart FFTF, appropriate National Environmental Policy Act review, including extensive formal public involvement, would be conducted.

If it were determined that MOX fuel (rather than uranium-only fuel) were needed for FFTF operations, the MOX fuel fabrication alternatives may be eliminated, depending on the amount of surplus plutonium that would be required for tritium production. The alternatives immobilizing all 50 t (55 tons) of the surplus plutonium considered in the SPD EIS (Alternatives 11 and 12) would be eliminated for the same reason.

Appendix E
Facility Data

This appendix provides predesign data on the construction and operation requirements for the facilities required to accomplish the surplus plutonium disposition activities. Tables E–1 through E–24 present data on schedule, construction area requirements, operation area requirements, construction employment requirements, major construction resource requirements, operation employment requirements, and operation resource requirements for each of the four candidate sites (Hanford Site [Hanford], Idaho National Engineering and Environmental Laboratory [INEEL], Pantex Plant [Pantex], and Savannah River Site [SRS]). For the candidate lead assembly fabrication facilities at Argonne National Laboratory–West, Hanford, Los Alamos National Laboratory, Lawrence Livermore National Laboratory, and SRS, the schedule, operation employment requirements, and operation resource requirements are presented in Tables E–25 through E–28.

The alternatives addressed in the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS) provide options for collocation of facilities at Hanford in the Fuels and Materials Examination Facility. Resource requirements for the pit conversion facility are the same whether the facility is collocated with the other facilities or is installed alone. The same applies for the immobilization facility except as indicated in Tables E–9, E–12, and E–15, and for the mixed oxide (MOX) facility except as indicated in Tables E–20 through E–22.

Next Section

Appendix F
Impact Assessment Methods

This appendix briefly describes the methods used to evaluate the potential direct, indirect, and cumulative effects of the alternatives for surplus plutonium disposition. Included are impact assessment methods for air quality and noise, geology and soils, water resources, ecological resources, cultural and paleontological resources, land use and visual resources, infrastructure, waste management, socioeconomics, human health risk, facility accidents, transportation, environmental justice, and cumulative impacts. Each section is organized so that first the affected resource is described and then the impact assessment method is presented. Detailed descriptions of the methods for facility accidents and transportation impacts analysis are presented as Appendixes K and L, respectively.

Although impacts were generally described as either major or minor, this assignment was made in different ways, depending on the resource. For air quality, for example, estimated pollutant emissions from the proposed facilities were compared with the appropriate regulatory standards or guidelines. For human health risk, estimated radionuclide exposure to humans from the proposed facilities were compared with applicable dose limits. Comparison with regulatory standards is a commonly used method for benchmarking environmental impact and is done here to provide perspective on the magnitude of identified impacts.

Other indicators of impact were also established to focus the analysis on impacts that could be major. The analysis of waste management impacts, for example, focused on alternatives where additional waste generation would be a large percentage of current site waste generation, although a major impact was suggested only where waste generation would exceed the capacity of existing waste management facilities. Cumulative impacts were also evaluated with a view to ensuring that actions with minor impacts individually could not have major impacts collectively.

Impacts in all resource areas were analyzed consistently; that is, the impact values were estimated using a consistent set of input variables and computations. Moreover, efforts were made to ensure that calculations in all areas used accepted protocols and up-to-date models. Finally, like presentations were developed to facilitate the comparison of alternatives.

F.1 AIR QUALITY AND NOISE

F.1.1 Description of Affected Resources

F.1.1.1 Air Quality

Air pollution refers to any substance in the air that could harm human or animal populations, vegetation, or structures, or that unreasonably interferes with the comfortable enjoyment of life and property. For purposes of the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS), only outdoor air pollutants were addressed. They may be in the form of solid particles, liquid droplets, gases, or a combination of these forms. Generally, they can be categorized as primary pollutants (those emitted directly from identifiable sources) and secondary pollutants (those produced in the air by interaction between two or more primary pollutants or by reaction with normal atmospheric constituents, which may be influenced by sunlight). Air pollutants are transported, dispersed, or concentrated by meteorological and topographical conditions. Thus, air quality is affected by air pollutant emission characteristics, meteorology, and topography.

Ambient air quality in a given location can be described by comparing the concentrations of various pollutants in the atmosphere with the appropriate standards. Ambient air quality standards have been established by Federal and State agencies, allowing an adequate margin of safety for protection of public health and welfare

from the adverse effects of pollutants in the ambient air. Pollutant concentrations higher than the corresponding standards are considered unhealthy; those below such standards, acceptable.

The pollutants of concern are primarily those for which Federal and State ambient air quality standards have been established, including criteria air pollutants, hazardous air pollutants, and other toxic air compounds. Criteria air pollutants are those listed in 40 CFR 50, *National Primary and Secondary Ambient Air Quality Standards* (EPA 1997a). Hazardous air pollutants and other toxic compounds are those listed in Title I of the 1990 Clean Air Act (CAA) as amended, those regulated by the National Emissions Standards for Hazardous Air Pollutants (NESHAP), and those that have been proposed or adopted for regulation by the respective State or are listed in State guidelines. Also of concern are air pollutant emissions that may contribute to the depletion of stratospheric ozone or global warming. Construction activities, particularly those that involve modification of existing facilities, may be subject to certain NESHAP requirements, for example, the reporting, training, and work practice requirements for asbestos renovation (EPA 1997b). Provisions of other NESHAP requirements, such as those for benzene (EPA 1997c), would likely not apply because the amounts stored and used for construction and operation of these facilities would be small. Provisions of NESHAP for radionuclides are discussed in Chapter 5 and Appendix F.10.

Areas with air quality better than the National Ambient Air Quality Standards (NAAQS) for criteria air pollutants are designated as being in attainment; areas with air quality worse than the NAAQS for such pollutants, as nonattainment areas. Areas may be designated as unclassified when sufficient data for attainment status designation are lacking. Attainment status designations are assigned by county, metropolitan statistical area, consolidated metropolitan statistical area, or portions thereof. Air Quality Control Regions designated by the U.S. Environmental Protection Agency (EPA) are listed in 40 CFR 81, *Designation of Areas for Air Quality Planning Purposes.*

For locations that are in an attainment area for criteria air pollutants, prevention of significant deterioration (PSD) regulations limit pollutant emissions from new sources and establish allowable increments of pollutant concentrations. Three PSD classifications are specified with the criteria established in the CAA amendments. Class I areas include national wilderness areas, memorial parks larger than 2,020 ha (5,000 acres), and national parks larger than 2,430 ha (6,000 acres), and areas that have been redesignated as Class I. Class II areas are all areas not designated as Class I. No Class III areas have been designated.

Designation as a nonattainment area for criteria air pollutants triggers control requirements designated to achieve attainment status by specified dates. In addition, facilities that constitute major new emission sources cannot be constructed in a nonattainment area without permits that impose stringent pollution control requirements to ensure progress toward compliance.

The region of influence (ROI) for air quality is that area around a site potentially affected by air pollutant emissions caused by the surplus plutonium disposition alternatives. The air quality impact area normally evaluated is the area in which concentrations of criteria air pollutants would increase more than a significant amount in a Class II area. Significance varies according to the averaging period: 2,000 $\mu g/m^3$ for 1 hr for carbon monoxide; 25 $\mu g/m^3$ for 3 hr for sulfur dioxide; 5 $\mu g/m^3$ for 24 hr for sulfur dioxide and particulate matter with an aerodynamic diameter less than or equal to 10 microns (PM_{10}); and 1 $\mu g/m^3$ annually for sulfur dioxide, PM_{10}, and nitrogen dioxide (EPA 1997d). Generally, this covers a few kilometers downwind from the source. For sources within 100 km (62 mi) of a Class I area, the air quality impact area evaluated would include the Class I area if the average 24-hr increase in concentration were greater than 1$\mu g/m^3$. The size of the ROI depends on emission source characteristics, pollutant types, emission rates, and meteorological and topographical conditions. For purposes of this analysis, where most of the sites are large, impacts were evaluated at the site boundary, along roads within the sites to which the public has access, and anywhere else the contributions to pollutant concentrations could exceed the established significance levels.

Baseline air quality is typically described in terms of pollutant concentrations modeled for existing sources at each site and background air pollutant concentrations measured near the sites. For this analysis, concentrations for existing sources were obtained from existing source documents or by modeling recent emissions data. Data from the *Storage and Disposition Final PEIS* (DOE 1996a) were incorporated where appropriate.

The maximum concentrations of toxic air pollutants at or beyond the site boundary were compared with Federal and State regulations or limits. To determine human health risk (see Appendix F.10), modeling outputs on chemical concentrations in air were weighed against chemical-specific toxicity values. Emissions of radionuclides to the air (see Appendix F.10) were evaluated in terms of a total dosage standard.

F.1.1.2 Noise

Sound results from the compression and expansion of air or some other medium when an impulse is transmitted through it. Sound requires a source of energy and a medium for transmitting the sound wave. Propagation of sound is affected by various factors, including meteorology, topography, and barriers. Noise is undesirable sound that interferes or interacts negatively with the human or natural environment. Noise may disrupt normal activities (e.g., hearing, sleep), damage hearing, or diminish the quality of the environment.

Sound-level measurements used to evaluate the effects of nonimpulsive sound on humans are compensated by an A-weighting scale that accounts for the hearing response characteristics (i.e., frequency) of the human ear. Sound levels are expressed in decibels, or in the case of A-weighted measurements, decibels A-weighted. The EPA has developed noise-level guidelines for different land-use classifications. Some States and localities have established noise control regulations or zoning ordinances that specify acceptable noise levels by land-use category.

Noise from facility operations and associated traffic could affect human and animal populations. Because most nontraffic noise associated with construction and operation of the proposed facilities would be distant from offsite noise-sensitive receptors, the contribution to offsite noise levels should be small. Impacts associated with transportation access routes, including noise from increased traffic, could result in small increases in noise along these routes. The ROI for each of the sites includes the site and surrounding areas, including transportation corridors, where proposed activities might increase noise levels. Transportation corridors most likely to experience increased noise levels are those roads within a few miles of the site boundary that carry most of the site's employee and shipping traffic.

Sound-level data representative of site environs were obtained from existing reports and from calculations of the sound levels typical of prevailing traffic volumes along the transportation corridors. The acoustic environment was further described in terms of existing noise sources for each site.

F.1.2 Description of Impact Assessment

F.1.2.1 Air Quality

Potential air quality impacts of pollutant emissions from construction and normal operations were evaluated for each alternative (see Table F–1). That assessment included a comparison of effects of each alternative with applicable Federal and State ambient air quality standards and concentration limits. The more stringent standards, EPA or State, served as the assessment criteria. Criteria for hazardous and toxic air pollutants include those listed in Title III of the 1990 CAA Amendments, the NESHAP, and standards and guidelines adopted by the respective states. The SPD incremental change in concentrations of pollutants was compared with the PSD Class II allowable increments. Impacts on Class I PSD areas were evaluated where there was a Class I area within 100 km (62 mi) of the site.

Table F–1. Impact Assessment Protocol for Air Quality and Noise

Resource	Required Data		Measure of Impact
	Affected Environment	Facility Design	
Air quality			
Criteria air pollutants and other regulated pollutants[a]	Ambient concentration ($\mu g/m^3$) of air pollutants, and concentrations of pollutants from existing sources at site	Emission (kg/yr) of air pollutants from facility and facility construction or modification; source characteristics (e.g., stack height and diameter, exit temperature and velocity); shipments and workforce estimates	Contribution of proposed alternative to concentrations of each pollutant at or beyond site boundary; total concentration of each pollutant at or beyond site boundary; percent of applicable standard
Toxic/hazardous air pollutants[b]	Ambient concentrations ($\mu g/m^3$) of toxic air pollutants; concentrations of pollutants from existing sources at site	Emission rate (kg/yr) of toxic air pollutants from facility; source characteristics (e.g., stack height and diameter, exit temperature and velocity)	Contribution of proposed alternative to concentrations of each pollutant at or beyond the site boundary; total concentration of each pollutant at or beyond site boundary; percent of applicable standard
Noise	Sound levels at sensitive offsite receptors (e.g., at nearby residences, along major access routes); sound levels at noise-sensitive wildlife habitat (nearby threatened and endangered wildlife habitat)	Descriptions of major construction and operations sources; shipment and workforce estimates	Increase in day/night average sound level at sensitive receptors

[a] Carbon monoxide; hydrogen fluoride; lead; nitrogen oxides; ozone; particulate matter with an aerodynamic diameter less than or equal to 10μg; sulfur dioxide; total suspended particulates.

[b] Title III pollutants, pollutants regulated under the National Emissions Standard for Hazardous Air Pollutants, and other State-regulated pollutants.

Operational air pollutant emissions data for each alternative (other than No Action) were based on engineering design reports; construction emissions data for each alternative, on engineering design reports, emission factors for construction equipment listed in *Compilation of Air Pollutant Emission Factors, Vol. II - Mobile Sources* (EPA 1991:vol. II, 7-1–7-7), and emission factors for fugitive dust from construction listed in *Compilation of Air Pollutant Emission Factors* (EPA 1996a:13.2-1; 13.2-2; 13.2.2-1–13.2.2-8; 13.2.3-1–13.2.3-7; 13.2.4-1–13.2.4-9; 13.2.5-1–13.2.5-21). Traffic emissions were estimated using EPA's MOBILE5b and PART 5 emissions calculation models.

For each alternative, contributions to offsite air pollutant concentrations were modeled on the basis of guidance presented in the *Guidelines on Air Quality Models* (EPA 1997e). The EPA-recommended Industrial Source Complex Model, Version 3 (ISC3), was selected as the most appropriate model to perform the air dispersion modeling, because it is designed to support the EPA regulatory modeling program and is capable of handling multiple sources and source types. The short-term version of ISC3, ISCST3, was used to calculate

concentrations with averaging times of 1 to 24 hours and annual average concentrations. Concentrations for the No Action Alternative were based on information provided in the *Storage and Disposition Final PEIS* (DOE 1996a).

The modeling analysis incorporated conservative assumptions, which tend to overestimate the pollutant concentrations. The "highest-high" concentration for each pollutant and averaging time was selected for comparison with the applicable assessment criterion, instead of the less conservative EPA-recommended "highest-high" and "highest second-highest" concentration for long-term and short-term averaging times, respectively. The concentrations evaluated were the maximum occurring at or beyond the site boundary or a public access road, and included the contribution of the alternative and that of existing onsite sources. Available monitoring data, which reflect both onsite and offsite sources, were also taken into consideration. Concentrations of the criteria air pollutants, hazardous air pollutants, and toxic air compounds were presented for each alternative. Construction equipment activity emissions were evaluated as a volume source for each alternative using the ISC3 model. The total concentration, including the contribution from each alternative and the percent of the applicable standard, were presented. This percentage reflects the variability of the No Action concentrations, the standards and guidelines among sites and the differences among the alternatives.

The effects of traffic related to construction and operation for each alternative were evaluated by calculating the emissions of criteria pollutants from worker vehicles and shipping activities.

One year of sequential hourly onsite meteorological data from the sites and upper-air data for appropriate locations from the National Climactic Data Center were used in the air quality modeling. For consistency, the data were for the same year considered in the *Storage and Disposition Final PEIS* (DOE 1996a).

Additional assumptions were incorporated in the air quality modeling at each site. For example, to model emissions from a generic process stack for mixed oxide fuel fabrication, a single source within the facility was used, assuming a stack height of 8 m (26 ft), a stack diameter of 0.3 m (1 ft), a stack exit temperature equal to the ambient temperature, and a stack exit velocity of 0.03 m/s (0.1 ft/s). Where they could be obtained, however, actual stack locations and stack parameters were used to model pollutant concentrations.

The analysis tends to overestimate pollutant concentrations, since the location of the maximum site boundary concentrations due to surplus plutonium disposition facilities was assumed to be the same as the location of maximum concentrations of other pollutant sources at the site.

Ozone is typically formed as a secondary pollutant in the ambient air (troposphere). It is formed from such primary pollutants as nitrogen oxides and volatile organic compounds, which emanate from vehicular (mobile), natural, and other stationary sources. It is not emitted directly as a pollutant from the sites. Although ozone may thus be regarded appropriately as a regional issue, specific ozone precursors, notably nitrogen dioxide and volatile organic compounds, were analyzed as applicable to the alternatives under consideration.

The CAA, as amended, required that Federal actions conform to the host State's "State Implementation Plan." A State Implementation Plan provides for the implementation, maintenance, and enforcement of NAAQS for the six criteria pollutants: sulfur dioxide; particulate matter with an aerodynamic diameter smaller than or equal to 10 μm in diameter (PM_{10}); carbon monoxide; ozone; nitrogen dioxide; and lead. Its purpose is to eliminate or reduce the severity and number of violations of NAAQS and to expedite the attainment of these standards. No department, agency, or instrumentality of the Federal Government shall engage in or support in any way (i.e., provide financial assistance for, license or permit, or approve) any activity that does not conform to an applicable implementation plan. The final rule for *Determining Conformity of General Federal Actions to State or Federal Implementation Plans* (EPA 1993) took effect on January 31, 1994. Hanford, Pantex, the Idaho National Engineering and Environmental Laboratory (INEEL), the Savannah River Site

(SRS), Los Alamos National Laboratory (LANL), and Lawrence Livermore National Laboratory (LLNL) are within areas currently designated as attainment for criteria air pollutants. Therefore, the surplus plutonium disposition alternatives being considered at these sites are not affected by the provisions of the conformity rule. Rocky Flats Environmental Technology Site (RFETS) is in an area designated nonattainment for ozone, PM_{10}, and carbon monoxide. Applicability of the conformity rule to the RFETS is discussed in Section 4.2.1.6 on No Action.

Emissions of potential stratospheric ozone-depleting compounds such as chlorofluorocarbons were not evaluated, for no emissions of these pollutants were identified in the engineering design reports.

Emissions of pollutants that are potential contributors to global warming (e.g., carbon dioxide, nitrous oxide chlorofluorocarbons, and methane) were evaluated using emission data in the engineering design reports. These emission were compared with annual releases of these pollutants from other sources.

F.1.2.2 Noise

Also addressed in the SPD EIS assessment were the onsite and offsite acoustic impacts of construction and operation of the proposed facilities (see Table F–1). That analysis drew from available information (e.g., engineering design reports) on the types of noise sources and the locations of the proposed facilities relative to the site boundary and noise-sensitive locations. Its focus was the degree of change in noise levels at sensitive receptors (e.g., residences near the site boundary and along access routes, and schools along access routes) with respect to ambient conditions. (A change in noise level of less than 3 decibels is generally not detectable by the human ear. An increase of 10 decibels is roughly equivalent to a doubling of the perceived sound.) Most nontraffic noise sources associated with construction and operation of the surplus plutonium disposition facilities are far enough from offsite noise-sensitive receptors that the contribution to offsite noise levels should be small. Projections of traffic noise during construction and operations were based on the employment and shipment projections provided in the engineering design reports.

F.2 GEOLOGY AND SOILS

F.2.1 Description of Affected Resources

Geologic resources include consolidated and unconsolidated earth materials, including mineral assets such as ore and aggregate materials, and fossil fuels such as coal, oil, and natural gas. Geologic conditions include hazards such as earthquakes, faults, volcanoes, landslides, and land subsidence. Soil resources include the loose surface materials of the earth in which plants grow, usually consisting of mineral particles from disintegrating rock, organic matter, and soluble salts.

The ROI for geology and soils includes all areas subject to disturbance by construction and operation of surplus plutonium disposition facilities, and those areas beneath these facilities that would remain inaccessible for the life of the facilities.

Geology and soils were considered with respect to natural conditions that could affect the alternative, as well as those portions of the resource that could be affected by the alternative. Geology and soils conditions that could affect the integrity and safety of the surplus plutonium disposition alternatives include large-scale geologic hazards and attributes of the soil beneath the proposed facility. Geology and soils resources that could be affected by the surplus plutonium disposition alternatives include economically valuable mineral resources and prime farmland soils.

F.2.2 Description of Impact Assessment

Facility construction and operations for the surplus plutonium disposition alternatives were considered from the perspective of impacts on specific geologic resources and soil attributes. Construction impacts would predominate in effects on geologic and soil resources; hence, key factors in the analysis were the land area to be disturbed during construction and occupied during operations (see Table F–2). The main objective was avoidance of the siting of facilities over unstable soils—i.e., soils prone to liquefaction, shrink-swell, or erosion.

Table F–2. Impact Assessment Protocol for Geology and Soils

Resource	Required Data		Measure of Impact
	Affected Environment	Facility Design	
Soil attributes	Presence of any unstable soils at proposed facility location	Location of proposed facility on the site	Location of facility on unstable soils
Valuable mineral and energy resources	Presence of any valuable mineral or energy resources at proposed facility location	Location of proposed facility on the site	Destruction or rendering inaccessible of valuable mineral or energy resources
Prime farmland soils	Presence of prime farmland soils at proposed facility location	Location of proposed facility on the site	Conversion of prime farmland soils to nonagricultural use

Included in the geology and soils impact analysis was consideration of the risks to the proposed facilities of large-scale geologic hazards such as faulting and earthquakes, lava extrusions and other volcanic activity, landslides, sinkholes, and salt dissolution—i.e., conditions that tend to affect broad expanses of land. While evidence of impacts in facility-specific areas was developed, there was no attempt to revisit the basic conclusion of the *Storage and Disposition Final PEIS* (DOE 1996a:4-45–47, 4-148–150, 4-204–206, 4-309–311) in this regard: that the risks of such hazards to storage and disposition facilities at the candidate sites are acceptable. The findings of that analysis, which focused on the presence of the hazard and the distance of the facilities from it, were accepted as generally applicable to the surplus plutonium disposition facilities. Efforts were also made to determine if locating the surplus plutonium disposition facilities at a specific site could destroy, or preclude the use of, valuable mineral or energy resources.

Pursuant to the Farmland Protection Policy Act (FPPA) (7 USC 4201 et seq.), and the regulations (7 CFR 658) promulgated as result thereof, the presence of prime farmland was also evaluated. This act requires agencies to make FPPA evaluations part of the National Environmental Policy Act (NEPA) process, the main purpose being to reduce the conversion of farmland to nonagricultural uses by Federal projects and programs. Prime farmland, as defined in 7 CFR 657, is land that contains the best combination of physical and chemical characteristics for producing crops. It includes cropland, pasture land, rangeland, and forest land. Potential prime farmlands not acquired prior to June 22, 1982, the effective date of the FPPA, are exempt from its provisions (DOE 1996b:4-22).

F.3 WATER RESOURCES

F.3.1 Description of Affected Resources

Water resources are the surface and subsurface waters that are suitable for human consumption, agricultural purposes, or irrigation or industrial/commercial purposes, and that could be impacted by the proposed action.

This analysis involved the review of engineering estimates of expected water use and effluent discharges from proposed construction, operation, maintenance, and decontamination and decommissioning (D&D) of the proposed facilities, and ultimately the impacts of the activities on the local surface water and groundwater.

F.3.2 Description of Impact Assessment

The water resources evaluation for the SPD EIS tiers from the corresponding analysis presented in the *Storage and Disposition Final PEIS* (DOE 1996a). Its purpose was to evaluate the differences in the impacts where changes would be incurred in the assumed water usage to accommodate the facilities involved in the planned disposition activities. Determination of the impacts of the alternatives on water resources (see Table F–3) consisted of a comparison of field-generated data with regulatory standards, design parameters commonly used in the water and wastewater design industry, and accepted industry standards.

Table F–3. Impact Assessment Protocol for Water Resources[a]

	Required Data		
Resource	**Affected Environment**	**Facility Design**	**Measure of Impact**
Surface water quality	Surface waters near the facilities in terms of stream classifications and changes in water quality	Anticipated effluent quantity and quality	Noncompliance of surface water quality with relevant standards of Clean Water Act or with State regulations
Groundwater quality	Groundwater near the facilities in terms of classification, presence of designated sole source aquifers, and changes in quality of groundwater	Quantity and quality of anticipated withdrawals from, or discharges to, groundwater	Concentrations of contaminants in groundwater exceeding standards established in accordance with Safe Drinking Water Act or State regulations
Surface water availability	Surface waters near the facilities, including average flow; 7-day, 10-year low flow; and numbers of downstream users	Volume of withdrawals from, and discharges to, surface waters	Changes in availability to downstream users of water for drinking, irrigation, or animal feeding[b]
Groundwater availability	Groundwater near the facilities, including numbers of all groundwater users, existing water rights for major water users, and contractual agreements for water supply use within impacted area	Volume of withdrawals and discharges to groundwater	Changes in availability of groundwater for human consumption, irrigation, or animal feeding
Flooding impacts	Locations of 100- and 500-year floodplains	Facility location on the site	Construction of facilities in a floodplain[c]

[a] For flows above the design capacity of existing water and sewage treatment systems.
[b] An impact is assumed if withdrawals exceed 10 percent of the 7-day, 10-year low flow of the receiving stream.
[c] A floodplain assessment is a prerequisite to construction on a floodplain.

Certain assumptions were integral to this analysis: (1) that all water and sewage treatment facilities would be approved by the appropriate permitting authority, and thus that the impacts of project-specific withdrawals from the water treatment plants and effluent discharges from the sewage treatment plant would be in accordance with established standards; (2) that the sewage treatment facilities would meet the effluent

limitations imposed by their respective National Pollutant Discharge Elimination System (NPDES) permits; and (3) that any stormwater runoff from construction or operations activities would be handled in accordance with the regulations of the appropriate permitting authority. It was also assumed that, during construction, siltation fencing or other erosion control devices would be used to mitigate short-term adverse impacts from siltation, and that as appropriate, stormwater holding ponds would be constructed to lessen the impacts of rainfall events on the receiving streams.

Further assumptions regarding water resources impacts were based in part on results of the analysis. The first step in the analysis was to determine whether any revisions in project water and wastewater flows had occurred between the time of the *Storage and Disposition Final PEIS* (DOE 1996a) and the collection of data for the SPD EIS. If no such determination was made, and if no evidence of an impact on water resources had been presented in the *Storage and Disposition Final PEIS* (DOE 1996a), then it was assumed that no such impact would be incurred. If the analysis reflected a revision downward in the assumed water use for a proposed activity, but there had been no finding of impact for that activity in the *Storage and Disposition Final PEIS* (DOE 1996a), then no impact was attributed to that activity. If the analysis reflected an increase in water use, then an evaluation of the design capacity of the water and wastewater treatment facilities was made to determine whether their design capacity would be exceeded by the additional flows. If the combined flow—i.e., the existing flow plus those from the proposed activities—were less than the design capacity of the water and sewage treatment plants, then it was assumed that there would be no impact on water availability for local users, nor on the receiving stream from sewage treatment plant effluent discharges. If the flows from the proposed facilities were found to exceed the design capacity of the existing water or sewage treatment facilities, then the following extensive analyses of the impact of these flows were conducted.

Surface Water Availability. The analysis of the potential impacts on water availability entailed comparing the rate of surface water use for the specific alternative, the associated effluent discharges, and the use and classification of water in downstream waterways. For facilities intending to use surface water, an evaluation of the total use and the 7-day, 10-year low-flow conditions of the receiving stream was made. Discharges of effluent back into the receiving stream were included in the evaluation. If net losses were found to exceed 10 percent of the 7-day, 10-year low flow, an impact was assumed. Where groundwater was the source of water, discharges to surface water were interpreted as adding to the flow in the receiving stream. If the increases exceeded 200 percent of the 7-day, 10-year low flow, then an impact was assumed.

Surface Water Quality. The evaluation of the service water quality impacts focused on the quality and quantity of the effluent to be discharged and the quality of the receiving stream upstream and downstream from the proposed facilities. The evaluation of effluent quality featured review of the expected design parameters, such as the design average and maximum flows, as well as the effluent parameters reflected in the existing or expected NPDES permit. Those parameters include biochemical oxygen demand, total suspended solids, metals, coliform bacteria, organic and inorganic chemicals, radionuclides, and any other parameters that affect the local environment. Water quality management practices were reviewed to ensure that NPDES permit limitations would be met. Factors that currently degrade water quality were also identified.

During construction, the receiving stream could be affected by construction site runoff and sedimentation. Such impacts relate to the amount of land disturbed, the type of soil at the site, the topography, and weather conditions. They would be minimized by application of standard management practices for storm-water and erosion control.

During operations, receiving waters could be affected by increased runoff from parking lots, buildings, or other cleared areas. Storm water from these areas could be contaminated with materials deposited by airborne pollutants, automobile exhaust and residues, and process effluents. Impacts of storm-water discharges could be highly specific, and mitigation would depend on management practices, the design of holding facilities, the

topography, and adjacent land use. Data from the existing water quality database were compared with expected flows from the new facilities to determine the relative impacts on the quality of the water in the receiving stream.

Groundwater Availability. Effects of the proposed action on groundwater supplies were determined by analyzing potential withdrawal rates for the construction and operations phases of the action. Estimates of withdrawal from the affected aquifers were provided. Additionally, instances in which groundwater use could exceed a large portion of the locally developed groundwater supplies were identified.

Groundwater Quality. Potential groundwater quality impacts associated with effluent discharges during the construction and operations phases were examined. The groundwater quality projections were then weighed against federal and state groundwater quality standards, effluent limitations, and drinking water standards to determine the impacts of each alternative. Also evaluated were the effects of construction and operations activities on the movement of existing groundwater contamination plumes, and the consequences thereof for groundwater use in the area.

Floodplain Impacts. Once the regional 100- and 500-year floodplains were identified from maps and other existing documents, the likely impacts thereon of proposed surplus plutonium disposition facility, construction, and operations activities were analyzed. For any facilities proposed for location in a floodplain, a floodplain assessment was prepared. Where possible, the surplus plutonium disposition facilities were sited to ensure compliance with Executive Order 11988, *Floodplain Management*, and 10 CFR 1022, *Compliance With Floodplain/Wetlands Environmental Review Requirements.*

F.4 ECOLOGICAL RESOURCES

F.4.1 Description of Affected Resources

Ecological resources include terrestrial and aquatic resources (plants and animals), wetlands, and threatened and endangered species that could be affected by proposed construction and operations at the proposed surplus plutonium disposition sites. In accord with the *Storage and Disposition Final PEIS* (DOE 1996a), the ROI for habitat impacts from facility construction and operations, is the area within a 1.6-km (1-mi) radius of the proposed facility.

F.4.2 Description of Impact Assessment

The proposed alternatives would involve, at a minimum, land disturbance during modifications to existing facilities and may require site clearing for construction of new facilities (see Table F–4). Accordingly, ecological impacts were assessed in terms of potential disturbances or loss of nonsensitive terrestrial and aquatic habitats and the potential effects on nearby sensitive habitats. For purposes of this SPD EIS, sensitive habitats include those areas occupied by threatened and endangered species, State-protected species, and wetlands.

F.4.2.1 Nonsensitive Habitat Impacts

During the construction phase, ecological resources could be affected through disturbance or loss of habitat resulting from site clearing, land disturbance, human intrusion, and noise. Terrestrial resources could be directly affected through changes in vegetative cover important to individual animals of certain species with limited home ranges, such as small mammals and songbirds. Likely impacts include increased direct mortality and susceptibility to predation. Activities associated with the construction and operation of facilities (e.g., human intrusion and noise) could also compel the migration of the wildlife to adjacent areas with similar

Table F–4. Impact Assessment Protocol for Ecological Resources

Resource	Required Data		Measure of Impact
	Affected Environment	Facility Design	
Nonsensitive terrestrial and aquatic habitats	Vegetation and wildlife within a 1.6-km (1-mi) radius of proposed facility locations	Area disturbed by construction of proposed facility	Decrease in acreage of undisturbed local and regional nonsensitive habitats
Sensitive terrestrial and aquatic habitats, including wetlands	Sensitive species habitats within a 1.6-km (1-mi) radius of proposed facility locations	Area disturbed by construction of proposed facility	Decrease in extent of sensitive habitats in ROI Determination by USFWS and State agencies that facility construction could disturb sensitive habitats

Key: ROI, region of influence; USFWS, U.S. Fish and Wildlife Service.

habitat. If the receiving areas were already supporting the maximum sustainable wildlife, competition for limited resources and habitat degradation could be fatal to some species. Therefore, the analysis of impacts on terrestrial wildlife was based largely on the extent of plant community loss or modification.

Construction or modification of facilities, and the operation thereof, could directly affect aquatic resources through increased runoff and sedimentation, increased flows, and the introduction of thermal and chemical changes to the water. However, various mitigation techniques should minimize construction impacts, and discharges of contaminants to surface waters from routine operations are expected to be limited by engineering control practices. Therefore, impacts are expected to be minimal.

F.4.2.2 Sensitive Habitat Impacts

Impacts on threatened and endangered species, State-protected species, and their habitats during construction of the proposed surplus plutonium disposition facilities were determined in a manner similar to that for nonsensitive habitats. A list of sensitive species that could be present at each site was compiled. Plans were developed for preconstruction surveys, as necessary, to determine the presence of any Federal- or State-listed species within the ROI. Those plans call for consulting the U.S. Fish and Wildlife Service and various State agencies to confirm that potential impacts on sensitive habitats are acceptable or can be mitigated.

Most construction impacts on wetlands are related to the displacement of wetlands by filling, draining, or dredging activities. Operational impacts thereon could result from effluents, surface water or groundwater withdrawals, or the creation of new wetlands. Loss of wetlands resulting from construction and operation of the surplus plutonium disposition facilities was addressed by comparing data on the location and areal extent of wetlands in the ROI with the land area requirements for the proposed facilities.

F.5 CULTURAL AND PALEONTOLOGICAL RESOURCES

F.5.1 Description of Affected Resources

Cultural resources are the indications of human occupation and use of the landscape as defined and protected by a series of Federal laws, regulations, and guidelines. For the SPD EIS, the potential impacts of proposed surplus plutonium disposition activities were assessed separately for each of the three general categories of cultural resources: prehistoric, historic, and Native American. Paleontological resources are the physical remains, impressions, or traces of plants or animals from a former geological age, and may be sources of information on paleoenvironments and the evolutionary development of plants and animals. Although not

governed by the same historic preservation laws as cultural resources, they could be affected by the proposed surplus plutonium disposition activities in much the same manner.

Prehistoric resources are physical remains of human activities that predate written records; they generally consist of artifacts that may alone or collectively yield otherwise inaccessible information about the past. Historic resources consist of physical remains that postdate the emergence of written records; in the United States, they are architectural structures or districts, archaeological objects, and archaeological features dating from 1492 and later. Ordinarily, sites less than 50 years old are not considered historic, but exceptions can be made for such properties if they are of particular importance, such as structures associated with Cold War themes. Native American resources are sites, areas, and materials important to Native Americans for religious or heritage reasons. Such resources may include geographical features, plants, animals, cemeteries, battlefields, trails, and environmental features.

The primary ROI used for the cultural and paleontological resource analyses encompasses the land areas directly disturbed by construction and operation of the proposed facilities. The natural setting of those resources was considered a contextual component thereof.

F.5.2 Description of Impact Assessment

The SPD EIS study addressed the potential direct and indirect impacts on cultural resources at each of the candidate sites from the proposed action and alternatives (see Table F–5). The assessment of direct impacts focused on ground-disturbing activities and alterations to existing resources, particularly those listed or eligible for listing on the National Register of Historic Places (National Register), and those considered important to Native Americans. Potential indirect impacts of surplus plutonium disposition activities were also assessed—impacts associated with reduced access to a resource site, as well as impacts associated with increased traffic and visitation in sensitive areas.

For specific sites, depending on the alternative, more detailed information was required—e.g., file investigations, Native American consultation, implementation of the American Indian Policy of the DOE, predictive modeling—to determine the types, numbers, and locations, as well as the National Register eligibility or importance in other respects of resources in the proposed project area.

Plans were drawn up for consultation with each State Historic Preservation Officer and reviews of existing DOE site cultural resource surveys and management plans to determine the National Register eligibility and importance of the resources, and to assess measures designed to mitigate the impacts of the proposed actions.

The measure of impact on a particular resource will depend largely on specific cultural resource management agreements with the candidate sites, the consultations with project-specific State Historic Preservation Officers and affected Native American tribes, and overall compliance with Section 106 of the National Historic Preservation Act.

F.6 LAND RESOURCES

F.6.1 Description of Affected Resources

Land resources include the land on and contiguous to each candidate site; the physical features that influence current or proposed uses; local urban and rural population density; pertinent State, county, and municipal land-use plans and regulations; land ownership and availability; and the aesthetic characteristics of the site and surrounding areas.

Table F–5. Impact Assessment Protocol for Cultural and Paleontological Resources

Resource	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Prehistoric resources	Site cultural resource inventory/management plan reflecting listing or eligibility for listing on National Register Existing programmatic agreements	Location of proposed facility on the site Areas to be disturbed	Potential for physical destruction, damage, or alteration; isolation or alteration of the character of the property; introduction of visual, audible, or atmospheric elements out of character; and neglect of resources listed or eligible for listing on the National Register. Noncompliance with existing laws, regulations, and programmatic agreements
Historic resources	Site cultural resource inventory/management plan reflecting listing or eligibility for listing on National Register Existing programmatic agreements	Location of proposed facility on the site Areas to be disturbed	Potential for physical destruction, damage, or alteration; isolation or alteration of the character of the property; introduction of visual, audible, or atmospheric elements out of character; and neglect of resources listed or eligible for listing on the National Register. Noncompliance with existing laws, regulations, and programmatic agreements.
Native American resources	Site cultural resource inventory/management plan reflecting listing or eligibility for listing on National Register Existing programmatic agreements Resources identified through consultations with American Indian Tribal Governments	Location of proposed facility on the site Areas to be disturbed	Potential for disturbance of Native American resources as determined through consultations with potentially affected American Indian Tribal Governments (per DOE Order 1230.2) Noncompliance with existing laws, regulations, and programmatic agreements.
Paleontological resources	Site cultural resource inventory/management plan Existing Programmatic Agreements	Location of proposed facility on the site Areas to be disturbed	Potential for appropriation, excavation, injury, or destruction of resources without permission (per Antiquities Act of 1906). Noncompliance with existing laws, regulations, and programmatic agreements

Land resources analysis for the SPD EIS determined the potential beneficial or adverse impacts on land use and visual resources for the defined ROI. The ROI for land use at each candidate site varies due to disparities in population density and growth trends, the extent of Federal land ownership, adjacent land-use patterns and trends, and other geographic or safety considerations. The ROI for visual resources includes those lands within the viewshed of the proposed action and alternatives.

F.6.2 Description of Impact Assessment

F.6.2.1 Land-Use Analysis

Requirements for the SPD EIS included estimating the impacts of the alternatives on land use within each DOE site, adjacent Federal or State lands, adjacent communities, and wildlife or resource areas. At issue were the net land area affected; its relationship to conforming and nonconforming land uses; current growth trends, land values, and other socioeconomic factors pertaining to land use; and the projected modifications to other facility activities and missions consistent with the proposed alternatives (see Table F–6). Land-use impacts could vary considerably from site to site, depending on existing facility land-use configurations, adjoining land uses, plans for transportation security, proximity to residential areas, and other environmental and containment factors.

Table F–6. Impact Assessment Protocol for Land Resources

	Required Data		
Resource	**Affected Environment**	**Facility Design**	**Measure of Impact**
Land use area used	Total site acreage; available acreage	Location of proposed facility on the site; total land area requirements	Facility land requirements greater than 30% of available acreage
Compatibility with existing or future land-use plans, policies, or regulations	Existing facility and regional land-use configurations; applicable plans, policies, or regulations	Location of proposed facility on the site; facility D&D procedures; expected modifications of other facility activities and missions to accommodate proposed alternatives	Incompatibility with existing facility or adjacent land use; encroachment by disturbed area onto sensitive lands protected by existing management plans or policies; significant long-term or permanent loss of land use resulting from facility construction, operation, or D&D
Visual resources	Delineation of nearby visual resources and viewsheds, including Class I areas	Location of proposed facility on the site; facility dimensions and appearance	Significant reduction of assigned VRM classification for a notable viewshed

Key: D&D, decontamination and decommissioning; VRM, Visual Resource Management.

Evaluation of existing land uses at each of the potentially affected sites required review of existing and future facility land-use plans. Where land adjacent to the proposed site is managed by local government, applicable community general plans, zoning ordinances, and population growth trend data were reviewed. Where such land is managed or under the jurisdiction of a Federal or State land management agency, the respective agency resource management plans and policies were reviewed. Total land area requirements include those areas to be occupied by the footprint of each building and nonbuilding support area, in conjunction with all paved roads, parking areas, graveled areas, and construction laydown areas, and any land graded and cleared of vegetation. Land area requirements were identified using proposed facility data reports.

F.6.2.2 Visual Resources Analysis

Visual resource impacts are changes in the physical features of the landscape attributable to the proposed action. Visual resource assessment was based on the Bureau of Land Management Visual Resource Management (VRM) classification scheme. Impacts on scenic or visual resources were analyzed by identifying existing VRM classifications and documenting any potential reductions therein at each of the alternative locations as a result of the proposed action or alternatives (see Table F–6). Existing class designation were derived from an inventory of scenic qualities, sensitivity levels, and distance zones for particular areas. The

elements of scenic quality are landforms, vegetation, water, color, adjacent scenery, scarcity, and cultural modification. Scenic value is determined by the variety and harmonious composition of the elements of scenic quality. Sensitivity levels are determined by user volumes and user attention. Distance zones concern the visibility from travel routes or observation points.

Important concerns of the visual resources analysis were the degree of contrast between the proposed action and the surrounding landscape, the location and sensitivity levels of public vantage points, and the visibility of the proposed action from the vantage points. The distance from a vantage point to the affected area and atmospheric conditions were also taken into consideration, for distance and haze can diminish the degree of contrast and visibility. A qualitative assessment of the degree of contrast between the proposed facilities or activities and the existing visual landscape was also presented. Reduction of an assigned VRM classification could result if the affected area could be seen from the vantage point with a high sensitivity level.

F.7 INFRASTRUCTURE

F.7.1 Description of Affected Resources

Site infrastructure includes physical resources required to support the construction and operation of facilities. It includes the capacities of the onsite road and rail transportation networks; electric power and electrical load capacities; natural gas, coal, and fuel oil capacities; and water supply system capacities.

The ROI is generally limited to the boundaries of DOE sites. However, should infrastructure requirements exceed site capacities, the ROI would be expanded (for analysis) to include the sources of additional supply. For example, if electrical demand (with added facilities) exceeded site availability, then the ROI would be expanded to include the likely source of additional power: the power pool currently supplying the site.

F.7.2 Description of Impact Assessment

In general, infrastructure impacts were assessed by evaluating the requirements of each alternative against the site capacities. An impact assessment was made for each resource (road networks, rail interfaces, electricity, fuel, and water) for the various alternatives (see Table F–7). Tables reflecting site availability and infrastructure requirements were developed for each alternative. Data for these tables were obtained from reports describing the existing infrastructure at the sites, and from the data reports for each facility. If necessary, design mitigation considerations conducive to reduction of the infrastructure demand were also identified.

Any projected demand for infrastructure resources exceeding site availability can be regarded as an indicator of environmental impact. Whenever projected demand approaches or exceeds capacity, further analysis for that resource is warranted. Often, design changes can mitigate the impact of additional demand for a given resource. For example, substituting fuel oil for natural gas (or vice versa) for heating or industrial processes can be accomplished at little cost during the design of a facility, provided the potential for impact is identified early. Similarly, a dramatic "spike" in peak demand for electricity can sometimes be mitigated by changes to operational procedures or parameters.

F.8 WASTE MANAGEMENT

F.8.1 Description of Affected Resources

The operation of surplus plutonium disposition support facilities would generate several types of waste, depending on the alternative. Such wastes include the following:

Table F–7. Impact Assessment Protocol for Infrastructure

Resource	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Transportation Roads (km) Railroads (km)	Site capacity and current usage	Facility requirements	Additional requirement (with added facilities) exceeding site capacity
Electricity Energy consumption (MWh/yr) Peak load (MW)	Site capacity and current usage	Facility requirements	Additional requirement (with added facilities) exceeding site capacity
Fuel Natural gas (m^3/yr) Oil (l/yr) Coal (t/yr)	Site capacity and current usage	Facility requirements	Additional requirement (with added facilities) exceeding site capacity
Water (l/yr)	Site capacity and current usage	Facility requirements	Additional requirement (with added facilities) exceeding site capacity

- **Transuranic:** Waste containing more than 100 nCi of alpha-emitting transuranic (TRU) isotopes with half-lives greater than 20 year per gram of waste, except for (1) high-level waste; (2) waste that DOE has determined, with the concurrence of EPA, does not need the degree of isolation required by 40 CFR 191, and (3) waste that the U.S. Nuclear Regulatory Commission (NRC) has approved for disposal, case by case in accordance with 10 CFR 61. Mixed transuranic waste contains hazardous components regulated under the Resource Conservation and Recovery Act (RCRA).

- **Low-level:** Waste that contains radioactivity and is not classified as high-level waste, TRU waste, or spent nuclear fuel,[1] or the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as low-level waste, provided the TRU concentration is less than 100 nCi/g of waste.

- **Mixed low-level:** Low-level waste that also contains hazardous components regulated under the RCRA.

- **Hazardous:** Under the RCRA, a solid waste that, because of its characteristics, may (1) cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible illness, or (2) pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed. Hazardous wastes appear on special EPA lists or possess at least one of the following characteristics: ignitability, corrosivity, reactivity, or toxicity. This category does not include source, special nuclear, or byproduct material as defined by the Atomic Energy Act.

- **Nonhazardous:** Discarded material including solid, liquid, semisolid, or contained gaseous material resulting from industrial, commercial, mining, and agricultural operations, and from community activities. This category does not include source, special nuclear, or byproduct material as defined by the Atomic Energy Act.

[1] Fuel withdrawn from a nuclear reactor following irradiation, the constituent elements of which have not been separated by reprocessing.

The alternatives for surplus plutonium disposition could have an impact on existing site facilities devoted to the treatment, storage, and disposal of these categories of waste.

For new facilities, construction wastes would be similar to those generated by any construction project of comparable scale. Wastes generated during the modification of existing nuclear facilities, however, could produce additional radioactive or hazardous demolition debris.

Waste management activities in support of the disposition of surplus plutonium would be contingent on Records of Decision (RODs) issued for the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (DOE 1997a). Depending on future waste type–specific RODs, in accordance with that EIS, wastes could be treated and disposed of on the site or at regionally or centrally located waste management centers. According to the TRU Waste ROD issued on January 20, 1998, TRU and TRU mixed waste would be treated on the site according to the current planning-basis Waste Isolation Pilot Plant Waste Acceptance Criteria and shipped to the Waste Isolation Pilot Plant (WIPP) for disposal. The impacts of disposing of TRU waste at WIPP are described in the *Waste Isolation Pilot Plant Disposal Phase Final Supplemental Environmental Impact Statement* (DOE 1997b). Current schedules for shipment of TRU waste to WIPP would accommodate shipment of contact-handled TRU waste from surplus plutonium disposition facilities beginning in 2016 (DOE 1997c:17). Therefore, it is assumed TRU waste would be stored on the site until 2016.

F.8.2 Description of Impact Assessment

As shown in Table F–8, impacts were assessed by comparing the projected waste stream volumes generated from the proposed activities at each site with current site waste generation rates and storage volumes.[2] Furthermore, projected waste generation rates for the proposed activities were compared with processing rates and capacities of those existing treatment, storage, and disposal facilities likely to be involved in managing the additional waste. Most likely, each waste type would be managed at many different facilities; for simplicity, however, it was assumed that the entire waste volume would be managed at one treatment facility, one storage facility, and one disposal facility.

Table F–8. Impact Assessment Protocol for Waste Management

Resource	Required Data		Measure of Impact
	Affected Environment	Facility Design	
Waste management capacity TRU waste Low-level waste Mixed low-level waste Hazardous waste Nonhazardous waste	Site generation rates (m^3/yr) for each waste type Site management capacities (m^3) or rates (m^3/yr) for potentially affected treatment, storage, and disposal facilities for each waste type	Construction and operations generation rates (m^3/yr) for each waste type	SPD facility waste generation rates are a large percentage of existing site generation rates and a large percentage of capacities of applicable waste management facilities.
Disposal capacity for transuranic waste (including mixed TRU waste)	TRU waste volume (m^3) expected to be disposed of at WIPP Capacity at WIPP (m^3)	Total TRU waste generated (m^3) for SPD facilities	Combination of SPD facility TRU waste generation, and existing TRU waste generation exceeds capacity of WIPP.

Key: SPD, surplus plutonium disposition; TRU, transuranic; WIPP, Waste Isolation Pilot Plant.

[2] For the SPD EIS, only the impacts relative to the capacities of waste management facilities were considered. Environmental impacts of waste management facility operation are evaluated in other facility-specific or sitewide NEPA documents.

Next Section

F.9 SOCIOECONOMICS

F.9.1 Description of Affected Resources

Socioeconomic impacts may be defined as the environmental consequences of a proposed action in terms of demographic and economic changes. Two types of jobs would be created as a result of DOE's adopting any of the surplus plutonium disposition alternatives: (1) construction-related jobs, transient in nature and short in duration, and thus less likely to impact public services; and (2) jobs related to plant operations, required for a decade or more and thus possibly creating additional service requirements in the ROI.

F.9.2 Description of Impact Assessment

Before the socioeconomic analyses could begin, the socioeconomic environment had to be defined for two geographic regions, the regional economic area (REA) and ROI. The REA is used to assess potential effects of an action on the regional economy. REAs are the broad markets defined by the economic linkages among and between the regional industrial and service sectors and the communities within a region. These linkages determine the nature and magnitude of any multiplier effect associated with a change in economic activity.

For example, as work expands at a given site, the money spent on accomplishing this work flows into the local economy; it is spent on additional jobs, goods, and services within the REA. Using the Regional Input-Output Modeling System (RIMS II) developed by the Bureau of Economic Analysis of the U.S. Department of Commerce, the regional economic impacts of a proposed project can be estimated over the life of the project.

Similarly, potential demographic impacts were assessed for the ROI. The ROI could represent a smaller geographic area—one in which only the housing market and local community services would be significantly affected by a given alternative. Site-specific ROIs were identified as those counties in which at least 90 percent of the site's workforce reside. This distribution reflects existing residential preferences for people currently employed at the sites and was used to estimate the distribution of new workers required to support the alternatives.

For each REA, data were compiled on the current socioeconomic conditions, including unemployment rates, economic sector activities, and the civilian labor force. For each ROI, statistics were compiled on the housing demand and community services. These data were combined with population forecasts developed using U.S. Census Bureau data to project changes to reflect the various siting alternatives being considered. Site-specific data were then used to help determine whether the overall workforce would be increased by the alternatives being considered (see Table F–9).

In some cases, a site's overall workforce was projected to decrease at the same time additional workers would be needed to support an alternative under consideration in the SPD EIS. In these cases, there would be little change in the site's overall workforce from current levels, and thus very little change in requirements for community services would be expected from a particular alternative. In the alternative, where the projected increases in the site workforce were greater than current levels, the impacts on community services were assessed by determining the increase in community services required to maintain the current status.

F.10 HUMAN HEALTH RISK DURING NORMAL OPERATIONS

F.10.1 Description of Affected Resources

Assessments for the SPD EIS aimed in part at enhancing public understanding of the potential impacts of each of the alternatives on their own health and that of workers. Included was a description of the radiological and

Table F–9. Impact Assessment Protocol for Socioeconomics

Resource	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Workforce requirements	Site workforce projections from DOE sites	Estimated construction and operating staff requirements and timeframes	Workforce requirements added to sites' workforce projections
REA civilian labor force	Labor force projections based on State population projections	Estimated construction and operating staff requirements and timeframes	Workforce requirements as a percentage of the civilian labor force
Unemployment rate	1996 unemployment rates in counties surrounding sites and in host States	Estimated construction and operating staff requirements	Projected change in unemployment rates
Health care services Number of hospital beds per 100,000 residents	Latest available rates based on telephone interviews with area hospitals and State hospital associations	Estimated influx of new health care facilities to meet construction and operating staff requirements	Projected change in numbers to maintain current rates
Number of physicians per 100,000 residents	Latest available rates based on AMA data	Estimated influx of new health care employees to meet construction and operating staff requirements	Projected change in numbers to maintain current rates
Housing—Percent of occupied housing units	Latest available rates from the U.S. Census Bureau	Estimated influx of new housing units needed for influx of construction and operating staff requirements	Projected change in numbers to maintain current rates
Schools Percent operating capacity for school districts in ROI	Latest available rates based on telephone interviews with school districts	Estimated influx of new students generated by movement of employees and their families into ROI	Projected change in operating capacity for school districts in ROI
Teacher-to-student ratio	Latest available rates based on telephone interviews with school districts	Estimated influx of new students generated by movement of employees and their families into ROI	Projected change in number of teachers to maintain current teacher-to-student ratio
Community services Ratio of police to 100,000 residents	Latest number of sworn officers based on telephone interviews with police departments	Estimated influx of new officers to meet construction and operating staff requirements	Projected change in number of officers to maintain current police-to-resident ratio
Ratio of firefighters to 100,000 residents	Latest number of firefighters based on telephone interviews with fire departments	Estimated influx of new firefighters to meet construction and operating requirements	Projected change in number of firefighters to maintain current firefighter-to-resident ratio

Key: AMA, American Medical Association; REA, regional economic area; ROI, region of influence.

chemical releases resulting from construction activities and normal operations for each alternative, including No Action, and the impacts on public and occupational health.

The risks from radiation were not added to those from hazardous chemicals, given the considerable uncertainty as to their combined effects. Impacts of some chemicals are enhanced by radiation, while those of others are not affected or can even be reduced. The reverse also holds true: chemicals can increase, decrease, or not influence radiological effects.

For the public, impacts on individuals (maximally exposed and average exposed) and on the population within 80 km (50 mi) of the site were evaluated; for workers, the focus was impacts on individuals and on the total facility workforces. The basic health risk issue addressed was whether any of the alternatives would result in undue numbers of health effects (e.g., cancers among workers or the public). Since protection of human health is regulated by DOE, EPA, NRC, and the Occupational Safety and Health Administration (OSHA), estimates of public and worker doses and associated health risks are also necessary to demonstrate that surplus plutonium disposition facilities are being designed in compliance with the applicable standards issued by these agencies.

F.10.2 Description of Impact Assessment

F.10.2.1 Public Health Risks

The health risks to the general public were determined in the following ways: (1) for present operations, doses stated in the most recent environmental or safety reports were used to calculate health risks; and (2) for operations of the proposed facilities, incremental radiological and chemical doses were modeled using specific facility data and site-dependent parameters and converted into their associated health risks.

Radiological and chemical impacts associated with for the No Action Alternative were estimated from projected releases from all site facilities that are expected to be operating at the time the actions assessed in this SPD EIS commence. For each of the other alternatives, radiological and chemical effluents were obtained from facility data reports specific to each surplus plutonium disposition process.

Public health risk assessments from radiological releases during normal operations of the proposed facilities at the candidate sites were performed using the Generation II (GENII) computer code, to calculate doses from inhalation, ingestion of terrestrial foods, and direct exposure to radiation in plumes or on the ground. This type of assessment uses site-dependent factors, including meteorology, population distributions, agricultural production, and facility locations on a given site. As reflected in Table F–10, doses were calculated for the maximally exposed individual (MEI) member of the public, for the average exposed member of the public, and for the total population living within 80 km (50 mi) of a given release location (NRC 1977:1.109.30).

Total site doses were compared with regulatory limits and, for perspective, with background radiation levels in the vicinity of the site. These doses were also converted into a projected number of fatal cancers using a risk estimator of 500 fatal cancers per 1 million person-rem derived from data prepared by the National Research Council's Committees on the Biological Effects of Ionizing Radiations and by the International Commission on Radiological Protection Publication 60 (ICRP 1991). The calculated health effects were compared with those arising among the same population groups from other causes.

Since portions of the surplus plutonium disposition processes could involve the use of hazardous chemicals, there could be hazardous chemical emissions that have the potential to affect human health. As indicated in Table F–10, two general types of hazardous materials were assessed: (1) those that are carcinogenic and (2) those that are not carcinogenic but could adversely affect organs or tissues.

Table F–10. Impact Assessment Protocol for Human Health Risk

Risk	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Radiation: public			
Offsite MEI dose via airborne pathways	Current annual dose (mrem) to MEI via all airborne pathways at site	Annual radionuclide release rates (Ci) to air from proposed facility. Stack height. Location of proposed facility on the site.	Annual dose greater than 10 mrem via airborne releases (NESHAP limit).
Offsite MEI dose via liquid pathways	Current annual dose (mrem) to MEI via all liquid pathways at site	Not applicable. There are no liquid releases directly from proposed facility.	Annual dose via liquid releases greater than 4 mrem (SDWA limit is used as basis).
Offsite MEI dose via all pathways, including air, water, and others (e.g., direct radiation)	Current annual dose (mrem) to MEI via all pathways at site Annual radionuclide release rates to air and water from site release locations Joint frequency meteorological data Water dilution factors Distances from radionuclide release points to site boundary for 16 cardinal directions Exposure information associated with other potential pathways (e.g., direct radiation from each site area)	Annual radionuclide releases to air and via any other pathway (e.g., direct radiation) from proposed facility. No liquid releases directly from facility are expected. Stack height. Location of proposed facility on the site. Exposure information associated with other potential pathways (e.g., direct radiation).	Annual dose greater than 100 mrem via all pathways (DOE 5400.5)
Dose to population within 80 km (50 mi) of site via all pathways	Current annual population dose (person-rem) via all pathways at site Projected population distribution within an 80-km (50-mi) radius from radionuclide release points Latest available milk, meat, and vegetable distributions within an 80-km (50-mi) radius from radionuclide release points Joint frequency meteorological data Water usage values (e.g., fish harvest, number of water drinkers) Water dilution factors	Annual radionuclide release rates (Ci) to air from proposed facility. No liquid releases directly from facility are expected. Stack height. Location of proposed facility on the site.	Annual population dose greater than 100 person-rem via all pathways (proposed 10 CFR 834).
Radiation: occupational			
Average dose to involved (facility) worker[a]	Not applicable	Annual average dose (mrem) to the facility worker.	Annual dose of more than 750 mrem. This value represents 15% of 10 CFR 835 and 10 CFR 20 limit of 5,000 mrem/yr and 37.5% of DOE administrative control level of 2,000 mrem/yr, and has been chosen to ensure that dose received by average worker is well below dose limits and administrative control level.

Table F–10. Impact Assessment Protocol for Human Health Risk (continued)

Risk	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Average dose to noninvolved (site) worker[a]	Current annual average dose (mrem) among all noninvolved workers at site	Not applicable.	Annual dose of more than 250 mrem. This value represents 5% of 10 CFR 835 limit of 5,000 mrem/yr and 12.5% of the DOE administrative control level of 2,000 mrem/yr, and has been chosen to ensure that dose received by average worker is well below dose limits and administrative control level.
Total dose to involved (facility) workers	Not applicable	Annual total dose (person-rem) among all facility workers. Number of facility workers.	Annual dose of more than 750 mrem times number of involved workers.
Total dose to noninvolved (site) workers	Current annual total dose (person-rem) among all workers at site Number of noninvolved workers	Not applicable.	Annual dose of more than 250 mrem times number of noninvolved workers at site.
Radiation: construction workers			
Average dose to construction worker[a]	Level of existing contamination and dose expected from working in that area of site	Annual average and total dose to construction worker.	For average worker, 50% of values given above for public's MEI. This is based on interpretation of a construction worker as a member of the public and application of a reduction factor of 2 in going to an average rather than a maximally exposed worker.
Total dose to construction workers		Numbers of construction workers.	For total workforce, number of workers in workforce times doses for an average worker.
Hazardous chemicals: public			
Offsite MEI latent cancer incidence risk	Distribution of population in ROI Joint frequency meteorological data	Airborne release (kg/yr) of hazardous chemicals.	Probability of latent cancer incidence for MEI.
Offsite MEI noncancer risk	Distribution of population in ROI Joint frequency meteorological data	Airborne release (kg/yr) of hazardous chemicals.	Likelihood of noncancer effects for MEI.

[a] More meaningful in determining health risk than dose to maximally exposed worker, which varies significantly each year. Monitoring, however, will ensure that dose to the maximally exposed worker remains within regulatory limits.

Key: CFR, Code of Federal Regulations; MEI, maximally exposed individual; NESHAP, National Emission Standards for Hazardous Air Pollutants; ROI, region of influence; SDWA, Safe Drinking Water Act.

Hazardous chemical concentrations in the ambient air of the ROI were modeled using the ISCST3 air emissions model recommended by EPA (EPA 1996b). Latent cancer incidence risks for the maximally exposed individual in the offsite population from chemical releases under normal operation were estimated by comparing the concentrations of airborne hazardous chemicals to chemical-specific cancer inhalation unit risk factors established by EPA. For chronic noncarcinogenic effects, airborne concentrations were compared with EPA's chemical-specific reference concentrations, and a hazard index was calculated for each alternative at each site.

F.10.2.2 Occupational Health Risks

Health risks from radiological exposure were determined for two types of workers: the facility worker, or the worker inside one of the plutonium-processing facilities; and the site worker, or the worker elsewhere on the site but not involved in plutonium processing. Health risks to individual workers and to total workforces were assessed.

The facility worker's dose was based on data from design reports on specific surplus plutonium disposition facilities. It was assumed that the noninvolved site worker only receives a dose that results from his primary onsite activities. No additional dose to these workers would be expected from surplus plutonium disposition facility operation.

Worker doses were converted into the number of projected fatal cancers using the risk estimator of 400 fatal cancers per 1 million person-rem given in the International Commission on Radiological Protection Publication 60 (ICRP 1991). This risk estimator, compared with that for members of the public, reflects the absence of the most radiosensitive age groups (i.e., infants and children) in the workforce.

F.11 FACILITY ACCIDENTS

F.11.1 Description of Affected Resources

Processing any hazardous material poses a risk of accidents impacting involved workers (workers directly involved in facility processes), noninvolved workers (workers on the site but not directly involved in facility processes), and members of the public. The consequences of such accidents could involve the release of radioactive or chemical material or the release of hazardous (e.g., explosive) energy, beyond the intended confines of the process. Risk is determined by the development of a representative spectrum of accidents, each of which is conservatively characterized by a likelihood (i.e., expected frequency of occurrence) and a consequence.

For the purpose of this analysis, involved workers were defined as workers in the immediate vicinity of the process involved in the accident; noninvolved workers, as workers located at the closer of 1,000 m (3,281 ft) from the accident (emission) source or the site boundary; and members of the public, as persons residing outside the site boundary and within 80 km (50 mi) of the facility.

F.11.2 Description of Impact Assessment

To avoid duplication, the analysis of potential accidents performed for the SPD EIS took full cognizance of the corresponding analyses in the *Storage and Disposition Final PEIS* (DOE 1996a), including accident sequence development, source term definition, and consequence analysis. The analysis focused on the likelihoods and consequences of a variety of a bounding spectrum of accidents postulated for each alternative, from high-consequence, low-frequency accidents to low-consequence, high-frequency accidents.

One objective of the accident analysis, a follow-on to a hazard analysis, was to translate each source term into a probabilistic distribution of consequences based on site-specific modeling of meteorological dispersion of the hazardous material and resulting uptake of that material by members of the human population. To predict the impacts of postulated accidents on the health of workers and the public, source terms were translated into consequences using the Melcor Accident Consequence Code System (MACCS2).

Metrics used to measure the impact of each accident include the accident frequency, the mean and 95th percentile doses for the noninvolved worker at the closer of 1,000 m (3,281 ft) or the site boundary, the mean

and 95th percentile doses for the MEI at the site boundary, and the mean and 95th percentile doses for members of the general public within 80 km (50 mi) of the facility. Additionally, the individual doses were translated into the probability of latent cancer fatality, and the dose to the general public into the expected number of latent cancer fatalities (see Table F–11). Additional information on the development of accident sequences, source term definition, and consequence analysis can be found in Appendix K.

Table F–11. Impact Assessment Protocol for Facility Accidents

	Required Data		
Accident	**Affected Environment**	**Facility Design**	**Measure of Impact**
Operational events External events NPH events	Meteorological data Data on population within 80 km (50 mi) of facility Site boundary data	Accident source terms Accident frequencies Facility location	Radiological dose at 1,000 m (3,281 ft) from accident source Probability of latent cancer fatality given dose at 1,000 m (3,281 ft) Radiological dose to offsite MEI Probability of latent cancer fatality given dose at site boundary Dose to general public within 80 km (50 mi) of facility Latent cancer fatalities among general public within 80 km (50 mi) of facility

Key: MEI, maximally exposed individual; NPH, natural phenomena hazard.

F.12 TRANSPORTATION IMPACTS

F.12.1 Description of Affected Resources

Overland transportation of any commodity involves a risk to both transportation crew members and members of the public. This risk results directly from transportation-related accidents and indirectly from the increased levels of pollution from vehicle emissions, regardless of cargo. The transportation of plutonium, radioactive waste, or other nuclear materials can pose additional risks owing to the unique properties of the material.

Accordingly, DOE, NRC, and the U.S. Department of Transportation have instituted strict policies and regulations governing the transport of such materials. The requirements are applicable throughout a shipment's ROI, which encompasses the onsite roadways, as well as the public roads between DOE sites and between DOE sites and commercial sites. For site-to-site transport, for example, shippers are required to use interstate highways predominantly.

F.12.2 Description of Impact Assessment

The risk from incident-free transportation was assessed for persons living within 0.8 km (0.5 mi) of the route; the risk from hypothetical accidents, for persons living within 80 km (50 mi) of the route. Assessment of the human health risks of overland transportation is crucial to a complete appraisal of the environment impacts of transportation associated with the surplus plutonium disposition alternatives.

The impacts associated with overland transportation were calculated per shipment, and then multiplied by the number of shipments. This approach allowed for maximum flexibility in determining the risk for a variety of alternatives (see Table F–12).

Table F–12. Impact Assessment Protocol for Transportation

Risk	Required Data: Affected Environment	Required Data: Facility Design	Measure of Impact
Incident-free transportation			
Radiation dose to crew		Origin and destination of shipments Characterization of vehicles and material shipped	Dose and latent cancer fatalities to crew
Radiation dose to public On-link Off-link During stops	Population within 0.8 km (0.5 mi) of route Number of persons using a highway Traffic conditions along route	Origin and destination of shipments Characterization of vehicles and material shipped	Dose and latent cancer fatalities to public
Maximally exposed crew member		Origin and destination of shipments Characterization of vehicles and material shipped Location of workers	Radiation doses compared with 10 CFR 20 limits (2 mrem/hr and 100 mrem/yr)
Maximally exposed member of public		Origin and destination of shipments Characterization of vehicles and material shipped	Radiation doses compared with 10 CFR 20 limits (2 mrem/hr and 100 mrem/yr)
Health risks from vehicle emissions		Origin and destination of shipments Characterization of vehicles	Fatalities
Transportation accidents			
Radiological risk to public	Population within 80 km (50 mi) of route	Origin and destination of shipments Characterization of vehicles and material shipped	Doses and latent cancer fatalities
Nonradiological risk to public (nonradiological)	Traffic conditions along route	Origin and destination of shipments	Fatalities
Maximally exposed individual		Origin and destination of shipments Characterization of vehicles and material shipped	Doses and latent cancer fatalities

Key: CFR, Code of Federal Regulations.

Fundamental assumptions of this analysis were consistent with those of the *Storage and Disposition Final PEIS* (DOE 1996a), and the same computer codes, release data, and accident scenarios were used. The HIGHWAY computer program was used for selecting highway routes for transporting radioactive materials by truck. The HIGHWAY database is a computerized road atlas that currently describes approximately 386,242 km (240,000 mi) of roads. A complete description of the interstate system and all U.S. highways is included in the database. Most of the principal State highways and many local and community roadways are

also identified. The code is updated periodically to reflect current road conditions, and has been benchmarked against the reported mileages and observations of commercial trucking firms.

The first analytic step in the ground transportation analysis was to determine the incident-free and accident risk factors per shipment, for transportation of the various types of hazardous materials. As with any risk estimate, the risk factors were calculated as the product of the probability and the magnitude of the exposure. Accident risk factors were calculated for radiological and nonradiological traffic accidents. The probabilities (much lower than unity [i.e., 1]) and the magnitudes of exposure were multiplied, yielding risk numbers. Incident-free risk factors were calculated for crew and public exposure to radiation emanating from the package and for public exposure to the chemical toxicity of the transportation vehicle exhaust. The probability of incident-free exposure is unity.

The RADTRAN4 computer code (Neuhauser and Kanipe 1993) was used for the incident-free and accident risk assessments to estimate the impacts on collective populations. RADTRAN 4 was developed by Sandia National Laboratories to calculate population risk associated with the transportation of radioactive materials by a variety of modes: truck, rail, air, ship, and barge. Calculations are in terms of the probabilities and consequences of potential exposure events.

The RISKIND computer code (Yuan et al. 1993) was used to estimate the incident-free doses to MEIs and to develop impact estimates for use in the accident consequence assessment. This code was developed for DOE's Office of Civilian Radioactive Waste Management to analyze the exposure of individuals during incident-free transportation. It also allows for a detailed assessment of the consequences for individuals and population subgroups of severe transportation accidents in various environmental settings.

RISKIND calculations supplemented the collective risk results achieved with RADTRAN 4; they addressed areas of specific concern to individuals and population subgroups. Essentially, the RISKIND analyses answered the "what if" questions, such as, "What if I live next to a site access road?" or "What if an accident happens near my town?"

Radiological doses, expressed in units of rem, were multiplied by the ICRP 60 (ICRP 1991) conversion factors and the estimated numbers of shipments to produce risk estimates in units of latent cancer fatalities. The vehicle emission risk factors were calculated in terms of latent fatalities; the vehicle accident risk factors, in fatalities. The nonradiological risk factors were multiplied by the number of shipments.

For each alternative, risks of both incident-free and accident conditions were assessed. For the incident-free assessment, risks were calculated for "collective populations" of potentially exposed individuals and for MEIs. (The collective population risk is a measure of the radiological risk posed to society as a whole by the alternative being considered. It was the primary means of comparing the various alternatives.) The accident assessment had two components: (1) a probabilistic risk assessment, which addressed the probabilities and consequences of a range of possible transportation accident environments, including low-probability accidents with high consequences and high-probability accidents with low consequences; and (2) an accident consequence assessment, which concerned only the consequences of the most severe transportation accidents postulated.

F.13 ENVIRONMENTAL JUSTICE

F.13.1 Description of Affected Resources

Constituting the affected environment are the low-income and minority populations residing in the potentially affected area. For the analysis of environmental justice relative to incident-free transportation, that area was

defined as a corridor 1.6 km (1 mi) wide centered on rail or truck routes. For analyses pertaining to transportation accidents and evaluations of environmental justice in facility environs, it consisted of the geographical area within an 80 km (50 mi) distance of the accident site or facility.

Minority populations were split among four groups: Hispanic, Asians, Blacks, and Native Americans. The population group designated as Hispanic includes all persons who identified themselves as having Hispanic origins, regardless of race. For example, a person self-identified as Asian and of Hispanic origin was included among Hispanics. Persons self-identified as Asian and not of Hispanic origin were included in the Asian population.

Block group spatial resolution was used throughout the analysis (see Table F–13). The U.S. Census Bureau defines block group to include 250–500 housing units with 400 being typical. The minority population residing in the affected area was determined from data contained in Table P12 of Standard Tape File 3A published by the U.S. Bureau of the Census (DOC 1992). Low-income populations were estimated from data in Table P121 (DOC 1992:B-28, B-29), which provides statistical data characterizing income status relative to the poverty threshold for each block group.

Table F–13. Impact Assessment Protocol for Environmental Justice

Resource	Required Data		Measure of Impact
	Affected Environment	Health Effects	
Minority population	Minority population data at block group spatial resolution from Table P12 of STF3A (DOC 1992)		Disproportionately high annual population dose to minority population (CEQ 1997:app. A)
	Distribution within 80 km (50 mi) of each candidate site	Population dose for sectors within 80-km (50-mi) radius of candidate site	
	Distribution within 1.6 km (1 mi) of transportation corridors	Population dose for areas within 1.6-km (1-mi) radius of transportation corridor	
Low-income population	Low-income population data at block group spatial resolution from Table P121 of STF3A (DOC 1992)		Disproportionately high annual population dose to low-income population (CEQ 1997:app. A)
	Distribution within 80 km (50 mi) of each candidate site	Population dose for sectors within 80-km (50-mi) radius of candidate site	
	Distribution within 1.6 km (1 mi) of transportation corridor	Population dose for areas within 1.6-km (1-mi) radius of transportation corridor	

Key: CEQ, Council on Environmental Quality; DOC, U.S. Department of Commerce; STF, Standard Tape File.

F.13.2 Description of Impact Assessment

Formal requirements for inclusion of environmental justice concerns in environmental documentation were initiated by Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low Income Populations*, issued in February 1994. The Council on Environmental Quality has oversight responsibility for implementation of the Executive order in documentation prepared under the provisions of NEPA. The Council issued draft guidance for environmental justice in May 1996 (CEQ 1997). These guidelines provide the foundation for evaluation of environmental justice in this SPD EIS.

Analysis of environmental justice for the SPD EIS focused on the "block group," one of the geographical aggregations of demographic data typically provided by the Bureau of the Census (DOC 1992). Block groups provide the finest spatial resolution available for evaluation of low-income populations. It is rare, however, that the boundaries of block groups coincide with those of affected areas. Uniform population distribution within block groups is also uncommon. Such uniformity was assumed, however, for purposes of SPD EIS population estimates. Thus, for each block group, the percentage of the population included in the population count equaled the percentage of the geographical area of the block group that lay within the affected area. An upper bound for the potentially affected population was obtained by including the total population of partially included block groups in the population count; a lower bound, by excluding the total population of such block groups from the count.

The following definitions were used in the evaluation:

- **Minority individuals:** Persons who are members of any of the following population groups: Hispanic; American Indian, Eskimo, or Aleut (Native Americans); Asian or Pacific Islander; or Black. This definition includes all persons except those self-designated as not of Hispanic origin and as either White or "Other Race" (one of the classifications used by the U.S. Bureau of the Census in the 1990 census).

- **Minority population:** The total number of minority individuals residing within a potentially affected area.

- **Low-income individuals:** All persons whose self-reported income is below the poverty threshold as adopted by the U.S. Census Bureau (DOC 1992:app. B, B-28).

- **Low-income population:** The total number of low-income individuals residing within a potentially affected area.

If the analysis of health or other environmental effects showed that the actions consistent with the proposed alternatives would have significant impacts on the general population, then additional analysis of impacts on the minority and low-income populations was conducted. The analysis method was identical to that described for the evaluation of radiological impacts on the general population. Given the impracticality of extrapolating block level population and income data, minority and low-income populations within each block group were assumed to increase in direct proportion to the increase in general population from the year 1990 to the year of interest.

F.14 CUMULATIVE IMPACTS

Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time (40 CFR 1508.7). The cumulative impact analysis for the SPD EIS involved combining the

impacts of the SPD EIS alternatives (including No Action) with the impacts of other past, present, and reasonably foreseeable activities in an ROI.

The ROIs for different resources can vary widely in extent. For example, the ROI for land use would include all impacts on land use in the environs of the specific area affected by the program alternatives. For groundwater, the ROI would generally be smaller, encompassing only those groundwater flow systems affected by the program alternatives. The ROI for socioeconomics could include all the cities and towns directly or indirectly affected by activities.

In general, cumulative impacts were calculated by adding the values for the baseline,[3] the proposed action, and other future actions. This cumulative value was then weighed against the appropriate impact indicators to determine the potential for impact. For this cumulative impact assessment, it was conservatively assumed that all facilities would operate concurrently at the DOE sites. Only selected indicators of cumulative impacts (see Table F–14) were evaluated.

Table F–14. Selected Indicators of Cumulative Impact

Category	Indicator
Resource use	Land occupied
	Electricity use
	Water use
	Workers required
Socioeconomics	Percent change in regional employment
Air quality	Percent of NAAQS for criteria pollutants
Human health	Offsite population
	MEI dose
	Total dose
	Fatalities
	Workers
	Average dose
	Total dose
	Fatalities
Waste generation	TRU waste
	LLW
	Mixed LLW
	Hazardous waste
	Sanitary wastewater

Key: LLW, low-level waste; MEI, maximally exposed individual; NAAQS, National Ambient Air Quality Standards; TRU, transuranic.

The analysis focused on the potential for cumulative impacts at each candidate site from DOE actions under detailed consideration at the time of this SPD EIS (see Table F–15). Non-DOE actions were also considered where information was readily available. Public documents prepared by agencies of Federal, State, and local government were the primary sources of information for the non-DOE actions.

It is assumed that construction impacts would not be cumulative, because such construction is typically of short duration, and construction impacts are generally temporary. D&D of the proposed facilities was not addressed in the cumulative impact estimates. Given the uncertainty regarding the timing of D&D, any impact estimate at this time would be highly speculative. A detailed evaluation of D&D will be provided in follow-on NEPA documentation closer to the actual time of those actions.

[3] The conditions attributable to actions, past and present, by DOE and other public and private entities.

Table F–15. Other Past, Present, and Reasonably Foreseeable Actions Included in the Cumulative Impact Assessment

Activities	Hanford	INEEL	Pantex	SRS
Storage and Disposition of Weapons-Usable Fissile Materials	X	X	X	X
Disposition of Surplus Highly Enriched Uranium				X
Construction and Operation of a Tritium Extraction Facility at SRS				X
Interim Management of Nuclear Materials at SRS				X
SRS Waste Management				X
Tritium Supply and Recycling				X
Waste Management	X	X	X	X
Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management	X	X		X
Foreign Research Reactor Spent Nuclear Fuel		X		X
Tank Waste Remediation System	X			
Shutdown of the River Water System at SRS				X
Hanford Reach of the Columbia River - Comprehensive River Conservation Study	X

Appendix G
Air Quality

This appendix provides detailed data that support the air quality impact assessments in Chapter 4. Data are provided for the four candidate sites: the Hanford Site (Hanford), Idaho National Engineering and Environmental Laboratory (INEEL), the Pantex Plant (Pantex), and the Savannah River Site (SRS).

G.1 HANFORD

G.1.1 Assessment Data

Emission rates for criteria, hazardous, and toxic air pollutants at Hanford are presented in Table F.1.2.2–1 of the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement (PEIS)* (DOE 1996a:F-6). These emission rates were used as input into the modeled No Action Alternative pollutant concentrations presented in that environmental impact statement (EIS) and reflect projected Hanford facility emissions for 2005. The storage alternative selected for Hanford results in no change in these concentrations (DOE 1996a:4-34). In addition to the concentrations projected for 2005, the concentrations for the Phased Implementation Alternative—Phase II Operation of the vitrification facilities presented in the *Tank Waste Remediation System Final EIS* (DOE 1996b:5-68) were included in the estimate of the No Action concentration for surplus plutonium disposition as shown in Table G–1. Other onsite activities related to programs analyzed in EISs for spent nuclear fuel and waste management are also included. Other activities at Hanford that may occur during the time period 2005–2015 are discussed in the cumulative impacts section. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–1. Estimated Concentrations ($\mu g/m^3$) From No Action at Hanford

Pollutant	Averaging Period	PEIS Estimated Base Year (2005)	Tank Waste Remediation	Other Onsite From PEIS	No Action
Carbon monoxide	8 hours	0.08	34	0	34.1
	1 hour	0.30	48	0	48.3
Nitrogen dioxide	Annual	0.03	0.12	0.1	0.25
PM_{10}	Annual	<0.01	0.0079	0	0.0179
	24 hours	0.02	0.75	0	0.77
Sulfur dioxide	Annual	<0.01	0.02	1.6	1.63
	24 hours	<0.01	1.6	7.3	8.91
	3 hours	0.01	3.6	26	29.6
	1 hour	0.02	4.0	29	32.9
Total suspended particulates	Annual	<0.01	0.0079	0	0.0179
	24 hours	<0.02	0.75	0	0.77
Benzene	Annual	(a)	0.000006	0	0.000006
Ethylene glycol	24 hours	(a)	0	0	0

[a] No sources of this pollutant have been identified at the site.
Key: PEIS, *Storage and Disposition Final PEIS*.

G.1.2 Facilities

G.1.2.1 Pit Conversion Facility

G.1.2.1.1 Construction of Pit Conversion Facility

Potential air quality impacts from modification of the Fuels and Materials Examination Facility (FMEF) and construction of support facilities for pit disassembly and conversion at Hanford were analyzed using the Industrial Source Complex Model, Short-Term, Version 3 (ISCST3) as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from soil disturbance by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–2.

Table G–2. Emissions (kg/yr) From Construction of Pit Conversion Facility in FMEF at Hanford

Pollutant	Diesel Equipment and Construction Fugitive Emissions	Vehicles
Carbon monoxide	1,000	7,920
Nitrogen dioxide	2,400	2,120
PM_{10}	3,500	7,220
Sulfur dioxide	160	0
Volatile organic compounds	200	976
Total suspended particulates	9,300	7,220

Key: FMEF, Fuels and Materials Examination Facility.
Source: UC 1998a.

Maximum air pollutant concentrations from construction activities are summarized in Table G–3.

Table G–3. Concentrations ($\mu g/m^3$) From Construction of Pit Conversion Facility in FMEF at Hanford

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	34.1	0.277	34.4
	1 hour	40,000	48.3	1.88	50.2
Nitrogen dioxide	Annual	100	0.25	0.0199	0.27
PM_{10}	Annual	50	0.0179	0.029	0.047
	24 hours	150	0.77	0.323	1.09
Sulfur dioxide	Annual	50	1.63	0.00133	1.63
	24 hours	260	8.91	0.0148	8.93
	3 hours	1,300	29.6	0.1	29.7
	1 hour	1,000	32.9	0.301	33.2
	1 hour	700[b]	32.9	0.301	33.2
Total suspended particulates	Annual	60	0.0179	0.0771	0.095
	24 hours	150	0.77	0.857	1.63

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.
Key: FMEF, Fuels and Materials Examination Facility.
Source: EPA 1997; WDEC 1994.

G.1.2.1.2 Operation of Pit Conversion Facility

Potential air quality impacts from operation of the pit conversion and support facilities at Hanford were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–4.

Table G–4. Emissions (kg/yr) From Operation of Pit Conversion Facility in FMEF at Hanford

Pollutant	Emergency Generator	Process	Vehicles
Carbon monoxide	520	0	41,800
Nitrogen dioxide	2,000	0	11,200
PM_{10}	50	0	38,100
Sulfur dioxide	34	0	0
Volatile organic compounds	58	0	5,150
Total suspended particulates	50	0	38,100

Key: FMEF, Fuels and Materials Examination Facility.
Source: UC 1998a.

Maximum air pollutant concentrations resulting from the emergency diesel generators and process sources, plus the No Action concentrations, are summarized in Table G–5. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–5. Concentrations ($\mu g/m^3$) From Operation of Pit Conversion Facility in FMEF at Hanford

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	34.1	0.144	34.2
	1 hour	40,000	48.3	0.978	49.3
Nitrogen dioxide	Annual	100	0.25	0.0166	0.267
PM_{10}	Annual	50	0.0179	0.000415	0.0183
	24 hours	150	0.77	0.00461	0.775
Sulfur dioxide	Annual	50	1.63	0.000282	1.63
	24 hours	260	8.91	0.00313	8.91
	3 hours	1,300	29.6	0.0213	29.6
	1 hour	1,000	32.9	0.064	33.0
	1 hour	700[b]	32.9	0.064	33.0
Total suspended particulates	Annual	60	0.0179	0.000415	0.0183
	24 hours	150	0.77	0.00461	0.775

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.
Key: FMEF, Fuels and Materials Examination Facility.
Source: EPA 1997; WDEC 1994.

G.1.2.2 Immobilization Facility

G.1.2.2.1 Construction of Immobilization Facility

Potential air quality impacts from modification of FMEF and construction of support facilities for plutonium conversion and immobilization (ceramic or glass) at Hanford were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from soil disturbance by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–6.

Table G–6. Emissions (kg/yr) From Construction of Immobilization Facility in FMEF at Hanford

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	810	0	0	26,000
Nitrogen dioxide	2,090	0	0	6,960
PM_{10}	160[b]	121[b]	19[b]	23,700
Sulfur dioxide	210	0	0	0
Volatile organic compounds	170	0	0	3,200
Total suspended particulates	160	121	19	23,700

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for the purpose of this analysis resulting in some overestimate of PM_{10} concentrations.
Key: FMEF, Fuels and Materials Examination Facility.
Source: UC 1998b, 1998c.

Maximum air pollutant concentrations from construction activities are summarized in Table G–7.

Table G–7. Concentrations ($\mu g/m^3$) From Construction of Immobilization Facility in FMEF at Hanford

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Ceramic or Glass	Total
Carbon monoxide	8 hours	10,000	34.1	0.224	34.3
	1 hour	40,000	48.3	1.52	49.8
Nitrogen dioxide	Annual	100	0.25	0.0173	0.267
PM_{10}	Annual	50	0.0179	0.00248	0.0204
	24 hours	150	0.77	0.0903	0.86
Sulfur dioxide	Annual	50	1.63	0.00174	1.63
	24 hours	260	8.91	0.0194	8.93

G.1.2.3 MOX Facility

G.1.2.3.1 Construction of MOX Facility

Potential air quality impacts from construction of new mixed oxide (MOX) and support facilities at Hanford were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from soil disturbance by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–10.

Table G–10. Emissions (kg/yr) From Construction of New MOX Facility at Hanford

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	3,200	0	0	32,800
Nitrogen dioxide	8,400	0	0	8,790
PM_{10}	640[b]	5,350	1,090[b]	29,900
Sulfur dioxide	850	0	0	0
Volatile organic compounds	660	0	0	4,040
Total suspended particulates	640	10,500	1,090	29,900
Toxics[c]	0	<1	0	0

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for the purpose of this analysis, resulting in some overestimate of PM_{10} concentrations.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction.
Source: UC 1998d.

Maximum air pollutant concentrations from construction activities are summarized in Table G–11.

Table G–11. Concentrations ($\mu g/m^3$) From Construction of New MOX Facility at Hanford

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	34.1	0.885	35.0
	1 hour	40,000	48.3	6.02	54.3
Nitrogen dioxide	Annual	100	0.25	0.0697	0.32
PM_{10}	Annual	50	0.0179	0.0576	0.0755

	1 hour	700[b]	32.9	1.60	34.5
Total suspended particulates	Annual	60	0.0179	0.102	0.12
	24 hours	150	0.77	4.71	5.48
Toxics[c]	Annual	0.12	0.000006	0.000008	0.000014

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] At Hanford, the level is not to be exceeded more than twice in any 7 consecutive days.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) may be emitted during construction and were analyzed as benzene.
Source: EPA 1997; WDEC 1994.

G.1.2.3.2 Operation of MOX Facility

Potential air quality impacts from operation of the new MOX and support facilities at Hanford were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–12.

Table G–12. Emissions (kg/yr) From Operation of New MOX Facility at Hanford

Pollutant	Emergency Generator	Process	Vehicles
Carbon monoxide	374	0	34,200
Nitrogen dioxide	1,738	0	9,170
PM_{10}	122	0	31,200
Sulfur dioxide	114	0	0
Volatile organic compounds	142	0	4,210
Total suspended particulates	122	0	31,200
Toxics[a]	0	1,000	0

[a] Toxic hydrocarbons may be emitted as ethylene glycol.
Source: UC 1998d.

Maximum air pollutant concentrations resulting from the emergency diesel generators and process sources, plus the No Action concentrations, are summarized in Table G–13. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–13. Concentrations ($\mu g/m^3$) From Operation of New MOX Facility at Hanford

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	34.1	0.103	34.2
	1 hour	40,000	48.3	0.704	49.0
Nitrogen dioxide	Annual	100	0.25	0.0144	0.264
PM_{10}	Annual	50	0.0179	0.00101	0.0189
	24 hours	150	0.77	0.0113	0.781
Sulfur dioxide	Annual	50	1.63	0.000946	1.63

G.1.2.4.2 Operation of Pit Conversion and Immobilization Facilities

Potential air quality impacts from operation of pit conversion, ceramic or glass immobilization, and support facilities at Hanford were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–16.

Table G–16. Emissions (kg/yr) From Operation of Pit Conversion and Immobilization Facilities in FMEF at Hanford

	Pit Conversion			Immobilization			
Pollutant	Emergency Generator	Process	Vehicles	Emergency Generator	Ceramic Process	Glass Process	Vehicles
Carbon monoxide	520	0	41,800	390	3,500[a]	0	36,600
Nitrogen dioxide	2,000	0	11,200	1,810	0	0	9,810

G.1.2.5 Pit Conversion and MOX Facilities

G.1.2.5.1 Construction of Pit Conversion and MOX Facilities

Potential air quality impacts from modification of FMEF and construction of support facilities for pit disassembly and conversion and MOX fuel fabrication at Hanford were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–18.

Table G–18. Emissions (kg/yr) From Construction of Pit Conversion and MOX Facilities in FMEF at Hanford

	Pit Conversion		MOX			
Pollutant	Diesel Equipment and Construction Fugitive Emissions	Vehicles	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	1,000	7,920	648	0	0	32,800
Nitrogen dioxide	2,400	2,120	1,670	0	0	8,790
PM_{10}	3,500	7,220	128[b]	4,750	363[b]	29,900
Sulfur dioxide	160	0	170	0	0	0
Volatile organic compounds	200	976	133	0	0	4,040
Total suspended particulates	9,300	7,220	128	9,350	363	29,900
Toxics[c]	0	0	0	<1	0	0

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for the purpose of this analysis resulting in some overestimate of PM_{10} concentrations.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction.
Key: FMEF, Fuels and Materials Examination Facility.
Source: UC 1998a, 1998d.

Maximum air pollutant concentrations from construction activities are summarized in Table G–19.

G.1.2.5.2 Operation of Pit Conversion and MOX Facilities

Potential air quality impacts from operation of pit conversion, MOX, and support facilities at Hanford were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–20.

Table G–19. Concentrations ($\mu g/m^3$) From Construction of Pit Conversion and MOX Facilities in FMEF at Hanford

G.2 INEEL

G.2.1 Assessment Data

Emission rates for criteria, hazardous, and toxic pollutants at INEEL are presented in Table F.1.2.4–1 of the *Storage and Disposition Final PEIS* (DOE 1996a:F-10). These emission rates were used as input into the modeled No Action pollutant concentrations presented in that document and reflect INEEL facility emissions for 1990, which were assumed to be representative of No Action for 2005. The storage alternative selected for INEEL results in no change in these concentrations (DOE 1996a:4-138). Other onsite activities related to programs analyzed in EISs for spent nuclear fuel and waste management are also included in the estimates of the No Action concentration for surplus plutonium disposition shown in Table G–30. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–30. Estimated Concentrations ($\mu g/m^3$) From No Action at INEEL

Pollutant	Averaging Period	PEIS Estimated Base Year (2005)	Other Onsite From PEIS	No Action
Carbon monoxide	8 hours	284	18	302
	1 hour	614	605	1,219
Nitrogen dioxide	Annual	4	7	11
PM_{10}	Annual	3	0	3
	24 hours	33	6	39
Sulfur dioxide	Annual	6	0	6
	24 hours	135	2	137
	3 hours	579	12	591
Benzene	Annual	0.029	0	0.029
Ethylene glycol	24 hours	0[a]	0	0

[a] No concentration of this pollutant was reported in the source document.

G.2.2 Facilities

G.2.2.1 Pit Conversion Facility

G.2.2.1.1 Construction of Pit Conversion Facility

Potential air quality impacts from modification of the Fuel Processing Facility (FPF) and construction of new support facilities at INEEL for pit disassembly and conversion were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from soil disturbance by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–31.

Maximum air pollutant concentrations from construction activities are summarized in Table G–32 but are not expected to result in the exceedance of the ambient air quality standards.

Table G–31. Emissions (kg/yr) From Construction of Pit Conversion Facility in FPF at INEEL

Pollutant	Diesel Equipment and Construction Fugitive Emissions	Vehicles
Carbon monoxide	1,300	28,900
Nitrogen dioxide	5,600	7,270
PM_{10}	3,900	21,800
Sulfur dioxide	370	0
Volatile organic compounds	460	3,530

Key: FPF, Fuel Processing Facility.
Source: UC 1998e.

Table G–32. Concentrations ($\mu g/m^3$) From Construction of Pit Conversion Facility in FPF at INEEL

G.2.2.1.2 Operation of Pit Conversion Facility

Potential air quality impacts from operation of the pit conversion and support facilities at INEEL were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from boilers, emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–33.

Table G–33. Emissions (kg/yr) From Operation of Pit Conversion Facility in FPF at INEEL

Pollutant	Boilers	Emergency Generator	Process	Vehicles
Carbon monoxide	580	520	0	74,100
Nitrogen dioxide	18,000	2,000	0	18,600
PM_{10}	1,250	50	0	56,000
Sulfur dioxide	30,000	34	0	0
Volatile organic compounds	62	58	0	9,050

Key: FPF, Fuel Processing Facility.
Source: UC 1998e.

Maximum air pollutant concentrations resulting from the boilers, emergency diesel generators, and process sources, plus the No Action concentrations, are summarized in Table G–34.

Table G–34. Concentrations ($\mu g/m^3$) From Operation of Pit Conversion Facility in FPF at INEEL

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	302	0.253	302
	1 hour	40,000	1,219	0.80	1,220
Nitrogen dioxide	Annual	100	11	0.0838	11.1
PM_{10}	Annual	50	3	0.00477	3.00
	24 hours	150	39	0.0494	39.1
Sulfur dioxide	Annual	80	6	0.101	6.10
	24 hours	365	137	1.01	138
	3 hours	1,300	591	5.42	596

Key: FPF, Fuel Processing Facility.
Source: EPA 1997; ID DHW 1995.

At the nearest prevention of significant deterioration (PSD) Class I area, Craters of the Moon National Monument, the contribution to air pollutant concentrations is less than 0.01 $\mu g/m^3$ for nitrogen dioxide, particulate matter with an aerodynamic diameter less than or equal to 10 μm (PM_{10}), and sulfur dioxide, except for the 24-hr sulfur dioxide value, which is 0.05 $\mu g/m^3$, and the 3-hr sulfur dioxide value, which is 0.23 $\mu g/m^3$. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

G.2.2.2 MOX Facility

G.2.2.2.1 Construction of MOX Facility

Potential air quality impacts from construction of new MOX and support facilities at INEEL were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–35.

Maximum air pollutant concentrations from construction activities are summarized in Table G–36.

Table G–35. Emissions (kg/yr) From Construction of New MOX Facility at INEEL

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	3,200	0	0	99,200
Nitrogen dioxide	8,400	0	0	24,900
PM_{10}	640	5,330	1,090	74,900
Sulfur dioxide	850	0	0	0
Volatile organic compounds	660	0	0	12,100
Toxics[b]	0	<1	0	0

[a] Does not include fugitive emissions from the concrete batch plant.
[b] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction.
Source: *UC 1998f.*

G.3 PANTEX

G.3.1 Assessment Data

Emission rates for criteria, hazardous, and toxic air pollutants at Pantex are presented in Table 4.7.2.1–3 of the *Final Environmental Impact Statement for the Continued Operation of Pantex* (DOE 1996c:4-147). These emission rates were used as input into the modeled pollutant concentrations presented in that document and reflect Pantex facility emissions for over a 10-year period to about 2006. These concentrations are assumed to be representative of No Action for 2005 and include the upgrade storage alternative selected for Pantex and discussed in the *Storage and Disposition Final PEIS* (DOE 1996a:4-190). Other onsite activities related to programs analyzed in EISs for stockpile stewardship management and waste management are added to these concentrations as shown in Table G–43. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–43. Estimated Concentrations ($\mu g/m^3$) From No Action at Pantex

Pollutant	Averaging Period	PEIS No Action[a]	Other Onsite From PEIS	No Action
Carbon monoxide	8 hours	602	17.5	620
	1 hour	2,900	92.8	2,990

G.3.2.1.2 Operation of Pit Conversion Facility

Potential air quality impacts from operation of the pit conversion and support facilities at Pantex were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from boilers, emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–46.

Maximum air pollutant concentrations resulting from the boilers, emergency diesel generators and process sources, plus the No Action concentrations, are summarized in Table G–47. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–46. Emissions (kg/yr) From Operation of New Pit Conversion Facility at Pantex

Pollutant	Boilers	Emergency Generator	Process	Vehicles
Carbon monoxide	780	520	0	38,800
Nitrogen dioxide	700	2,000	0	10,800
PM_{10}	300	50	0	37,300
Sulfur dioxide	13	34	0	0
Volatile organic compounds	132	58	0	4,920
Total suspended particulates	300	50	0	37,300

G.3.2.2 MOX Facility

G.3.2.2.1 Construction of MOX Facility

Potential air quality impacts from construction of new MOX and support facilities at Pantex were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–48.

Maximum air pollutant concentrations from construction activities are summarized in Table G–49.

Table G–48. Emissions (kg/yr) From Construction of New MOX Facility at Pantex

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	3,200	0	0	31,200
Nitrogen dioxide	8,400	0	0	8,660
PM_{10}	640[b]	5,360	1,090[b]	30,000
Sulfur dioxide	850	0	0	0
Volatile organic compounds	660	0	0	3,960
Total suspended particulates	640	10,600	1,090	30,000
Toxics[c]	0	<1	0	0

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for the purpose of this analysis resulting in some overestimate of PM_{10} concentrations.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction.
Source: UC 1998h.

Table G–49. Concentrations ($\mu g/m^3$) From Construction of New MOX Facility at Pantex

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	620	1.88	621
	1 hour	40,000	2,990	11.8	3,000
Nitrogen dioxide	Annual	100	1.94	0.144	2.09
PM_{10}	Annual	50	8.79	0.119	8.91
	24 hours	150	89.4	5.85	95.3
Sulfur dioxide	Annual	80	0	0.0146	0.0146
	24 hours	365	0.00002	0.175	0.175
	3 hours	1,300	0.00008	0.765	0.765

Total suspended particulates	3 hours	200	(b)	46.0	46.0
	1 hour	400	(b)	188	188
Toxics[c]	24 hours	3[d]	7.8[e]	0.00091	7.8
	1 hour	75[d]	19.4	0.0162	19.4

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Three- and 1-hr concentrations for total suspended particulates were not listed in the source document.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction and were analyzed as benzene.
[d] Effects-screening level of the Texas Natural Resources and Conservation Commission. Such levels are not ambient air standards, but merely "tools" used by the Toxicology and Risk Assessment staff to evaluate impacts of air pollutant emissions. Thus, exceedance of the screening levels by ambient air contaminants does not necessarily indicate a problem. That circumstance, however, would prompt a more thorough evaluation.
[e] Twenty-four-hour concentration was estimated from the 1-hr concentration.
Source: EPA 1997; TNRCC 1997a, 1997b.

G.3.2.2.2 Operation of MOX Facility

Potential air quality impacts from operation of the new MOX and support facilities at Pantex were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from boilers, emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–50.

Table G–50. Emissions (kg/yr) From Operation of New MOX Facility at Pantex

Pollutant	Boilers	Emergency Generator	Process	Vehicles
Carbon monoxide	900	374	0	34,800
Nitrogen dioxide	1,225	1,738	0	9,660
PM_{10}	206	122	0	33,400
Sulfur dioxide	9	114	0	0
Volatile organic compounds	85	142	0	4,410
Total suspended particulates	206	122	0	33,400
Toxics	0	0	1,000	0

Source: UC 1998h.

Maximum air pollutant concentrations resulting from the boilers, emergency diesel generators and process sources, plus the No Action concentrations, are summarized in Table G–51. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–51. Concentrations ($\mu g/m^3$) From Operation of New MOX Facility at Pantex

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Contribution	Total
Carbon monoxide	8 hours	10,000	620	0.306	620
	1 hour	40,000	2,990	1.64	2,990
Nitrogen dioxide	Annual	100	1.94	0.0351	1.98
PM_{10}	Annual	50	8.79	0.00298	8.79

G.4 SRS

G.4.1 Assessment Data

Emission rates for criteria, hazardous, and toxic air pollutants at SRS are presented in Table F.1.2.7–1 of the *Storage and Disposition Final PEIS* (DOE 1996a:F-18). These emission rates were used as input into the modeled No Action pollutant concentrations presented in that EIS and reflect SRS facility emissions for 1990. Concentration estimates that include the Upgrade with RFETS nonpit material storage option selected for SRS presented in the *Storage and Disposition Final S&D PEIS* (DOE 1996a:4-299) plus the other onsite activities related to programs analyzed in EISs related to foreign research reactor spent nuclear fuel, HEU disposition, interim management of nuclear materials, spent nuclear fuel, stockpile stewardship management, tritium supply and recycling, and waste management (DOE 1996a:4-953, 4-954) are assumed to be representative of No Action for 2005 and are shown in Table G–56. Other activities at SRS, which may occur during the time period 2005–2015, are discussed in the cumulative impacts section. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–56. Estimated Concentrations ($\mu g/m^3$) From No Action at SRS

Pollutant	Averaging Period	PEIS No Action	Other Onsite From PEIS	No Action
Carbon monoxide	8 hours	22.12	41.88	64
	1 hour	171.58	107.1	279
Nitrogen dioxide	Annual	5.77	3.53	9.30
PM_{10}	Annual	3.01	1.125	4.14
	24 hours	50.71	5.68	56.4
Sulfur dioxide	Annual	14.71	0.386	15.1
	24 hours	200.1	19.09	219
	3 hours	849.46	112.2	962
Total suspended particulates	Annual	12.6	2.065	14.7
Benzene	24 hours	31.711	0.001	31.7

G.4.2 Facilities

G.4.2.1 Pit Conversion Facility

G.4.2.1.1 Construction of Pit Conversion Facility

Potential air quality impacts from construction of new pit conversion and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–57.

Maximum air pollutant concentrations from construction activities are summarized in Table G–58.

Table G–57. Emissions (kg/yr) From Construction of New Pit Conversion Facility at SRS

Pollutant	Diesel Equipment and Construction Fugitive Emissions	Vehicles
Carbon monoxide	5,700	24,200
Nitrogen dioxide	13,000	7,020
PM_{10}	19,300	24,800
Sulfur dioxide	1,200	0
Volatile organic compounds	400	3,240
Total suspended particulates	43,400	24,800

G.4.2.2 Immobilization Facility in Building 221–F

G.4.2.2.1 Construction of Immobilization Facility in Building 221–F

Potential air quality impacts from modification of Building 221–F and construction of support facilities for plutonium conversion and immobilization (ceramic or glass) at SRS were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–61.

Table G–61. Emissions (kg/yr) From Construction of Immobilization Facility in Building 221–F at SRS

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	1,070	0	0	49,200
Nitrogen dioxide	2,750	0	0	14,300
PM_{10}	210[b]	410[b]	47[b]	50,400
Sulfur dioxide	280	0	0	0
Volatile organic compounds	220	0	0	6,590
Total suspended particulates	210	410	47	50,400

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for the purpose of this analysis resulting in some overestimate of PM_{10} concentrations.
Source: UC 1998j, 1998k.

Maximum air pollutant concentrations from construction activities are summarized in Table G–62.

Table G–62. Concentrations ($\mu g/m^3$) From Construction of Immobilization Facility in Building 221–F at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Ceramic or Glass	Total

G.4.2.2.2 Operation of Immobilization Facility in Building 221–F

Potential air quality impacts from operation of the ceramic or glass immobilization and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from boilers, emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–63.

Table G–63. Emissions (kg/yr) From Operation of Immobilization Facility in Building 221–F at SRS

Pollutant	Boilers	Emergency Generator	Ceramic Process	Glass Process	Vehicles
Carbon monoxide	140	390	3,500	0	41,300
Nitrogen dioxide	4,540	1,810	0	0	12,000
PM_{10}	350	130	0	0	42,300
Sulfur dioxide	13,300	120	0	0	0
Volatile organic compounds	30	150	0	0	5,530
Total suspended particulates	350	130	0	0	42,300

Source: UC 1998j, 1998k.

Maximum air pollutant concentrations resulting from the boilers, emergency diesel generators, and process sources, plus the No Action concentrations, are summarized in Table G–64. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Table G–64. Concentrations ($\mu g/m^3$) From Operation of Immobilization Facility in Building 221–F at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Ceramic	Total With Ceramic	Glass	Total With Glass
Carbon monoxide	8 hours	10,000	64	0.148	64.1	0.066	64.1

G.4.2.3 Immobilization Facility in New Construction

G.4.2.3.1 Construction of New Immobilization Facility

Potential air quality impacts from construction of new ceramic or glass immobilization and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–65.

Table G–65. Emissions (kg/yr) From Construction of New Immobilization Facility at SRS

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	4,550	0	0	52,600
Nitrogen dioxide	11,750	0	0	15,300
PM_{10}	899[b]	3,270	2,076[b]	53,800
Sulfur dioxide	1,190	0	0	0
Volatile organic compounds	930	0	0	7,040
Total suspended particulates	899	6,140	2,076	53,800

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for this analysis resulting in some overestimate of PM_{10} concentrations.
Source: UC 1998l, 1998m.

Maximum air pollutant concentrations from construction activities are summarized in Table G–66.

Table G–66. Concentrations ($\mu g/m^3$) From Construction of New Immobilization Facility at SRS

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a]	No Action	Ceramic or Glass	Total
Carbon monoxide	8 hours	10,000	64	0.648	64.6
	1 hour	40,000	279	2.94	282

G.4.2.4 MOX Facility

G.4.2.4.1 Construction of MOX Facility

Potential air quality impacts from construction of new MOX and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–69.

Maximum air pollutant concentrations from construction activities are summarized in Table G–70.

Table G–69. Emissions (kg/yr) From Construction of New MOX Facility at SRS

Pollutant	Diesel Equipment	Construction Fugitive Emissions[a]	Concrete Batch Plant	Vehicles
Carbon monoxide	3,200	0	0	29,300
Nitrogen dioxide	8,400	0	0	8,490
PM_{10}	640[b]	4,740	1,090[b]	30,000
Sulfur dioxide	850	0	0	0
Volatile organic compounds	660	0	0	3,920
Total suspended particulates	640	9,340	1,090	30,000
Toxics[c]	0	<1	0	0

[a] Does not include fugitive emissions from the concrete batch plant.
[b] PM_{10} emissions were assumed to be the same as total suspended particulate emissions for this analysis resulting in some overestimate of PM_{10} concentrations.
[c] Various toxic air pollutants (e.g., lead, benzene, hexane) could be emitted during construction.

Toxics[b]	24 hours	650	0.195	0.0585	0.254

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.
[b] Toxic hydrocarbons may be emitted as ethylene glycol and other pollutants and were analyzed as ethylene glycol. The State standard for ethylene glycol is a 24-hr average of 650 $\mu g/m^3$.
Source: EPA 1997; SCDHEC 1996.

G.4.2.5 Pit Conversion and Immobilization Facilities

G.4.2.5.1 Construction of Pit Conversion and Immobilization Facilities

Potential air quality impacts from construction of new pit conversion, immobilization (ceramic and glass), and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Similar analyses were conducted for potential air quality impacts from modification of Building 221–F and construction of support facilities for plutonium conversion and immobilization (ceramic and glass). Construction impacts result from emissions from fuel-burning construction equipment, particulate matter emissions from soil disturbance by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–73.

Table G–73. Emissions (kg/yr) From Construction of New Pit Conversion Facility and Immobilization in Building 221–F or New Construction at SRS

	Pit Conversion		Immobilization (Ceramic or Glass)							
	Diesel Equipment and Construction Fugitive Emissions		Diesel Equipment		Construction Fugitive Emissions[a]		Concrete Batch Plant		Vehicles	
Pollutant		Veh	221–F	New	221–F	New	221–F	New	221–F	New

G.4.2.7 Immobilization and MOX Facilities

G.4.2.7.1 Construction of Immobilization and MOX Facilities

Potential air quality impacts from construction of new immobilization (ceramic or glass), MOX, and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Similar analyses were conducted for potential air quality impacts from modification of Building 221–F and construction of support facilities for plutonium conversion and immobilization (ceramic or glass). Construction impacts result from emissions from diesel fuel-burning construction equipment, particulate matter emissions from disturbance of soil by construction equipment and other vehicles (construction fugitive emissions), operation of a concrete batch plant, employee vehicles, and trucks moving materials and wastes. Emissions from construction of a new facility are higher than for modification of an existing facility described previously. Emissions from these sources are summarized in Table G–81.

Maximum air pollutant concentrations from construction activities are summarized in Table G–82.

Table G–81. Emissions (kg/yr) From Construction of Immobilization in Building 221–F or New Construction, and New MOX Facility at SRS

	Immobilization (Ceramic or Glass)								MOX			
	DE		CFE[a]		CBP		Veh					
Pollutant	221–F	New	221–F	New	221–F	New	221–F	New	DE	CFE[a]	CBP	Veh

G.4.2.7.2 Operation of Immobilization and MOX Facilities

Potential air quality impacts from operation of the modified or new immobilization (ceramic or glass), new MOX, and support facilities at SRS were analyzed using ISCST3 as described in Appendix F.1. Operation impacts result from emissions from boilers, emergency diesel generators, process emissions, employee vehicles, and trucks moving materials and wastes. Emissions from these sources are summarized in Table G–83.

Maximum air pollutant concentrations resulting from the boilers, emergency diesel generators, and process sources, plus the No Action concentrations, are summarized in Table G–84. Radiological impacts, including those from emissions to the air, are discussed in Appendix J.

Next Section

Appendix H
Waste Management

This appendix describes the impacts on the waste management infrastructure that would occur if the proposed surplus plutonium disposition facilities were located at the Hanford Site (Hanford), Idaho National Engineering and Environmental Laboratory (INEEL), Pantex Plant (Pantex), or Savannah River Site (SRS), or if lead assembly fabrication activities were located at INEEL (Argonne National Laboratory–West [ANL–W]), Hanford, Lawrence Livermore National Laboratory (LLNL), Los Alamos National Laboratory (LANL), or SRS. The waste types evaluated in this section are transuranic (TRU) waste (including mixed TRU waste), low-level waste (LLW), mixed LLW, hazardous waste, nonhazardous solid waste, and nonhazardous liquid waste. Major adverse impacts are not expected at any of the U.S. Department of Energy (DOE) sites, although Pantex may have to convert some existing storage capacity into storage space for TRU waste and LLW. Facilities for drum-gas testing, real-time radiography, and loading the TRU waste package transporter (TRUPACT) for shipment to the Waste Isolation Pilot Plant (WIPP) may also be required at Pantex. The *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS) assumes that all TRU waste generated by surplus plutonium disposition facilities would have to be stored on the site until WIPP is ready to accept this waste in 2016 (DOE 1997a:17). Impacts from additional TRU waste storage at the DOE sites should not be major. A description of the methods used to estimate impacts on waste management facilities is presented in Appendix F.8.

Decisions in the Records of Decision (RODs) for the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (WM PEIS) (DOE 1997b) could affect where DOE would send wastes in the future and could result in the closing of some existing waste management facilities and construction of new facilities at DOE sites. The ROD for TRU waste issued on January 20, 1998, states that each of the DOE sites that currently has or will generate TRU waste will prepare and store its TRU waste on the site for eventual shipment to WIPP. RODs for LLW, mixed LLW, and hazardous waste are pending.

H.1 HANFORD

H.1.1 Assessment Data

Impacts on Hanford waste management facilities were estimated using information on existing environmental conditions from Chapter 3 and information on the characteristics of the proposed surplus plutonium disposition facilities from Chapter 2 and the facility data reports. A description of the methods used to evaluate impacts on waste management facilities is presented in Appendix F.8.

H.1.2 Facilities

H.1.2.1 Pit Conversion Facility

H.1.2.1.1 Construction of Pit Conversion Facility

Table H–1 compares the expected construction waste generation rates for the facility that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves modification of uncontaminated buildings only (UC 1998a). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–1. Potential Waste Management Impacts of Construction of Pit Conversion Facility in FMEF at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	13	560	2
Nonhazardous			
Liquid	1,300	200,000	1
Solid	28	43,000	<1

[a] See definitions in Appendix F.8.
[b] UC 1998a.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in U.S. Department of Transportation (DOT) approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998a). Hazardous waste generation for this facility is estimated to be 2 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998a). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be less than 1 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998a). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this facility is estimated to be 1 percent of existing annual site waste generation, 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the Washington Public Power Supply System (WPPSS) Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.1.2 Operation of Pit Conversion Facility

The waste management facilities within the pit conversion facility would process, temporarily store, and ship all wastes generated. Table H–2 compares the expected waste generation rates from operating the new facility at Hanford with the existing generation rates for Hanford waste. No high-level waste (HLW) would be generated by the facility (UC 1998a). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in

Table H–2. Potential Waste Management Impacts of Operation of Pit Conversion Facility in FMEF at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	18	450	4
LLW	60	3,902	2
Mixed LLW	1	847	<1
Hazardous	2	560	<1
Nonhazardous			
Liquid	40,000	200,000	20
Solid	1,800	43,000	4

[a] See definitions in Appendix F.8.
[b] UC 1998d.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facility (UC 1998a). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this facility is estimated to be 4 percent of existing annual waste generation and 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 180 m^3 (235 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 2 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage, and 1 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 860 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 260 m^2 (310 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at Hanford should not be major.

The 180 m^3 (235 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and

accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation. Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998a). A total of 600 m^3 (785 yd^3) of LLW would be generated over the operation period. LLW generation for this facility is estimated to be 2 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 m^3 (780 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998a). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this facility is estimated to be 1 m^3/yr (1.3 yd^3/yr) or less than 1 percent of existing annual waste generation, and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating life of the facility, the 10 m^3 (13 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998a). Hazardous waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998a). The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 4 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and process wastewater from lab sinks and drains, mop water, and cooling tower blowdown. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998a). Nonhazardous liquid waste generation for this facility is estimated to be 20 percent of the existing annual site waste generation, 17 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 17 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.2 Immobilization Facility

H.1.2.2.1 Construction of Immobilization Facility

Table H–3 compares the expected construction waste generation rates for the immobilization facility that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves modification of uncontaminated buildings only (UC 1998b, 1998c). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for both the ceramic and glass immobilization technologies and would be the same for the 17-t (19-ton) and 50-t (55-ton) immobilization scenarios, because the same size facility would be built under any scenario (UC 1998a, 1998b).

Table H–3. Potential Waste Management Impacts of Construction of Immobilization Facility in FMEF at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	4	560	1
Nonhazardous			
Liquid	3,700	200,000	2
Solid	150	43,000	<1

[a] See definitions in Appendix F.8.
[b] UC 1998b, 1998c.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints, chemicals, as well as rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998b, 1998c). Hazardous waste generation for this facility is estimated to be 1 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998b, 1998c). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonhazardous solid waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998b, 1998c). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this facility is estimated to be 2 percent of existing annual site waste generation, 2 percent of the

235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 2 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.2.2 Operation of Immobilization Facility

The waste management facilities within the immobilization facility would process, temporarily store, and ship all wastes generated. Table H–4 compares the expected waste generation rates from operating the new facility at Hanford with the existing generation rates for Hanford waste. Although HLW would be used in the immobilization process, no HLW would be generated by the facility (UC 1998b, 1998c). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for both ceramic and glass immobilization technologies, but varies between the 17-t (19-ton) and the 50-t (55-ton) immobilization cases (UC 1998b, 1998c). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

Table H–4. Potential Waste Management Impacts of Operation of Immobilization Facility in FMEF at Hanford

	Estimated Waste Generation (m^3/yr)[b]		Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation	
Waste Type[a]	17 t	50 t		17 t	50 t
TRU[d]	95	126	450	21	28
LLW	60	80	3,902	2	2
Mixed LLW	1	1	847	<1	<1
Hazardous	30	30	560	5	5
Nonhazardous					
Liquid	23,000	25,000	200,000	12	13
Solid	230	230	43,000	1	1

[a] See definitions in Appendix F.8.
[b] UC 1998b, 1998c.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998b, 1998c). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this facility is estimated to be 21 to 28 percent of existing annual waste generation and 5 to 7 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 950 to 1,260 m^3 (1,240 to 1,650 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 8 to 11 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently

in storage and 6 to 7 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 4,500 to 6,000 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 1,400 to 1,800 m^2 (1,670 to 2,150 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.14 to 0.18 ha (0.35 to 0.44 acre) of land at Hanford should not be major.

The 950 to 1,260 m^3 (1,240 to 1,650 yd^3) of TRU waste generated by this facility would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facility before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998b, 1998c). A total of 600 to 800 m^3 (780 to 1,000 yd^3) of LLW would be generated over the operation period. LLW generation for this facility is estimated to be 2 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 to 800 m^3 (780 to 1,000 yd^3) of waste would require 0.17 to 0.23 ha (0.42 to 0.57 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, and scintillation vials from the analytical laboratory (UC 1998b, 1998c). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this facility is estimated to be 1 m^3/yr (1.3 yd^3/yr), or less than 1 percent of existing annual waste generation. The 1 m^3/yr (1.3 yd^3/yr) of mixed LLW would be less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating life of this facility, the 10 m^3 (13 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional mixed LLW at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubrication oils, film processing fluids, hydraulic fluids, coolants, paints, chemicals, batteries, fluorescent light tubes, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998b, 1998c). Assuming that all hazardous waste is managed onsite, hazardous waste generation for this facility is estimated to be 5 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop wastes, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998b, 1998c). The remaining solid sanitary waste would

be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 1 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from cooling tower blowdown. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998b, 1998c). Nonhazardous-liquid-waste generation for this facility is estimated to be 12 to 13 percent of the existing annual site waste generation, 10 to 11 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 10 to 11 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.3 MOX Facility

H.1.2.3.1 Construction of MOX Facility

Table H–5 compares the expected construction waste generation rates for the facility that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves new construction or modification of uncontaminated buildings only (UC 1998d). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. The amount of waste generated during construction would vary if the Fuels and Materials Examination Facility (FMEF) needs to be modified to accept the mixed oxide (MOX) facility versus constructing a new building (UC 1998c:attachment).

Table H–5. Potential Waste Management Impacts of Construction of MOX Facility in FMEF or New Construction at Hanford

	Estimated Waste Generation (m^3/yr)[b]		Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation	
Waste Type[a]	FMEF	New		FMEF	New
Hazardous	6	11	560	1	2
Nonhazardous					
Liquid	12,000	13,000	200,000	6	7
Solid	280	820	43,000	1	2

[a] See definitions in Appendix F.8.
[b] UC 1998d.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints, chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998d). Hazardous waste generation for this facility is estimated to be 1 to 2 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial

practice and shipped to offsite facilities for recycling or disposal (UC 1998d). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonhazardous solid waste generation for this facility is estimated to be 1 to 2 percent of existing annual waste generation. Because these wastes would be managed at offsite facilities, the additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998d). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid-waste generation for this facility is estimated to be 6 to 7 percent of existing annual site waste generation, 5 to 6 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 5 to 6 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.3.2 Operation of MOX Facility

The waste management facilities within the MOX facility would process, temporarily store, and ship all wastes generated. Table H–6 compares the expected waste generation rates from operating the new facility at Hanford with the existing generation rates for Hanford waste. No HLW would be generated by the facility (UC 1998d). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation during operations would be the same whether the MOX facility is located in FMEF or in a new building (UC 1998d:attachment). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

Table H–6. Potential Waste Management Impacts of Operation of MOX Facility in FMEF or New Construction at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	46	450	10
LLW	34	3,902	1
Mixed LLW	2	847	<1
Hazardous	<1	560	<1
Nonhazardous			
Liquid	25,000	200,000	13
Solid	<150	43,000	<1

[a] See definitions in Appendix F.8.
[b] UC 1998d.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.

Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998d). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this facility is estimated to be 10 percent of existing annual waste generation and 3 percent of the 1,820-m^3/yr (2,380-yd^3/yr) planned capacity of the Waste Receiving and Processing Facility. A total of 460 m^3 (600 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 4 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage and 3 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 2,200 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 660 m^2 (790 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at Hanford should not be major.

The 460 m^3 (600 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facility before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998d). A total of 340 m^3 (445 yd^3) of LLW would be generated over the operation period. LLW generation for this facility is estimated to be 1 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 340 m^3 (440 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes solvents contaminated with plutonium and scintillation vials from the analytical laboratory (UC 1998d). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this facility is estimated to be 2 m^3/yr (2.6 yd^3/yr) or less than 1 percent of existing annual waste generation. The 2 m^3/yr (2.6 yd^3/yr) of mixed LLW would be less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating life of this facility, the 20 m^3 (26 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubricants, oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998d). Hazardous waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998d). The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, and cooling tower blowdown; and treated wastewater from the liquid effluent treatment system. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998d). Nonhazardous-liquid-waste generation for this facility is estimated to be 13 percent of the existing annual site waste generation, 11 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 11 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.4 Pit Conversion and Immobilization Facilities

H.1.2.4.1 Construction of Pit Conversion and Immobilization Facilities

Table H–7 compares the expected construction waste generation rates for the facilities that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves modification of uncontaminated buildings only (UC 1998a, 1998b, 1998c). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for both the ceramic and glass immobilization technologies and would be the same for the 17-t (19-ton) and 50-t (55-ton) immobilization scenarios, because the same size facility would be built under any scenario (UC 1998b, 1998c).

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998a, 1998b, 1998c). Hazardous waste generation for this combination of facilities is estimated to be 3 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998a, 1998b, 1998c). Nonrecyclable

Table H–7. Potential Waste Management Impacts of Construction of Pit Conversion and Immobilization Facilities in FMEF at Hanford

	Estimated Waste Generation (m^3/yr)[b]			Percent of Site Waste Generation		
Waste Type[a]	Pit Conversion	Immobilization (Ceramic or Glass)	Site Waste Generation (m^3/yr)[c]	Pit Conversion	Immobilization (Ceramic or Glass)	Both Facilities
Hazardous	13	4	560	2	1	3
Nonhazardous						
Liquid	1,300	3,700	200,000	1	2	3
Solid	28	150	43,000	<1	<1	<1

[a] See definitions in Appendix F.8.
[b] UC 1998a, 1998b, 1998c.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility.

solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be less than 1 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998a, 1998b, 1998c). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this combination of facilities is estimated to be 3 percent of existing annual site waste generation, 3 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 3 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.4.2 Operation of Pit Conversion and Immobilization Facilities

The waste management facilities within the pit conversion and immobilization facilities would process, temporarily store, and ship all wastes generated. Table H–8 compares the expected waste generation rates from operating the new facilities at Hanford with the existing generation rates for Hanford waste. Although HLW would be used in the immobilization process, no HLW would be generated by the facilities (UC 1998a, 1998b, 1998c). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for both the ceramic and glass immobilization technologies, but varies between the 17-t (19-ton) and the 50-t (55-ton) immobilization cases (UC 1998b, 1998c). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

Table H–8. Potential Waste Management Impacts of Operation of Pit Conversion and Immobilization Facilities in FMEF at Hanford

	Estimated Waste Generation (m^3/yr)[b]				Percent of Site Waste Generation			
		Immobilization (Ceramic or Glass)		Site Waste		Immobilization (Ceramic or Glass)		
Waste Type[a]	Pit Conversion	17 t	50 t	Generation (m^3/yr)[c]	Pit Conversion	17 t	50 t	Both Facilities
TRU[d]	18	95	126	450	4	21	28	25 to 32
LLW	60	60	80	3,902	2	2	2	3 to 4
Mixed LLW	1	1	1	847	<1	<1	<1	<1
Hazardous	2	30	30	560	<1	5	5	6
Nonhazardous								
Liquid	40,000	23,000	25,000	200,000	20	12	13	32 to 33
Solid	1,800	230	230	43,000	4	1	1	5

[a] See definitions in Appendix F.8.
[b] UC 1998a, 1998b, 1998c.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998a, 1998b, 1998c). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this combination of facilities is estimated to be 25 to 32 percent of existing annual waste generation and 6 to 8 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 1,130 to 1,440 m^3 (1,480 to 1,880 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 10 to 13 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage and 7 to 8 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 5,400 to 6,900 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 1,600 to 2,100 m^2 (1,910 to 2,510 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.16 to 0.21 ha (0.40 to 0.51 acre) of land at Hanford should not be major.

The 1,130 to 1,440 m^3 (1,480 to 1,880 yd^3) of TRU waste generated by these facilities would be approximately 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP, and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing

onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998a, 1998b, 1998c). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998c). A total of 1,200 to 1,400 m^3 (1,570 to 1,830 yd^3) of LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 3 to 4 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480 m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,200 to 1,400 m^3 of waste would require 0.34 to 0.40 ha (0.84 to 0.99 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998a, 1998b, 1998c). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this combination of facilities is estimated to be 2 m^3/yr (2.6 m^3/yr) or less than 1 percent of existing annual waste generation, and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating lives of these facilities, the 20 m^3 (26 ft^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998a, 1998b, 1998c). Hazardous waste generation for this combination of facilities is estimated to be 6 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998a, 1998b, 1998c). The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 5 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and, process wastewater from lab sinks and drains, mop water, and cooling tower blowdown. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998a, 1998b, 1998c). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 32 to 33 percent of the existing annual site waste generation, 27 to 28 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 27 to 28 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.5 Pit Conversion and MOX Facilities

H.1.2.5.1 Construction of Pit Conversion and MOX Facilities

Table H–9 compares the expected construction waste generation rates for the facilities that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves new construction or modification of uncontaminated buildings only (UC 1998a, 1998d). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. The amount of waste generated during construction would vary if FMEF needs to be modified to accept the MOX facility versus constructing a new building (UC 1998d:attachment).

Table H–9. Potential Waste Management Impacts of Construction of Pit Conversion and MOX Facilities in FMEF or New MOX Facility at Hanford

	Estimated Waste Generation (m^3/yr)[b]			Site Waste	Percent of Site Waste Generation		
	Pit	MOX		Generation	Pit		Both
Waste Type[a]	Conversion	FMEF	New	(m^3/yr)[c]	Conversion	MOX	Facilities
Hazardous	13	6	11	560	2	1 to 2	3 to 4
Nonhazardous							
Liquid	1,300	12,000	13,000	200,000	1	6 to 7	7
Solid	28	280	820	43,000	<1	1 to 2	1 to 2

[a] See definitions in Appendix F.8.
[b] UC 1998a, 1998d.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998a, 1998d). Hazardous waste generation for this combination of facilities is estimated to be 3 to 4 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998a, 1998d). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 1 to 2 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998a, 1998d). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities.

Nonhazardous liquid waste generation for this combination of facilities is estimated to be 7 percent of existing annual site waste generation, 6 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 6 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.5.2 Operation of Pit Conversion and MOX Facilities

The waste management facilities within the pit conversion and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–10 compares the expected waste generation rates from operating the new facilities at Hanford with the existing generation rates for Hanford waste. No HLW would be generated by the facilities (UC 1998a, 1998d). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation during operations would be the same whether the MOX facility is located in FMEF or in a new building (UC 1998d:attachment). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

Table H–10. Potential Waste Management Impacts of Operation of Pit Conversion and MOX Facilities in FMEF or New MOX Facility at Hanford

	Estimated Waste Generation (m^3/yr)[b]		Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation		
Waste Type[a]	Pit Conversion	MOX		Pit Conversion	MOX	Both Facilities
TRU[d]	18	46	450	4	10	14
LLW	60	34	3,902	2	1	2
Mixed LLW	1	2	847	<1	<1	<1
Hazardous	2	<1	560	<1	<1	1
Nonhazardous						
Liquid	40,000	25,000	200,000	20	13	33
Solid	1,800	<150	43,000	4	<1	5

[a] See definitions in Appendix F.8.
[b] UC 1998a, 1998d.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998a, 1998d). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facililty at Hanford.

TRU waste generation for this combination of facilities is estimated to be 14 percent of existing annual waste generation and 4 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 640 m^3 (837 yd^3) of TRU waste would be generated over the 10-year operation period.

This would be 6 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage and 4 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 3,000 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 900 m^2 (1,100 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at Hanford should not be major.

The 640 m^3 (837 yd^3) of TRU waste generated by these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation. Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998a). A total of 940 m^3 (1,230 yd^3) of LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 2 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 940 m^3 (1,230 yd^3) of waste would require 0.27 ha (0.67 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998a, 1998d). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this combination of facilities is estimated to be 3 m^3/yr (3.9 yd^3/yr) or less than 1 percent of existing annual waste generation, and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating lives of these facilities, the 30 m^3 (39 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998a, 1998d). Hazardous waste generation for this combination of facilities is estimated to be 1 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with

standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998a, 1998d). The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 5 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, and cooling tower blowdown; and treated wastewater from the liquid effluent treatment system. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998a, 1998d). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 33 percent of the existing annual site waste generation, 28 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 28 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.6 Immobilization and MOX Facilities

H.1.2.6.1 Construction of Immobilization and MOX Facilities

Table H–11 compares the expected construction waste generation rates for the facilities that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves new construction or modification of uncontaminated buildings only (UC 1998b, 1998c, 1998d). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for ceramic and glass immobilization technologies (UC 1998b, 1998c), although the amount of waste generated during construction would vary if FMEF needs to be modified to accept the immobilization and MOX facilities versus constructing a new building for MOX (UC 1998d).

Table H–11. Potential Waste Management Impacts of Construction of Collocating Immobilization and MOX Facilities in FMEF or New MOX Facility at Hanford

	Estimated Waste Generation (m^3/yr)[b]					Percent of Site Waste Generation			
	IF in FMEF (Ceramic or Glass)		MOX		Site Waste Generation	IF		Both Facilities	
Waste Type[a]	w/ MOX	w/o MOX	FMEF	New	(m^3/yr)[c]	Ceramic or Glass	MOX	Both in FMEF	New MOX
Hazardous	7	4	6	11	560	1	1-2	2	3
Nonhazardous									
Liquid	6,300	3,700	12,000	13,000	200,000	2-3	6-7	9	8
Solid	230	150	280	820	43,000	<1-1	1-2	1	2

[a] See definitions in Appendix F.8.
[b] UC 1998b, 1998c, 1998d.
[c] From the waste management section in Chapter 3.
Key: FMEF, Fuels and Materials Examination Facility; IF, Immobilization Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous

waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998b, 1998c, 1998d). Hazardous waste generation for this combination of facilities is estimated to be 2 to 3 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998b, 1998c, 1998d). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 1 to 2 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998b, 1998c, 1998d). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this combination of facilities is estimated to be 8 to 9 percent of existing annual site waste generation, 7 to 8 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 7 to 8 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.6.2 Operation of Immobilization and MOX Facilities

The waste management facilities within the immobilization and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–12 compares the expected waste generation rates from operating the new facilities at Hanford with the existing generation rates for Hanford waste. Although HLW would be used in the immobilization process, no HLW would be generated by the facilities (UC 1998b, 1998c, 1998d). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for ceramic and glass immobilization technologies (UC 1998b, 1998c) and would be the same whether the MOX facility is located in FMEF or in a new building (UC 1998d:attachment). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998b, 1998c, 1998d). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time

Table H–12. Potential Waste Management Impacts of Operation of Collocating Immobilization and MOX Facilities in FMEF or New MOX Facility at Hanford

	Estimated Waste Generation (m^3/yr)[b]			Percent of Site Waste Generation

[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this combination of facilities is estimated to be 31 percent of existing annual waste generation and 8 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 1,410 m^3 (1,840 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 12 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage, and 8 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 6,700 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 2,000 m^2 (2,400 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.20 ha (0.49 acre) of land at Hanford should not be major.

The 1,410 m^3 (1,840 yd^3) of TRU waste generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste (UC 1998b, 1998c). LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998b, 1998c, 1998d). A total of 940 m^3 (1,230 yd^3) of LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 2 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition*

Final PEIS (DOE 1996a:E-9), 940 m^3 (1,230 yd^3) of waste would require 0.27 ha (0.67 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, and scintillation vials from the analytical laboratory (UC 1998b, 1998c, 1998d). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this combination of facilities is estimated to be 3 m^3/yr (3.9 yd^3/yr) or less than 1 percent of existing annual waste generation, and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating life of these facilities, the 30 m^3 (39 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubricants, oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998b, 1998c, 1998d). Hazardous waste generation for this combination of facilities is estimated to be less than 6 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998b, 1998c, 1998d). The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 1 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown; and treated wastewater from the liquid effluent treatment system. Wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer that connects to the WPPSS wastewater treatment system (UC 1998b, 1998c, 1998d). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 24 percent of the existing annual site waste generation, 20 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 20 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

H.1.2.7 Pit Conversion, Immobilization, and MOX Facilities

H.1.2.7.1 Construction of Pit Conversion, Immobilization, and MOX Facilities

Table H–13 compares the expected construction waste generation rates for the facilities that may be constructed at Hanford with the existing generation rates for Hanford waste. No radioactive waste would be generated during the 3-year construction period because this action involves new construction and modification of uncontaminated buildings only (UC 1998a, 1998b, 1998c, 1998d). In addition, no soil contaminated with

hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for ceramic and glass immobilization technologies (UC 1998b, 1998c).

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, motor oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during the 3-year construction period would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998a, 1998b, 1998c, 1998d). Hazardous waste generation for this combination of facilities is estimated to be 5 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Hanford hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998a, 1998b, 1998c, 1998d). Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 2 percent of existing annual waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998a, 1998b, 1998c, 1998d). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that much of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this combination of facilities is estimated to be 9 percent of existing annual site waste generation, 8 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 8 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.1.2.7.2 Operation of Pit Conversion, Immobilization, and MOX Facilities

The waste management facilities within the pit conversion, immobilization, and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–14 compares the expected waste generation rates from operating the new facilities at Hanford with the existing generation rates for Hanford waste. Although HLW would be used in the immobilizatoin process, no HLW would be generated by the facilities (UC 1998a, 1998b, 1998c, 1998d). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for ceramic and glass immobilization technologies (UC 1998b, 1998c). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford will be evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Program EIS* being prepared by the DOE Richland Operations Office (DOE 1997c).

Table H–14. Potential Waste Management Impacts of Operation of Pit Conversion and Immobilization Facilities in FMEF and New MOX Facilities at Hanford

	Estimated Waste Generation (m^3/yr)[b]				Percent of Site Waste Generation			
Waste Type[a]	Pit Conversion	Immobilization (Ceramic or Glass)	MOX	Site Waste Generation (m^3/yr)[c]	Pit Conversion	Immobilization (Ceramic or Glass)	MOX	All Facilities

[a] See definitions in Appendix F.8.
[b] *UC 1998a, 1998b, 1998c, 1998d.*
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: FMEF, Fuels and Materials Examination Facility; LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, sweepings, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facility (UC 1998a, 1998b, 1998c, 1998d). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for this combination of facilities is estimated to be 35 percent of existing annual waste generation and 9 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. A total of 1,590 m^3 (2,080 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 14 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage, and 9 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 7,600 drums would be

required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 2,300 m^2 (2,750 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.23 ha (0.57 acre) of land at Hanford should not be major.

The 1,590 m^3 (2,080 yd^3) of TRU waste generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste (UC 1998a, 1998b, 1998c). LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998a, 1998b, 1998c, 1998d). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998d). A total of 1,540 m^3 (2,010 yd^3) of LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 4 percent of existing annual waste generation, less than 1 percent of the 1.74 million-m^3 (2.28 million-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,540 m^3 of waste would require 0.44 ha (1.1 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998a, 1998b, 1998c, 1998d). Mixed LLW would be stabilized, packaged, and stored onsite for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Hanford currently treats and disposes of mixed LLW on the site. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this combination of facilities is estimated to be 4 m^3/yr (5.2 yd^3/yr) or less than 1 percent of existing annual waste generation, and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating lives of these facilities, the 40 m^3 (52 yd^3) of mixed LLW generated would be less than 1 percent of the 16,800-m^3 (22,000-yd^3) storage capacity of the Central Waste Complex, and less than 1 percent of the 14,200-m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998a, 1998b, 1998c, 1998d). Hazardous waste generation for this combination of facilities is estimated to be 6 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998a, 1998b, 1998c, 1998d). The remaining solid sanitary

waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 5 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, boiler blowdown; and treated wastewater from the liquid effluent treatment system. Nonhazardous process wastewater would be treated, if necessary, before being discharged to the 400 Area sanitary sewer which connects to the WPPSS wastewater treatment system (UC 1998a, 1998b, 1998c, 1998d). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 44 percent of the existing annual site waste generation, 37 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 37 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, the management of this additional waste should not have a major impact on the system.

Next Section

H.2 INEEL

H.2.1 Assessment Data

Impacts on INEEL waste management facilities were estimated using information on existing environmental conditions from Chapter 3 and information on the characteristics of the proposed surplus plutonium disposition facilities from Chapter 2 and the facility data reports. A description of the methods used to evaluate impacts on waste management facilities is presented in Appendix F.8.

H.2.2 Facilities

H.2.2.1 Pit Conversion Facility

H.2.2.1.1 Construction of Pit Conversion Facility

Table H–15 compares the expected construction waste generation rates for the pit conversion facility that may be constructed at INEEL with the existing site waste generation rates. No radioactive waste would be generated during the 3-year construction period because this facility involves the modification of an uncontaminated building (UC 1998e). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and applicable Federal and State regulations.

Table H–15. Potential Waste Management Impacts of Construction of Pit Conversion Facility in FPF at INEEL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	16	835	2
Nonhazardous			
Liquid	2,300	2,000,000	<1
Solid	40	62,000	<1

[a] See definitions in Appendix F.8.
[b] UC 1998e.
[c] From the waste management section in Chapter 3.
Key: FPF, Fuel Processing Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998e). Hazardous waste generation for this facility is estimated to be 2 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the INEEL hazardous waste management system.

Nonhazardous solid waste includes office garbage, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite recycling or onsite disposal facilities (UC 1998e). Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore would not be included in the waste volumes. Construction debris would be disposed of in the INEEL onsite landfill complex in the Central Facilities Area (CFA). Nonrecyclable solid sanitary waste would be sent off the site for disposal in the Bonneville County

landfill. Nonhazardous solid waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation. Assuming all nonhazardous solid waste were disposed of on the site, this additional waste would require less than 1 percent of the 48,000-m^3/yr (62,800-yd^3/yr) capacity in the CFA landfill complex. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers, and water closets (UC 1998e). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that most of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation, 1 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the Fuel Processing Facility (FPF) sanitary sewer system, and less than 1 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the Idaho Nuclear Technology and Engineering Center (INTEC) Sewage Treatment Plant. Therefore, the generation of nonhazardous liquid waste should not have a major impact on the system during construction.

H.2.2.1.2 Operation of Pit Conversion Facility

The waste management facilities within the pit conversion facility would process, temporarily store, and ship all wastes generated. Table H–16 compares the expected waste generation rates from operating the new facility at INEEL with the existing site waste generation rates. No HLW would be generated by the pit conversion facility (UC 1998e). Depending in part on decisions in the ROD for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commerical facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage and disposal of radioactive, hazardous, and mixed wastes at INEEL are described in the *DOE Programmatic Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management Programs Final EIS* (DOE 1995a).

Table H–16. Potential Waste Management Impacts of Operation of Pit Conversion Facility in FPF at INEEL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	18	(e)	NA
LLW	60	2,624	2
Mixed LLW	1	180	1
Hazardous	2	835	<1
Nonhazardous			
Liquid	41,000	2,000,000	2
Solid	1,800	62,000	3

[a] See definitions in Appendix F.8.
[b] UC 1998e.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.

Key: FPF, Fuel Processing Facility; LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the pit conversion facility. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Longer-term storage, drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned Waste Characterization Facility at INEEL (UC 1998e). TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.

TRU waste generation for this facility is estimated to be 18 m^3/yr (24 yd^3/yr) or a total of 180 m^3 (235 yd^3) over the 10-year operation period. This would be less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) capacity of the planned Advanced Mixed Waste Treatment Project and less than 1 percent of the 177,300-m^3 (231,900-yd^3) storage capacity available at the Radioactive Waste Management Complex. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 860 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 260 m^2 (310 yd^2) would be required. The impacts of storing additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at INEEL should not be major.

The 180 m^3 (235 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and is within the 168,500-m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operation would originate from activities in the processing areas that contain the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facility before being transferred for additional treatment and/or disposal in existing facilities on the site. Liquid LLW would be evaporated or solidified before being packaged for accumulation. Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998e). LLW generation for this facility is estimated to be 2 percent of existing annual waste generation, 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex, and less than 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of the Radioactive Waste Management Complex. If the LLW were treated at Waste Experimental Reduction Facility, the 60 m^3 (78 yd^3) of annual waste generation would be less than 1 percent of the 49,610 m^3 (64,890 yd^3) annual facility capacity. A total of 600-m^3 (780-yd^3) LLW would be generated over the operation period. Using the 6,264 m^3/ha (3,315 yd^3/acre) disposal land usage factor for INEEL published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 m^3 (780 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space. Therefore, impacts of the management of this additional LLW at INEEL should not be major.

Mixed LLW includes solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998e). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for INEEL. INEEL currently treats some mixed LLW on the site and ships some to Envirocare of Utah. Onsite disposal is planned in a new mixed LLW disposal facility. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this facility is estimated to be 1 m^3/yr (1.3 yd^3/yr) or 1 percent of the existing annual waste generation, and less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project.

Over the operating life of this facility, the 10 m^3 (13 yd^3) of mixed LLW generated would be less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex. Therefore, the management of this additional waste at INEEL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at onsite and offsite permitted facilities (UC 1998e). Hazardous waste generation for this facility is estimated to be less than 1 percent of the existing annual waste generation and 1 percent of the 1,600-m^3 (2,090-yd^3) onsite storage capacity. Assuming that all the hazardous waste were treated at the Waste Experimental Reduction Facility, this additional waste would be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) capacity of the system. Therefore, impacts on the hazardous waste management system at INEEL should not be major.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998e). The remaining solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 3 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from sinks, showers and water closets, and process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and boiler blowdown. Nonhazardous wastewater would be treated, if necessary, before being discharged to the FPF sanitary sewer that connects to the INTEC wastewater treatment system (UC 1998e). Nonhazardous liquid waste generation for this facility is estimated to be 2 percent of the existing annual site waste generation, 25 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the FPF sanitary sewer system, and 1 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the INTEC Sewage Treatment Plant. Therefore, the management of this additional waste should not have a major impact on the system.

H.2.2.2 MOX Facility

H.2.2.2.1 Construction of MOX Facility

Table H–17 compares the expected construction waste generation rates for the new MOX facility that may be constructed at INEEL with the existing site waste generation rates. No radioactive waste would be generated during the 3-year construction period because this facility involves new construction only (UC 1998f). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998f). Hazardous waste generation for this facility is estimated to be 1 percent of the existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on the INEEL hazardous waste management system.

Table H–17. Potential Waste Management Impacts of Construction of New MOX Facility at INEEL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	11	835	1
Nonhazardous			
Liquid	13,000	2,000,000	1
Solid	820	62,000	1

[a] See definitions in Appendix F.8.
[b] UC 1998f.
[c] From the waste management section in Chapter 3.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite recycling or onsite disposal facilities (UC 1998f). Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Construction debris would be disposed of in the onsite INEEL landfill complex in the CFA. Nonrecyclable solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonhazardous solid waste generation for this facility is estimated to be 1 percent of existing annual waste generation. Assuming all nonhazardous solid waste was to be disposed of on the site, this additional waste would require 2 percent of the 48,000-m^3/yr (62,800-yd^3/yr) capacity in the CFA landfill complex. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers and water closets, and wastewater from dewatering (UC 1998f). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at facilities on the site, even though it is likely that most of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this facility is estimated to be 1 percent of existing annual waste generation, 8 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the FPF sanitary sewer system, and less than 1 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the INTEC Sewage Treatment Plant. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.2.2.2.2 Operation of MOX Facility

The waste management facilities within the MOX facility would process, temporarily store, and ship all wastes generated. Table H–18 compares the expected waste generation rates from operating the new facility at INEEL with the existing site waste generation rates. No HLW would be generated by the MOX facility (UC 1998f). Depending in part on decisions in the ROD for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment,storage and disposal of radioactive, hazardous, and mixed wastes at INEEL are described in the *DOE Programmatic Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management Programs EIS* (DOE 1995a).

TRU wastes generated during operations include spent filters, sweepings, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that

Table H–18. Potential Waste Management Impacts of Operation of New MOX Facility at INEEL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	46	(e)	NA
LLW	34	2,624	1
Mixed LLW	2	180	1
Hazardous	<1	835	<1
Nonhazardous			
Liquid	25,000	2,000,000	1
Solid	<150	62,000	<1

[a] See definitions in Appendix F.8.
[b] UC 1998f.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.
Key: LLW, low-level waste, NA, not applicable; TRU, transuranic.

all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the MOX facility (UC 1998f). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned Waste Characterization Facility at INEEL. TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.

TRU waste generated by this facility is estimated to be 46 m^3/yr (60 yd^3/yr) or a total of 460 m^3 (600 yd^3) over the 10-year operation period. This would be 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) capacity of the planned Advanced Mixed Waste Treatment Project and less than 1 percent of the 177,300-m^3 (231,900-yd^3) storage capacity available at the Radioactive Waste Management Complex. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 2,200 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 660 m^2 (790 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at INEEL should not be major.

The 460 m^3 (600 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operation would originate from activities in the processing areas containing the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998f). LLW generation for this facility is estimated to be 1 percent of existing annual waste generation, less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex, and less than 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of the Radioactive Waste Management

Complex. If the LLW were to be treated at the Waste Experimental Reduction Facility, the 34 m^3 (44 yd^3) of annual waste generation would be less than 1 percent of the 49,610 m^3 (64,890 yd^3) annual facility capacity. A total of 340-m^3 (445-yd^3) LLW would be generated over the period of operation. Using the 6,264 m^3/ha (3,315 yd^3/acre) disposal land usage factor for INEEL published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 340 m^3 (445 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space. Therefore, impacts of the management of this additional LLW at INEEL should not be major.

Mixed LLW includes solvents contaminated with plutonium and scintillation vials from the analytical laboratory (UC 1998f). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for INEEL. INEEL currently treats mixed LLW on the site and ships some mixed LLW to Envirocare of Utah. Onsite disposal is planned in a new mixed LLW disposal facility. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for this facility is estimated to be 2 m^3/yr (2.6 yd^3/yr) or 1 percent of existing annual waste generation. The 2 m^3/yr (2.6 yd^3/yr) of mixed LLW would be less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project. Over the operating life of this facility, the 20 m^3 (26 yd^3) of mixed LLW generated would be less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex. Therefore, the management of this additional waste at INEEL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at onsite and offsite permitted facilities (UC 1998f). Hazardous waste generation for this facility is estimated to be less than 1 percent of existing annual waste generation and 1 percent of the 1,600-m^3 (2,090-yd^3) onsite storage capacity. Assuming that all the hazardous waste were to be treated at the Waste Experimental Reduction Facility, this additional waste would be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) capacity of the system. Therefore, impacts on the hazardous waste management system at INEEL should not be major.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998f). The remaining solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be less than 1 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from sinks, showers and water closets, process wastewater from lab sinks and drains, mop water, cooling tower blowdown, boiler blowdown, and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the FPF sanitary sewer that connects to the INTEC wastewater treatment system (UC 1998f). Nonhazardous liquid waste generation for this facility is estimated to be 1 percent of existing annual site waste generation, 15 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the FPF sanitary sewer system, and 1 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the INTEC Sewage Treatment Plant. Therefore, the management of this additional waste should not have a major impact on the system.

H.2.2.3 Pit Conversion and MOX Facilities

H.2.2.3.1 Construction of Pit Conversion and MOX Facilities

Table H–19 compares the expected construction waste generation rates for the facilities that may be constructed at INEEL with the existing site waste generation rates. No radioactive waste would be generated during the 3-year construction period because these facilities involve new construction and modification of uncontaminated buildings only (UC 1998e, 1998f). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–19. Potential Waste Management Impacts of Construction of Pit Conversion Facility in FPF and New MOX Facility at INEEL

	Estimated Waste Generation (m^3/yr)[b]		Site Waste	Percent of Site Waste Generation		
WasteType[a]	Pit Conversion	MOX	Generation (m^3/yr)[c]	Pit Conversion	MOX	Both Facilities
Hazardous	16	11	835	2	1	3
Nonhazardous						
Liquid	2,300	13,000	2,000,000	<1	1	1
Solid	40	820	62,000	<1	1	1

[a] See definitions in Appendix F.8.
[b] UC 1998e, 1998f.
[c] From the waste management section in Chapter 3.
Key: FPF, Fuel Processing Facility.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998e, 1998f). Hazardous waste generation for these facilities is estimated to be 3 percent of existing annual hazardous waste generation. The additional waste load generated during construction should not have a major impact on INEEL hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite recycling or disposal facilities on the site (UC 1998e, 1998f). Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Construction debris would be disposed of in the onsite INEEL landfill complex in the CFA. Nonrecyclable solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonhazardous solid waste generation for these facilities is estimated to be 1 percent of existing annual waste generation. Assuming all nonhazardous solid waste was to be disposed on the site, this additional waste would require 2 percent of the 48,000-m^3/yr (62,800-yd^3/yr) capacity in the CFA landfill complex. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers and water closets, and wastewater from dewatering (UC 1998e, 1998f). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at facilities on the site, even though it is likely that most of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous

liquid waste generation for these facilities is estimated to be 1 percent of existing annual waste generation, 9 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the FPF sanitary sewer system, and less than 1 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the INTEC Sewage Treatment Plant. Therefore, the management of this additional waste should not have a major impact on the system during construction.

H.2.2.3.2 Operation of Pit Conversion and MOX Facilities

The waste management facilities within the pit conversion and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–20 compares the expected waste generation rates from operating the new facilities at INEEL with the existing site waste generation rates. No HLW would be generated by the pit conversion and MOX facilities (UC 1998e, 1998f). Depending in part on decisions in the ROD for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage and disposal of radioactive, hazardous, and mixed wastes at INEEL are described in the *DOE Programmatic Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management Programs EIS* (DOE 1995a).

Table H–20. Potential Waste Management Impacts of Operation of Pit Conversion Facility in FPF and New MOX Facility at INEEL

	Estimated Waste Generation (m^3/yr)[b]		Site Waste	Percent of Site Waste Generation		
Waste Type[a]	Pit Conversion	MOX	Generation (m^3/yr)[c]	Pit Conversion	MOX	Both Facilities
TRU[d]	18	46	(e)	NA	NA	NA
LLW	60	34	2,624	2	1	4
Mixed LLW	1	2	180	1	1	2
Hazardous	2	<1	835	<1	<1	<1
Nonhazardous						
Liquid	41,000	25,000	2,000,000	2	1	3
Solid	1,800	<150	62,000	3	<1	3

[a] See definitions in Appendix F.8.
[b] UC 1998e, 1998f.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.

Key: FPF, Fuel Processing Facility; LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during operations include spent filters, sweepings, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap (UC 1998e, 1998f). Lead gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste (UC 1998e). TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the pit conversion and MOX facilities (UC 1998e, 1998f). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned Waste Characterization Facility at INEEL (UC 1998e). TRU waste is not routinely generated at INEEL, although 39,300 m^3 (51,400 yd^3) of contact-handled TRU waste is currently in storage.

TRU waste generation for these facilities is estimated to be 64 m^3/yr (84 yd^3/yr) or a total of 640 m^3 (837 yd^3) over the 10-year operation period. This would be 1 percent of the 6,500-m^3 (8,500-yd^3) capacity of the planned Advance Mixed Waste Treatment Project and less than 1 percent of the 177,300-m^3 (231,900-yd^3) storage capacity available at the Radioactive Waste Management Complex. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 3,000 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 900 m^2 (1,100 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at INEEL should not be major.

The 640 m^3 (837 yd^3) of TRU waste generated by these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500- m^3 (220,400-yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operation would originate from activities in the processing areas containing the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste (UC 1998e). LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for accumulation (UC 1998e, 1998f). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998e). LLW generation for these facilities is estimated to be 4 percent of existing annual waste generation, 1 percent of the 112,000-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex, and less than 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of the Radioactive Waste Management Complex. If the LLW were to be treated at the Waste Experimental Reduction Facility, the 94 m^3 (123 yd^3) of annual waste generation would be less than 1 percent of the 49,610 m^3 (64,880 yd^3) annual facility capacity. A total of 940-m^3 (1,230-yd^3) LLW would be generated over the operation period. Using the 6,264 m^3/ha (3,315 yd^3/acre) disposal land usage factor for INEEL published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 940 m^3 (1,230 yd^3) of waste would require 0.15 ha (0.37 acre) of disposal space. Therefore, impacts of the management of this additional LLW at INEEL should not be major.

Mixed LLW includes solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998e, 1998f). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for INEEL. INEEL currently treats mixed LLW on the site and ships some mixed LLW to Envirocare of Utah. Onsite disposal is planned in a new mixed LLW disposal facility. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for these facilities is estimated to be 3 m^3/yr (4 yd^3/yr), or 2 percent of existing annual waste generation, and less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project. Over the operating life of these facilities, the 30 m^3 (39 yd^3) of mixed LLW generated would be less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex. Therefore, the management of this additional waste at INEEL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operation includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at onsite and offsite permitted facilities (UC 1998e, 1998f). Hazardous waste generation for these facilities is estimated to be less than 1 percent of existing annual waste generation and 2 percent of the 1,600-m^3 (2,090-yd^3) onsite

storage capacity. Assuming that all the hazardous waste would be treated at the Waste Experimental Reduction Facility, this additional waste would be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) capacity of the system. Therefore, impacts on the hazardous waste management system at INEEL should not be major.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998e, 1998f). The remaining solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonrecyclable, nonhazardous solid waste generated by these facilities is estimated to be 3 percent of existing annual waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at INEEL.

Nonhazardous liquid waste includes sanitary waste from sinks, showers and water closets, process wastewater from lab sinks and drains, mop water, cooling tower blowdown, boiler blowdown, and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the FPF sanitary sewer that connects to the INTEC wastewater treatment system (UC 1998e, 1998f). Nonhazardous liquid waste generation for these facilities is estimated to be 3 percent of existing annual waste generation, 40 percent of the 166,000-m^3/yr (217,000-yd^3/yr) capacity of the FPF sanitary sewer system, and 2 percent of the 3.2 million-m^3/yr (4.2 million-yd^3/yr) capacity of the INTEC Sewage Treatment Plant. Therefore, management of this additional waste should not have a major impact on the system.

H.3 PANTEX

H.3.1 Assessment Data

Impacts on Pantex waste management facilities were estimated using information on existing environmental conditions from Chapter 3 and information on the characteristics of the proposed surplus plutonium disposition facilities from Chapter 2 and the facility data reports. A description of the methods used to evaluate impacts on waste management facilities is presented in Appendix F.8.

H.3.2 Facilities

H.3.2.1 Pit Conversion Facility

H.3.2.1.1 Construction of Pit Conversion Facility

Table H–21 compares the expected construction waste generation rates for the new pit conversion facility that may be constructed at Pantex with the existing generation rates for Pantex waste. No radioactive waste would be generated during the 3-year construction period because this facility involves new construction only (UC 1998g). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–21. Potential Waste Management Impacts of Construction of New Pit Conversion Facility at Pantex

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	50	486	10
Nonhazardous			
Liquid	5,300	473,125	1
Solid	120	8,007	1

[a] See definitions in Appendix F.8.
[b] UC 1998g.
[c] From the waste management section in Chapter 3.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998g). Hazardous waste generation for this facility is estimated to be 10 percent of existing annual site hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Pantex hazardous waste management system.

Nonhazardous solid waste includes office garbage, concrete and steel waste, and other trash from construction of the new facilities and concrete soil, and reinforcing steel from demolition of three existing storage bunkers. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to onsite and offsite disposal and recycling facilities. It was assumed that waste concrete would require disposal, although it is likely that this waste would be stockpiled on the site and crushed for reuse. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes (UC 1998g). Construction debris would be disposed of in the onsite Class 2 construction waste landfill.

Nonrecyclable solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonhazardous-solid-waste generation for the pit conversion facility is estimated to be 1 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers, and water closets (UC 1998g). To be conservative it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that most of this waste would be collected in portable toilets and treated and disposed of off the site. Nonhazardous liquid waste generation for this facility is estimated to be 1 percent of existing annual site waste generation, and 1 percent of the 946,250-m^3/yr (1,237,700-yd^3/yr) capacity of the sanitary wastewater treatment system. Therefore, impacts during construction should not be major.

H.3.2.1.2 Operation of Pit Conversion Facility

The waste management facilities within the pit conversion facility would process, temporarily store, and ship all wastes generated. Table H–22 compares the expected waste generation rates from operating the new facility at Pantex with the existing generation rates for Pantex waste. No HLW would be generated by the pit conversion facility (UC 1998g). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment and storage of radioactive, hazardous, mixed, and nonhazardous wastes at Pantex are described in the *Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (DOE 1996b).

Table H–22. Potential Waste Management Impacts of Operation of New Pit Conversion Facility at Pantex

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	18	(e)	NA
LLW	60	139	43
Mixed LLW	1	24	4
Hazardous	2	486	<1
Nonhazardous			
Liquid	25,000	473,125	5
Solid	1,800	8,007	22

[a] See definitions in Appendix F.8.
[b] UC 1998g.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at Pantex.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the pit conversion facility (UC 1998g). Liquid TRU wastes would be evaporated or solidified before being packaged for storage.

Because TRU wastes are not routinely generated or stored at Pantex, facilities for longer-term storage, drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP need to be developed.

TRU waste generation for this facility is estimated to be 18 m^3/yr (24 yd^3/yr). Because TRU waste is not currently stored at Pantex, storage capacity would be provided within the pit conversion facility. A maximum of approximately 180 m^3 (235 yd^3) of TRU waste may need to be stored at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), approximately 860 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 260 m^2 (310 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste in the pit conversion facility at Pantex should not be major.

The 180 m^3 (235 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be packaged, certified, and accumulated at the new facilities before being transferred for treatment and interim storage at existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for storage. Tritium recovered from pit disassembly would be disposed of as LLW. Wastes would be stored on the site on an interim basis before being shipped off the site for disposal (UC 1998g). LLW generation for this facility is estimated to be 43 percent of existing annual waste generation, but only 8 percent of the 750-m^3/yr (980-yd^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility. Therefore, impacts of the management of this additional LLW at Pantex should not be major.

Most LLW generated at Pantex is currently sent to DOE's Nevada Test Site (NTS) for disposal, although LLWs could also be sent to commercial disposal facilities or other DOE sites. If the shipment of LLW to offsite disposal were delayed, a maximum of approximately 600-m^3 (780-yd^3) LLW may need to be stored at Pantex. This is about 25 percent of the approximately 2,400 m^3 (3,140 yd^3) of existing storage capacity at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), about 2,900 drums would be required to store the additional waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 860 m^2 (1,000 yd^2) is required. Impacts of the storage of additional quantities of LLW on 0.1 ha (0.25 acre) of land at Pantex should not be major. If it were determined that a new LLW storage facility was needed, appropriate NEPA documentation would be prepared.

As stated above, a total of 600 m^3 (780 yd^3) of LLW would be generated over the operation period. Using the 6,085 m^3/ha (3,221 yd^3/acre) disposal land usage factor for NTS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 m^3 (780 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at NTS or some other similar facility. Impacts at the disposal site from the use of this small area for disposal should not be major. Impacts of disposal of LLW at NTS are described in the *Final EIS for the NTS and Off-Site Locations in the State of Nevada* (DOE 1996c).

Mixed LLW includes solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits. Mixed LLW would be stabilized,

packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Pantex. Pantex currently ships mixed LLW to Envirocare of Utah and Diversified Scientific Services, Inc. of Tennessee. These facilities or other treatment or disposal facilities that meet DOE criteria would be used (UC 1998g). Mixed LLW generation for this facility is estimated to be 1 m^3/yr (1.3 yd^3/yr) or 4 percent of existing annual waste generation and, therefore, should not have a major impact on the mixed LLW management system at Pantex.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998g). Hazardous waste generation for this facility is estimated to be less than 1 percent of existing annual site waste generation and less than 1 percent of the 750-m^3/yr (980-yd^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility and, therefore, should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to onsite and offsite disposal and recycling facilities. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998g). The remaining solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 22 percent of existing annual site waste generation. This additional waste load should have not a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, and water closets and process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and boiler blowdown. Nonhazardous wastewater would be treated, if necessary, before being discharged to the Pantex wastewater treatment system (UC 1998g). Nonhazardous liquid waste generation for this facility is estimated to be 5 percent of existing annual site waste generation and 3 percent of the 946,250-m^3/yr (1,237,700-yd^3/yr) capacity to Pantex wastewater treatment system, and therefore should not have a major impact on the system.

H.3.2.2 MOX Facility

H.3.2.2.1 Construction of MOX Facility

Table H–23 compares the expected construction waste generation rates for the new facilities that may be constructed at Pantex with the existing generation rates for Pantex waste. No radioactive waste would be generated during the 3-year construction period because this facility involves new construction only (UC 1998h). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998h). Hazardous waste generation for this facility is estimated to be 2 percent of existing annual site hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Pantex hazardous waste management system.

Table H–23. Potential Waste Management Impacts of Construction of New MOX Facility at Pantex

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	11	486	2
Nonhazardous			
Liquid	13,000	473,125	3
Solid	820	8,007	10

[a] See definitions in Appendix F.8.
[b] UC 1998h.
[c] From the waste management section in Chapter 3.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to onsite and offsite disposal and recycling facilities. It was assumed that waste concrete would require disposal, although it is likely that this waste would be stockpiled on the site and crushed for reuse. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes (UC 1998h). Construction debris would be disposed of in the onsite Class 2 construction waste landfill. Nonrecyclable solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonhazardous-solid-waste generation for the MOX facility is estimated to be 10 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers, and water closets and wastewater from dewatering (UC 1998h). To be conservative it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that most of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for this facility is estimated to be 3 percent of existing annual site waste generation, and 1 percent of the 946,250-m^3/yr (1,237,700-yd^3/yr) capacity of the sanitary wastewater treatment system. Therefore, impacts during construction should not be major.

H.3.2.2.2 Operation of MOX Facility

The waste management facilities within the MOX facility would process, temporarily store, and ship all wastes generated. Table H–24 compares the expected waste generation rates from operating the new facility at Pantex with the existing generation rates for Pantex waste. No HLW would be generated by the MOX facility (UC 1998h). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated on the site or at other DOE sites or commerical facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment and storage of radioactive, hazardous, mixed, and nonhazardous wastes at Pantex are described in the *Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (DOE 1996b).

TRU wastes generated during operations include spent filters, sweepings, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the MOX facility (UC 1998h). Liquid TRU wastes would be evaporated

Table H–24. Potential Waste Management Impacts of Operation of New MOX Facility at Pantex

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	46	(e)	NA
LLW	34	139	24
Mixed LLW	2	24	8
Hazardous	<1	486	<1
Nonhazardous			
Liquid	25,000	473,125	5
Solid	<150	8,007	2

[a] See definitions in Appendix F.8.
[b] UC 1998h.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at Pantex.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

or solidified before being packaged for storage. Because TRU wastes are not routinely generated or stored at Pantex, facilities for longer-term storage, drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP need to be developed.

TRU waste generation for this facility is estimated to be 46 m^3/yr (60 yd^3/yr). Because TRU waste is not currently stored at Pantex, storage capacity would be provided within the MOX facility. A maximum of about 460 m^3 (600 yd^3) of TRU waste may need to be stored at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), about 2,200 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 660 m^2 (790 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste in the MOX facility at Pantex should not be major.

The 460 m^3 (600 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be packaged, certified, and accumulated at the new facilities before being transferred for treatment and interim storage at existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for storage. Wastes would be stored on the site on an interim basis before being shipped off the site for disposal (UC 1998h). LLW generation for this facility is estimated to be 24 percent of existing annual waste generation and 5 percent of the 750-m^3/yr (980-yd^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility. Therefore, impacts of the management of this additional LLW at Pantex should not be major.

Most LLW generated at Pantex is currently sent to NTS for disposal, although LLWs could also be sent to commercial disposal facilities or other DOE sites. If the shipment of LLW to offsite disposal were delayed, a maximum of about 340-m^3 (445-yd^3) LLW may need to be stored at Pantex. This is about 14 percent of the

approximately 2,400 m^3 (3,140 yd^3) of existing storage capacity at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), about 1,600 drums would be required to store the additional waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 490 m^2 (590 yd^2) is required. Impacts of the storage of additional quantities of LLW on 0.1 ha (0.25 acre) of land at Pantex should not be major. If it were determined that a new LLW storage facility was needed, appropriate NEPA documentation would be prepared.

As stated above, a total of 340-m^3 (445-yd^3) LLW would be generated over the operation period. Using the 6,085-m^3/ha (3,221-yd^3/acre) disposal land usage factor for NTS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 340 m^3 (445 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at NTS or some other similar facility. Impacts on the disposal site from the use of this small area for disposal should not be major. Impacts of disposal of LLW at NTS are described in the *Final EIS for the NTS and Off-Site Locations in the State of Nevada* (DOE 1996c).

Mixed LLW includes solvents contaminated with plutonium and scintillation vials from the analytical laboratory (UC 1998h). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Pantex. Pantex currently ships mixed LLW to Envirocare of Utah and Diversified Scientific Services, Inc. of Tennessee. These facilities or other treatment or disposal facilities that meet DOE criteria would be used (UC 1998g). Mixed LLW generation for this facility is estimated to be 2 m^3/yr (2.6 yd^3/yr) or 8 percent of existing annual waste generation, and, therefore, should not have a major impact on the mixed LLW management system at Pantex.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998h). Hazardous waste generation for this facility is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 750-m^3/yr (980-yd^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility, and, therefore, should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and shipped to onsite and offsite disposal and recycling facilities. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998h). The remaining solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be less than 2 percent of existing annual site waste generation. This additional waste load should have not a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and boiler blowdown; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the Pantex wastewater treatment system (UC 1998h). Nonhazardous liquid waste generation for this facility is estimated to be 5 percent of existing annual site waste generation and 3 percent of the 946,250-m^3/yr (1,237,700-yd^3) capacity of the Pantex wastewater treatment system. Therefore, impacts on the system should not be major.

H.3.2.3 Pit Conversion and MOX Facilities

H.3.2.3.1 Construction of Pit Conversion and MOX Facilities

Table H–25 compares the expected construction waste generation rates for the new facilities that may be constructed at Pantex with the existing generation rates for Pantex waste. No radioactive waste would be generated during the 3-year construction period because these facilities involve new construction only (UC 1998g, 1998h). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–25. Potential Waste Management Impacts of Construction of New Pit Conversion and MOX Facilities at Pantex

	Estimated Waste Generation (m^3/yr)[b]		Site Waste	Percent of Site Waste Generation		
Waste Type[a]	Pit Conversion	MOX	Generation (m^3/yr)[c]	Pit Conversion	MOX	Both Facilities
Hazardous	50	11	486	10	2	13
Nonhazardous						
Liquid	5,300	13,000	473,125	1	3	4
Solid	120	820	8,007	1	10	12

[a] See definitions in Appendix F.8.
[b] UC 1998g, 1998h.
[c] From the waste management section in Chapter 3.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998g, 1998h). Hazardous waste generation for these facilities is estimated to be 13 percent of existing annual site hazardous waste generation. The additional waste load generated during construction should not have a major impact on the Pantex hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other trash from construction of the new facilities and concrete, soil, and reinforcing steel from demolition of three existing storage bunkers. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to onsite and offsite disposal and recycling facilities. It was assumed that waste concrete would require disposal although it is likely that this waste would be stockpiled on the site and crushed for reuse. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes (UC 1998g, 1998h). Construction debris would be disposed of in the onsite Class 2 construction waste landfill. Nonrecyclable solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonhazardous-solid-waste generation for these facilities is estimated to be 12 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from any sinks, showers and water closets and wastewater from dewatering (UC 1998g, 1998h). To be conservative it was assumed that all nonhazardous liquid waste generated during construction would be managed at onsite facilities, even though it is likely that most of this waste would be collected in portable toilets and would be managed at offsite facilities. Nonhazardous liquid waste generation for these facilities is estimated to be 4 percent of existing annual site waste generation and

2 percent of the 946,250-m^3/yr (1,237,700-yd^3/yr) capacity of the sanitary wastewater treatment system. Therefore, impacts during the construction period should not be major.

H.3.2.3.2 Operation of Pit Conversion and MOX Facilities

The waste management facilities within the pit conversion and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–26 compares the expected waste generation rates from operating the new facilities at Pantex with the existing generation rates for Pantex waste. No HLW would be generated by the pit conversion facility or MOX facility (UC 1998g, 1998h). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment and storage of radioactive, hazardous, mixed, and nonhazardous wastes at Pantex are described in the *Final EIS for the Continued Operation of the Pantex Plant and Associated Storage of Nuclear Weapon Components* (DOE 1996b).

Table H–26. Potential Waste Management Impacts of Operation of New Pit Conversion and MOX Facilities at Pantex

	Estimated Waste Generation (m^3/yr)[b]		Site Waste	Percent of Site Waste Generation		
Waste Type[a]	Pit Conversion	MOX	Generation (m^3/yr)[c]	Pit Conversion	MOX	Both Facilities
TRU[d]	18	46	(e)	NA	NA	NA
LLW	60	34	139	43	24	68
Mixed LLW	1	2	24	4	8	13
Hazardous	2	<1	486	<1	<1	1
Nonhazardous						
Liquid	25,000	25,000	473,125	5	5	11
Solid	1,800	<150	8,007	22	2	24

[a] See definitions in Appendix F.8.
[b] UC 1998g, 1998h.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
[e] TRU waste is not routinely generated at Pantex.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during operations include spent filters, sweepings, used containers and equipment, paper and cloth wipes, analytical and quality control samples, solidified inorganic solutions, and dirty plutonium oxide scrap (UC 1998g, 1998h). Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste (UC 1998h). TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the pit conversion facility and MOX facility (UC 1998g, 1998h). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Because TRU wastes are not routinely generated or stored at Pantex, facilities for longer-term storage, drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would need to be developed.

TRU waste generation for these facilities is estimated to be 64 m^3/yr (84 yd^3/yr). Because TRU waste is not currently stored at Pantex, storage capacity would be provided within the pit conversion and MOX facilities. A maximum of about 640 m^3 (837 yd^3) of TRU waste may need to be stored at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), about 3,000 drums

would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 900 m^2 (1,100 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste in the pit conversion and MOX facilites at Pantex should not be major.

The 640 m^3 (837 yd^3) of TRU waste generated by these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for this facility (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glove-box lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste (UC 1998g). LLW would be packaged, certified, and accumulated at the new facilities before being transferred for treatment and interim storage at existing onsite facilities. Liquid LLW would be evaporated or solidified before being packaged for storage (UC 1998g, 1998h). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998g). Wastes would be stored on the site on an interim basis before being shipped off the site for disposal (UC 1998g, 1998h). LLW generation for these facilities is estimated to be 68 percent of existing annual site waste generation, 13 percent of the 750-m^3/yr (980-m^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility, and 39 percent of the 2,400-m^3 (3,140-yd^3) LLW storage capacity.

Most LLW generated at Pantex is currently sent to NTS for disposal, although LLWs could also be sent to commercial disposal facilities or other DOE sites. If the shipment of LLW to offsite disposal were delayed, a maximum of approximately 940-m^3 (1,230-yd^3) LLW may need to be stored at Pantex. This is approximately 39 percent of the approximately 2,400 m^3 (3,140 yd^3) of existing storage capacity at Pantex. Assuming that the waste were stored in 208-l (55-gal) drums, each with a capacity of 0.21 m^3 (0.27 yd^3), approximately 4,500 drums would be required to store the additional waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of approximately 1,300 m^2 (1,700 yd^2) is required. Impacts of the storage of additional quantities of LLW on 0.13 ha (0.32 acre) of land at Pantex should not be major. If it were determined that a new LLW storage facility was needed, appropriate NEPA documentation would be prepared.

As stated above, a total of 940-m^3 (1,230-yd^3) LLW would be generated over the operation period. Using the 6,085 m^3/ha (3,221 yd^3/acre) disposal land usage factor for NTS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 940 m^3 (1,230 yd^3) of waste would require 0.15 ha (0.37 acre) of disposal space at NTS or some other similar facility. Impacts on the disposal site from the use of this small area for disposal should not be major. Impacts of disposal of LLW at NTS are described in the *Final EIS for the NTS and Off-Site Locations in the State of Nevada* (DOE 1996c).

Mixed LLW includes solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998g, 1998h). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Pantex. Pantex currently ships mixed LLW to Envirocare of Utah and Diversified Scientific Services, Inc of Tennessee. These facilities or other treatment or disposal facilities that meet DOE criteria would be used (UC 1998g). Mixed LLW generation for these facilities is estimated to be 3 m^3/yr (4 yd^3/yr) or 13 percent of existing annual site waste generation and, therefore, should not have a major impact on the mixed LLW management system at Pantex.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (UC 1998g, 1998h). Hazardous waste generation for these facilities is estimated to be 1 percent of existing annual site waste generation and less than 1 percent of the 750-m^3/yr (980-yd^3/yr) capacity of the planned Hazardous Waste Treatment and Processing Facility, and, therefore, should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, machine shop cuttings, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to onsite and offsite disposal and recycling facilities. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998g, 1998h). The remaining solid sanitary waste would be sent off the site for disposal in a local landfill such as the Amarillo landfill. Nonrecyclable, nonhazardous solid waste generated by these facilities is estimated to be less than 24 percent of existing annual site waste generation. This additional waste load should have not a major impact on the nonhazardous solid waste management system at Pantex.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and boiler blowdown; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the Pantex wastewater treatment system (UC 1998g, 1998h). Nonhazardous liquid waste generation for these facilities is estimated to be 11 percent of existing annual site waste generation and 5 percent of the 946,250-m^3/yr (1,237,700-m^3/yr) capacity of the Pantex sanitary wastewater treatment system. Therefore, impacts on the system should not be major.

H.4 SRS

H.4.1 Assessment Data

Impacts on SRS waste management facilities were estimated using information on existing environmental conditions from Chapter 3 and information on the characteristics of the proposed surplus plutonium disposition facilities from Chapter 2 and the facility data reports. A description of the methods used to evaluate impacts on waste management is presented in Appendix F.8.

H.4.2 Facilities

H.4.2.1 Pit Conversion Facility

H.4.2.1.1 Construction of Pit Conversion Facility

Table H–27 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. No radioactive waste would be generated during the 3-year construction period because this action involves new construction only (UC 1998i). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–27. Potential Waste Management Impacts of Construction of New Pit Conversion Facility at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	50	74	68
Nonhazardous			
Liquid	5,300	416,100	1
Solid	120	6,670	2

[a] See definitions in Appendix F.8.
[b] UC 1998i.
[c] From the waste management section in Chapter 3.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998i). Hazardous waste generation for construction of this facility is estimated to be 68 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and shipped to offsite facilities for recycling or disposal (UC 1998i). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this facility is estimated to be 2 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998i). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for construction of this facility is estimated to be 1 percent of existing annual site waste generation, 2 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility and, therefore, should not have a major impact on the system during construction.

H.4.2.1.2 Operation of Pit Conversion Facility

The waste management facilities within the pit conversion facility would process, temporarily store, and ship all wastes generated. Table H–28 compares the expected waste generation rates from operating the new facility at SRS with the existing site waste generation rates. No HLW would be generated by the facility (UC 1998i). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

Table H–28. Potential Waste Management Impacts of Operation of New Pit Conversion Facility at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	18	427	4
LLW	60	10,043	1
Mixed LLW	1	1,135	<1
Hazardous	2	74	3
Nonhazardous			
Liquid	25,000	416,100	6
Solid	1,800	6,670	27

[a] See definitions in Appendix F.8.
[b] UC 1998i.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facility. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS (UC 1998i).

TRU waste generation for this facility is estimated to be 4 percent of existing annual site waste generation and 1 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 180 m^3 (235 yd^3) of TRU waste would be generated over the 10-year

operation period. This would be 3 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 860 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 260 m^2 (310 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at SRS should not be major.

The 180 m^3 (235 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities. Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998i). A total of 600 m^3 (780 yd^3) of LLW would be generated over the operation period. LLW generation for this facility is estimated to be 1 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 2 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 m^3 (780 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998i). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this facility is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of this facility, the 10 m^3 (13 yd^3) of mixed LLW generated would be 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998i). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this facility is estimated to be 3 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and less than 1 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass

bottles would be sent off the site for recycling (UC 1998i). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 27 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and steam condensate. Wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998i). Nonhazardous liquid waste generation for this facility is estimated to be 6 percent of the existing annual site waste generation, 9 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 2 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility, and therefore should not have a major impact on the system.

H.4.2.2 Immobilization Facility

H.4.2.2.1 Construction of Immobilization Facility

Table H–29 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. TRU waste and LLW would be generated during the 3-year modification of Building 221–F only because all other construction would involve new buildings. No mixed LLW would be generated (UC 1998j, 1998k, 1998l, 1998m). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies and is the same for the 17-t (19-ton) and 50-t (55-ton) immobilization scenarios, although construction waste generation would be different for modification of Building 221–F and construction of new buildings (UC 1998j, 1998k, 1998l, 1998m).

Table H–29. Potential Waste Management Impacts of Construction of Immobilization Facility in Building 221–F or New Construction at SRS

	Estimated Waste Generation (m^3/yr)[b]		Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation	
Waste Type[a]	Bldg. 221–F	New		Bldg. 221–F	New
TRU[d]	50	0	427	12	NA
LLW	500	0	10,043	5	NA
Hazardous	4	11	74	5	15
Nonhazardous					
Liquid	9,200	9,800	416,100	2	2
Solid	570	1,700	6,670	9	25

[a] See definitions in Appendix F.8.
[b] UC 1998j, 1998k, 1998l, 1998m.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during modification of Building 221–F include contaminated equipment and structures, protective clothing, and radiological survey waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be packaged and certified to current WIPP waste acceptance criteria at the

construction site (UC 1998i, 1998j). Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for construction of this facility is estimated to be 12 percent of existing annual site waste generation and 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 150 m^3 (196 yd^3) of TRU waste would be generated over the construction period. This would be 2 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 710 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 210 m^2 (250 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at SRS should not be major.

The 150 m^3 (196 yd^3) of TRU waste generated by construction of this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building 221–F includes demolition debris (e.g., process piping, equipment, and structures), protective clothing, and radiological survey waste. LLW would be packaged, certified, and accumulated at the construction site before being transferred for treatment and/or disposal in existing onsite facilities. Liquid LLW from flushing equipment and decontamination activities would be collected by an existing system in Building 221–F (UC 1998j, 1998k, 1998l, 1998m). A total of 1,500-m^3 (1,960-yd^3) LLW would be generated over the construction period. LLW generation for construction is estimated to be 5 percent of existing annual site waste generation, and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,500 m^3 (1,960 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, lubricants, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998j, 1998k, 1998l, 1998m). Hazardous waste generation for construction of this facility is estimated to be 5 to 15 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998j, 1998k, 1998l, 1998m). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this facility is estimated to be 9 to 25 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Next Section

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998j, 1998k, 1998l, 1998m). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for construction of this facility is estimated to be 2 percent of existing annual site waste generation, 3 to 4 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility and therefore should not have a major impact on the system during construction.

H.4.2.2.2 Operation of Immobilization Facility

The waste management facilities within the immobilization facility would process, temporarily store, and ship all wastes generated. Table H–30 compares the expected waste generation rates from operating the new facility at SRS with the existing site waste generation rates. Although HLW would be used in the immobilization process, no HLW would be generated by the facility (UC 1998j, 1998k, 1998l, 1998m). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for the ceramic and glass immobilization technologies, although the amount of waste generated would vary between the 17-t and the 50-t immobilization cases (UC 1998j, 1998k, 1998l, 1998m). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

Table H–30. Potential Waste Management Impacts of Operation of Immobilization Facility in Building 221–F or New Construction at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b] 17 t	50 t	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation 17 t	50 t
TRU[d]	95	126	427	22	30
LLW	60	80	10,043	1	1
Mixed LLW	1	1	1,135	<1	<1
Hazardous	30	30	74	41	41
Nonhazardous					
Liquid	26,000–28,000	28,000–30,000	416,000	6 to 7	7
Solid	230	230	6,670	3	3

[a] See definitions in Appendix F.8.
[b] UC 1998j, 1998k, 1998l, 1998m.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facility (UC 1998j, 1998k, 1998l, 1998m). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography,

and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this facility is estimated to be 22 to 30 percent of existing annual site waste generation and 6 to 7 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 950 to 1,260 m^3 (1,240 to 1,648 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 14 to 18 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 3 to 4 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 4,500 to 6,000 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 1,400 to 1,800 m^2 (1,670 to 2,150 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.14 to 0.18 ha (0.35 to 0.44 acre) of land at SRS should not be major.

The 950 to 1,260 m^3 (1,240 to 1,648 yd^3) of TRU waste generated by this facility would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998j, 1998k, 1998l, 1998m). A total of 600- to 800-m^3 (780- to 1,000-yd^3) LLW would be generated over the operation period. LLW generation for this facility is estimated to be 1 percent of existing annual site waste generation, less than 2 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 1 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 600 to 800 m^3 (780 to 1,000 yd^3) of waste would require approximately 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW includes leaded shielding, solvents contaminated with plutonium, and scintillation vials from the analytical laboratory (UC 1998j, 1998k, 1998l, 1998m). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this facility is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of this facility, the 10 m^3 (13 yd^3) of mixed LLW generated would be 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubricants, oils, film processing fluids, hydraulic fluids, coolants, paints, chemicals, batteries, fluorescent light tubes, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998j, 1998k, 1998l, 1998m). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this facility is estimated to be 41 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the

Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. Ash from the coal-fired steam generating plant would be disposed of in the onsite ash disposal landfills (UC 1998j, 1998k, 1998l, 1998m). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be 3 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from cooling tower blowdown and steam condensate. Nonhazardous wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998j, 1998k, 1998l, 1998m). Nonhazardous liquid waste generation for this facility is estimated to be 6 to 7 percent of the existing annual site waste generation, 9 to 11 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 3 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility and, therefore, should not have a major impact on the system.

H.4.2.3 MOX Facility

H.4.2.3.1 Construction of MOX Facility

Table H–31 compares the expected construction waste generation rates for the facility that may be constructed at SRS with the existing site waste generation rates. No radioactive waste would be generated during the 3-year construction period because this action involves new construction only (UC 1998n). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Table H–31. Potential Waste Management Impacts From Construction of New MOX Facility at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	11	74	15
Nonhazardous			
Liquid	13,000	416,100	3
Solid	820	6,670	12

[a] See definitions in Appendix F.8.
[b] UC 1998n.
[c] From the waste management section in Chapter 3.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998n). Hazardous waste generation for

construction of this facility is estimated to be 15 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998n). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this facility is estimated to be 12 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998n). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for construction of this facility is estimated to be 3 percent of existing annual site waste generation, 5 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system during construction should not be major.

H.4.2.3.2 Operation of MOX Facility

The waste management facilities within the MOX facility would process, temporarily store, and ship all wastes generated. Table H–32 compares the expected waste generation rates from operating the new facility at SRS with the existing site waste generation rates. No HLW would be generated by the facility (UC 1998n). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with the current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facility (UC 1998n). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this combination of facilities is estimated to be 11 percent of existing annual site waste generation and 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 460 m^3 (600 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 7 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3),

Table H–32. Potential Waste Management Impacts From Operation of New MOX Facility at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	46	427	11
LLW	34	10,043	<1
Mixed LLW	2	1,135	<1
Hazardous	<1	74	1
Nonhazardous			
Liquid	25,000	416,100	6
Solid	<150	6,670	<2

[a] See definitions in Appendix F.8.
[b] UC 1998n.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

about 2,200 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 660 m^2 (790 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at SRS should not be major.

The 460 m^3 (600 yd^3) of TRU waste generated by this facility would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facility before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998n). A total of 340 m^3 (445 yd^3) of LLW would be generated over the operation period. LLW generation for this facility is estimated to be less than 1 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 1 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687-m^3/ha (4,598-yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 340 m^3 (440 yd^3) of waste would require less than 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, management of this additional LLW at SRS should have no major impact.

Mixed LLW includes solvents contaminated with plutonium, and scintillation vials from the analytical laboratory (UC 1998n). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this facility is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of this facility, the 20-m^3 (26-yd^3) mixed LLW generated would be 2 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubricants, oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998n). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this facility is estimated to be 1 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and less than 1 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage building. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998n). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this facility is estimated to be less than 2 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown and steam condensate; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998n). Nonhazardous liquid waste generation for this facility is estimated to be 6 percent of the existing annual site waste generation, 9 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 2 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system should not be major.

H.4.2.4 Pit Conversion and Immobilization Facilities

H.4.2.4.1 Construction of Pit Conversion and Immobilization Facilities

Table H–33 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. TRU waste and LLW would be generated during the 3-year modification of Building 221–F only because all other construction would involve new buildings.

No mixed LLW would be generated (UC 1998i, 1998j, 1998k, 1998l, 1998m). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies and the 17-t (19-ton) and 50-t (55-ton) immobilization scenarios, although construction waste generation is different if existing buildings need to be modified versus constructing new buildings (UC 1998j, 1998k, 1998l, 1998m).

TRU wastes generated during modification of Building 221–F include contaminated equipment and structures, protective clothing, and radiological survey waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be packaged and certified to current WIPP waste acceptance

Table H–33. Potential Waste Management Impacts of Construction of Pit Conversion Facility and Immobilization Facility in Building 221–F or New Construction at SRS

	Estimated Waste Generation (m^3/yr)[b]				Percent of Site Waste Generation				
		Immobilization (Ceramic or Glass)				Immobilization (Ceramic or Glass)		Both Facilities	
Waste Type[a]	Pit Conversion	Bldg. 221–F	New	SiteWaste Generation (m^3/yr)[c]	Pit Conversion	Bldg. 221–F	New	Bldg. 221–F	New
TRU[d]	0	50	0	427	NA	12	NA	12	NA
LLW	0	500	0	10,043	NA	5	NA	5	NA
Hazardous	50	4	11	74	68	5	15	73	82
Nonhazardous									
Liquid	5,300	9,200	9,800	416,100	1	2	2	3	4
Solid	120	570	1,700	6,670	2	9	25	10	27

[a] See definitions in Appendix F.8.
[b] UC 1998i, 1998j, 1998k, 1998l, 1998m.

[d] Includes mixed TRU waste.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

criteria at the construction site (UC 1998j, 1998k). Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this combination of facilities is estimated to be 12 percent of existing annual site waste generation and 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 150 m^3 (196 yd^3) of TRU waste would be generated over the construction period. This would be 2 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums, each with the capacity of 0.21 m^3 (0.27 yd^3), about 710 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 210 m^2 (250 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at SRS should not be major.

The 150 m^3 (196 yd^3) of TRU waste generated by construction of these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building 221–F includes demolition debris (e.g., process piping, equipment, and structures), protective clothing, and radiological survey waste. LLW would be packaged, certified, and accumulated at the construction site before being transferred for treatment and/or disposal in existing onsite facilities. Liquid LLW from flushing equipment and decontamination activities would be collected by an existing system in Building 221–F (UC 1998j, 1998k, 1998l, 1998m). A total of 1,500 m^3 (1,960 yd^3) of LLW would be generated over the construction period. LLW generation for construction is estimated to be 5 percent of existing annual site waste generation, and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,500 m^3 (1,960 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at SRS. Therefore, the management of this additional LLW at SRS should have no major impact.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Hazardous waste generation for construction of this combination of facilities is estimated to be 73 to 82 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and shipped to offsite facilities for recycling or disposal (UC 1998i, 1998j, 1998k, 1998l, 1998m). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this combination of facilities is estimated to be 10 to 27 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets (UC 1998i, 1998j, 1998k, 1998l, 1998m). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for construction of this combination of facilities is estimated to be 3 to 4 percent of existing annual site waste generation, 5 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 1 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system during construction should not be major.

H.4.2.4.2 Operation of Pit Conversion and Immobilization Facilities

The waste management facilities within the pit conversion and immobilization facilities would process, temporarily store, and ship all wastes generated. Table H–34 compares the expected waste generation rates from operating the new facilities at SRS with the existing site waste generation rates. Although HLW would be used in the immobilization process, no HLW would be generated by the facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed in accordance with current site practices. Waste generation would be the same for the ceramic and glass immobilization technologies, although the amount of waste generated would vary between the 17-t (19-ton) and 50-t (55-ton) immobilization cases (UC 1998j, 1998k, 1998l, 1998m). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, and solidified inorganic solutions. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time

Table H–34. Potential Waste Management Impacts of Operation of New Pit Conversion Facility and Immobilization Facility in Building 221–F or New Construction at SRS

	Estimated Waste Generation (m^3/yr)[b]			Site Waste	Percent of Site Waste Generation			
	Pit	Immobilization		Generation	Pit	Immobilization		Both

TRU[d]	18	95	126	427	4	22	30	26 to 34
LLW	60	60	80	10,043	1	1	1	1
Mixed LLW	1	1	1	1,135	<1	<1	<1	<1
Hazardous	2	30	30	74	3	41	41	43
Nonhazardous								
Liquid	25,000	26,000–28,000	28,000–30,000	416,100	6	6 to 7	7	12 to 13
Solid	1,800	230	230	6,670	27	3	3	30

[a] See definitions in Appendix F.8.
[b] UC 1998i, 1998j, 1998k, 1998l, 1998m.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this combination of facilities is estimated to be 26 to 34 percent of existing annual site waste generation and 7 to 8 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,130 to 1,440 m^3 (1,480 to 1,880 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 16 to 21 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 3 to 4 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 5,400 to 6,900 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 1,600 to 2,100 m^2 (1,910 to 2,510 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.16 to 0.21 ha (0.40 to 0.52 acre) of land at SRS should not be major.

The 1,130 to 1,440 m^3 (1,480 to 1,880 yd^3) of TRU waste generated by these facilities would be approximately 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998m). A total of 1,200- to 1,400-m^3 (1,570- to 1,830-yd^3) LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 1 percent of existing annual site waste generation, 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 4 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS

published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,200 to 1,400 m^3 (1,570 to 1,830 yd^3) of waste would require 0.14 to 0.16 ha (0.35 to 0.40 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW includes leaded shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998i, 1998j, 1998k, 1998l, 1998m). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this combination of facilities is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of these facilities, the 20 m^3 (26 yd^3) of mixed LLW generated would be 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this combination of facilities is estimated to be 43 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage building. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998i, 1998j, 1998k, 1998l, 1998m). Ash from the coal-fired steam generating plant would be disposed of in the onsite ash disposal landfills (UC 1998j, 1998k, 1998l, 1998m). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 30 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and steam condensate. Nonhazardous wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998i, 1998j, 1998k, 1998l, 1998m). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 12 to 13 percent of the existing annual site waste generation, 18 to 20 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 5 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system should not be major.

H.4.2.5 Pit Conversion and MOX Facilities

H.4.2.5.1 Construction of Pit Conversion and MOX Facilities

Table H–35 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. No radioactive waste would be generated because all construction would involve new buildings (UC 1998i, 1998n). In addition, no soil contaminated

Table H–35. Potential Waste Management Impacts of Construction of New Pit Conversion and MOX Facilities at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b] Pit Conversion	MOX	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation Pit Conversion	MOX	Both Facilities
Hazardous	50	11	74	68	15	82
Nonhazardous						
Liquid	5,300	13,000	416,100	1	3	4
Solid	120	820	6,670	2	12	14

[c] From the waste management section in Chapter 3.

with hazardous or radioactive constituents would be generated during the 3-year construction period. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998i, 1998n). Hazardous waste generation for construction of this combination of facilities is estimated to be 82 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and shipped to offsite facilities for recycling or disposal (UC 1998i, 1998n). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this combination of facilities is estimated to be 14 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998i, 1998n). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous-liquid-waste generation for construction of this combination of facilities is estimated to be 4 percent of existing annual site waste generation, 7 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 2 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system during construction should not be major.

H.4.2.5.2 Operation of Pit Conversion and MOX Facilities

The waste management facilities within the pit conversion and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–36 compares the expected waste generation rates from operating the new facilities at SRS with the existing site waste generation rates. No HLW would be generated by the

Table H–36. Potential Waste Management Impacts of Operation of New Pit Conversion and MOX Facilities at SRS

Key: LLW, low-level waste; TRU, transuranic.

facilities (UC 1998i, 1998n). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

TRU wastes generated during operations include spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998i, 1998n). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this combination of facilities is estimated to be 15 percent of existing annual site waste generation, and 4 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 640 m^3 (837 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 9 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 2 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 3,000 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 900 m^2 (1,100 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.1 ha (0.25 acre) of land at SRS should not be major.

The 640 m^3 (837 yd^3) of TRU waste generated by these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998i, 1998n). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998m). A total of 940-m^3 (1,230-yd^3) LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 1 percent of existing annual site waste generation, 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 3 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 940 m^3 (1,230 yd^3) of waste would require 0.11 ha (0.27 acre) of disposal space at SRS. Therefore, the management of this additional LLW at SRS should have no major impact.

Mixed LLW includes leaded shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998i, 1998n). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this combination of facilities is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of these facilities, the 30 m^3 (39 yd^3) of mixed LLW generated would be 2 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite facilities (UC 1998i, 1998n). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this combination of facilities is estimated to be 4 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 1 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage building. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998i, 1998n). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be less than 29 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and steam condensate; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998i, 1998n). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 12 percent of the existing annual site waste generation, 18 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 5 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility and,

therefore, should not have a major impact on the system. Impacts on the wastewater treatment infrastructure are evaluated in the sections that describe infrastructure impacts.

H.4.2.6 Immobilization and MOX Facilities

H.4.2.6.1 Construction of Immobilization and MOX Facilities

Table H–37 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. TRU waste and LLW would be generated during the 3-year modification of Building 221–F only because all other construction would involve new buildings. No mixed LLW would be generated (UC 1998j, 1998k, 1998l, 1998m, 1998n). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies, although construction waste generation is different if existing buildings need to be modified versus constructing new buildings (UC 1998j, 1998k, 1998l, 1998m).

Table H–37. Potential Waste Management Impacts of Construction of Immobilization Facility in Building 221–F or New Construction and New MOX Facility at SRS

	Estimated Waste Generation (m^3/yr)[b]				Percent of Site Waste Generation				
	Immobilization (Ceramic or Glass)				Immobilization (Ceramic or Glass)			Both Facilities	
Waste Type[a]	Bldg. 221–F	New	MOX	Site Waste Generation (m^3/yr)[c]	Bldg. 221–F	New	MOX	Bldg. 221–F	New
TRU[d]	50	0	0	427	12	NA	NA	12	NA
LLW	500	0	0	10,043	5	NA	NA	5	NA
Hazardous	4	11	11	74	5	15	15	20	30
Nonhazardous									
Liquid	9,200	9,800	13,000	416,100	2	2	3	5	5
Solid	570	1,700	820	6,670	9	25	12	21	38

[a] See definitions in Appendix F.8.
[b] UC 1998j, 1998k, 1998l, 1998m, 1998n.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during modification of Building 221–F include contaminated equipment and structures, protective clothing, and radiological survey waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be packaged and certified to current WIPP waste acceptance criteria at the construction site (UC 1998j, 1998k). Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS. TRU waste generation for this combination of facilities is estimated to be 12 percent of existing annual site waste generation and 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 150 m^3 (196 yd^3) of TRU waste would be generated over the construction period. This would be 2 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 710 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 210 m^2 (250 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at SRS should not be major.

The 150 m^3 (196 yd^3) of TRU waste generated by construction of these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building 221–F includes demolition debris (e.g., process piping, equipment, and structures), protective clothing, and radiological survey waste. LLW would be packaged, certified, and accumulated at the construction site before being transferred for treatment and/or disposal in existing onsite facilities. Liquid LLW from flushing equipment and decontamination activities would be collected by an existing system in Building 221–F (UC 1998j, 1998k, 1998l, 1998m). A total of 1,500-m^3 (1,960-yd^3) LLW would be generated over the construction period. LLW generation during construction is estimated to be 5 percent of existing annual site waste generation, and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,500 m^3 (1,960 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at SRS. Therefore, the management of this additional LLW at SRS should have no major impact.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998j, 1998k, 1998l, 1998m, 1998n). Hazardous waste generation for construction of this combination of facilities is estimated to be 20 to 30 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and shipped to offsite facilities for recycling or disposal (UC 1998j, 1998k, 1998l, 1998m, 1998n). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling and, therefore, were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of this combination of facilities is estimated to be 21 to 38 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998j, 1998k, 1998l, 1998m, 1998n). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation for construction of this combination of facilities is estimated to be 5 percent of existing annual site waste generation, 8 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 2 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system during construction should not be major.

H.4.2.6.2 Operation of Immobilization and MOX Facilities

The waste management facilities within the immobilization and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–38 compares the expected waste generation rates from operating

Table H–38. Potential Waste Management Impacts of Operation of Immobilization Facility in Building 221–F or New Construction and New MOX Facility at SRS

	Estimated Waste Generation (m^3/yr)[b]		Site Waste	Percent of Site Waste Generation		
Waste Type[a]	Immobilization (Ceramic or Glass)	MOX	Generation (m^3/yr)[c]	Immobilization (Ceramic or Glass)	MOX	Both Facilities
TRU[d]	95	46	427	22	11	33
LLW	60	34	10,043	1	<1	1
Mixed LLW	1	2	1,135	<1	<1	<1
Hazardous	30	<1	74	41	1	42
Nonhazardous						
Liquid	26,000–28,000	25,000	416,100	6 to 7	6	12 to 13
Solid	230	<150	6,670	3	2	6

[a] See definitions in Appendix F.8.
[b] UC 1998j, 1998k, 1998l, 1998m, 1998n.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

the new facilities at SRS with the existing site waste generation. Although HLW would be used in the immobilization process, no HLW would be generated by the facilities (UC 1998j, 1998k, 1998l, 1998m, 1998n). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed in accordance with current site practices. Waste generation would be the same for the ceramic and glass immobilization technologies (UC 1998j, 1998k, 1998l, 1998m). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998j, 1998k, 1998l, 1998m, 1998n). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS. TRU waste generation for this combination of facilities is estimated to be 33 percent of existing annual site waste generation and 8 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,410 m^3 (1,840 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 20 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and 4 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 6,700 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 2,000 m^2 (2,400 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.20 ha (0.49 acre) of land at SRS should not be major.

The 1,410 m^3 (1,840 yd^3) of TRU waste generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3

(220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, and solidified inorganic solutions. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998j, 1998k, 1998l, 1998m, 1998n). A total of 940-m^3 (1,230-yd^3) LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 1 percent of existing annual site waste generation, 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 3 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 940-m^3 (1,230-yd^3) waste would require 0.11 ha (0.27 acre) of disposal space at SRS. Therefore, impacts of the management of this additional LLW at SRS should not be major.

Mixed LLW includes lead shielding, solvents contaminated with plutonium, and scintillation vials from the analytical laboratory (UC 1998j, 1998k, 1998l, 1998m, 1998n). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this combination of facilities is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of these facilities, the 30-m^3 (39-yd^3) mixed LLW generated would be 2 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, lubricants, oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998j, 1998k, 1998l, 1998m, 1998n). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this combination of facilities is estimated to be 42 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998j, 1998k, 1998l, 1998m, 1998n). Ash from the coal-fired steam generating plant would be disposed of in the onsite ash disposal landfills (UC 1998j, 1998k, 1998l, 1998m). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be less than 6 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and steam condensate; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if

necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998j, 1998k, 1998l, 1998m, 1998n). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 12 to 13 percent of the existing annual site waste generation, 18 to 19 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 5 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility, and therefore should not have a major impact on the system.

H.4.2.7 Pit Conversion, Immobilization, and MOX Facilities

H.4.2.7.1 Construction of Pit Conversion, Immobilization, and MOX Facilities

Table H–39 compares the expected construction waste generation rates for the facilities that may be constructed at SRS with the existing site waste generation rates. TRU waste and LLW would be generated during the 3-year modification of Building 221–F only because all other construction would involve new buildings.

Table H–39. Potential Waste Management Impacts of Construction of New Pit Conversion and MOX Facilities and Immobilization Facility in Building 221–F or New Construction at SRS

	Estimated Waste Generation (m^3/yr)[b]					Percent of Site Waste Generation					
		IF (Ceramic or Glass)			Site Waste Generation		IF (Ceramic or Glass)			All Facilities	
Waste Type[a]	PCF	221–F	New	MOX	(m^3/yr)[c]	PCF	221–F	New	MOX	221–F	New
TRU[d]	0	50	0	0	427	NA	12	NA	NA	12	NA
LLW	0	500	0	0	10,043	NA	5	NA	NA	5	NA
Hazardous	50	4	11	11	74	68	5	15	15	88	97
Nonhazardous											
Liquid	5,300	9,200	9,800	13,000	416,100	1	2	2	3	7	7
Solid	120	570	1,700	820	6,670	2	9	25	12	23	40

[a] See definitions in Appendix F.8.
[b] UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: IF, immobilization facility; LLW, low-level waste; NA, not applicable; PCF, pit conversion facility; TRU, transuranic.

No mixed LLW would be generated (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). In addition, no soil contaminated with hazardous or radioactive constituents would be generated during construction. However, if any were generated, the waste would be managed in accordance with site practice and all applicable Federal and State regulations. Construction waste generation would be the same for the ceramic and glass immobilization technologies, although construction waste generation is different if existing buildings need to be modified versus constructing new buildings (UC 1998j, 1998k, 1998l, 1998m).

TRU wastes generated during modification of Building 221–F include contaminated equipment and structures, protective clothing, and radiological survey waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be packaged and certified to current WIPP waste acceptance criteria at the construction site (UC 1998j, 1998k). Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for modification of Building 221–F is estimated to be 12 percent of existing annual site waste generation, and 3 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste

Characterization and Certification Facility. A total of 150 m^3 (196 yd^3) of TRU waste would be generated over the construction period. This would be 2 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 710 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 210 m^2 (250 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at SRS should not be major.

The 150 m^3 (196 yd^3) of TRU waste generated by construction of these facilities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building 221–F includes demolition debris (e.g., process piping, equipment, and structures), protective clothing and radiological survey waste. LLW would be packaged, certified, and accumulated at the construction site before being transferred for treatment and/or disposal in existing onsite facilities. Liquid LLW from flushing equipment and decontamination activities would be collected by an existing system in Building 221–F (UC 1998j, 1998k, 1998l, 1998m). A total of 1,500-m^3 (1,960-yd^3) of LLW would be generated over the construction period. LLW generation for construction is estimated to be 5 percent of existing annual site waste generation, and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,500 m^3 (1,960 yd^3) of waste would require 0.17 ha (0.42 acre) of disposal space at SRS. Therefore, the management of this additional LLW at SRS should have no major impact.

Hazardous waste generated during construction includes liquids such as spent cleaning solutions, lubricants, oils, hydraulic fluids, antifreeze solutions, paints and chemicals, and rags or wipes contaminated with these materials. These wastes are typically generated during construction of an industrial facility. Any hazardous waste generated during construction would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m). Hazardous waste generation for construction of this combination of facilities is estimated to be 88 to 97 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste includes office garbage, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal (UC 1998i, 1998j, 1998k, 1998l, 1998m). Nonrecyclable solid sanitary waste would be sent off the site for disposal. Waste metals would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonhazardous-solid-waste generation during construction of these facilities is estimated to be 23 to 40 percent of existing annual site waste generation. The additional waste load generated during construction should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets and wastewater from dewatering (UC 1998i, 1998j, 1998k, 1998l, 1998m). To be conservative, it was assumed that all nonhazardous liquid waste generated during construction would be managed at the Central Sanitary Wastewater Treatment Facility, even though it is likely that much of this waste would be collected in portable toilets and managed at offsite facilities. Nonhazardous liquid waste generation during construction of these facilities is estimated to be 7 percent of existing annual site waste generation, 10 percent of the 276,000-m^3/yr

(361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 3 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility, and therefore should not have a major impact on the system during construction.

H.4.2.7.2 Operation of Pit Conversion, Immobilization, and MOX Facilities

The waste management facilities within the pit conversion, immobilization, and MOX facilities would process, temporarily store, and ship all wastes generated. Table H–40 compares the expected waste generation rates from operating the new facilities at SRS with the existing site waste generation rates. Although HLW would be used in the immobilization process, no HLW would be generated by the facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that the LLW, mixed LLW, hazardous waste, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Waste generation would be the same for the ceramic and glass immobilization technologies (UC 1998j, 1998k, 1998l, 1998m). Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

Table H–40. Potential Waste Management Impacts of Operation of New Pit Conversion and MOX Facilities and Immobilization Facility in Building 221–F or New Construction at SRS

	Estimated Waste Generation (m^3/yr)[b]			Site Waste	Percent of Site Waste Generation			
		Immobilization		Generation		Immobilization		All
Waste Type[a]	PCF	(Ceramic or Glass)	MOX	(m^3/yr)[c]	PCF	(Ceramic or Glass)	MOX	Facilities
TRU[d]	18	95	46	427	4	22	11	37
LLW	60	60	34	10,043	1	1	<1	2
Mixed LLW	1	1	2	1,135	<1	<1	<1	<1
Hazardous	2	30	<1	74	3	41	1	45
Nonhazardous								
Liquid	25,000	26,000–28,000	25,000	416,100	6	6 to 7	6	18 to 19
Solid	1,800	230	<150	6,670	27	3	2	33

[a] See definitions in Appendix F.8.
[b] UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; NA, not applicable; PCF, pit conversion facility; TRU, transuranic.

TRU wastes generated during operations include metal cladding from fuel elements, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality-control samples, solidified inorganic solutions, and dirty plutonium oxide scrap. Lead-lined gloves are likely to be managed as mixed TRU waste. It is anticipated that all TRU waste would be contact-handled waste. TRU wastes would be treated, packaged, and certified to WIPP waste acceptance criteria at the new facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for this combination of facilities is estimated to be 37 percent of existing annual site waste generation and 9 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 1,590 m^3 (2,080 yd^3) of TRU waste would be generated over the 10-year operation period. This would be 23 percent of the 6,977 m^3 (9,126 yd^3) of contact-handled

TRU waste currently in storage, and 5 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS. Assuming that the waste were stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 7,600 drums would be required to store this waste. Assuming that these drums can be stacked two high, that each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space, a storage area of about 2,300 m^2 (2,750 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on 0.23 ha (0.57 acre) of land at SRS should not be major.

The 1,590 m^3 (2,080 yd^3) of TRU waste generated by these facilities would be 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500 m^3 (220,400 yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW includes used equipment, wipes, protective clothing, solidified inorganic solutions, and tritium. It is likely that the LLW generated during operations would originate from activities in the processing areas containing the glovebox lines but not from operations within the gloveboxes. Operations within the gloveboxes are likely to generate mostly TRU waste. LLW would be treated, packaged, certified, and accumulated at the new facilities before being transferred for additional treatment and/or disposal in existing onsite facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Tritium recovered from pit disassembly would be disposed of as LLW (UC 1998i). A total of 1,540-m^3 (2,010-yd^3) LLW would be generated over the operation period. LLW generation for this combination of facilities is estimated to be 2 percent of existing annual site waste generation, 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 5 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687 m^3/ha (4,598 yd^3/acre) disposal land usage factor for SRS published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 1,540 m^3 (2,010 yd^3) of waste would require 0.18 ha (0.42 acre) of disposal space at SRS. Therefore, the management of this additional LLW at SRS should have no major impact.

Mixed LLW includes leaded shielding, solvents contaminated with plutonium, scintillation vials from the analytical laboratory, and hazardous constituents that were introduced as part of the incoming pits (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Mixed LLW would be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for this combination of facilities is estimated to be less than 1 percent of existing annual site waste generation, and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of these facilities, the 40 m^3 (52 yd^3) of mixed LLW generated would be 2 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations includes spent cleaning solutions, vacuum pump oils, film processing fluids, hydraulic fluids, antifreeze solutions, paints, chemicals, batteries, fluorescent light tubes, lead packaging, and contaminated rags or wipes. Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Assuming that all hazardous waste is managed on the site, hazardous waste generation for this combination of facilities is estimated to be 45 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 6 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste includes office garbage, coal ash, machine shop waste, and other industrial wastes from utility and maintenance operations. Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Ash from the coal-fired steam generating plant would be disposed of in the onsite ash disposal landfills (UC 1998j, 1998k, 1998l, 1998m). The remaining solid sanitary waste would be sent off the site for disposal. Nonrecyclable, nonhazardous solid waste generated by this combination of facilities is estimated to be 33 percent of existing annual site waste generation. This additional waste load should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets; process wastewater from lab sinks and drains, mop water, cooling tower blowdown, and steam condensate; and treated wastewater from the liquid effluent treatment system. Nonhazardous wastewater would be treated, if necessary, before being discharged to the F-Area sanitary sewer system that connects to the Central Sanitary Wastewater Treatment Facility (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). Nonhazardous liquid waste generation for this combination of facilities is estimated to be 18 to 19 percent of the existing annual site waste generation, 28 percent of the 276,000-m^3/yr (361,000-yd^3/yr) capacity of the F-Area sanitary sewer, and 7 to 8 percent of the 1.03 million-m^3/yr (1.35 million-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system should not be major.

Next Section

H.5 LEAD ASSEMBLY FABRICATION

This section describes the impacts on the waste management infrastructure that may occur if lead assembly fabrication were to occur at ANL–W, Hanford, LLNL, LANL, or SRS. For each site, separate sections are presented for construction and operations.

H.5.1 ANL–W

H.5.1.1 Construction

Wastes would be generated during modification of the Fuel Manufacturing Facility (FMF) and the Zero Power Physics Reactor (ZPPR) for lead assembly fabrication. Table H–41 compares the expected waste generation rates for the modification of facilities at ANL–W with the existing generation rates for INEEL waste. LLW would be generated during modification of contaminated areas of FMF and ZPPR, although no TRU waste, mixed waste, or hazardous wastes should be generated (O'Connor et al. 1998a).

Table H–41. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at ANL–W

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
LLW	18	2,624	1
Nonhazardous			
Liquid	37	2,000,000	<1
Solid	11	62,000	<1

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998a.
[c] From the waste management section in Chapter 3; waste generation rates for INEEL.
Key: ANL–W, Argonne National Laboratory–West; LLW, low-level waste.

LLW generated during modification of the FMF and ZPPR buildings would include used equipment, decontamination wastes, and protective clothing (O'Connor et al. 1998a). A total of 36 m^3 (47 yd^3) of LLW would be generated during the 2-year modification period. LLW generation for these activities is estimated to be 1 percent of existing annual waste generation, less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the Radioactive Waste Management Complex (RWMC), and less than 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of RWMC. Using the 6,264-m^3/ha (3,315 yd^3/acre) disposal land usage factor for RWMC published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 36 m^3 (47 yd^3) of waste would require less than 0.1 ha (0.25 acre) of disposal space at INEEL. Therefore, impacts of the management of this additional LLW at ANL–W and INEEL should not be major.

Nonhazardous solid waste would include office garbage, construction debris, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice, and would be disposed of in the onsite CFA landfill complex or shipped to offsite facilities for recycling. Nonrecyclable nonhazardous solid waste generated during modification is estimated to be less than 1 percent of existing annual site waste generation and less than 1 percent of the 48,000-m^3/yr (62,800-yd^3/yr) capacity of the CFA landfill complex. The additional waste load generated during the modification period should not have a major impact on the nonhazardous solid waste management system at ANL–W or INEEL.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals, and water closets. To be conservative, it was assumed that all nonhazardous liquid waste generated during modification would be

managed at the ANL–W sanitary wastewater treatment facility. Nonhazardous liquid waste generation for modification is estimated to be less than 1 percent of the existing annual waste generation for the INEEL, and 1 percent of the 6,057-m^3/yr (7,923-yd^3/yr) capacity of the ANL–W sanitary wastewater treatment facility. Therefore, this waste load should not have a major impact on the ANL–W sanitary wastewater treatment system.

H.5.1.2 Operations

Table H–42 compares the expected waste generation rates from lead assembly fabrication at ANL–W with the existing INEEL waste generation rates. No HLW would be generated by the proposed activities. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. This SPD EIS also assumes that LLW, mixed LLW, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at ANL–W and INEEL are described in the *DOE Programmatic Spent Nuclear Fuel Management and INEL Environmental Restoration and Waste Management Final EIS* (DOE 1995a).

Table H–42. Potential Waste Management Impacts of Operation of Facilities for Lead Assembly Fabrication at ANL–W

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	41	NA	NA
LLW	200	2,624	8
Mixed LLW	1	180	1
Hazardous	<1	835	<1
Nonhazardous			
Liquid	1,600	2,000,000	<1
Solid	1,300	62,000	2

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998a.
[c] From the waste management section in Chapter 3; waste generation rates for INEEL.
[d] Includes mixed TRU waste.
Key: ANL–W, Argonne National Laboratory–W; LLW, low-level waste; NA, not applicable; TRU, transuranic.

TRU wastes generated during lead assembly fabrication would include glovebox gloves, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, metallography waste, and sludges (O'Connor et al. 1998a). It is anticipated that all TRU waste would be contact-handled waste. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Long-term storage, drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned Waste Characterization Facility at INEEL. TRU waste is not routinely generated at INEEL.

TRU waste generation for these activities at ANL–W is estimated to be 41 m^3/yr (54 yd^3/yr), or 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) capacity of the planned Advanced Mixed Waste Treatment Project. A total of 132 m^3 (173 yd^3) of waste would be generated over the 3-year operation period. This would be less than 1 percent of the 39,300 m^3 (51,404 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 177,300-m^3 (231,908-yd^3) storage capacity available at INEEL.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW may include room trash (e.g., blotter paper, wipes, mop heads); protective clothing; solidified sludges; ion exchange resins; metal cans and rods; and wastewater from the laundry, analytical laboratory, and decontamination process (O'Connor et al. 1998a). LLW would be packaged, certified, and accumulated before being transferred for treatment and disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generation for these activities is estimated to be 8 percent of existing annual site waste generation, less than 1 percent of the 49,610-m^3/yr (64,880-yd^3/yr) capacity of the WERF, 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at the RWMC, and 1 percent of the 37,700-m^3/yr (49,300-yd^3/yr) disposal capacity of the RWMC. Using the 6,264-m^3/ha (3,315 yd^3/acre) disposal land usage factor for the RWMC published in the *Storage and Disposition Final PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.11 ha (0.27 acre) of disposal space at INEEL. Therefore, impacts of the management of this additional LLW at ANL–W and INEEL should not be major.

Mixed LLW may include sludges, cleaning solvents, and analytical waste (O'Connor et al. 1998a). Mixed LLW will be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for ANL–W. INEEL currently treats mixed LLW onsite and ships some mixed LLW to Envirocare of Utah. Onsite disposal is planned in a new mixed LLW disposal facility. These facilities or other treatment or disposal facilities that meet DOE criteria would be used. Mixed LLW generation for these activities is estimated to be 1 percent of existing annual waste generation and less than 1 percent of the 6,500-m^3/yr (8,500-yd^3/yr) planned capacity of the Advanced Mixed Waste Treatment Project. The 4 m^3 (5.2 yd^3) of mixed LLW expected to be generated would be less than 1 percent of the 112,400-m^3 (147,000-yd^3) storage capacity at RWMC. Therefore, the management of this additional waste at ANL–W and INEEL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations would include small quantities of process ends. Hazardous waste would be packaged for treatment and disposal at onsite and offsite permitted facilities (O'Connor et al. 1998a). Hazardous waste generation for these activities is estimated to be less than 1 percent of existing annual waste generation and less than 1 percent of the 1,600-m^3 (2,090-yd^3) onsite storage capacity. Assuming that all the hazardous waste was to be treated at the Waste Experimental Reduction Facility, this additional waste would be less than 1 percent of the 49,610-m^3/yr (64,890-yd^3/yr) capacity of the system, and therefore should not have a major impact on the hazardous waste management system at ANL–W or INEEL.

Nonhazardous solid waste would include office and lunch room garbage, packaging materials, sewage sludges, and other industrial wastes from utility and maintenance operations (O'Connor et al. 1998a). Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site for disposal in the Bonneville County landfill. Nonrecyclable, nonhazardous solid waste generated by these activities is estimated to be 2 percent of existing annual site waste generation. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at ANL–W or INEEL.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals and water closets, and wastewater from cooling tower blowdown (O'Connor et al. 1998a). Nonhazardous liquid waste generation for these activities is estimated to be less than 1 percent of the existing annual waste generation for INEEL and 26 percent of the 6,057-m^3/yr (7,923-yd^3/yr) capacity of the ANL–W sanitary wastewater treatment facility.

Therefore, this additional waste should not have a major impact on the ANL–W sanitary wastewater treatment system.

H.5.2 Hanford

H.5.2.1 Construction

Table H–43 compares the expected waste generation rates for the modification of Hanford facilities for lead assembly fabrication with the existing generation rates for Hanford waste. No radioactive waste would be generated during modification because this action involves modification of uncontaminated buildings only (O'Connor et al. 1998b).

Table H–43. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Nonhazardous			
Liquid	15	200,000	<1
Solid	50	43,000	<1

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998b.
[c] Taken from the waste management section in Chapter 3.

Nonhazardous solid waste includes office garbage, construction debris, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Richland Sanitary Landfill. Nonrecyclable nonhazardous solid waste generated during modification is estimated to be less than 1 percent of existing annual waste generation. The additional waste load generated during the 2-year modification period should not have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets. To be conservative, it was assumed that all nonhazardous liquid waste generated during modification would be managed at onsite facilities. Nonhazardous liquid waste generated during modification is estimated to be less than 1 percent of existing annual site waste generation, less than 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and less than 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, this waste load is unlikely to have a major impact on the system during the modification period.

H.5.2.2 Operations

Table H–44 compares the expected waste generation rates from lead assembly fabrication at Hanford with the existing site waste generation rates. No HLW would be generated during lead assembly fabrication. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, and nonhazardous waste

Table H–44. Potential Waste Management Impacts of Operation of Facilities for Lead Assembly Fabrication at Hanford

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	41	450	9
LLW	200	3,902	5
Mixed LLW	1	847	<1
Hazardous	<1	560	<1
Nonhazardous			
Liquid	1,600	200,000	1
Solid	1,300	43,000	3

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998b.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste
Key: LLW, low-level waste; TRU, transuranic.

would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at Hanford are being evaluated in the *Hanford Site Solid (Radioactive and Hazardous) Waste Programs EIS* that is being prepared by the DOE Richland Operations Office (DOE 1997c).

TRU wastes generated during operations would include glovebox gloves, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, metallography waste, and sludges (O'Connor et al. 1998b). It is anticipated that all TRU waste would be contact-handled waste. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at the Waste Receiving and Processing Facility at Hanford.

TRU waste generation for these activities is estimated to be 9 percent of existing annual site waste generation and 2 percent of the 1,820-m^3/yr (2,380-yd^3/yr) planned capacity of the Waste Receiving and Processing Facility. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. This would be 1 percent of the 11,450 m^3 (14,977 yd^3) of contact-handled TRU waste currently in storage and 1 percent of the 17,000-m^3 (22,200-yd^3) storage capacity available at Hanford.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW may include room trash (e.g., blotter paper, wipes, mop heads); protective clothing; solidified sludges; ion exchange resins; metal cans and rods; and wastewater from the laundry, analytical laboratory, and decontamination process (O'Connor et al. 1998b). LLW would be packaged, certified, and accumulated before being transferred for treatment and disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generation for these activities is estimated to be 5 percent of existing annual site waste generation, less than 1 percent of the 1,740,000-m^3 (2,280,000-yd^3) disposal capacity of the LLW Burial Grounds, and less than 1 percent of the 230,000-m^3 (301,000-yd^3) capacity of the Grout Vaults. Using the 3,480-m^3/ha (1,842-yd^3/acre) disposal land usage factor for Hanford published in the *Final Storage and Disposition PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would

require 0.2 ha (0.49 acre) of disposal space at Hanford. Therefore, impacts of the management of this additional LLW at Hanford should not be major.

Mixed LLW may include sludges, cleaning solvents, and analytical waste (O'Connor et al. 1998b). Mixed LLW will be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for Hanford. Mixed LLW generation for these activities is estimated to be less than 1 percent of existing annual waste generation and less than 1 percent of the 1,820-m^3/yr (2,380-yd^3/yr) capacity of the Waste Receiving and Processing Facility. Over the operating life of this facility, the 4 m^3 (5.2 yd^3) of mixed LLW expected to be generated would be less than 1 percent of the 16,800-m^3 (21,970-yd^3) storage capacity of the Central Waste Complex and less than 1 percent of the 14,200 m^3 (18,600-yd^3) disposal capacity in the Radioactive Mixed Waste Disposal Facility. Therefore, the management of this additional waste at Hanford should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations would include small quantities of process ends. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (O'Connor et al. 1998b). Hazardous waste generation for these activities is estimated to be less than 1 percent of existing annual waste generation. These wastes should not have a major impact on the hazardous waste management system at Hanford.

Nonhazardous solid waste would include office and lunch room garbage, packaging materials, sewage sludges, and other industrial wastes from utility and maintenance operations (O'Connor et al. 1998b). Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site for disposal in the Richland Sanitary Landfill. Nonrecyclable, nonhazardous solid waste generated by these activities is estimated to be 3 percent of existing annual site waste generation. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at Hanford.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals and water closets, and wastewater from cooling tower blowdown (O'Connor et al. 1998b). Nonhazardous liquid waste generation for these activities is estimated to be 1 percent of the existing annual site waste generation, 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the 400 Area sanitary sewer, and 1 percent of the 235,000-m^3/yr (307,000-yd^3/yr) capacity of the WPPSS Sewage Treatment Facility. Therefore, this additional waste load should not have a major impact on the system.

H.5.3 LLNL

H.5.3.1 Construction

Table H–45 compares the expected waste generation rates for the modification of LLNL facilities for lead assembly fabrication with the existing generation rates for LLNL waste. No radioactive waste would be generated during modification because this action involves modification of uncontaminated buildings only (O'Connor et al. 1998c).

Nonhazardous solid waste includes office garbage, construction debris, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite facilities for recycling or disposal. Waste metals and other recyclable solid wastes would be sent off the site for recycling, and therefore were not included in the waste volumes. Nonrecyclable solid sanitary waste would be sent off the site and would likely be disposed of in the Vasco

Table H–45. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at LLNL

WasteType[a]	Estimated Waste Generation (m^3/yr) [b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Nonhazardous			
Liquid	17	456,000	<1
Solid	12	4,282	<1

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998c.
[c] From the waste management section in Chapter 3.

Road Landfill. Nonrecyclable nonhazardous solid waste generated during modification is estimated to be 1 percent of existing annual waste generation. The additional waste load generated during the 2-year modification period should not have major impact on the nonhazardous solid waste management system at LLNL.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals, and water closets. To be conservative, it was assumed that all nonhazardous liquid waste generated during modification would be discharged to the LLNL sewer system. Nonhazardous liquid waste generated during modification is estimated to be less than 1 percent of existing annual site waste generation and less than 1 percent of the 2,763,271-m^3/yr (3,614,358-yd^3/yr) capacity of the LLNL sanitary sewer, and therefore is unlikely to have a major impact on the LLNL sewer system or the city of Livermore Water Reclamation Plant during the modification period.

H.5.3.2 Operations

Table H–46 compares the expected waste generation rates from lead assembly fabrication at LLNL with the existing site waste generation rates. No HLW would be generated during lead assembly fabrication. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment and storage of radioactive, hazardous, and mixed wastes at LLNL are described in the *Final EIS Continued Operation of LLNL and SNL-Livermore* (DOE 1992).

TRU wastes generated during operations would include glovebox gloves, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, metallography waste, and sludges (O'Connor et al. 1998c). It is anticipated that all TRU waste would be contact-handled waste. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LLNL facilities.

TRU waste generation for these activities is estimated to be 152 percent of existing annual site waste generation. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. This would be 51 percent of the 257 m^3 (336 yd^3) of contact-handled TRU waste currently in storage, and 4 percent of the 3,335 m^3 (4,362 yd^3) of onsite storage capacity. Assuming that the waste is stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 630 drums would be needed to store this waste. Assuming that these drums can be stacked two high, each drum occupies an area of 0.4 m^2 (4 ft^2), and

Table H–46. Potential Waste Management Impacts of Operation of Facilities for Lead Assembly Fabrication at LLNL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	41	27	152
LLW	200	124	161
Mixed LLW	1	353	<1
Hazardous	<1	579	<1
Nonhazardous			
Liquid	1,600	456,000	<1
Solid	1,300	4,282	30

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998c.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste
Key: LLW, low-level waste; TRU, transuranic.

adding a 50 percent factor for aisle space and shipping and receiving space, a storage area of about 190 m^2 (227 yd^2) would be required. Impacts of the storage of additional quantities of TRU waste on less than 0.1 ha (0.25 acre) of land at LLNL should not be major.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW may include room trash (e.g., blotter paper, wipes, mop heads); protective clothing; solidified sludges; ion exchange resins; metal cans and rods; and wastewater from the laundry, analytical laboratory, and decontamination process (O'Connor et al. 1998c). LLW would be packaged, certified, and accumulated before being transferred for treatment and storage in existing facilities on the site. LLW generation for these activities is estimated to be 161 percent of existing annual site waste generation and 26 percent of the 771-m^3/yr (1,008-yd^3/yr) capacity of the size reduction facility. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. This would be 13 percent of the 5,255-m^3 (6,874-yd^3) onsite storage capacity, and would not be expected to require LLNL to build additional storage capacity because this waste would be shipped to a disposal facility on a routine basis. If additional storage space were required, and assuming that the waste is stored in 208-l (55-gal) drums each with a capacity of 0.21 m^3 (0.27 yd^3), about 3,300 drums would be needed to store this waste. Assuming that these drums can be stacked two high, each drum occupies an area of 0.4 m^2 (4 ft^2), and adding a 50 percent factor for aisle space and shipping and receiving space, a storage area of about 1,000 m^2 (1,196 yd^2) would be required. Impacts of the storage of additional quantities of LLW on 0.1 ha (0.25 acre) of land at LLNL should not be major.

LLW from LLNL is currently shipped to NTS for disposal. The additional LLW from conduct of lead assembly fabrication at LLNL would be 4 percent of the 20,000 m^3 (26,000 yd^3) of LLW disposed at NTS in 1995 and less than 1 percent of the 500,000-m^3 (650,000-yd^3) disposal capacity at NTS. Using the 6,085-m^3/ha (3,221-yd^3/acre) disposal land usage factor for NTS published in the *Final Storage and Disposition PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.12 ha (0.30 acre) of disposal space at NTS or a similar facility. Therefore, impacts of the management of this additional LLW at the disposal site should not be major. Impacts of disposal of LLW at NTS are described in the *Final EIS for the NTS and Off-Site Locations in the State of Nevada* (DOE 1996c).

Mixed LLW may include sludges, cleaning solvents, and analytical waste (O'Connor et al. 1998c). Mixed LLW will be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for LLNL. Mixed LLW disposal would occur off the site. Mixed LLW generation for these activities is estimated to be less than 1 percent of existing annual waste generation and less than 1 percent of the 1,000-m^3/yr (1,310-yd^3/yr) capacity of the Building 513 and 514 Waste Treatment Facility. Over the operating life of this facility, the 4 m^3 (5.2 yd^3) of mixed LLW expected to be generated would be less than 1 percent of the 2,825-m^3 (3,695-yd^3) onsite storage capacity. Therefore, the management of this additional waste at LLNL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations would include small quantities (< 1 m^3/yr [< 1.3 yd^3/yr]) of process ends. Hazardous waste would be treated and packaged for disposal at offsite permitted commercial facilities (O'Connor et al. 1998c). Hazardous waste generated by these activities is estimated to be less than 1 percent of existing annual waste generation, less than 1 percent of the 1,000-m^3/yr (1,310-yd^3/yr) capacity of the Building 513 and 514 Waste Treatment Facility, and less than 1 percent of the 2,825-m^3 (3,695-yd^3) hazardous waste storage capacity. Because the additional waste load is very small, management of this waste should not have a major impact on the hazardous waste management system at LLNL.

Nonhazardous solid waste would include office and lunch room garbage, packaging materials, sewage sludges, and other industrial wastes from utility and maintenance operations (O'Connor et al. 1998c). Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site for disposal in the Vasco Road Landfill. Nonrecyclable, nonhazardous solid waste generated by these activities is estimated to be 30 percent of existing annual site waste generation. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at LLNL.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals and water closets, and wastewater from cooling tower blowdown (O'Connor et al. 1998c). After monitoring to ensure that the wastewater meets discharge limits, sanitary wastewaters from lead assembly fabrication along with other sanitary wastewaters from LLNL and Sandia National Laboratory–Livermore, would be routed to the city of Livermore Water Reclamation Plant. Nonhazardous liquid waste generation for these activities is estimated to be less than 1 percent of the existing annual site waste generation, and less than 1 percent of the 2,763,271-m^3/yr (3,614,358-yd^3/yr) capacity of the LLNL sanitary sewer and therefore should not have a major impact on LLNL and the city of Livermore sanitary wastewater treatment systems.

H.5.4 LANL

H.5.4.1 Construction

Table H–47 compares the expected waste generation rates for the modification of LANL facilities for lead assembly fabrication with the existing generation rates for LANL waste. TRU waste and LLW would be generated during modification of the glovebox line in Building PF–4, although no mixed waste or hazardous wastes would be generated (O'Connor et al. 1998d).

TRU wastes generated during modification of Building PF–4 would include contaminated equipment and gloveboxes. It is anticipated that all TRU waste would be contact-handled waste. No liquid TRU waste is anticipated. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LANL facilities (O'Connor et al. 1998d).

Table H–47. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at LANL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	3	262	1
LLW	3	1,585	<1
Nonhazardous Liquid	10	692,857	<1

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998d:33.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

TRU waste generation for modification of Building PF–4 is estimated to be 1 percent of existing annual site waste generation, and less than 1 percent of the 1,080-m^3/yr (1,413-yd^3/yr) TRU waste volume reduction capacity. A total of 5 m^3 (6.5 yd^3) of TRU waste would be generated over the 2-year modification period. This would be less than 1 percent of the 11,262 m^3 (14,731 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 24,355-m^3 (31,856-yd^3) storage capacity available at LANL.

In addition, the 5 m^3 (6.5 yd^3) of TRU waste generated by modification of this building would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts of disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW generated during modification of Building PF–4 would include decontamination wastes and protective clothing. It is expected that no radioactive liquid LLW would be generated (O'Connor et al. 1998d). A total of 5 m^3 (6.5 yd^3) of LLW would be generated during the modification period. LLW generation for these activities is estimated to be less than 1 percent of existing annual waste generation, 1 percent of the 663-m^3 (867-yd^3) LLW storage capacity, and less than 1 percent of the 252,000-m^3 (329,616-yd^3) capacity of the TA–54 LLW disposal area. Using the 12,562-m^3/ha (6,649-yd^3/acre) disposal land usage factor for LANL published in the *Final Stockpile Stewardship and Management PEIS* (SSM PEIS) (DOE 1996d:H-9), 5 m^3 (6.5 yd^3) of waste would require less than 0.1 ha (0.25 acre) of disposal space at LANL. Therefore, impacts of the management of this additional LLW at LANL should not be major.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals, and water closets. To be conservative, it was assumed that all nonhazardous liquid waste generated during modification would be managed at the LANL sanitary wastewater treatment plant. Nonhazardous liquid waste generation for modification is estimated to be less than 1 percent of the existing annual waste generation, less than 1 percent of the 1,060,063-m^3/yr (1,386,562-yd^3/yr) capacity of the sanitary wastewater treatment plant, and less than 1 percent of the 567,750-m^3/yr (742,617-yd^3/yr) capacity of the sanitary tile fields. Therefore, this waste load would not have a major impact on the LANL sanitary wastewater treatment system.

H.5.4.2 Operations

Table H–48 compares the expected waste generation rates from lead assembly fabrication at LANL with the existing site waste generation rates. No HLW would be generated during lead assembly fabrication. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998,

Table H–48. Potential Waste Management Impacts of Operation of Facilities for Lead Assembly Fabrication at LANL

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	41	262	16
LLW	200	1,585	13
Mixed LLW	1	90	1
Hazardous	<1	942	<1
Nonhazardous			
Liquid	1,600	692,857	<1
Solid	1,300	5,453	24

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998d:34.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. The SPD EIS also assumes that LLW, mixed LLW, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts of treatment, storage, and disposal of waste at LANL, including expansion of the LLW disposal facility, are evaluated in the *Draft Sitewide EIS for Continued Operation of LANL* (DOE 1998).

TRU wastes generated during operations would include glovebox gloves, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, metallography waste, and sludges (O'Connor et al.1998d). It is anticipated that all TRU waste would be contact-handled waste. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time radiography, and loading the TRUPACT for shipment to WIPP would occur at other as yet unidentified LANL facilities.

TRU waste generation for these activities is estimated to be 16 percent of existing annual site waste generation and 4 percent of the 1,080-m^3/yr (1,413-yd^3/yr) TRU waste volume reduction capacity. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. This would be 1 percent of the 11,262 m^3 (14,731 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 24,355-m^3 (31,856-yd^3) storage capacity available at LANL.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts from disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW may include room trash (e.g., blotter paper, wipes, mop heads); protective clothing; solidified sludges; ion exchange resins; metal cans and rods; and wastewater from the laundry, analytical laboratory, and decontamination process (O'Connor et al. 1998d). LLW would be packaged, certified, and accumulated before being transferred for treatment and disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generation for these activities is estimated to be 13 percent of existing annual site waste generation, 106 percent of the 663-m^3 (867-yd^3) LLW storage capacity, and less than 1 percent of the 252,000-m^3 (329,616-yd^3) capacity of the TA–54 LLW disposal area. Because the waste would be sent for disposal on a regular basis, storage should not be a problem. Using the 12,562-m^3/ha (6,649-yd^3/acre) disposal land usage factor for LANL published in the SSM PEIS

(DOE 1996d:H-9), 700 m^3 (916 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at LANL. It is estimated that without any waste contribution from lead assembly fabrication, the existing disposal space in the TA–54 LLW disposal facility will be exahausted within the next 10 years. Expansion of the LLW disposal capacity at LANL is evaluated in the *Draft Sitewide EIS for Continued Operation of LANL* (DOE 1998). Impacts from the management of the additional SPD LLW at LANL should not be major.

Mixed LLW may include sludges, cleaning solvents, and analytical waste (O'Connor et al. 1998d). Mixed LLW will be stabilized, packaged, and stored on the site for treatment and disposal in a manner consistent with the site treatment plan for LANL. Mixed LLW disposal would occur off the site. Mixed LLW generation for these activities is estimated to be 1 percent of existing annual waste generation, and 1 percent of the 583-m^3 (762.6-yd^3) mixed LLW storage capacity. Therefore, the management of this additional waste at LANL should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations would include small quantities of process ends. Hazardous waste would be packaged for treatment and disposal at offsite permitted commercial facilities (O'Connor et al. 1998d). Hazardous waste generation for these activities is estimated to be less than 1 percent of existing annual waste generation and less than 1 percent of the 1,864-m^3 (2,438-yd^3) hazardous waste storage capacity. These wastes should not have a major impact on the hazardous waste management system at LANL.

Nonhazardous solid waste would include office and lunch room garbage, packaging materials, sewage sludges, and other industrial wastes from utility and maintenance operations (O'Connor et al. 1998d). Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be disposed of in the Los Alamos County Landfill. Nonrecyclable, nonhazardous solid waste generated by these activities is estimated to be 24 percent of existing annual site waste generation. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at LANL.

Nonhazardous liquid waste would include sanitary waste from sinks, showers, urinals and water closets, and wastewater from cooling tower blowdown (O'Connor et al. 1998d). Nonhazardous liquid waste generation for these activities is estimated to be less than 1 percent of the existing annual site waste generation, less than 1 percent of the 1,060,063-m^3/yr (1,386,562-yd^3/yr) capacity of the sanitary wastewater treatment plant, and less than 1 percent of the 567,750-m^3/yr (742,617-yd^3/yr) capacity of the sanitary tile fields, and therefore should not have a major impact on the system.

H.5.5 SRS

H.5.5.1 Construction

Table H–49 compares the expected waste generation rates for the modification of facilities at SRS with the existing generation rates for SRS waste. No radioactive or mixed waste would be generated during modification because the areas of the buildings that will be modified are uncontaminated.

The small amount of hazardous waste generated during building modification would include batteries, fluorescent light tubes, and liquids such as cleaning solutions, lubricants, oils, and hydraulic fluids (O'Connor et al. 1998e). These wastes are typical of those generated during construction of an industrial facility. Any hazardous waste generated during modification would be packaged in DOT-approved containers and shipped off the site to permitted commercial treatment and disposal facilities. Hazardous waste generation

Table H–49. Potential Waste Management Impacts of Modification of Facilities for Lead Assembly Fabrication at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
Hazardous	1	74	1
Nonhazardous			
Liquid	2,350	416,100	1
Solid	19	6,670	<1

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998e:35.
[c] From the waste management section in Chapter 3.

for modification of this facility is estimated to be 1 percent of existing annual site waste generation. The additional waste load generated during the 2-year modification period should not have a major impact on the SRS hazardous waste management system.

Nonhazardous solid waste would include office garbage, construction debris, scrap lumber, concrete and steel waste, and other construction trash. Nonhazardous solid waste would be packaged in conformance with standard industrial practice and shipped to offsite commercial facilities for recycling or disposal. Waste metals would be sent off the site for recycling, and therefore, were not included in the waste volumes. Nonrecyclable, solid sanitary waste would be sent off the site for disposal. Nonhazardous-solid-waste generation during modification of this facility is estimated to be less than 1 percent of existing annual site waste generation. The additional waste load generated during the modification period should not have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste would include sanitary waste from any sinks, showers, urinals, and water closets. To be conservative, it was assumed that all nonhazardous liquid waste generated during modification would be managed at the Central Sanitary Wastewater Treatment Facility. Nonhazardous liquid waste generation for modification of this facility is estimated to be 1 percent of existing annual site waste generation, 2 percent of the 136,274-m^3/yr (178,246-yd^3/yr) capacity of the H-Area sanitary sewer, and less than 1 percent of the 1,030,000-m^3/yr (1,347,240-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility, and therefore, should not have a major impact on the system during the modification period.

H.5.5.2 Operations

Table H–50 compares the expected waste generation rates from lead assembly fabrication at SRS with the existing site waste generation rates. No HLW would be generated during lead assembly fabrication. Depending in part on decisions in the RODs for the WM PEIS, wastes could be treated and disposed of on the site or at other DOE sites or commercial facilities. Per the ROD for TRU waste issued on January 20, 1998, TRU and mixed TRU waste would be certified on the site to current WIPP waste acceptance criteria and shipped to WIPP for disposal. This EIS also assumes that LLW, mixed LLW, and nonhazardous waste would be treated, stored, and disposed of in accordance with current site practices. Impacts from treatment, storage, and disposal of radioactive, hazardous, and mixed wastes at SRS are described in the *SRS Waste Management Final EIS* (DOE 1995b).

TRU wastes generated during operations would include glovebox gloves, spent filters, used containers and equipment, paper and cloth wipes, analytical and quality control samples, metallography waste, and sludges (O'Connor et al. 1998e). It is anticipated that all TRU waste would be contact-handled waste. Liquid TRU wastes would be evaporated or solidified before being packaged for storage. Drum-gas testing, real-time

Table H–50. Potential Waste Management Impacts of Operation of Facilities for Lead Assembly Fabrication at SRS

Waste Type[a]	Estimated Waste Generation (m^3/yr)[b]	Site Waste Generation (m^3/yr)[c]	Percent of Site Waste Generation
TRU[d]	41	427	10
LLW	200	10,043	2
Mixed LLW	1	1,135	<1
Hazardous	<1	74	<1
Nonhazardous			
Liquid	1,600	416,100	<1
Solid	1,300	6,670	19

[a] See definitions in Appendix F.8.
[b] O'Connor et al. 1998e:38.
[c] From the waste management section in Chapter 3.
[d] Includes mixed TRU waste.
Key: LLW, low-level waste; TRU, transuranic.

radiography, and loading the TRUPACT for shipment to WIPP would occur at the planned TRU Waste Characterization and Certification Facility at SRS.

TRU waste generation for these activities is estimated to be 10 percent of existing annual site waste generation, and 2 percent of the 1,720-m^3/yr (2,250-yd^3/yr) planned capacity of the TRU Waste Characterization and Certification Facility. A total of 132 m^3 (173 yd^3) of TRU waste would be generated over the 3-year operation period. This would be 2 percent of the 6,977 m^3 (9,125 yd^3) of contact-handled TRU waste currently in storage, and less than 1 percent of the 34,400-m^3 (44,995-yd^3) storage capacity available at SRS.

The 132 m^3 (173 yd^3) of TRU waste generated by these activities would be less than 1 percent of the 143,000 m^3 (187,000 yd^3) of contact-handled TRU waste that DOE plans to dispose of at WIPP, and within the 168,500-m^3 (220,400-yd^3) limit for WIPP (DOE 1997d:3-3). Impacts from disposal of TRU waste at WIPP are described in the *WIPP Disposal Phase Final Supplemental EIS* (DOE 1997d).

LLW may include room trash (e.g., blotter paper, wipes, mop heads); protective clothing; solidified sludges; ion exchange resins; metal cans and rods; and wastewater from the laundry, analytical laboratory, and decontamination process (O'Connor et al. 1998e). LLW would be packaged, certified, and accumulated before being transferred for treatment and disposal in existing onsite facilities. A total of 700 m^3 (916 yd^3) of LLW would be generated over the 3-year operation period. LLW generation for these activities is estimated to be 2 percent of existing annual site waste generation, 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and 2 percent of the 30,500-m^3 (39,900-yd^3) capacity of the Low-Activity Waste Vaults. Using the 8,687-m^3/ha (4,598-yd^3/acre) disposal land usage factor for SRS published in the *Final Storage and Disposition PEIS* (DOE 1996a:E-9), 700 m^3 (916 yd^3) of waste would require 0.1 ha (0.25 acre) of disposal space at SRS. Therefore, impacts from the management of this additional LLW at SRS should not be major.

Mixed LLW may include sludges, cleaning solvents, and analytical waste (O'Connor et al. 1998e). Mixed LLW will be stabilized, packaged, and stored on the site for treatment and offsite disposal in a manner consistent with the site treatment plan for SRS. Mixed LLW generation for these activities is estimated to be less than 1 percent of existing annual site waste generation and less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of this facility, the 4 m^3 (5.2 yd^3) of mixed LLW expected to be generated would be less than 1 percent of the 1,900-m^3

(23,320-yd^3/yr) capacity of the Consolidated Incineration Facility. Over the operating life of this facility, the 4 m^3 (5.2 yd^3) of mixed LLW expected to be generated would be less than 1 percent of the 1,900-m^3 (2,490-yd^3) capacity of the Mixed Waste Storage Buildings. Therefore, the management of this additional waste at SRS should not have a major impact on the mixed LLW management system.

Hazardous waste generated during operations would include small quantities of process ends (O'Connor et al. 1998e). Hazardous waste would be packaged for treatment and disposal at a combination of onsite and offsite permitted facilities. Assuming that all hazardous waste is managed on the site, hazardous waste generation for these activities is estimated to be less than 1 percent of existing annual site waste generation, less than 1 percent of the 17,830-m^3/yr (23,320-yd^3/yr) capacity of the Consolidated Incineration Facility, and less than 1 percent of the 5,200-m^3 (6,800-yd^3) capacity of the hazardous waste storage buildings. The management of these additional hazardous wastes at SRS should not have a major impact on the hazardous waste management system.

Nonhazardous solid waste would include office and lunch room garbage, packaging materials, sewage sludges, and other industrial wastes from utility and maintenance operations (O'Connor et al. 1998e). Nonhazardous solid waste would be packaged in conformance with standard industrial practice. Recyclable solid wastes such as office paper, metal cans, and plastic and glass bottles would be sent off the site for recycling. The remaining solid sanitary waste would be sent off the site to a commercial facility for disposal. Nonrecyclable, nonhazardous solid waste generated by these activities is estimated to be 19 percent of existing annual site waste generation. It is unlikely that this additional waste load would have a major impact on the nonhazardous solid waste management system at SRS.

Nonhazardous liquid waste includes sanitary waste from sinks, showers, urinals and water closets, and wastewater from cooling tower blowdown (O'Connor et al. 1998e). Nonhazardous liquid waste generation for these activities is estimated to be less than 1 percent of the existing annual site waste generation, 1 percent of the 136,274-m^3/yr (178,246-yd^3/yr) capacity of the H-Area sanitary sewer, and less than 1 percent of the 1,030,000-m^3/yr (1,347,240-yd^3/yr) capacity of the Central Sanitary Wastewater Treatment Facility. Therefore, impacts on the system should not be major.

Appendix I
Socioeconomics

This appendix presents detailed information on the potential socioeconomic impacts associated with the influx of construction workers during the construction of the three new surplus plutonium disposition facilities as well as the workers needed to operate the facilities as described in the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS). This information supports the socioeconomic assessments described in Chapter 4. Site-specific input data used in the evaluation of these socioeconomic impacts are provided or referenced where appropriate, including projections for employment, unemployment, population, housing units, student enrollment, teachers employed, police officers, firefighters, hospital beds, and doctors. Tables I–1 through I–40 present data for the four candidate sites: Hanford Site (Hanford), Idaho National Engineering and Environmental Laboratory (INEEL), Pantex Plant (Pantex), and Savannah River Site (SRS).

I.1 Hanford

Table I–1. Hanford Projected Site Employment

Year	Employment	Change From Previous (%)	Change From 1997 (%)
1997	12,900	–	–

Appendix J
Human Health Risks

This appendix presents detailed information on the potential impacts to humans associated with incident-free (normal) releases of radioactivity from the proposed surplus plutonium disposition facilities. This information supports the human health assessments described in Chapter 4. In addition, site-specific input data used in the evaluation of these human health impacts are also provided or referenced where appropriate. The surplus plutonium disposition facilities would be at one or more of four U.S. Department of Energy (DOE) candidate sites: the Hanford Site (Hanford), Idaho National Engineering and Environmental Laboratory (INEEL), the Pantex Plant (Pantex), and the Savannah River Site (SRS). Information is also presented on the human health impacts of mixed oxide (MOX) fuel lead assembly fabrication activities at five potential DOE sites: Argonne National Laboratory–West (ANL–W) at INEEL, Hanford, Lawrence Livermore National Laboratory (LLNL), Los Alamos National Laboratory (LANL), and SRS.

J.1 HANFORD

J.1.1 Assessment Data

To perform the dose assessments for the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS), different types of data were collected and generated. In addition, calculational assumptions were made. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessments.

J.1.1.1 Meteorological Data

The meteorological data used for the Hanford dose assessments was in the form of a joint frequency data (JFD) file. A JFD file is a table that lists the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–1 presents the JFD used in the dose assessments for Hanford.

J.1.1.2 Population Data

The Hanford population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2010 (about midlife of operations) for areas within 80 km (50 mi) of the locations for the proposed surplus plutonium disposition facilities. The site population in 2010 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at the Fuels and Materials Examination Facility (FMEF) in the 400 Area, the location from which radionuclides are assumed to be released during incident-free operations. Table J–2 presents the population data used for the dose assessments at Hanford.

J.1.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distribution described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each

Source: Neitzel 1996.

county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the Hanford population from the ingestion pathway. The consumption rates used in the dose assessments were those for the maximally exposed individual (MEI) and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. Hanford food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.1.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the data reports for the pit conversion, immobilization, and MOX facilities (UC 1998a, 1998b, 1998c, 1998d).

J.1.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the proposed surplus plutonium disposition facilities at Hanford, the following additional assumptions and factors were considered, in accordance with the guidelines established in U.S. Nuclear Regulatory Commission (NRC) Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).

- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.

- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.

- Reported stack heights were used for atmospheric releases. The resultant doses were conservative as use of the actual stack height instead of the effective stack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.1.2 Facilities

The following sections present all viable radiological impact scenarios that could be associated with different combinations of incident-free facility operations at Hanford.

J.1.2.1 Pit Conversion Facility

J.1.2.1.1 Construction of Pit Conversion Facility

No radiological risk would be incurred by members of the public from construction and modification of a pit conversion facility at Hanford. According to recent surveys conducted in the 400 Area, a construction worker would not be expected to receive any additional dose above natural background levels (Antonio 1998). Nonetheless, if deemed necessary, workers may be monitored (badged) as a precautionary measure.

J.1.2.1.2 Operation of Pit Conversion Facility

Tables J–3 and J–4 present the incident-free radiological impacts of the operation of a pit conversion facility at Hanford.

Table J–3. Potential Radiological Impacts on the Public of Operation of Pit Conversion Facility in FMEF at Hanford

Population within 80 km for year 2010	
Dose (person-rem)	6.9
Percent of natural background[a]	5.9×10^{-3}
10-year latent fatal cancers	0.034
Maximally exposed individual	
Annual dose (mrem)	0.017
Percent of natural background[a]	5.7×10^{-3}
10-year latent fatal cancer risk	8.5×10^{-8}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	0.017
10-year latent fatal cancer risk	8.5×10^{-8}

[a] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 116,300 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Hanford in 2010 (387,800).

Key: FMEF, Fuels and Materials Examination Facility.

Source: Model results.

Table J–4. Potential Radiological Impacts on Involved Workers of Operation of Pit Conversion Facility in FMEF at Hanford

Number of badged workers	383
Total dose (person-rem/yr)	192
10-year latent fatal cancers	0.77
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Key: FMEF, Fuels and Materials Examination Facility.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.1.2.2 Immobilization Facility

J.1.2.2.1 Construction of Immobilization Facility

No radiological risk would be incurred by members of the public from the construction and modification of an immobilization (ceramic or glass) facility at Hanford. According to recent radiation surveys conducted in the 400 Area, a construction worker would not be expected to receive any additional dose above natural background levels (Antonio 1998). Nonetheless, if deemed necessary, workers may be monitored (badged) as a precautionary measure.

J.1.2.2.2 Operation of Immobilization Facility

Tables J–5 and J–6 present all possible incident-free radiological impact scenarios for the operation of a ceramic or glass immobilization facility at Hanford.

Table J–5. Potential Radiological Impacts on the Public of Operation of Immobilization Facility in FMEF at Hanford

	17 t		50 t	
Impact	**Ceramic**	**Glass**	**Ceramic**	**Glass**
Population within 80 km for year 2010				
Dose (person-rem)	7.8×10^{-3}	7.1×10^{-3}	0.016	0.015
Percent of natural background[a]	6.7×10^{-6}	6.1×10^{-6}	1.4×10^{-5}	1.3×10^{-5}
10-year latent fatal cancers	3.9×10^{-5}	3.6×10^{-5}	8.0×10^{-5}	7.5×10^{-5}
Maximally exposed individual				
Annual dose (mrem)	1.1×10^{-4}	9.7×10^{-5}	2.2×10^{-4}	2.0×10^{-4}
Percent of natural background[a]	3.7×10^{-5}	3.2×10^{-5}	7.3×10^{-5}	6.7×10^{-5}
10-year latent fatal cancer risk	5.5×10^{-10}	4.9×10^{-10}	1.1×10^{-9}	1.0×10^{-9}
Average exposed individual within 80 km[b]				
Annual dose (mrem)	2.0×10^{-5}	1.8×10^{-5}	4.1×10^{-5}	3.9×10^{-5}
10-year latent fatal cancer risk	1.0×10^{-10}	9.0×10^{-11}	2.1×10^{-10}	2.0×10^{-10}

[a] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 116,300 person-rem.
[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Hanford in 2010 (387,800).

J.1.2.3 MOX Facility

J.1.2.3.1 Construction of MOX Facility

No radiological risk would be incurred by members of the public from the construction and modification of a MOX facility at Hanford. According to recent radiation surveys conducted in the 400 Area, a construction worker would not be expected to receive any additional dose above natural background levels (Antonio 1998). Nonetheless, if deemed necessary, workers may be monitored (badged) as a precautionary measure.

J.1.2.3.2 Operation of MOX Facility

Tables J–7 and J–8 present the incident-free radiological impacts of the operation of a MOX facility at Hanford. The facility would either be located within the existing FMEF or a new facility would be built adjacent to FMEF.

Table J–7. Potential Radiological Impacts on the Public of Operation of MOX Facility in FMEF or New Construction at Hanford

Impact	**FMEF[a]**	**New[a]**
Population dose within 80 km for year 2010		
Dose (person-rem)	0.051	0.11
Percent of natural background[b]	4.4×10^{-5}	9.5×10^{-5}
10-year latent fatal cancers	2.6×10^{-4}	5.5×10^{-4}
Maximally exposed individual		
Annual dose (mrem)	6.9×10^{-4}	1.8×10^{-3}
Percent of natural background[b]	2.3×10^{-4}	6.0×10^{-4}
10-year latent fatal cancer risk	3.5×10^{-9}	9.0×10^{-9}
Average exposed individual within 80 km[c]		
Annual dose (mrem)	1.3×10^{-4}	2.8×10^{-4}
10-year latent fatal cancer risk	6.5×10^{-10}	1.4×10^{-9}

[a] The difference in impacts is attributable to different stack heights.
[b] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 116,300 person-rem.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Hanford in 2010 (387,800).
Key: FMEF, Fuels and Materials Examination Facility.
Source: Model results.

Table J–8. Potential Radiological Impacts on Involved Workers of Operation of MOX Facility in FMEF or New Construction at Hanford

Number of badged workers	350
Total dose (person-rem/yr)	175
10-year latent fatal cancers	0.70
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Key: FMEF, Fuels and Materials Examination Facility.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.1.2.4 Pit Conversion and Immobilization Facilities

J.1.2.4.1 Construction of Pit Conversion and Immobilization Facilities

No radiological risk would be incurred by members of the public from the construction and modification of pit conversion and immobilization (ceramic or glass) facilities at Hanford. According to recent radiation surveys conducted in the 400 Area, a construction worker would not be expected to receive any additional dose above natural background levels (Antonio 1998). Nonetheless, if deemed necessary, workers may be monitored (badged) as a precautionary measure.

J.1.2.4.2 Operation of Pit Conversion and Immobilization Facilities

Tables J–9 and J–10 present all possible incident-free radiological impact scenarios for the operation of the pit conversion and immobilization facilities at Hanford.

Table J–9. Potential Radiological Impacts on the Public of Operation of Pit Conversion and Immobilization Facilities in FMEF at Hanford

Impact	Pit Conversion	Immobilization (50 t) Ceramic	Immobilization (50 t) Glass	Total[a]
Population within 80 km for year 2010				
Dose (person-rem)	6.9	0.016	0.015	6.9
Percent of natural background[b]	5.9×10^{-3}	1.4×10^{-5}	1.3×10^{-5}	5.9×10^{-3}
10-year latent fatal cancers	0.034	8.0×10^{-5}	7.5×10^{-5}	0.034
Maximally exposed individual				
Annual dose (mrem)	0.017	2.2×10^{-4}	2.0×10^{-4}	0.017
Percent of natural background[b]	5.7×10^{-3}	7.3×10^{-5}	6.7×10^{-5}	5.8×10^{-3}
10-year latent fatal cancer risk	8.5×10^{-8}	1.1×10^{-9}	1.0×10^{-9}	8.6×10^{-8}
Average exposed individual within 80 km[c]				
Annual dose (mrem)	0.017	4.1×10^{-5}	3.9×10^{-5}	0.017
10-year latent fatal cancer risk	8.5×10^{-8}	2.1×10^{-10}	2.0×10^{-10}	8.5×10^{-8}

[a] Totals represent the largest possible sums for each public category. Totals are additive in all cases because the same groups or individuals would receive doses from both facilities.
[b] The annual natural background radiation level at Hanford is 300 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 116,300 person-rem.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Hanford in 2010 (387,800).

J.2 INEEL

J.2.1 Assessment Data

To perform the dose assessments for the SPD EIS, different types of data were collected and generated. In addition, calculational assumptions were made. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) that were used for the assessments.

J.2.1.1 Meteorological Data

The meteorological data used for the INEEL dose assessments was in the form of JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–17 presents the JFD used in the dose assessments for INEEL.

J.2.1.2 Population Data

The INEEL population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2010 (about midlife of operations) for areas within 80 km (50 mi) of the locations for the proposed surplus plutonium disposition facilities. The site population in 2010 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at the Idaho Nuclear Technology and Engineering Center (INTEC), the location from which radionuclides are assumed to be released during incident-free operations. Table J–18 presents the population data used for the dose assessments at INEEL.

J.2.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distribution described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII–leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the INEEL population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. INEEL food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.2.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the data reports for the pit conversion and MOX facilities (UC 1998e, 1998f).

J.2.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the proposed surplus plutonium disposition facilities at INEEL, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.
- Reported stack heights were used for atmospheric releases. The resultant doses were conservative as use of the actual stack height instead of the effective stack height negates plume rise.
- The calculated doses are 50-year committed doses from 1 year of intake.

J.2.2 Facilities

The following sections present all viable radiological impact scenarios that could be associated with different combinations of incident-free facility operations at INEEL.

J.2.2.1 Pit Conversion Facility

J.2.2.1.1 Construction of Pit Conversion Facility

No radiological risk would be incurred by members of the public from construction and modification of a pit conversion facility in the Fuel Processing Facility (FPF) at INEEL. According to a recent radiation survey (Mitchell et al. 1997) conducted in the INTEC area, a construction worker could receive about 5 mrem/yr above natural background levels from exposure to radiation deriving from other activities, past or present, at the site. Construction worker exposures would be kept as low as is reasonably achievable, and workers would be monitored (badged) as appropriate.

J.2.2.1.2 Operation of Pit Conversion Facility

Tables J–19 and J–20 present the incident-free radiological impacts of the operation of a pit conversion facility at INEEL.

Table J–19. Potential Radiological Impacts on the Public of Operation of Pit Conversion Facility in FPF at INEEL

Population within 80 km for year 2010	
Dose (person-rem)	2.2
Percent of natural background[a]	3.3×10^{-3}
10-year latent fatal cancers	0.011
Maximally exposed individual	
Annual dose (mrem)	0.015
Percent of natural background[a]	4.2×10^{-3}
10-year latent fatal cancer risk	7.5×10^{-8}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	0.012
10-year latent fatal cancer risk	6.0×10^{-8}

[a] The annual natural background radiation level at INEEL is 361 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 66,000 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of INEEL in 2010 (182,800).

Key: FPF, Fuel Processing Facility.

Source: Model results.

Table J–20. Potential Radiological Impacts on Involved Workers of Operation of Pit Conversion Facility in FPF at INEEL

Number of badged workers	341
Total dose (person-rem/yr)	170
10-year latent fatal cancers	0.68
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Key: FPF, Fuel Processing Facility.

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: UC 1998e.

J.2.2.2 MOX Facility

J.2.2.2.1 Construction of MOX Facility

No radiological risk would be incurred by members of the public from the construction of a new MOX facility at INEEL. According to a recent radiation survey (Mitchell et al. 1997) conducted in the INTEC area, a construction worker could receive about 5 mrem/yr above natural background levels from exposure to radiation deriving from other activities, past or present, at the site. Construction worker exposures would be kept as low as is reasonably achievable, and workers would be monitored (badged) as appropriate.

J.2.2.2.2 Operation of MOX Facility

Tables J–21 and J–22 present the incident-free radiological impacts of the operation of a MOX facility at INEEL.

Table J–21. Potential Radiological Impacts on the Public of Operation of New MOX Facility at INEEL

Population within 80 km for year 2010	
Dose (person-rem)	0.014
Percent of natural background[a]	2.1×10^{-5}
10-year latent fatal cancers	7.0×10^{-5}
Maximally exposed individual	
Annual dose (mrem)	1.2×10^{-3}
Percent of natural background[a]	3.3×10^{-4}
10-year latent fatal cancer risk	6.0×10^{-9}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	7.7×10^{-5}
10-year latent fatal cancer risk	3.9×10^{-10}

[a] The annual natural background radiation level at INEEL is 361 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 66,000 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of INEEL in 2010 (182,800).

Source: Model results.

Table J–22. Potential Radiological Impacts on Involved Workers of Operation of New MOX Facility at INEEL

Number of badged workers	350
Total dose (person-rem/yr)	175
10-year latent fatal cancers	0.70
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: UC 1998f.

J.2.2.3 Pit Conversion and MOX Facilities

J.2.2.3.1 *Construction of Pit Conversion and MOX Facilities*

No radiological risk would be incurred by members of the public from the construction and modification of a pit conversion facility in FPF and construction of a new MOX facility at INEEL. According to a recent radiation survey (Mitchell et al. 1997) conducted in the INTEC area, a construction worker could receive about 5 mrem/yr above natural background levels from exposure to radiation deriving from other activities, past or present, at the site. Construction worker exposures would be kept as low as is reasonably achievable, and workers would be monitored (badged) as appropriate.

J.2.2.3.2 Operation of Pit Conversion and MOX Facilities

Tables J–23 and J–24 present the incident-free radiological impacts of operation of pit conversion and MOX facilities at INEEL.

Table J–23. Potential Radiological Impacts on the Public of Operation of Pit Conversion Facility in FPF and New MOX Facility at INEEL

Impact	Pit Conversion	MOX	Total[a]
Population within 80 km for year 2010			
Dose (person-rem)	2.2	0.014	2.2
Percent of natural background[b]	3.3×10^{-3}	2.1×10^{-5}	3.3×10^{-3}
10-year latent fatal cancers	0.011	7.0×10^{-5}	0.011
Maximally exposed individual			
Annual dose (mrem)	0.015	1.2×10^{-3}	0.016
Percent of natural background[b]	4.2×10^{-3}	3.3×10^{-4}	4.5×10^{-3}
10-year latent fatal cancer risk	7.5×10^{-8}	6.0×10^{-9}	8.0×10^{-8}
Average exposed individual within 80 km[c]			
Annual dose (mrem)	0.012	7.7×10^{-5}	0.012
10-year latent fatal cancer risk	6.0×10^{-8}	3.9×10^{-10}	6.0×10^{-8}

[a] Totals are additive in all cases because the same groups or individuals would receive doses from both facilities.
[b] The annual natural background radiation level at INEEL is 361 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 66,000 person-rem.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of INEEL in 2010 (182,800).
Key: FPF, Fuel Processing Facility.
Source: Model results.

Table J–24. Potential Radiological Impacts on Involved Workers of Operation of Pit Conversion Facility in FPF and New MOX Facility at INEEL

Impact	Pit Conversion	MOX	Total
Number of badged workers	341	350	691
Total dose (person-rem/yr)	170	175	345
10-year latent fatal cancers	0.68	0.70	1.4
Average worker dose (mrem/yr)	500	500	500[a]
10-year latent fatal cancer risk	2.0×10^{-3}	2.0×10^{-3}	2.0×10^{-3}

[a] Represents an average of the doses for both facilities.
Key: FPF, Fuel Processing Facility.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.3 PANTEX

J.3.1 Assessment Data

To perform the dose assessments for the SPD EIS, different types of data were collected and generated. In addition, calculational assumptions were made. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) that were used for the assessments.

J.3.1.1 Meteorological Data

The meteorological data used for the Pantex dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–25 presents the JFD used in the dose assessments for Pantex.

J.3.1.2 Population Data

The Pantex population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2010 (about midlife of operations) for areas within 80 km (50 mi) of the locations for the proposed plutonium disposition facilities. The site population in 2010 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at Zone 4, the location from which radionuclides are assumed to be released during incident-free operations. Table J–26 presents the population data used for the dose assessments at Pantex.

J.3.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distribution described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the Pantex population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. Pantex food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.3.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the data reports for pit conversion and MOX facilities (UC 1998g, 1998h).

J.3.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the proposed surplus plutonium disposition facilities at Pantex, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases were to the air.

- Reported stack heights were used for atmospheric releases. The resultant doses were conservative as use of the actual stack height instead of the effective sack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.3.2 Facilities

The following sections present all viable radiological impact scenarios that could be associated with different combinations of incident-free facility operations at Pantex.

J.3.2.1 Pit Conversion Facility

J.3.2.1.1 Construction of Pit Conversion Facility

No radiological risk would be incurred by members of the public from the construction of a new pit conversion facility at Pantex. According to a recent radiation survey (DOE 1997a) conducted in Zone 4, a construction worker would not be expected to receive any additional radiation exposure above natural background levels in the area. Nonetheless, construction workers may be monitored (badged) as a precautionary measure.

J.3.2.1.2 Operation of Pit Conversion Facility

Tables J–27 and J–28 present the incident-free radiological impacts of the operation of a pit conversion facility at Pantex.

Table J–27. Potential Radiological Impacts on the Public of Operation of New Pit Conversion Facility at Pantex

Population within 80 km for year 2010	
Dose (person-rem)	0.58
Percent of natural background[a]	5.8×10^{-4}
10-year latent fatal cancers	2.9×10^{-3}
Maximally exposed individual	
Annual dose (mrem)	0.062
Percent of natural background[a]	0.019
10-year latent fatal cancer risk	3.1×10^{-7}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	1.9×10^{-3}
10-year latent fatal cancer risk	9.5×10^{-9}

[a] The annual natural background radiation level at Pantex is 332 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 99,300 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Pantex in 2010 (299,000).

Source: Model results.

Table J–28. Potential Radiological Impacts on Involved Workers of Operation of New Pit Conversion Facility at Pantex

Number of badged workers	383
Total dose (person-rem/yr)	192
10-year latent fatal cancers	0.77
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998g.

J.3.2.2 MOX Facility

J.3.2.2.1 Construction of MOX Facility

No radiological risk would be incurred by members of the public from construction of a new MOX facility at Pantex . According to a recent radiation survey (DOE 1997a) conducted in Zone 4, a construction worker would not be expected to receive any additional radiation exposure above natural background levels in the area. Nonetheless, construction workers may be monitored (badged) as a precautionary measure.

J.3.2.2.2 Operation of MOX Facility

Tables J–29 and J–30 present the incident-free radiological impacts of the operation of a MOX facility at Pantex.

Table J–29. Potential Radiological Impacts on the Public of Operation of New MOX Facility at Pantex

Population within 80 km for year 2010	
Dose (person-rem)	0.010
Percent of natural background[a]	1.0×10^{-5}
10-year latent fatal cancers	5.0×10^{-5}
Maximally exposed individual	
Annual dose (mrem)	5.5×10^{-3}
Percent of natural background[a]	1.7×10^{-3}
10-year latent fatal cancer risk	2.8×10^{-8}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	3.3×10^{-5}
10-year latent fatal cancer risk	1.7×10^{-10}

[a] The annual natural background radiation level at Pantex is 332 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 99,300 person-rem.
[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Pantex in 2010 (299,000).
Source: Model results.

Table J–30. Potential Radiological Impacts on Involved Workers of Operation of New MOX Facility at Pantex

Number of badged workers	350
Total dose (person-rem/yr)	175
10-year latent fatal cancers	0.70
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998h.

J.3.2.3 Pit Conversion and MOX Facilities

J.3.2.3.1 Construction of Pit Conversion and MOX Facilities

No radiological risk would be incurred by members of the public from the construction of new pit conversion and MOX facilities at Pantex. According to a recent radiation survey (DOE 1997a) conducted in Zone 4, a construction worker would not be expected to receive any additional radiation exposure above natural background levels in the area. Nonetheless, construction workers may be monitored (badged) as a precautionary measure.

J.3.2.3.2 Operation of Pit Conversion and MOX Facilities

Tables J–31 and J–32 present the incident-free radiological impacts of operation of the pit conversion and MOX facilities at Pantex.

Table J–31. Potential Radiological Impacts on the Public of Operation of New Pit Conversion and MOX Facilities at Pantex

Impact	Pit Conversion	MOX	Total[a]
Population within 80 km for year 2010			
Dose (person-rem)	0.58	0.010	0.59
Percent of natural background[b]	5.8×10^{-4}	1.0×10^{-5}	5.9×10^{-4}
10-year latent fatal cancers	2.9×10^{-3}	5.0×10^{-5}	3.0×10^{-3}
Maximally exposed individual			
Annual dose (mrem)	0.062	5.5×10^{-3}	0.068
Percent of natural background[b]	0.019	1.7×10^{-3}	0.021
10-year latent fatal cancer risk	3.1×10^{-7}	2.8×10^{-8}	3.4×10^{-7}
Average exposed individual within 80 km[c]			
Annual dose (mrem)	1.9×10^{-3}	3.3×10^{-5}	1.9×10^{-3}
10-year latent fatal cancer risk	9.5×10^{-9}	1.7×10^{-10}	9.7×10^{-9}

[a] Totals are additive in all cases because the same groups or individuals would receive doses from both facilities.
[b] The annual natural background radiation level at Pantex is 332 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 99,300 person-rem.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of Pantex in 2010 (299,000).
Source: Model results.

Table J–32. Potential Radiological Impacts on Involved Workers of Operation of New Pit Conversion and MOX Facilities at Pantex

Impact	Pit Conversion	MOX	Total
Number of badged workers	383	350	733
Total dose (person-rem/yr)	192	175	367
10-year latent fatal cancers	0.77	0.70	1.5
Average worker dose (mrem/yr)	500	500	500[a]
10-year latent fatal cancer risk	2.0×10^{-3}	2.0×10^{-3}	2.0×10^{-3}

[a] Represents an average of the doses for both facilities.

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.4 SRS

J.4.1 Assessment Data

To perform the dose assessments for the SPD EIS, different types of data were collected and generated. In addition, calculational assumptions were made. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) that were used for the assessments.

J.4.1.1 Meteorological Data

The meteorological data used for the SRS dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD data file was based on measurements taken over a period of several years at a specific location (F-Area) and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–33 presents the JFD data used in the dose assessments for SRS.

J.4.1.2 Population Data

The SRS population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2010 (about midlife of operations) for areas within 80 km (50 mi) of the locations for the proposed surplus plutonium disposition facilities. The site population in 2010 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at the Actinide Packaging and Storage Facility and Building 221–F in F-Area, the locations from which radionuclides are assumed to be released during incident-free operations. Tables J–34 and J–35 present the population data used for the dose assessments at SRS.

J.4.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII (leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs). Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels are then used in the assessment of doses to the SRS population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. SRS food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.4.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the data reports for pit conversion, immobilization, and MOX facilities (UC 1998i, 1998j, 1998k, 1998l, 1998m, 1998n).

J.4.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the facilities at SRS, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.
- Reported stack heights were used for atmospheric releases. The resultant doses were conservative as use of the actual stack height instead of the effective stack height negates plume rise.
- The calculated doses are 50-year committed doses from 1 year of intake.

J.4.2 Facilities

The following sections present all viable radiological impact scenarios that could be associated with different combinations of incident-free facility operations at SRS.

J.4.2.1 Pit Conversion Facility

J.4.2.1.1 Construction of Pit Conversion Facility

No radiological risk would be incurred by members of the public from the construction of a new pit conversion facility at SRS. Construction worker exposures to radiation that derives from other activities at the site, past and present, would also be kept as low as is reasonably achievable. Construction workers would be monitored (badged) as appropriate. Summaries of radiological impacts of these activities are presented in Table J–36 for workers at risk.

Table J–36. Potential Radiological Impacts on Construction Workers of New Pit Conversion Facility at SRS

Annual average number of workers	316
Total dose (person-rem/yr)	1.3
Annual latent fatal cancers[a]	5.2×10^{-4}
Average worker dose (mrem/yr)	4
Annual latent fatal cancer risk	1.6×10^{-6}

[a] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Note: The radiological limit for a construction worker is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: ICRP 1991; NAS 1990; UC 1998i.

J.4.2.1.2 Operation of Pit Conversion Facility

Tables J–37 and J–38 present the incident-free radiological impacts of the operation of a new pit conversion facility at SRS.

Table J–37. Potential Radiological Impacts on the Public of Operation of New Pit Conversion Facility at SRS

Population within 80 km for year 2010	
Dose (person-rem)	1.6
Percent of natural background[a]	6.9×10^{-4}
10-year latent fatal cancers	8.0×10^{-3}
Maximally exposed individual	
Annual dose (mrem)	3.7×10^{-3}
Percent of natural background[a]	1.3×10^{-3}
10-year latent fatal cancer risk	1.9×10^{-8}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	2.0×10^{-3}
10-year latent fatal cancer risk	1.0×10^{-8}

[a] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 231,700 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of SRS in 2010 (about 785,400).

Source: Model results.

Table J–38. Potential Radiological Impacts on Involved Workers of Operation of New Pit Conversion Facility at SRS

Number of badged workers	383
Total dose (person-rem/yr)	192
10-year latent fatal cancers	0.77
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998i.

J.4.2.2 Immobilization Facility

J.4.2.2.1 Construction of Immobilization Facility

No radiological risk would be incurred by members of the public from the modification of Building 221–F or new construction for plutonium conversion and immobilization (ceramic or glass) at SRS. Construction worker exposures to radiation that derives from other activities at the site, past or present, would also be kept as low as is reasonably achievable. Construction workers would be monitored (badged) as appropriate. Summaries of radiological impacts of these activities are presented in Table J–39 for workers at risk.

Table J–39. Potential Radiological Impacts on Construction Workers of Immobilization Facility in Building 221–F or New Construction at SRS

Impact	Bldg. 221–F[a]	New[a]
Annual average number of workers	315	347
Total dose (person-rem/yr)	4.7	1.4
Annual latent fatal cancers[b]	1.9×10^{-3}	5.6×10^{-4}
Average worker dose (mrem/yr)	15	4
Annual latent fatal cancer risk	6.0×10^{-6}	1.6×10^{-6}

[a] The values would be the same for immobilization in either ceramic or glass.
[b] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Note: The radiological limit for a construction worker is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.4.2.2.2 Operation of Immobilization Facility

Tables J–40 and J–41 present all possible incident-free radiological impact scenarios of the operation of an immobilization facility at SRS.

Table J–40. Potential Radiological Impacts on the Public of Operation of Immobilization Facility in Building 221–F or New Construction at SRS[a]

	17 t		50 t	
Impact	**Ceramic**	**Glass**	**Ceramic**	**Glass**
Population within 80 km for year 2010				
Dose (person-rem)	2.3×10^{-3}	2.2×10^{-3}	4.9×10^{-3}	4.5×10^{-3}
Percent of natural background[b]	1.0×10^{-6}	1.0×10^{-6}	2.1×10^{-6}	1.9×10^{-6}
10-year latent fatal cancers	1.2×10^{-5}	1.1×10^{-5}	2.5×10^{-5}	2.3×10^{-5}
Maximally exposed individual				
Annual dose (mrem)	2.4×10^{-5}	2.2×10^{-5}	5.0×10^{-5}	4.6×10^{-5}
Percent of natural background[b]	8.1×10^{-6}	7.5×10^{-6}	1.7×10^{-5}	1.6×10^{-5}
10-year latent fatal cancer risk	1.2×10^{-10}	1.1×10^{-10}	2.5×10^{-10}	2.3×10^{-10}
Average exposed individual within 80 km[c]				
Annual dose (mrem)	2.9×10^{-6}	2.8×10^{-6}	6.3×10^{-6}	5.7×10^{-6}
10-year latent fatal cancer risk	1.5×10^{-11}	1.4×10^{-11}	3.2×10^{-11}	2.9×10^{-11}

[a] Impacts were assessed to be essentially identical for operations at either Building 221–F or the new facility.
[b] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive about 231,000 person-rem.
[c] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of the SRS facilities in 2010 (about 783,000).
Source: Model results.

Table J–41. Potential Radiological Impacts on Involved Workers of Operation of Immobilization Facility in Building 221–F or New Construction at SRS[a]

	17 t		50 t	
Impact	**Bldg. 221–F**	**New**	**Bldg. 221–F**	**New**
Number of badged workers	258	232	290	257
Total dose (person-rem/yr)	194	174	218	193
10-year latent fatal cancers	0.77	0.70	0.87	0.77
Average worker dose (mrem/yr)	750	750	750	750
10-year latent fatal cancer risk	3.0×10^{-3}	3.0×10^{-3}	3.0×10^{-3}	3.0×10^{-3}

[a] The values would be the same for immobilization in either ceramic or glass.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.4.2.3 MOX Facility

J.4.2.3.1 Construction of MOX Facility

No radiological risk would be incurred by members of the public from the construction of a new MOX facility at SRS. Construction worker exposures to radiation that derives from other activities at the site, past or present, would also be kept as low as is reasonably achievable. Construction workers would be monitored (badged) as appropriate. Summaries of radiological impacts of these activities are presented in Table J–42 for workers at risk.

Table J–42. Potential Radiological Impacts on Construction Workers of New MOX Facility at SRS

Annual average number of workers	292
Total dose (person-rem/yr)	1.2
Annual latent fatal cancers[a]	4.8×10^{-4}
Average worker dose (mrem/yr)	4
Annual latent fatal cancer risk	1.6×10^{-6}

[a] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.

Note: The radiological limit for a construction worker is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

Source: ICRP 1991; NAS 1990; UC 1998n.

J.4.2.3.2 Operation of MOX Facility

Tables J–43 and J–44 present the incident-free radiological impacts of the operation of a MOX facility at SRS.

Table J–43. Potential Radiological Impacts on the Public of Operation of New MOX Facility at SRS

Population within 80 km for year 2010	
Dose (person-rem)	0.029
Percent of natural background[a]	1.3×10^{-5}
10-year latent fatal cancers	1.5×10^{-4}
Maximally exposed individual	
Annual dose (mrem)	3.1×10^{-4}
Percent of natural background[a]	1.1×10^{-4}
10-year latent fatal cancer risk	1.6×10^{-9}
Average exposed individual within 80 km[b]	
Annual dose (mrem)	3.7×10^{-5}
10-year latent fatal cancer risk	1.9×10^{-10}

[a] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive 231,700 person-rem.

[b] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of SRS in 2010 (785,400).

Source: Model results.

Table J–44. Potential Radiological Impacts on Involved Workers of Operation of New MOX Facility at SRS

Number of badged workers	350
Total dose (person-rem/yr)	175
10-year latent fatal cancers	0.70
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

10-year latent fatal cancers	0.77	0.70	1.5
Average worker dose (mrem/yr)	500	500	500[a]
10-year latent fatal cancer risk	2.0×10^{-3}	2.0×10^{-3}	2.0×10^{-3}

[a] Represents an average of the doses for both facilities.
Note: The radiological limit for an individual worker is 5,000 mrem/yr (DOE 1995). However, the maximum dose to a worker involved in operations would be kept below the DOE administrative control level of 2,000 mrem/yr. An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.
Source: UC 1998i, 1998n.

J.4.2.6 Immobilization and MOX Facilities

J.4.2.6.1 Construction of Immobilization and MOX Facilities

No radiological risk would be incurred by members of the public from the modification of Building 221–F or new construction for plutonium conversion and immobilization (ceramic or glass) and construction of a new MOX facility at SRS. Construction worker exposures to radiation deriving from other activities, past or present, at the site would also be kept as low as is reasonably achievable. Construction workers would be monitored (badged) as appropriate. Summaries of radiological impacts of these activities are presented in Table J–51 for workers at risk.

Table J–51. Potential Radiological Impacts on Construction Workers of Immobilization Facility in Building 221–F or New Construction and New MOX Facility at SRS

	Immobilization[a]			Total	
Impact	Bldg. 221–F	New	MOX	With Bldg. 221–F	With New
Annual average number of workers	315	347	292	607	639
Total dose (person-rem/yr)	4.7	1.4	1.2	5.9	2.6
Annual latent fatal cancers[b]	1.9×10^{-3}	5.6×10^{-4}	4.8×10^{-4}	2.4×10^{-3}	1.0×10^{-3}
Average worker dose (mrem/yr)	15	4	4	9.7[c]	4[c]
Annual latent fatal cancer risk	6.0×10^{-6}	1.6×10^{-6}	1.6×10^{-6}	3.9×10^{-6}	1.6×10^{-6}

[a] The values would be the same for immobilization in either ceramic or glass.
[b] Values are based on a risk factor of 400 latent fatal cancers per million person-rem set by the National Research Council's Committee on the Biological Effects of Ionizing Radiations.
[c] Represents an average of the doses for both facilities.
Note: The radiological limit for a construction worker is 100 mrem/yr because they are categorized as members of the public (DOE 1993). An effective ALARA program would ensure that doses are reduced to levels that are as low as is reasonably achievable.

J.4.2.6.2 Operation of Immobilization and MOX Facilities

Tables J–52 and J–53 present the incident-free radiological impacts of operation of the immobilization and MOX facilities at SRS.

Table J–52. Potential Radiological Impacts on the Public of Operation of Immobilization Facility in Building 221–F or New Construction and New MOX Facility at SRS

Impact	Immobilization (17 t)[a]		MOX	Total[b]
	Ceramic	Glass		
Population within 80 km for year 2010				
Dose (person-rem)	2.3×10^{-3}	2.2×10^{-3}	0.029	0.031
Percent of natural background[c]	1.0×10^{-6}	1.0×10^{-6}	1.3×10^{-5}	1.4×10^{-5}
10-year latent fatal cancers	1.2×10^{-5}	1.1×10^{-5}	1.5×10^{-4}	1.6×10^{-4}
Maximally exposed individual				
Annual dose (mrem)	2.4×10^{-5}	2.2×10^{-5}	3.1×10^{-4}	3.3×10^{-4}
Percent of natural background[c]	8.1×10^{-6}	7.5×10^{-6}	1.1×10^{-4}	1.2×10^{-4}
10-year latent fatal cancer risk	1.2×10^{-10}	1.1×10^{-10}	1.6×10^{-9}	1.7×10^{-9}
Average exposed individual within 80 km[d]				
Annual dose (mrem)	2.9×10^{-6}	2.8×10^{-6}	3.7×10^{-5}	4.0×10^{-5}
10-year latent fatal cancer risk	1.5×10^{-11}	1.4×10^{-11}	1.9×10^{-10}	2.1×10^{-10}

[a] Impacts were assessed to be essentially identical for operations at either Building 221–F or the new facility.
[b] Totals represent the largest possible sums for each public category. Totals are additive in all cases because the same groups or individuals would receive doses from both facilities.
[c] The annual natural background radiation level at SRS is 295 mrem for the average individual; the population within 80 km (50 mi) in 2010 would receive about 231,000 person-rem.
[d] Obtained by dividing the population dose by the number of people projected to live within 80 km (50 mi) of the SRS facilities in 2010 (about 783,000).

J.5 LEAD ASSEMBLY FABRICATION

J.5.1 ANL–W

J.5.1.1 Assessment Data

This section presents applicable data and assumptions used in the assessment of lead assembly human health risks at ANL–W at INEEL. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessment.

J.5.1.1.1 Meteorological Data

The meteorological data used for the ANL–W dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–17 presents the JFD used in the dose assessments for ANL–W.

J.5.1.1.2 Population Data

The INEEL population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2005 for areas within 80 km (50 mi) of the proposed facility location. The site population in 2005 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at ANL–W, the location from which radionuclides are assumed to be released during incident-free operations. Table J–57 presents the population data used for the lead assembly dose assessments at ANL–W.

J.5.1.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. ANL–W food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.5.1.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the Oak Ridge National Laboratory (ORNL) *ANL-W MOX Fuel Lead Assemblies Data Report for the Surplus Plutonium Disposition Environmental Impact Statement* (O'Connor et al. 1998a).

Key: ANL–W, Argonne National Laboratory–West.
Source: DOC 1992.

J.5.1.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the lead assembly facility at ANL–W, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.

- Reported stack heights were used for atmospheric releases and were assumed to be the effective stack height. The resultant doses were conservative because use of the actual stack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.5.1.2 Human Health Impacts

Potential radiological impacts on the public and workers resulting from normal lead assembly operations are presented in Section 4.27.1.4. Potential impacts on postirradiation examination facility workers are presented in Section 4.27.6.2.

J.5.2 Hanford

J.5.2.1 Assessment Data

This section presents applicable data and assumptions used in the assessment of lead assembly human health risks at Hanford. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessment.

J.5.2.1.1 Meteorological Data

The meteorological data used for the Hanford dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–1 presents the JFD used in the dose assessments for Hanford.

J.5.2.1.2 Population Data

The Hanford population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2005 for areas within 80 km (50 mi) of the proposed facility location. The site population in 2005 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at FMEF in the 400 Area, the location from which radionuclides are assumed to be released during incident-free operations. Table J–58 presents the population data used for lead assembly dose assessments at Hanford.

J.5.2.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food

grown in that area. Hanford food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition Final PEIS* (HNUS 1996).

J.5.2.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are reported in the ORNL *Hanford MOX Fuel Lead Assemblies Data Report for the Surplus Plutonium Disposition Environmental Impact Statement* (O'Connor et al. 1998b).

J.5.2.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the lead assembly facility at Hanford, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).

- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).

- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.

- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.

- Reported stack heights were used for atmospheric releases and were assumed to be the effective stack height. The resultant doses were conservative because use of the actual stack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.5.2.2 Human Health Impacts

Potential radiological impacts on the public and workers resulting from normal lead assembly operations are presented in Section 4.27.2.4.

J.5.3 LLNL

J.5.3.1 Assessment Data

This section presents applicable data and assumptions used in the assessment of lead assembly human health risks at LLNL. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessment.

J.5.3.1.1 Meteorological Data

The meteorological data used for the LLNL dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken at a specific location and height. Annual meteorological conditions were used for normal operation. Table J–59 presents the JFD used in the dose assessments for LLNL.

J.5.3.1.2 Population Data

The LLNL population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2005 for areas within 80 km (50 mi) of the proposed facility location. The site population in 2005 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at Building 332, the location from which radionuclides are assumed to be released during incident-free operations. Table J–60 presents the population data that were used for lead assembly dose assessments at LLNL.

J.5.3.1.3 Agricultural Data

The 1992 Census of Agriculture (DOC 1992) was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food

categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. LLNL food production and consumption data used for the dose assessments in the SPD EIS were obtained from the 1992 Census data for LLNL (DOC 1992).

J.5.3.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the ORNL *LLNL MOX Fuel Lead Assemblies Data Report for the Surplus Plutonium Disposition Environmental Impact Statement* (O'Connor et al. 1998c).

J.5.3.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the lead assembly facility at LLNL, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.
- Reported stack heights were used for atmospheric releases and were assumed to be the effective stack height. The resultant doses were conservative because use of the actual stack height negates plume rise.
- The calculated doses are 50-year committed doses from 1 year of intake.

J.5.3.2 Human Health Impacts

Potential radiological impacts on the public and workers resulting from normal lead assembly operations are presented in Section 4.27.3.4.

J.5.4 LANL

J.5.4.1 Assessment Data

This section presents applicable data and assumptions used in the assessment of lead assembly human health risks at LANL. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessment.

J.5.4.1.1 Meteorological Data

The meteorological data used for the LANL dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken at a specific location and height. Annual meteorological conditions were used for normal operation. Table J–61 presents the JFD used in the dose assessments for LANL.

J.5.4.1.2 Population Data

The LANL population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2005 for areas within 80 km (50 mi) of the proposed facility location. The site population in 2005 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered at Technical Area 55 (TA–55), the location from which radionuclides are assumed to be released during incident-free operations. Table J–62 presents the population data used for lead assembly dose assessments at LANL.

J.5.4.1.3 Agricultural Data

The 1992 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-m (50-mi) assessment area were assumed to consume only food grown in that area. LANL food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Draft Environmental Impact Statement on Management of Certain Plutonium Residues and Scrub Alloy Stored at the Rocky Flats Environmental Technology Site* (DOE 1997b).

J.5.4.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the ORNL *LANL MOX Fuel Lead Assemblies Data Report for the Surplus Plutonium Disposition Environmental Impact Statement* (O'Connor et al. 1998d).

J.5.4.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the lead assembly facility at LANL, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).
- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.
- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.

- Reported stack heights were used for atmospheric releases and were assumed to be the effective stack height. The resultant doses were conservative, because use of the actual stack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.5.4.2 Human Health Impacts

Potential radiological impacts on the public and workers resulting from normal lead assembly operations are presented in Section 4.27.4.4.

J.5.5 SRS

J.5.5.1 Assessment Data

This section presents applicable data and assumptions used in the assessment of lead assembly human health risks at SRS. Appendix F.10 provides a summary of the methods and tools (e.g., the GENII computer code) used for the assessment.

J.5.5.1.1 Meteorological Data

The meteorological data used for the SRS dose assessments was in the form of a JFD file. A JFD file is a table listing the percentages of time the wind blows in a certain direction, at a certain speed, and within a certain stability class. The JFD file was based on measurements taken over a period of several years at a specific location (H-Area) and height. Average annual meteorological conditions, averaged over the measurement period, were used for normal operation. Table J–63 presents the JFD used in the dose assessments for SRS.

J.5.5.1.2 Population Data

The SRS population distribution was based on the *1990 Census of Population and Housing Data* (DOC 1992). Projections were determined for the year 2005 for areas within 80 km (50 mi) of the proposed facility location. The site population in 2005 was assumed to be representative of the population over the operational period evaluated. The population was spatially distributed on a circular grid with 16 directions and 10 radial distances out to an 80-km (50-mi) distance. The grid was centered within H-Area, the location from which radionuclides are assumed to be released during incident-free operations. Table J–64 presents the population data used for the lead assembly dose assessments at SRS.

J.5.5.1.3 Agricultural Data

The 1987 Census of Agriculture was the source used to generate site-specific data for food production. Food production was spatially distributed on a circular grid similar to that used for the population distributions described previously. This food grid (or wheel) was generated by combining the fraction of a county in each segment (e.g., south, southwest, north-northeast) and the county production of the eight food categories analyzed by GENII—leafy vegetables, root vegetables, fruits, grains, beef, poultry, milk, and eggs. Each county's food production was assumed to be distributed uniformly over the given county's land area. These categorized food wheels were then used in the assessment of doses to the population from the ingestion pathway. The consumption rates used in the dose assessments were those for the MEI and average exposed individual. People living within the 80-km (50-mi) assessment area were assumed to consume only food grown in that area. SRS food production and consumption data used for the dose assessments in the SPD EIS were obtained from the *Health Risk Data for Storage and Disposition of Final PEIS* (HNUS 1996).

J.5.5.1.4 Source Term Data

Incident-free radiological releases, stack heights, and release locations are provided in the ORNL *SRS MOX Fuel Lead Assemblies Data Report for the Surplus Plutonium Disposition Environmental Impact Statement* (O'Connor et al. 1998e).

J.5.5.1.5 Other Calculational Assumptions

To estimate radiological impacts of incident-free operations of the facilities at SRS, the following additional assumptions and factors were considered, in accordance with the guidelines established in NRC Regulatory Guide 1.109 (NRC 1977).

- Ground surfaces were assumed to have no previous deposition of radionuclides.
- The annual external exposure time to the plume and to soil contamination was 0.7 year for the MEI (NRC 1977).
- The annual external exposure time to the plume and to soil contamination was 0.5 year for the population (NRC 1977).
- The annual inhalation exposure time to the plume was 1 year for the MEI and general population (NRC 1977).

- The exposed individual or population was assumed to have the characteristics and habits (e.g., inhalation and ingestion rates) of the adult human.

- A semi-infinite/finite plume model was used for air immersion doses. Other pathways evaluated were ground exposure, inhalation, ingestion of food crops, and ingestion of contaminated animal products. Drinking water, aquatic food ingestion, and any other pathway that may involve liquid exposure were not examined because all releases are to the air.

- Reported stack heights were used for atmospheric releases and were assumed to be the effective stack height. The resultant doses were conservative because use of the actual stack height negates plume rise.

- The calculated doses are 50-year committed doses from 1 year of intake.

J.5.5.2 Human Health Impacts

Potential radiological impacts on the public and workers resulting from normal lead assembly operations are presented in Section 4.27.5.4.

Appendix K
Facility Accidents

K.1 IMPACT ASSESSMENT METHODS FOR FACILITY ACCIDENTS

K.1.1 Introduction

The potential for facility accidents and the magnitude of their consequences are important factors for making reasonable choices among the various surplus plutonium disposition alternatives analyzed in the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS). Guidance on implementation of 40 CFR 1502.22, as amended (EPA 1992), requires the evaluation of impacts that have a low frequency of occurrence but high consequences. Further, public comments received during the scoping process have clearly indicated the public's concern with facility safety and health risks and the need to address these concerns in the decisionmaking process.

For the No Action Alternative, potential accidents are defined in existing facility documentation, such as Safety Analysis Reports (SARs), hazards assessment documents, National Environmental Policy Act (NEPA) documents, and probabilistic risk assessments (PRAs). The accidents include radiological and chemical accidents that have a low frequency of occurrence but high consequences, and a spectrum of other accidents that have a higher frequency of occurrence and lesser consequences. The data in these documents include accident scenarios, materials at risk, source terms (quantities of hazardous materials released to the environment), and consequences.

For each facility, a hazards analysis document identifying and estimating the effects of all major hazards that could affect the environment, workers, and the public would be issued in conjunction with the conceptual design package. Additional accident analyses for identified major hazards would be provided in a preliminary SAR issued during the period of definitive design (Title II) review. A final SAR would be prepared during the construction period and issued before testing began as final documented evidence that the new facility could be operated in a manner that did not pose any undue risk to the health and safety of workers and the public.

In determining the potential for facility accidents and the magnitude of their consequences, the SPD EIS considers two important concepts in the presentation of results: (1) risk and (2) uncertainties and conservatism.

K.1.1.1 Risk

One type of metric that can be obtained from the accident analysis results presented in the SPD EIS is accident risk. Risk is usually defined as the product of the consequences and estimated frequency of a given accident. Accident consequences may be presented in terms of dose (e.g., person-rem) or health effects (e.g., latent cancer fatalities [LCFs]). The accident frequency is the number of times the accident is expected to occur over a given period of time (e.g., per year). In general, the frequency of design basis and beyond-design-basis accidents is much lower than 1 per year, and therefore is approximately equal to the probability of the accident during 1 year. If an accident is expected to occur once every 1,000 years (i.e., a frequency of 1.0×10^{-3} per year) and the consequences of the accident are five LCFs, then the risk is $1.0\times10^{-3}\times5 = 5.0\times10^{-3}$ LCF per year.

A number of specific types of risk can be directly calculated from the MACCS2 results reported in the SPD EIS. One type of risk, average individual risk, is the product of the total consequences experienced by the population and the accident frequency, divided by the population. For example, if an accident has a frequency of 1.0×10^{-3} per year, the consequence thereof is 5 LCFs, and the population in which the fatalities are experienced is 100,000, then the average individual risk is $1.0\times10^{-3} \times 5/100{,}000 = 5.0\times10^{-8}$ LCF per year.

It is important to note that this metric is meaningful only when the mean value for consequence is used, because risk itself is not a random parameter, even though it involves underlying randomness. It is also noteworthy that the value of the average individual risk depends on the size of the area for which the population is defined. In general, the larger the area considered, the smaller the average individual risk for a given accident. The choice of an 80-km (50-mi) radius is common practice.

The average individual risk is a measure of the risk that an average individual (in this case within 80 km [50 mi] of the accident) experiences from specified accidents at the facility. This risk can be compared with other average individual risks, such as the risk of dying from a motor vehicle accident (about 1 in 80), the risk of death from fires (about 1 in 500), or the risk of accidental poisoning (about 1 in 1,000). These comparisons are not meant to imply that risks of an LCF caused by U.S. Department of Energy (DOE) operations are trivial, but only to show how they compare with other, more common risks. Radiological risks to the general public from DOE operations are considered to be involuntary risks as opposed to voluntary risks, such as operating a motor vehicle.

It is also possible to calculate population risk, which is the product of the total consequences experienced by the population and accident frequency. For example, if an accident has a frequency of 1.0×10^{-3} per year and the consequences of the accident is 5 LCFs, then the population risk is $1.0\times10^{-3}\times5 = 5.0\times10^{-3}$ LCF per year. Population risk is a measure of the expected number of consequences experienced by the population as a whole over the course of a year. Like average individual risk, population risk is sensitive to the size of the area for which the population is defined.

It would be inappropriate, however, to simply take the LCFs given the dose at 1,000 m (3,281 ft) or the LCFs given the dose at the site boundary and multiply them by the corresponding accident frequencies in an attempt to obtain the maximum individual risk to the noninvolved worker or the maximally exposed individual (MEI) member of the public. The reasons for this are discussed in the following paragraphs.

The distribution of centerline consequences from which the reported doses are obtained is constructed by modeling the accidental release many times using different weather conditions (i.e., windspeed, wind direction, stability class, and rainfall) each time. For each weather condition, the centerline consequences at 1,000 m (3,281 ft) and at the site boundary are calculated, and those values contribute to their respective distributions. Thus, given the accidental release, there is a 95 percent chance that the centerline consequences at 1,000 m (3,281 ft) and at the site boundary will fall below the reported 95th percentile consequences, and the expected consequences would be equal to the reported mean consequences. It is noteworthy, however, that the actual locations of the centerline consequences vary with wind direction, so the reported consequences are not associated with a specific point at 1,000 m (3,281 ft) or the site boundary. It is known only that the centerline consequences, wherever they might be, are characterized by the reported values.

A problem arises if the above consequences are used to characterize individual risk. Although there is always some location that is exposed to the centerline consequences, no location is associated with the risk obtained by multiplying the centerline consequences by the accident frequency, because the direction of the plume centerline changes for each set of weather conditions. As a result, the risk to an individual at the location of maximum risk is likely to be much lower than the risk calculated by multiplying the centerline consequences by the accident frequency. In fact, because there are 16 sectors, and because doses decrease with lateral movement away from the centerline even within a sector, risk values generated in this way would tend to overstate the risk by a factor of as much as 100, and possibly more. The values are bounding, but have a potentially misleading degree of conservatism. Ultimately, the Melcor Accident Consequence Code System (MACCS2) is capable of calculating individual consequences at the point of maximum consequences (as reported in the SPD EIS), but it is not configured to calculate individual risk at the point of maximum risk.

K.1.1.2 Uncertainties and Conservatism

The analyses of accidents are based on calculations relevant to hypothetical sequences of events and models of their effects. The models provide estimates of the frequencies, source terms, pathways for dispersion, exposures, and the effects on human health and the environment that are as realistic as possible within the scope of the analysis. In many cases, a paucity of experience with the accidents postulated leads to uncertainty in the calculation of their consequences and frequencies. This fact has prompted the use of models or input values that yield conservative estimates of consequence and frequency. All alternatives have been evaluated using uniform methods and data, allowing for a fair comparison of all alternatives.

Although average individual and population risks can be calculated from the information in the SPD EIS, the equations for such calculations involve accident frequency, a parameter whose calculation is subject to considerable uncertainty. The uncertainty in estimates of the frequency of highly unlikely events can be several orders of magnitude. This is the reason accident frequencies are reported in the SPD EIS qualitatively, in terms of broad frequency bins, as opposed to numerically. Similarly, any metric that includes frequency as a factor will have at least as much, and generally more, uncertainty associated with it. Therefore, the consequence metrics have been preserved as the primary accident analysis results, and accident frequencies identified qualitatively, to provide a perspective on risk that does not imply an unjustified level of precision.

K.1.2 Safety Design Process

Surplus plutonium disposition facilities would be designed to comply with current Federal, State, and local laws, DOE orders, and industrial codes and standards. This would result in a plant that is highly resistant to the effects of natural phenomena, including earthquake, flood, tornado, and high wind, as well as credible events as appropriate to the site, such as fire, explosions, and man-made threats.

The design process for the surplus plutonium disposition facilities would comply with the requirements for safety analysis and evaluation in DOE Orders 430.1 and 5480.23. These orders require that the safety assessment be an integral part of the design process to ensure compliance with all DOE construction and operation safety criteria by the time the facilities are constructed and in operation.

The safety analysis process begins early in conceptual design with the identification of hazards that could produce unintended adverse safety consequences to workers or the public. As the design develops, failure modes and effects analyses (FMEAs) are performed to identify events capable of releasing hazardous material. The kinds of events considered include equipment failure, spills, human error, fire, explosions, criticality, earthquake, electrical storms, tornado, flood, and aircraft crash. These postulated events become focal points for design changes or improvements to prevent unacceptable accidents. The analyses continue as the design progresses, the object being to assess the need for safety equipment and the performance of such equipment. Eventually, the safety analyses are formally documented in a SAR and, if appropriate, a PRA. The PRA documents the estimated frequency and consequences of a complete spectrum of accidents and helps to identify where design improvements could make meaningful safety improvements.

The first SAR, completed at the conclusion of conceptual design, includes identification of hazards and some limited assessment of a few enveloping design basis accidents. It includes deterministic safety analysis and FMEA of major systems. A comprehensive preliminary SAR, completed by the end of the preliminary design, provides a broad assessment of the range of design basis accident scenarios and the performance of equipment provided in the facility specifically for accident consequence mitigation. A limited PRA may be included in that analysis.

The SAR continues to be developed during detailed design. The safety review of the report and any supporting PRA are completed and safety issues resolved before the initiation of facility construction. Also, a final SAR is produced that includes documentation of safety-related design changes made during construction and the impact of those changes on the safety assessment. It also includes the results of any safety-related research and development that was performed to support the safety assessment of the facility. Approval of the final SAR is required before the facility is allowed to commence operation.

K.1.3 Facility Accident Identification and Quantification

K.1.3.1 Background

Identification of accident scenarios for the surplus plutonium disposition facilities is fairly straightforward. The proposed facilities are simple, and their processes have been used in other facilities for other purposes. From an accident identification and quantification perspective, therefore, these processes are well known and understood. Very few of the proposed activities would differ from activities at other facilities.

New facilities would likely be designed, constructed, and operated to provide an even lower accident risk than other facilities that have used these types of processes. The new facilities would benefit from lessons learned in the operation of similar processes. They would be designed to surpass existing plutonium facilities in the ability to reduce the frequency of accidents and to mitigate the consequences thereof.

A large experience base exists for the design of the proposed surplus plutonium disposition facilities and processes. Because the principal hazard to workers and the public from plutonium is the inhalation of very small particles, the safety management approach that has evolved is centered on control of those particles. The control approach is to perform all operations that could release airborne plutonium particles in a glovebox. The glovebox protects workers from inhalation of the particles and provides a convenient means for the collection of any particle that becomes airborne on filters. Air from the gloveboxes, operating areas, and buildings is exhausted through multiple stages of high efficiency particulate air (HEPA) filters and monitored for radioactivity prior to release from the building. These exhaust systems are designed for effective performance even under the severe conditions of design basis accidents, such as major fires involving an entire process line.

While the new processes and facilities would be designed to reduce the risks of a wide range of possible accidents to a level deemed acceptable, some such risks would remain. As with all engineered structures—e.g., houses, bridges, dams—there is some level of earthquake or high wind the structure could not survive. While new plutonium facilities must be designed to very high standards—for instance, they must survive, with little plutonium release, a 1-in-10,000-year earthquake—an accident more severe than the design basis can always be postulated. Current DOE standards require that new facilities be designed to prevent to the extent possible, and then withstand, control, and mitigate, all credible process-related accidents. For safety analysis purposes, credible accidents are generally defined as accidents with frequencies greater than 1 in 1 million per year, including such natural phenomena–induced accidents as earthquakes, high winds, and flooding. The accidents considered in the design, construction, and operation of these facilities are generally called design basis accidents.

In addition to the accident risks from the design basis accidents, the new facilities would face risks from beyond-design-basis accidents. For most plutonium facilities, the design basis includes all types of process-related accidents that have occurred in past operations: major spills, leaks, transfer errors, process-related fires, explosions, and nuclear criticalities. Certain natural phenomena–initiated accidents also meet the DOE design basis criteria. While extremely unlikely, all new plutonium facilities, as essentially all manmade structures, could collapse under the influence of an earthquake. For most new plutonium facilities,

the worst possible accident is a beyond-design-basis earthquake that results in partial or total collapse of the structure, spills, possibly fires, and loss of confinement of the plutonium powder. Also conceivable are such external events as the crash of a large aircraft onto the structure with an ensuing fuel-fed fire. At most locations away from major airports, however, the likelihood is less than 1 in 10 million per year. For some locations, such as Pantex, the frequency is higher, so aircraft crash–initiated accidents are a basic consideration.

The accident analysis reported in the SPD EIS is less detailed than a formal PRA or facility safety analysis because it addresses bounding accidents (accidents with low frequency of occurrence and high consequence) and a representative spectrum of possible operational accidents (accidents with high frequency of occurrence and low consequence). The technical approach for the selection of accidents is consistent with the DOE Office of NEPA Oversight's *Recommendation for the Preparation of Environmental Assessments and Environmental Impact Statements* (DOE 1993), which recommends consideration of two major categories of accidents: design basis accidents and beyond-design-basis accidents.[1]

K.1.3.2 Identification of Accident Scenarios and Frequencies

A range of design basis and beyond-design-basis accident scenarios have been identified for each of the surplus plutonium disposition technologies (UC 1998a, 1998b, 1998c, 1998d, 1998e, 1998f, 1998g, 1998h, 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). For each technology, the wide range of process-related accidents possible during construction and operation of the facility have been evaluated to ensure that their consequences are low or the frequency of occurrence, extremely low.

All of the analyzed accidents would involve a release of small, respirable plutonium particles or direct gamma and neutron radiation, and to a lesser extent, fission products from a nuclear criticality. Analyses of each proposed operation for accidents involving hazardous chemicals are reflected in the data reports supporting the SPD EIS. However, as the quantities of hazardous chemicals to be handled are small relative to those of many industrial facilities, no major chemical accidents were identified. The general categories of process-related accidents considered include:

- Drops or spills of materials within and outside the gloveboxes
- Fires involving process equipment or materials, and room or building fires
- Explosions initiated by the process equipment or materials or by conditions or events external to the process
- Nuclear criticalities

For each of these accident categories, a conservative preliminary assessment of consequence was made, and where consequences were significant, one or more bounding accident scenarios were postulated. The building confinement and fire suppression systems would be adequate to reduce the risks of most spills and minor fires. The systems would be designed to prevent, to the extent practicable, larger fires and explosions. Great efforts have always been made to prevent nuclear criticalities, which have the potential to kill workers in their immediate vicinity. In all cases, standard practice is expected to keep the frequency of accidental nuclear criticalities as low as possible.

Because the DOE design criteria require that new plutonium processing buildings be of very robust, reinforced-concrete construction, very few events outside the building would have sufficient energy to threaten the building confinement. The principal concern would be the crash of a large commercial or military aircraft

[1] Some of the data reports supporting the SPD EIS use the terms "evaluation basis" and "beyond-evaluation-basis" to denote the two major categories of accidents. For clarity, the SPD EIS uses the terms "design basis" and "beyond-design-basis" throughout.

into the facility. Such an event, however, is highly unlikely. Only those crashes with a frequency greater than 10^{-7} per year are addressed in the SPD EIS.

Design basis and beyond-design-basis natural phenomena–initiated accidents are also considered. Because of the robust nature of construction of new plutonium facilities, the only design-basis natural phenomena-initiated accidents with the potential to impact the facility interior are seismic events. Similarly, seismic events also bound the consequences and risks posed by beyond-design-basis natural phenomena.

Accident frequencies are generally grouped into the bins of "anticipated," "unlikely," and "extremely unlikely," with estimated frequencies of greater than 10^{-2}, 10^{-2} to 10^{-4}, and 10^{-4} to 10^{-6} per year, respectively. The accidents evaluated represent a spectrum of accident frequencies and consequences ranging from low-frequency/high-consequence to high-frequency/low-consequence events. However, given the preliminary nature of the designs under consideration, it was not possible to assess quantitatively the frequency of occurrence of all the events addressed. The evaluation does not indicate the total risk of operating the facility, but does provide information on high-risk events that could be used to develop an accident risk ranking of the various alternatives.

K.1.3.3 Identification of Material at Risk

For each accident scenario, the material at risk—generally plutonium—was identified. Plutonium to be disposed of has a wide range of chemical and isotopic forms. The sources of plutonium vary among the various candidate facilities, and for specific facilities among various alternatives. Table K–1 presents the isotopic breakdowns that were used in the development of accident consequences in the SPD EIS. The vulnerability of material generally depends on the form of that material, the degree and robustness of containment, and the energetics of the potential accident scenario. For example, plutonium stored in strong, tight storage containers is not generally vulnerable to simple drops or spills, but may be vulnerable in a total collapse earthquake scenario.

Table K–1. Isotopic Breakdown of Plutonium Used in Accident Analysis

Isotope	Pit Disassembly, MOX, and Lead Assembly	Immobilization: Plutonium Conversion	Immobilization: First Stage, Hybrid Case	Immobilization: First Stage, 50-t Case
Plutonium 238	3.00×10^{-2}	0.0	0.0	1.98×10^{-2}
Plutonium 239	92.2	86.0	86.0	90.1
Plutonium 240	6.46	11.0	11.0	8.12
Plutonium 241	5.00×10^{-2}	1.49	1.49	5.74×10^{-1}
Plutonium 242	1.00×10^{-1}	4.95×10^{-1}	4.95×10^{-1}	2.48×10^{-1}
Americium 241	9.00×10^{-1}	9.90×10^{-1}	9.90×10^{-1}	9.31×10^{-1}

On an industrial scale, the quantities of hazardous chemicals are generally small. The occupational risks are generally limited to material handling and are managed under the required industrial hygiene program. No substantial hazardous chemical releases are expected.

K.1.3.4 Identification of Material Potentially Released to the Environment

The amount and particle size distribution of material aerosolized in an accident generally depends on the form of that material, the degree and robustness of containment, and the energetics of the potential accident scenario. Once the material is aerosolized, it must still travel through building confinement and filtration systems or bypass the systems before being released to the environment.

A standard DOE formula was used to estimate the source term for each accident at each of the proposed surplus plutonium facilities:

$$\text{Source Term} = \text{MAR} \times \text{DR} \times \text{ARF} \times \text{RF} \times \text{LPF}$$

where:

MAR = material at risk (curies or grams)
DR = damage ratio
ARF = airborne release fraction
RF = respirable fraction[2]
LPF = leak path factor

The value of each of these factors depends on the details of the specific accident scenario postulated. ARF and RF were estimated according to reference material in *Airborne Release Fractions/Rates and Respirable Fractions for Nonreactor Nuclear Facilities* (DOE-HDBK-3010-94) (DOE 1994a). Conservative HEPA filter efficiencies of 0.999 and 0.99 were assumed, based on two stages of filtration, for a total LPF of 1.0×10^{-5}; however, actual efficiencies would likely be 0.999 and 0.998 or better. For the Building 221–F ventilation system at the Savannah River Site (SRS), a total LPF of 4.9×10^{-3} was used to account for the F-Area sand filters.

No accident scenarios were identified that would result in a substantial release of plutonium or other radionuclides via liquid pathways.

K.1.4 Evaluation of Consequences of Accidents

K.1.4.1 Potential Receptors

For each potential accident, information is provided on accident consequences and frequencies to three types of receptors: (1) a noninvolved worker, (2) the maximally exposed member of the public, and (3) the offsite population. The first receptor, a noninvolved worker, is a hypothetical individual working on the site but not involved in the proposed activity. The worker is assumed to be downwind at a point 1,000 m (3,281 ft) from the accident. Although other distances closer to the accident could have been assumed, the calculations break down at distances of about 200 m (656 ft) or less due to limitations in modeling the effects of building wake and local terrain on dispersion of the released radioactive substances. A worker closer than 1,000 m (3,281 ft) to the accident would generally receive a higher dose; a worker farther away, a lower dose. At some sites where the distance from the accident to the nearest site boundary is less than 1,000 m (3,281 ft), the worker is assumed to be at the site boundary. The second receptor, a maximally exposed member of the public, is a hypothetical individual assumed to be downwind at the site boundary. Exposures received by this individual are intended to represent the highest doses to a member of the public. The third receptor, the offsite population, is all members of the public within 80 km (50 mi) of the accident location.

Consequences to workers directly involved in the processes under consideration are addressed generically, without attempt at an scenario-specific quantification of consequences. This approach to in-facility consequences was selected for two reasons. First, the uncertainties involved in quantifying accident consequences become overwhelming for most radiological accidents due to the high sensitivity of dose values to assumptions about the details of the release and the location and behavior of the impacted worker. Also, the dominant accident risks to the worker of facility operations are from standard industrial accidents, as opposed to bounding radiological accidents. The accident fatality risk for DOE has been reported as

[2] Respirable fractions are not applied in the assessment of doses based on noninhalation pathways, such as criticality.

2.3×10^{-5} per person per year. According to historical data on standard industrial accidents, the national average fatality risk from manufacturing operations is 3.5×10^{-5} per person per year.

K.1.4.2 Modeling of Dispersion of Releases to the Environment

The MACCS2 computer code (version 1.12) was used to estimate the consequences of accidents for the proposed surplus plutonium disposition facilities. A detailed description of the MACCS2 model is available in NUREG/CR-4691 (NRC 1990). Originally developed to model the radiological consequences of nuclear reactor accidents, this code has been used for the analysis of accidents for many EISs and other safety documentation, and is considered applicable to the analysis of accidents associated with the disposition of plutonium.

MACCS2 models the offsite consequences of an accident that releases a plume of radioactive materials into the atmosphere, specifically, the degree of dispersion versus distance as a function of historical wind direction, speed, and atmospheric conditions. Were such an accidental release to occur, the radioactive gases and aerosols in the plume would be transported by the prevailing wind and dispersed in the atmosphere, and the population would be exposed to radiation. MACCS2 generates the distribution of downwind doses at specified distances, as well as the distribution of population doses out to 80 km (50 mi).

As implemented, the MACCS2 model evaluates doses due to inhalation of aerosols, such as respirable plutonium, as well as exposure to the passing plume. This represents the major portion of the dose that a noninvolved worker or member of the public would receive as a result of a plutonium disposition facility accident. The longer-term effects of plutonium deposited on the ground and surface waters after the accident, including the resuspension and inhalation of plutonium and the ingestion of contaminated crops, were not modeled for the SPD EIS. These pathways have been studied and been found not to contribute as significantly to dosage as inhalation, and they are controllable through interdiction. Instead, the deposition velocity of the radioactive material was set to zero, so that material that might otherwise be deposited on surfaces remained airborne and available for inhalation. This adds a conservatism to inhalation doses that can become considerable at large distances (as much as two orders of magnitude at the 80 km [50 mi] limit). Thus, the method used in the SPD EIS is conservative compared with dose results that would be obtained if deposition and resuspension were taken into account.

Longer-term effects of fission products released in a nuclear criticality accident have been extensively studied. The principal concern is ingestion of iodine 131 via milk that becomes contaminated due to the ingestion of contaminated grains by milk cows. This pathway can be controlled if necessary. In terms of the effects of an accidental criticality, doses from this pathway are small.

The region around the facility is divided by a polar-coordinate grid centered on the facility itself. The user specifies the number of radial divisions and their endpoint distances. The angular divisions used to define the spatial grid correspond to the 16 directions of the compass.

MACCS2 was applied in a probabilistic manner using a weather bin–sampling technique. Centerline doses, as a function of distance, were calculated for each of 1,460 meteorological sequence samples, resulting in a distribution of doses reflecting variations in weather conditions at the time of the postulated accidental release. The code outputs the conditional probability of exceeding a dose as a function of distance. The mean and 95th percentile consequences are reported in the SPD EIS. Doses higher than the 95th percentile values would be expected only 5 percent of the time.

MACCS2 cannot be used to calculate directly the distribution of maximum doses (resulting from meteorological variations) around irregular contours, such as a site boundary. As a result, analyses that use

MACCS2 to calculate site boundary doses usually default to calculating doses at the distance corresponding to the shortest distance to the site boundary. In effect, the site boundary is treated as if it were circular, with a radius equal to the shortest distance from the facility to the actual site boundary. While this approximation is conservative with respect to dose (with the possible exception of doses from elevated plumes), it eliminates the use of some site-specific information, namely the site boundary location (other than the nearest point), wind direction, and any correlation between wind direction and other meteorological parameters. Because the primary purpose of the SPD EIS is to aid in decisions about facility locations, and because differences in dose values among the various options are largely a function of site-specific variations, a different approach was taken to more accurately characterize the potential for maximum doses at the site boundary.

For the SPD EIS, MACCS2 was used to generate intermediate results that could be further processed to obtain the distribution of doses around the site boundary, accounting for variations in site boundary distance as a function of direction. The specific instrument was the Type B result option of MACCS2, which renders the distribution of doses at a specified radial distance within a specified compass sector, given a release. Type B results were requested for the site boundary distance for each of the 16 compass sectors over which the meteorological data is defined. This resulted in 16 separate dose distributions; one for each specific location around the site boundary. The distribution of maximum doses around the site boundary was constructed by first summing the values of the Type B distributions for each dose value. The resulting distribution was then truncated for low dose values to the point where the remainder of the distribution was normalized. This produced the distribution of maximum doses around the site boundary, which is the distribution from which the mean and 95th percentile doses are reported.

Radiological consequences may vary somewhat as a result of variations in the duration of release. For longer releases, there is a greater chance of plume meander (i.e., variations in wind direction over the duration of release). MACCS2 models plume meander by increasing the lateral dispersion coefficient of the plume for longer release durations, thus lowering the dose. For perspective, doses from an homogenous, 1-hr release would be 30 percent lower than those of a 10-minute release as a result of plume meander; doses from a 2-hr release, 46 percent lower. The other effect of longer release durations is involvement of a greater variety of meteorological conditions in a given release, which reduces the variance of the resulting dose distributions. This would tend to lower high-percentile doses, raise low-percentile doses, and have no effect on the mean dose.

For the SPD EIS accident analysis, a duration of 10 minutes was assumed for all releases. This is consistent with the accident phenomenology expected for all scenarios, with the possible exception of fire. Depending on the circumstances, the time between fire ignition and extinction may be considerably longer, particularly for the larger, beyond-design-basis fires. However, even in a fire of long duration, it is possible to release substantial fractions of the total radiological source term in fairly short periods, as the fire consumes areas of high MAR concentrations. The assumption of a 10-minute release duration for fire is intended to generically account for this circumstance.

K.1.4.3 Modeling of Consequences of Releases to the Environment

The mean and 95th percentile consequences of accidental radiological releases, given variations in meteorological conditions at the time of the accident, are calculated as radiological doses in terms of rem. The mean consequences, or the expected consequences of the accident, are an appropriate statistic for use in risk estimates. The 95th percentile consequences represent bounding consequences of the accident; that is, if the accident were to occur and release the stated source term, there would be a 95 percent probability of lower than the stated consequences. This statistic is thus useful for characterizing the bounding consequence potential of the proposed activity under the stated accident condition. The consequences are also expressed as the

additional potential or likelihood of death from cancer for the noninvolved worker and the maximally exposed member of the public, and the expected number of incremental LCFs among the exposed population.

The probability coefficients for determining the likelihood of fatal cancer, given a dose, are taken from the *1990 Recommendations of the International Commission on Radiation Protection* (ICRP 1991). For low doses or low dose rates, respective probability coefficients of 4.0×10^{-4} and 1.0×10^{-3} fatal cancers per rem are applied for workers and the general public.[3] For high doses received at a high rate, respective probability coefficients of 8.0×10^{-4} and 1.0×10^{-3} fatal cancers per rem are applied for noninvolved workers and the public. These higher probability coefficients apply where doses are above 20 rem and dose rates above 10 rem per hour.

K.1.5 Accident Scenarios for Surplus Plutonium Disposition Facilities

Bounding design basis and beyond-design-basis accident scenarios have been developed from accident scenarios presented in each of the surplus plutonium disposition data reports (UC 1998a, 1998b, 1998c, 1998d, 1998e, 1998f, 1998g, 1998h, 1998i, 1998j, 1998k, 1998l, 1998m, 1998n). These scenarios are discussed in detail, along with specific assumptions for each facility and site, in these documents.

K.1.5.1 Accident Scenario Consistency

In preparing the accident analysis for the SPD EIS, the primary objective was to ensure consistency between the data reports so that results of the analyses for the proposed surplus plutonium disposition alternatives could be compared on as equal a footing as possible. In spite of efforts by all parties, some inconsistencies exist between the data reports. This does not imply technical inaccuracy in any analysis; it merely reflects the uncertainties and reliance on convention that are inherent in accident analyses in general. In order to provide a consistent analytical basis, information in the data reports has been modified or augmented as described below.

Aircraft Crash. It was decided early in the process of developing accident scenarios that aircraft crash scenarios would not be provided in the data reports, but would be developed, as appropriate, directly for the SPD EIS.

Frequencies of an aircraft crash into each facility for each alternative were developed in accordance with DOE-STD-3014 (DOE 1996a). The frequency of crashes involving aircraft capable of penetrating the subject facility (assumed to be all aircraft except those in general aviation) would be below 1.0×10^{-7} per year for all facilities except those at Pantex and the combination of Building 221–F and the Defense Waste Processing Facility (DWPF) at SRS. For facilities at Pantex, the frequency of impact would be 1.4×10^{-6} per year; for the combination of Building 221–F and DWPF, 1.1×10^{-7} per year.

Of the variety of impact conditions accounted for in the above frequency values (e.g., impact angle, direction, lateral distance from building center, speed) only a fraction would have the potential to produce consequences comparable to those reported in the SPD EIS, while other impacts (grazing impacts, impacts into office areas, etc.) would not result in significant radiological impacts. Therefore, it was qualitatively determined that the overall scenario frequency of aircraft crash into Building 221–F and DWPF at SRS, leading to radiological consequences, was below 1.0×10^{-7} per year, so that additional examination was unnecessary. Aircraft crashes at Pantex with the potential for significant consequences could occur more frequently than 1.0×10^{-7} per year, so these scenarios were analyzed further.

---

[3] Probability coefficients for the likelihood of nonfatal cancer are 8.0×10^{-5} for adult workers and 1.0×10^{-4} for the public. The probability coefficients for severe hereditary effects are 8.0×10^{-5} for adult workers and 1.3×10^{-4} for the public.

For the facilities at Pantex, the potential for an aircraft crash into vaults containing large quantities of plutonium powder was examined in relation to the potential for a crash into the facility as a whole. For the pit conversion and mixed oxide (MOX) facilities, the footprint of the vault would be considerably less than one-tenth that of the facility as a whole, indicating that vault impact frequencies would be on the order of, and perhaps less than, one-tenth the facility impact frequencies. Moreover, fewer types of aircraft would have the potential to penetrate the vault due to the robustness of the reinforced-concrete vault structures and their location in the basements of the facilities. Inside the vault, the storage containers would provide additional protection against the release of material. The protection provided by the vault structure and the storage containers can be regarded as conducive to a further reduction in the frequency of aircraft crashes into vault areas.

In response to public concern over the risk of an aircraft crash at Pantex, and consistent with a Memorandum of Understanding between the DOE Amarillo Area Office and the Federal Aviation Administration (FAA), an Overflight Working Group was established. This working group provided a number of recommendations for reducing the risk of an aircraft crash into any facility at Pantex. DOE supplemented the Memorandum of Understanding with an Interagency Agreement with the FAA. These actions resulted in the following recommendations:

- Modifying the vectoring of approaching aircraft to preclude extended flying over plant boundaries and reducing the number of aircraft turning on final approach over the plant
- Modifying holding patterns so that they are away from the plant
- Developing a new global positioning satellite (GPS), nonprecision approach to runway 22
- Replacing the backcourse localizer approach to runway 22 with an offset localizer approach
- Upgrading the lighting system for the approach to runway 4
- Establishing a hotline between the FAA and DOE
- Establishing new very high frequency omnidirection radio tactical (VORTAC) air navigation device locations
- Installing a GPS ground differential station, and commissioning a new GPS precision approach to runway 22

As of this date, all the recommendations except the last two have been implemented. The recommendation to install a precision approach is on hold until the FAA develops the standards for the augmentation system. While these changes cannot be quantitatively reflected in the frequency of aircraft crash as calculated by DOE-STD-3014, the improvements have been acknowledged as representing a reduction in the exposure of Pantex to aircraft, which translates to a reduction in the aircraft crash frequency at that site.

As a result of the above considerations, it was determined that the overall scenario frequency of an aircraft crash into a plutonium powder vault associated with either the pit conversion or MOX facility was below the threshold frequency of 1.0×10^{-7} per year. Additionally, it was qualitatively determined that in light of the above considerations, the overall frequency of aircraft impact into the pit or MOX facilities at Pantex was below 1×10^{-6} per year, or "beyond extremely unlikely." The development of consequences of an aircraft crash was therefore refocused on the MAR that could be in process areas at the time of the crash. To develop representative consequences, it was assumed that the aircraft impact would involve the process area containing

the largest amount of material in the most dispersable form. For the MOX facility, the impact was assumed to involve the unloading vessel and hopper storage, powder blending process, and MOX powder storage areas. These processes would contain the bulk of process plutonium in powder form. The total quantity of plutonium in powder form would be 1.8×10^{5} g (6.3×10^{3} oz), assuming that one-third of the plutonium in MOX powder storage was in powder form, one-third in green pellet form, and one third in the form of sintered pellets. However, given the potentially high energy densities associated with an aircraft crash, it was assumed that the green pellets would be equally vulnerable to release as powder, for a total effective powder quantity of 3.5×10^{5} g (1.2×10^{4} oz). For the pit conversion facility, the impact was assumed to involve the bisector, blending, canning, nondestructive analysis, and temporary storage areas, for a total of 6.0×10^{4}g (2.1×10^{3} oz) of plutonium in powder form.

The initial effect of the impact would be to disperse the material in a manner consistent with DOE-HDBK-3010-94 values for debris impact in powder. For this phenomenon, DOE-HDBK-3010-94 recommends bounding ARF and RF values of 1×10^{-2} and 0.2. However, according to *Particle Size of PuO_2 Generated by HYDOX-Ga Removal Process and Impact on Useability of DOE-HDBK-3010-94 ARF and RF Values* (Mishima 1997),[4] the range of powder fractions with an aerodynamic equivalent diameter (AED) of less than 10 microns (i.e., respirable) varies from 4.0×10^{-5} to 3.0×10^{-1}, with only 1 of the 10 analyzed samples exceeding 2.0×10^{-3}. Given that the debris impact could not subdivide the particles, an RF value of 3×10^{-2} was chosen. This choice was based on the assumption that 10 percent of the powder present at the time of impact would have a below-10-micron-AED fraction of 0.3, and the remainder, a below-10-micron-AED fraction of 2×10^{-3} or less. Combining this RF with the ARF of 1.0×10^{-2} results in a combined ARF and RF value of 3×10^{-4}, corresponding to a source term of 104 g (3.7 oz) for the MOX facility and 18 g (0.63 oz) for the pit conversion facility.

An aircraft crash could also induce a fire capable of entraining additional material in a lofted plume. The ARF and RF values for thermal stress are 6×10^{-3} and 1×10^{-2} respectively, which would result in a 20 percent increase in the source term. This additional source term should not contribute significantly to the noninvolved worker dose or the MEI dose, given the trajectory of the plume. However, it would contribute to the population dose. For simplicity, the source term was included in the ground-level release, for a total plutonium release of 22 g (0.78 oz) for the pit conversion facility and 125 g (4.4 oz) for the MOX facility.

Criticality. All of the data reports provide technically defensible information on criticality, but the analytical assumptions vary among the reports. To assess the significance of the variations, MACCS2 runs were performed for each criticality source term. The resulting doses varied by a factor of about 15 for all criticalities except the natural phenomena hazard (NPH) vault criticality in the immobilization data report. Doses from this criticality were roughly 100 times larger than any other doses and were dominated by aerosolized plutonium from the vault.

For the SPD EIS, it was decided to discard the NPH vault criticality on the grounds that it is, at most, an improbable event that is conditional on the occurrence of a beyond-design-basis earthquake and does not represent the potential consequences of an isolated criticality. Beyond-design-basis earthquakes have been addressed via a total collapse scenario in all data reports, and the additional assumption of a criticality occurring in addition to the total collapse does not significantly increase doses beyond those resulting from the collapse itself.

[4] The analyses documented therein encompass the HYDOX, gallium removal, milling, and MOX fuel fabrication processes, and are therefore relevant to all plutonium powder forms in the pit conversion and MOX facilities.

Of the remaining criticalities, the criticality in the rotary splitter tumbler in the glass immobilization data report produced the highest doses, dominated by fission products as opposed to plutonium. The source term for this criticality is based on a fission yield from 1.0×10^{19} fissions in an oxide powder.

For the SPD EIS, it was decided to use this source term for criticality for all facilities, because all facilities would handle oxide powder in quantities sufficient for criticality. The estimated frequency of extremely unlikely (i.e., 10^{-6} to 10^{-4} per year) reported in the immobilization data report was also used because it is the bounding estimate. (An extremely unlikely powder criticality was also cited in the MOX data report; in the pit conversion data report, likelihood was assessed in terms of undue criticality risk, of which three of the four identified criticalities had none.)

The criticality source term provided in the immobilization data report neglects some very short lived isotopes that would be expected in a criticality, namely bromine 85, iodine 136, krypton 89 and 90, and xenon 137. Since the half-lives of these isotopes are all less than 4 minutes, they do not have a significant direct impact on radiological consequences. However, the daughters of some of the isotopes are themselves radioactive; in particular, krypton 89 decays to rubidium 89, which has a half-life of 15 minutes. The significance of the daughters for overall consequences has been assessed for Pantex , which is considered bounding, since Pantex has the highest windspeeds and tends to carry the daughters the farthest for a given level of decay. As expected, the increase in dose is greatest for the noninvolved worker; approximately 25 percent higher for both the mean and 95th percentile. The dose increase decreases to 3 and 13 percent, respectively, for the mean and 95th percentile doses to the population within 80 km (50 mi). Dose increases at other sites are expected to be lower than corresponding increases at Pantex. Because these increases are small considering the great uncertainty inherent in the estimate of the total number of fissions, the source term in the immobilization data report remains a conservative estimate of the potential release from a criticality accident, and no modification of the source term has been made.

Design Basis Earthquake. Each data report presents an analysis of the design basis earthquake. The immobilization and MOX data reports provide source terms for that earthquake, while the pit conversion data reports indicate no release as a result of a design basis earthquake because the facility would be designed to withstand the event.

For the SPD EIS, a nonzero source term for pit conversion was generated by applying a building ventilation LPF of 1.0×10^{-5}, accounting for a HEPA filtered release, to the beyond-design-basis earthquake source term. It is recognized that this is a conservative procedure, in that the beyond-design-basis earthquake would release more material into the air within the building than a design basis earthquake. The combined ARF×RF for powder under beyond-design-basis earthquake conditions has been assessed as three times that for design basis earthquake conditions, and the total amount of vulnerable material may be somewhat greater. (For perspective, it resulted in a ratio of design basis earthquake to beyond-design-basis earthquake source term values that is somewhat higher than the corresponding ratio for MOX fuel fabrication, but lower than for plutonium conversion and immobilization.)

Beyond-Design-Basis Earthquake. All of the proposed operations would be in either existing or new facilities that would be expected to meet or exceed the requirements of DOE O 420.1 (DOE 1995) and DOE-STD-1020-94 (DOE 1994b) for reducing the risks associated with natural phenomena hazards. The proposed surplus plutonium disposition would be characterized as Performance Category 3 facilities. Such facilities would have to be designed or evaluated for a design basis earthquake with a mean annual exceedance probability of 5×10^{-4}, corresponding to a return period of 2,000 years. For sites such as Lawrence Livermore National Laboratory (LLNL), which are near tectonic plate boundaries, the requirements would include a mean annual seismic hazard exceedance probability of 1.0×10^{-3}, or a return period of 1,000 years.

The numerical seismic design requirements detailed in DOE-STD-1020-94 are structured such that there is assurance that specific performance goals are met. For plutonium facilities (Performance Category 3), the performance goal is that occupant safety, continued operation, and hazard confinement would be assured for earthquakes with an annual probability exceeding approximately 1×10^{-4}. There is sufficient conservatism in the design of buildings and the structures, systems, and components important to safety that these goals should be met given that they are designed against earthquakes with an estimated mean annual probability of 5×10^{-4}.

While the DOE order and standard require site-specific seismic evaluations, results of 1980s seismic studies were reported for all DOE sites to illustrate the variability among them. Estimated maximum horizontal ground surface accelerations for the design basis earthquake are 0.20g for Hanford, 0.17g for the Idaho National Engineering and Environmental Laboratory (INEEL), 0.57g for LLNL, 0.21g for the Los Alamos National Laboratory (LANL), 0.13g for Pantex, and 0.18g for SRS (DOE 1994c). In all cases, there is great uncertainty as to the annual probability of exceeding a specific ground acceleration for a site, as well as the maximum ground acceleration corresponding to a specific annual probability or return period. Estimated ground accelerations for earthquakes with a mean annual probability of 1×10^{-4} (corresponding to return periods of 10,000 years) are 0.39g for Hanford, 0.24g for INEEL, 0.82g for LLNL, 0.37g for LANL, 0.21g for Pantex, and 0.32g for SRS (DOE 1994c). In general, estimated ground accelerations for return periods exceeding 10,000 years have not been estimated for these DOE sites.

By contrast, nonnuclear structures at these sites and the surrounding community would be constructed to the standards of the Uniform Building Code for that region. These peak acceleration values are 50 to 82 percent of the peak acceleration design requirements for plutonium facilities in the same area and correspond approximately to DOE Performance Category 1 facilities with 500-year return intervals. During major earthquakes, structures built to these Uniform Building Code requirements would be expected to suffer significantly more damage than reinforced-concrete structures designed for plutonium operations.

At sites far from tectonic plate boundaries, deterministic techniques such as those used by the U.S. Nuclear Regulatory Commission (NRC) in evaluating safe-shutdown earthquakes for the siting of nuclear reactors have also been used to determine the maximum seismic ground motion requirements for facility designs. These techniques involve estimating the ground acceleration at the proposed plant either by assuming the largest historical earthquake within the tectonic province or by assessing the maximum earthquake potential of the appropriate tectonic structure or capable fault closest to the plant. For NRC-licensed reactors, this technique resulted in safe-shutdown earthquakes with estimated return periods in the 1,000- to 100,000-year range (DOE 1994c:C-17).

All the existing facilities under consideration in the SPD EIS have had seismic evaluations demonstrating that they meet the seismic evaluation requirements for the design basis earthquake. Some facilities, such as Building 332 at LLNL under consideration for preparation of the lead test assemblies, have had extensive evaluations of the ability of the structures, systems, and components important to safety to survive a range of seismic loadings. Evaluations reported in the *LLNL Site-Wide EIS* (DOE 1992) indicate that Building 332 would survive a postulated 0.8g earthquake and retain those features essential for the safe containment of radioactive materials. The estimated return interval for this level of ground accelerations is about 10,000 years. The facility was also examined for damage due to a 0.9g earthquake and found to be survivable (DOE 1992:app. D.5.2.1), albeit with some potential for loss of confinement due to equipment damage in safety systems (DOE 1992:table I-14).

The magnitude of potential earthquakes with return periods greater than 10,000 years is highly uncertain. For purposes of the SPD EIS, it was assumed that at all the candidate sites, earthquakes with return periods in the 100,000- to 10-million-year range might result in sufficient ground motion to cause major damage to even a modern, well-engineered and well-constructed plutonium facility. Therefore, in the absence of convincing

evidence otherwise, a total collapse of the plutonium facilities was assumed to be scientifically credible and within the rule of reason for return intervals in this range.

Each data report presents an analysis of total collapse. The immobilization and MOX data reports are fairly consistent in their use of damage estimates and release fractions. They assume that material in storage containers in vault storage would be adequately protected from the scenario energetics, for a damage ratio of zero in the vault. They also assume powder ARF and RF values of 1.0×10^{-3} and 0.3, respectively. The pit conversion data reports assume a damage ratio of 50 percent for material held in storage containers, applies cumulative ARF and RF values of 2.7×10^{-3} to powder subject to seismic vibration, free-fall spill, and turbulent air currents; and also presents a resuspension source term.

For the SPD EIS, the pit conversion source term was modified by adjusting the damage ratio in the vault from 0.5 to 0 based on the corresponding analyses in the immobilization and MOX data reports, and adjusting the ARF and RF values for powder to 1.0×10^{-3} and 0.3, respectively. It is recognized that these adjustments are in the nonconservative direction, but either set of assumptions is considered technically sound and defensible. The value of 2.7×10^{-3}, used in the pit conversion data report, is based on seismic-induced collapse of large structures into loose bulk powder; this assumption is considered unnecessarily conservative given the expectation of containered storage for the majority of the powder inventory at any given time. The resuspension source term was kept (and was not applied to either immobilization or MOX). Although worth noting, this difference between the data reports is not considered particularly significant, for the resuspension source term constitutes only 30 percent of the total.

The frequency for all beyond-design-basis earthquakes for all facilities is reported in the SPD EIS as extremely unlikely to beyond extremely unlikely (the pit conversion facility data report estimated a frequency of less than 1×10^{-6} per year.) They are reported as such because the uncertainties inherent in associating damage levels with earthquake frequencies become overwhelming below frequencies of about 1.0×10^{-5} per year.

Filtration Efficiency. The immobilization and MOX data reports use a building filtration efficiency of 1.0×10^{-5} for particulate releases (except for Building 221–F, which is filtered through the F-Area sand filter). The pit conversion data report uses a building filtration efficiency of 2.0×10^{-6}. For consistency, the pit conversion source terms have been adjusted to reflect an LPF of 1.0×10^{-5}. This is reasonable because it is expected that the ventilation efficiencies of all HEPA-filtered buildings would be essentially the same.

Beyond-Design-Basis Fire. The MOX data report presents an analysis of a beyond-design-basis fire whose basis in terms of scenario definition was from the *Data Report for Plutonium Conversion Facility*, (Smith, Wilkey, and Siebe 1996), which was produced for the *Storage and Disposition Final PEIS* (DOE 1996b). Neither the pit conversion nor the immobilization data reports contain analyses of a beyond-design-basis fire.

For the SPD EIS, beyond-design-basis fires were developed for pit conversion and immobilization by replacing the building filtration LPF with an LPF of 1.4 percent, in accordance with the beyond-design-basis scenario definition presented in the *Data Report for Plutonium Conversion Facility* and adapted for the MOX fuel fabrication analysis. (For perspective, it resulted in a ratio of design basis fire to beyond-design-basis fire source term values that are within a factor of 2 of the corresponding ratio for MOX fuel fabrication.)

It is understood that the LPF of 1.4 percent is based on a facility-specific analysis of the Plutonium Finishing Building (PF–4) in Technical Area 55 at LANL, and that an analysis of other facilities using the same phenomenological assumptions might yield somewhat different results. However, for the purpose of this analysis, and considering the degree of similarity expected between facilities as a result of required plutonium-handling practices, this value was used generically in the assessment of beyond-design-basis fire.

K.1.5.2 Facility Accident Scenarios

K.1.5.2.1 Pit Conversion Facility

A wide range of potential accident scenarios were considered for the pit conversion facility. These scenarios are considered in detail in the pit conversion facility data reports (UC 1998a, 1998e, 1998k, 1998l). The analysis assumes that the pit conversion facility is located in a new or upgraded existing building designed to withstand design basis natural phenomena hazards such as earthquakes, winds, tornadoes, and floods such that no unfiltered releases would be expected. Also, no site-specific accidents conducive to releases are identified. Therefore, the potential accident scenarios apply to all four candidate sites.

Analysis of the proposed process operations for the pit conversion facility identified the following broad categories of accidents: aircraft crash, criticality, design basis earthquake, beyond-design-basis earthquake, explosion, fire, leaks or spills, and tritium release. Basic characteristics of each of these postulated accidents are described below. Additional discussion of scenario development based on consistency concerns can be found in Section K.1.5.1.

Aircraft Crash. A crash of a large, heavy commercial or military aircraft directly into a reinforced-concrete facility could damage the structure sufficient to breach confinement and disperse material into the environment. A subsequent fuel-fed fire could provide energy to further damage structures and equipment, aerosolize material, and drive materials into the environment. Source terms are highly speculative but would be expected to exceed those from the beyond-design-basis earthquake. At all sites except Pantex, the frequency of such a crash is below 10^{-7} per year.

Criticality. Engineered and administrative controls should be available to ensure that the double-contingency principles are in place for all portions of the process. It is assumed that human error results in multiple failures leading to an inadvertent nuclear criticality. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year. A bounding source term resulting from 10^{19} fissions is assumed.

Design Basis Earthquake. The principal design basis natural phenomena event that could release material to the environment is the design basis earthquake. While the major safety systems, including building confinement and the building HEPA filtration system should continue to function, the vibratory motion would be expected to resuspend loose plutonium powder within gloveboxes and cause some minor spills. These would be picked up by the ventilation system and filtered by the HEPA filters before release from the building. Although highly uncertain, the source term should be much lower than that postulated for the beyond-design-basis earthquake. Based on an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 3.9×10^{-4} g (1.4×10^{-5} oz) is postulated. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-2} per year.

Beyond-Design-Basis Earthquake. The postulated beyond-design-basis earthquake is assumed to be of sufficient magnitude to cause total collapse of the process equipment, building walls, roof, and floors, and loss of the containment function of the building. The material in the building is assumed to be driven airborne by the seismic vibrations, free-fall during the collapse, and impact. Molten metal in furnaces is also assumed to burn in the aftermath of the collapse. An instantaneous plus-resuspension ground-level release of 39 g (1.4 oz) of respirable plutonium is estimated for the process area. While the release of an additional 2,529 g (89 oz) from the vault would be possible, it would be unlikely given the expected packaging of materials in the vault. The estimated frequency of this accident is in the range of 10^{-5} to 10^{-7} per year.

Explosion. The bounding explosion is a deflagration of a hydrogen gas mixture inside the hydride oxidation (HYDOX) furnace. The deflagration is assumed to result from multiple equipment failures and operator errors

that lead to a buildup of hydrogen and a flow of oxygen into the inert-atmosphere glovebox used in the HYDOX process. Also assumed is an MAR of 4.5 kg (9.9 lb) of plutonium powder, and given the venting of pressurized gas through the powder, bounding ARF and RF of 0.1 and 0.7, respectively. The explosive energy would be sufficient to damage glovebox windows but insufficient to threaten the building HEPA filter system. Based on an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 3.2×10^{-3} g (1.1×10^{-4} oz) is postulated. The estimated frequency of this accident is in the range of 10^{-2} to 10^{-4} per year.

Fire. According to the several safety analyses of the plutonium facility at LANL, the bounding fire within the pit conversion facility is a fire involving all of the gloves in a glovebox used for blending plutonium powder. A flammable cleaning liquid is assumed to be brought into the glovebox, in violation of procedure, then to spill and ignite. The gloves are assumed to be stowed outside the glovebox but to be ignited by the fire and completely consumed. An MAR of 2 g (0.07 oz) of plutonium dust is assumed for each of 12 gloves, with all of the 24 g (0.85 oz) assumed to be aerosolized. The sprinkler system is assumed to function and protect the room and remainder of the building. Also assumed are an ARF of 0.05 and an RF of 1.0, resulting in a 1.2-g (0.04-oz) release to the building ventilation system. Based on an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 1.2×10^{-5} g (4.2×10^{-7} oz) is postulated. The estimated frequency of this accident is in the range of 10^{-2} to 10^{-4} per year.

Leaks or Spills of Nuclear Material. The most catastrophic leak or spill postulated would result from a forklift or other large vehicle running over a package of nuclear material and breaching the storage container. If a 4-kg (8.8-lb) package of plutonium oxide were breached, a total airborne release of 0.44 g (0.016 oz) to the room would occur, and after HEPA filtration of the facility exhaust, a total release of 4.4×10^{-6}. This accident has an estimated frequency in the range of 10^{-4} to 10^{-6} per year.

Tritium Release. A major glovebox fire is assumed to heat multiple parts contaminated with up to 20 g (0.71 oz) of tritium and convert all of it into tritiated water vapor. Very conservatively, the ARF, RF, and LPF are all assumed to be 1.0, resulting in a release of 20 g (0.71 oz) (1.9×10^{-5} Ci) through the stack to the atmosphere. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year.

K.1.5.2.2 Immobilization Facility

A wide range of potential accident scenarios are reflected in the immobilization facility data reports (UC 1998b, 1998c, 1998f, 1998g, 1998i, 1998j). The analysis assumes that the immobilization facility is located in a new or upgraded existing building designed to withstand design basis natural phenomena hazards such as earthquakes, winds, tornadoes, and floods such that no unfiltered releases would be expected. Also, no site-specific accidents conducive to releases are identified. Therefore, the potential accident scenarios apply to all four candidate sites. Additional discussion of scenario development based on consistency concerns can be found in Section K.1.5.1.

Analysis of the proposed process operations identified specific scenarios for the conversion process, each of the immobilization options (ceramic and glass), and the canister-handling portion of the process. Design basis and beyond-design-basis earthquakes were identified for the overall facility. Identified as accidents specific to the plutonium conversion processes were a criticality, an explosion in HYDOX furnace, a calcining furnace–glovebox fire, and a hydrogen explosion in the plutonium conversion room. For the ceramic immobilization option, moreover, a sintering furnace–glovebox fire was identified; for the glass immobilization option, a melter eruption and a melter spill. All of the scenarios identified with the canister handling phase were negligible compared with the conversion and immobilization scenarios.

PLUTONIUM CONVERSION OPERATIONS

Criticality. Review of the possibility of accidents attributable to plutonium conversion operations indicated that the principal processes of concern include the halide wash operations, the HYDOX furnace, and the sorting/unpacking glovebox. Engineered and administrative controls should be available to ensure that the double-contingency principles are in place for all portions of the process. It is assumed that human error could result in multiple failures leading to an inadvertent nuclear criticality. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year. A bounding source term resulting from 10^{19} fissions is assumed.

Explosion in HYDOX Furnace. The bounding explosion is a deflagration of a hydrogen gas mixture inside the HYDOX furnace. The deflagration is assumed to result from multiple equipment failures and operator errors that lead to a buildup of hydrogen and a flow of oxygen into the inert-atmosphere glovebox used in the HYDOX process. Also assumed is an MAR of 4.8 kg (11 lb) of plutonium powder, and given the venting pressurized gas through the powder, bounding ARF and RF of 0.1 and 0.7, respectively. The explosive energy would be sufficient to damage glovebox windows but insufficient to threaten the building HEPA filter system. Based on an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 3.4×10^{-3} g (1.2×10^{-4} oz) is postulated. The estimated frequency of this accident is approximately 10^{-3} per year or in the unlikely range.

Hydrogen Explosion in Plutonium Conversion Room. A supply pipe leak in the plutonium conversion room could result in a hydrogen explosion. Conversion of plutonium metal is accomplished using the HYDOX process, which entails the introduction of hydrogen gas. Were the hydrogen supply piping to leak into the operating/maintenance room, the gas could be ignited by an electrical short or operating mechanical equipment, causing an explosion. Depending on the volume of the leak, the structural integrity of the glovebox glove ports could fail and disperse the plutonium oxide. It is assumed that the building ventilation does not fail, and that the two HEPA filters provide filtration prior to discharge of the powder to the stack. An entire day's inventory of 25 kg (55 lb) of plutonium oxide powder is assumed present in the plutonium conversion gloveboxes. Based on an ARF of 5×10^{-3}, an RF of 0.3, and an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 3.8×10^{-4} g (1.3×10^{-5} oz) of plutonium is postulated. The estimated frequency of this accident is approximately 10^{-3} per year or in the unlikely range.

Furnace-Initiated Glovebox Fire (Calcining Furnace). It is assumed that a fault in the calcining furnace results in the ignition of any combustibles (e.g., bags) left inside the glovebox. The fire would be self-limiting, but would cause suspension of the radioactive material. It is also assumed that the glovebox (including the window) maintains its structural integrity, but that the internal glovebox HEPA filter fails. All of the loose surface contamination within the glovebox, assumed to be 10 percent of the daily inventory (4.5 kg [9.9 lb] of plutonium) of the calcining furnace, is assumed to be involved. Based on an ARF of 6×10^{-3}, an RF of 0.01, and an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 2.7×10^{-7} g (9.5×10^{-9} oz) of plutonium is postulated. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year.

CERAMIC IMMOBILIZATION OPTION

Criticality. Review of the possibility of accidents attributable to the ceramic immobilization operations indicated that the principal operation of concern is the rotary splitter tumbler. Engineered and administrative controls should be available to ensure that the double-contingency principles are in place for all portions of the process. It is assumed that human error results in multiple failures leading to an inadvertent nuclear criticality. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year. A bounding source term resulting from 10^{19} fissions is assumed.

Design Basis Earthquake. The principal design basis natural phenomena event that could release material to the environment is the design basis earthquake. While the major safety systems, including building

confinement and the building HEPA filtration system should continue to function, the vibratory motion would be expected to suspend loose plutonium powder within gloveboxes and cause some minor spills. These would be picked up by the ventilation system and filtered by the HEPA filters before release from the building. Most material storage containers are assumed to be engineered to withstand design basis earthquakes without failing. For plutonium conversion, it is assumed that at the time of the event the entire day's inventory (25 kg [55 lb] of plutonium) is present in the form of oxide powder. For the ceramic immobilization portion, this includes the oxide inventories from the rotary splitter, oxide grinding, blend and granulate feed storage, drying and storage, pressing, inspection, and load trays and weigh areas. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 38 g (1.3 oz) of plutonium to the still-functioning building ventilation system and 3.8×10^{-4} g (1.3×10^{-5} oz) from the stack. The nominal frequency estimate for a design basis earthquake affecting new DOE plutonium facilities is 5×10^{-4} per year, or in the unlikely range.

Beyond-Design-Basis Earthquake. The postulated beyond-design-basis earthquake is assumed to be of sufficient magnitude to cause total collapse of the process equipment, building walls, roof, and floors, and loss of the containment function of the building. The material in the building is assumed to be driven airborne by the seismic vibrations, free-fall during the collapse, and impact. Material in storage containers in vaults would be adequately protected from the scenario energetics. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 19 g (0.67 oz) of plutonium at ground level. The estimated frequency of this accident is in the range of 10^{-5} to 10^{-7} per year.

Furnace-Initiated Glovebox Fire (Sintering Furnace). It is assumed that the sintering gas supplied to the furnace gloveboxes is a safe gas mixture—hydrogen and argon. Human errors are at issue—either a vendor/supplier that causes a supply of air or noninerting gas to be supplied to the furnace glovebox, or a piping error at the facility itself, in which oxygen is inadvertently substituted for the inert gas. Any combustibles (e.g., bags) left inside the glovebox could ignite, causing a glovebox fire. It is assumed that the fire is self-limiting, but causes suspension of the radioactive material. It is also assumed that the glovebox (including the window) maintains its structural integrity, but that the internal glovebox HEPA filter fails. All of the loose surface contamination within the glovebox, assumed to be 10 percent of the daily inventory (25 kg [55 lb] of plutonium) of the calcining furnace, is assumed to be involved. Based on an ARF of 6×10^{-3}, an RF of 0.01, and an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 1.5×10^{-6} g (5.3×10^{-8} oz) of plutonium is postulated. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year.

Glass Immobilization Option

Design Basis Earthquake. The principal design basis natural phenomena event that could release material to the environment is the design basis earthquake. While the major safety systems, including building confinement and the building HEPA filtration system should continue to function, the vibratory motion would be expected to suspend loose plutonium powder within gloveboxes and cause some minor spills. These would be picked up by the ventilation system and filtered by the HEPA filters before release from the building. Most material storage containers are assumed to be engineered to withstand design basis earthquakes without failing. For plutonium conversion, it is assumed that at the time of the event the entire day's inventory (25 kg [55 lb] of plutonium) is present in the form of oxide powder. For the glass immobilization portion, this includes oxide inventories from the rotary splitter, oxide grinding, blend melter, and feed storage. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 33 g (1.2 oz) of plutonium to the still-functioning building ventilation system and 3.3×10^{-4} g (1.2×10^{-5} oz) from the stack. The nominal frequency estimate for a design basis earthquake affecting new DOE plutonium facilities is 5×10^{-4} per year, or in the unlikely range.

Beyond-Design-Basis Earthquake. The postulated beyond-design-basis earthquake is assumed to be of sufficient magnitude to cause total collapse of the process equipment, building walls, roof, and floors, and loss of the containment function of the building. The material in the building is assumed to be driven airborne by the seismic vibrations, free-fall during the collapse, and impact. Material in storage containers in vaults storage would be adequately protected from the scenario energetics. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 17 g (0.60 oz) of plutonium released at ground level. The estimated frequency of this accident is in the range of 10^{-5} to 10^{-7} per year.

Melter Eruption. A melter eruption could result from the buildup of impurities in, or addition of impurities to, the glass frit or melt. Impurities range from water, which could cause a steam eruption, to chemical contaminants, which could react at elevated temperatures and produce a highly exothermic reaction (eruption or deflagration). The resulting sudden pressure increase could eject the fissile material bearing melt liquid into the processing glovebox structure. However the energy release would likely be insufficient to challenge the glovebox structure. It is assumed that the entire contents of the melter, about 1.4 kg (3.1 lb) of plutonium, are ejected into the glovebox. Based on an ARF of 4×10^{-4}, an RF of 1, and an LPF of 1.0×10^{-5} for two HEPAs, a stack release of 1.4×10^{-6} g (4.9×10^{-8} oz) of plutonium is postulated. The estimated frequency of this accident is approximately 2.5×10^{-3} per year, or in the unlikely range.

Melter Spill. A melter spill into the glovebox could occur due to improper alignment of the product glass cans during pouring operations. The melter glovebox enclosure and the off-gas exhaust ventilation system would confine radioactive material released in the spill. The glovebox structure and its associated filtered exhaust ventilation system would not be impacted by this event. It is assumed that the entire contents of the melter, about 1.4 kg (3.1 lb) of plutonium, are spilled into the glovebox. On the basis of an ARF of 2.4×10^{-5}, a RF of 1, and an LPF of 1.0×10^{-5} for two HEPAs, a stack release of 3.3×10^{-7} g (1.2×10^{-8} oz) of plutonium is postulated. The estimated frequency of this accident is approximately 3×10^{-4} per year, or in the unlikely range.

CAN-IN-CANISTER OPERATIONS

Can-Handling Accident (Before Shipment to Vitrification Facility). A can-handling accident would involve a can containing either ceramic pellets or a vitrified glass log of plutonium material. Studies supporting the DWPF SAR (DOE 1994c) indicate that the source term resulting from dropping or tipping a log of vitrified waste, even without credit for the steel canister, would be negligible. Both surplus plutonium immobilization technologies (ceramic and glass) result in a form with a durability that is comparable to that of the DWPF vitrified waste form. Consequently, no postulated can-handling event would result in a radioactive release to the environment.

Melter Spill (Melt Pour at Vitrification Facility). Analysis of a spill of melt material was included in studies performed in support of the DWPF SAR. According to that analysis, the source term resulting from the dropping or tipping a log of vitrified waste, even without credit for the steel canister, would be negligible. Both surplus plutonium immobilization technologies (ceramic and glass) result in a form with a durability that is comparable to the DWPF vitrified waste form. Consequently, it is postulated that no melter spill event results in a radioactive release to the environment.

Canister Handling Accident (After Melt Pour at DWPF). Analysis of events involving the handling and storage of vitrified waste canisters was included in studies performed in support of the DWPF SAR. Results of that analysis indicate that the source term resulting from the dropping or tipping of a log of vitrified waste, even without credit for the steel canister, would be negligible. Both surplus plutonium immobilization technologies (ceramic and glass) result in a form with a durability that is comparable to the DWPF vitrified

waste form. Consequently, it is postulated that no canister-handling event results in a radioactive release to the environment.

K.1.5.2.3 MOX Facility Accident Scenarios

A wide range of potential accident scenarios were considered in the analysis reflected in the MOX facility SPD EIS data reports, (UC 1998d, 1998h, 1998m, 1998n). The analysis assumes that the MOX facility is located in a new or upgraded existing building designed to withstand design basis natural phenomena hazards such as earthquakes, winds, tornadoes, and floods such that no unfiltered releases would be expected.

Analysis of the proposed process operations for the MOX facility identified the following broad categories of accidents: aircraft crash (Pantex only), criticality, design basis earthquake, beyond-design-basis earthquake, explosion in sintering furnace, fire, and beyond-design-basis fire. Basic characteristics of each of these postulated accidents are described below. Additional discussion of scenario development based on consistency concerns can be found in Section K.1.5.1.

Aircraft Crash. A crash of a large, heavy commercial or military aircraft directly into a reinforced-concrete facility could damage the structure sufficiently to breach confinement and disperse material into the environment. A subsequent fuel-fed fire could provide energy to further damage structures and equipment, aerosolize material, and drive materials into the environment. Source terms are highly speculative but would be expected to exceed those from the beyond-design-basis earthquake. At all sites except Pantex, the frequency of such a crash is below 10^{-7} per year.

Criticality. Review of the possibility of accidents for the MOX facility indicated no undue criticality risk associated with the proposed operations. Engineered and administrative controls should be available to ensure that the double-contingency principles are in place for all portions of the process. It is assumed that human error could result in multiple failures leading to an inadvertent nuclear criticality. The estimated frequency of this accident is in the range of 10^{-4} to 10^{-6} per year. A bounding source term resulting from 10^{19} fissions is assumed.

Design Basis Earthquake. The principal design basis natural phenomena event that could release material to the environment is the design basis earthquake. While the major safety systems, including building confinement and the building HEPA filtration system should continue to function, the vibratory motion would be expected to resuspend loose plutonium powder within gloveboxes and cause some minor spills. These would be picked up by the ventilation system and filtered by the HEPA filters before to release from the building. Material storage containers including cans, hoppers, and bulk storage vessels are assumed to be engineered to withstand design basis earthquakes without failing. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 4 g (0.14 oz) of plutonium (in the form of MOX powder) to the still-functioning building ventilation system and 4.0×10^{-5} g (3.5×10^{-7} oz) from the stack. The nominal frequency estimate for a design basis earthquake for new DOE plutonium facilities is 5×10^{-4} per year, or in the unlikely range.

Beyond-Design-Basis Earthquake. The postulated beyond-design-basis earthquake is assumed to be of sufficient magnitude to cause total collapse of the process equipment, building walls, roof, and floors, and loss of the containment function of the building. The material in the building is assumed to be driven airborne by the seismic vibrations, free-fall during the collapse, and impact. Although the source term is highly uncertain, an assessment of the MAR, ARF, and RF for each of the process areas indicated a potential for the release of 124 g (4.4 oz) of plutonium (in the form of MOX powder) at ground level. The estimated frequency of this accident is in the range of 10^{-5} to 10^{-7} per year.

Explosion in Sintering Furnace. The several furnaces proposed for the MOX fuel fabrication process all use nonexplosive mixtures of 6 percent hydrogen and 94 percent argon. Given the physical controls on the piping for nonexplosive and explosive gas mixtures, operating procedures, and other engineered safety controls, accidental use of an explosive gas is extremely unlikely, though not impossible. A bounding explosion or deflagration is postulated to occur in one of the three sintering furnaces in the MOX facility building. Multiple equipment failures and operator errors would be required to lead to a buildup of hydrogen and an inflow of oxygen into the inert furnace atmosphere. As much as 5.6 kg (12.3 lb) of plutonium in the form of MOX powder would be at risk, and a bounding ARF of 0.01 and RF of 1.0 is assumed. Based on an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 5.6×10^{-4} g (2.0×10^{-5} oz) of plutonium (in the form of MOX powder) is postulated. It is estimated that the frequency of this accident is in the range of 10^{-4} to 10^{-6} per year.

Fire. The design basis fire is postulated to occur in the pellet-processing area. The fire is assumed to involve all of the hydraulic fluid, lubricants, and other combustibles within that area. All of the MOX powder (5.6 kg [12.3 lb] of plutonium) in the pelleting press and feed hopper is assumed to be involved. Based on an ARF of 6×10^{-3}, an RF of 0.01, and an LPF of 1.0×10^{-5} for two HEPA filters, a stack release of 3.4×10^{-6} g (1.2×10^{-7} oz) of plutonium (in the form of MOX powder) is postulated. It is estimated that the frequency of this accident is in the range of 10^{-4} to 10^{-6} per year.

Beyond-Design-Basis Fire. The MOX facility would be built and operated such that there would be insufficient combustible materials to support a large fire. To bound the possible consequences of a major fire, a large quantity of combustible materials are assumed to be introduced into the process area near the blending area, which contains a fairly large amount of plutonium. A major fire is assumed to occur that causes the building ventilation and filtration systems to fail, possibly due to clogged HEPA filters. A total of 11 kg (24 lb) of plutonium in the form of MOX powder is assumed at risk. Based on an ARF of 6×10^{-3}, a RF of 0.01, and an LPF of 1.4×10^{-2} for two damaged, clogged HEPA filters, a stack release of 9.4×10^{-3} g (3.3×10^{-4} oz) of plutonium (in the form of MOX powder) is postulated. It is estimated that the frequency of this accident is less than 10^{-6} per year.

K.1.5.2.4 Lead Assembly Accident Scenarios

Design basis and beyond-design-basis accident scenarios have been developed for the fabrication of MOX fuel lead assemblies. These scenarios are discussed in detail, with specific assumptions for each facility and site, in the site data reports (O'Connor 1998a, 1998b, 1998c, 1998d, 1998e). In spite of efforts by all parties, however, some inconsistencies exist between the data reports. This does not imply technical inaccuracy in any analysis; it merely reflects the uncertainties and reliance on convention inherent in accident analyses in general. In preparing the accident analysis for the SPD EIS, therefore, information in the data reports was modified or augmented to ensure the consistency, as appropriate, that is necessary for a reliable comparison of lead assembly fabrication accidents and the other accidents analyzed herein. Modifications were made to ensure that to the extent practical, differences in analytical results were based on actual differences in facility conditions, as opposed to arbitrary differences in analytical methods or assumptions. One change, reflected in Table K–2, involved the assumption for all accidents of an isotopic composition of plutonium identical to that assumed in the analyses of pit disassembly and conversion and MOX fuel fabrication.

Criticality. Criticalities could be postulated in several areas (e.g., powder storage, the gloveboxes involved in mixing, the furnace, the fuel rod storage area). The estimated frequencies associated with these events would vary depending on the controls in place, the number of operator movements, and the amount of fissile material present. A generic approach was taken with respect to the selection of the specifics of this event, rather than selection of a criticality scenario associated with a specific operation in the lead assembly fabrication.

Table K–2. Isotopic Composition of Plutonium Used in Lead Assembly Accident Analysis

Isotope	Weight Percent
Plutonium 238	3.0×10^{-2}
Plutonium 239	92.2
Plutonium 240	6.46
Plutonium 241	5.0×10^{-2}
Plutonium 242	1.0×10^{-1}
Americium 241	9.0×10^{-1}

The criticality source term stipulated in the data reports was modified to make it identical to the corresponding source term used in the assessment of criticality in the pit conversion, immobilization, and MOX facilities. That source term is based on a fission yield from 1.0×10^{19} fissions in an oxide powder. The discussion provided in Section K.1.5 on criticality is also applicable here.

Design Basis Earthquake. An earthquake appropriate with the facility's design basis was selected. For this event, major portions of the process line gloveboxes are assumed to be breached, making the contents available for release. The storage vault and receiving area are assumed to have suitable storage containers for plutonium oxide that would survive the earthquake (storage containers with double containment). In-process material in gloveboxes is, however, more vulnerable, as are powder storage areas that may exist. Of particular concerns are the dispersable powders at the powder-blending stations. Finished pellets and fuel rods are thought to be generally nondispersable, even though they could escape the gloveboxes. In this earthquake, some non-seismically qualified process equipment could fail, and some process material spill. It is also conservatively assumed that glovebox filtration would fail.

The lead assembly data reports use ARF and RF values of 1.0×10^{-2} and 0.2, respectively, for plutonium oxide in cans involved in a design basis earthquake. These values are based on DOE-HDBK-3010-94 recommendations for the suspension of bulk powder by debris impact and air turbulence from falling objects. For consistency with the design basis accident analyses for the other facilities, these values were changed to 1.0×10^{-3} and 0.1, values based on DOE-HDBK-3010-94 recommendations for the suspension of bulk powder due to vibration of substrate from shock-impact to powder confinement (e.g., gloveboxes, cans) due to external energy (e.g., seismic vibrations). Such values are appropriate for earthquakes in which structural integrity is largely maintained and there is not a significant amount of debris or falling objects.

Beyond-Design-Basis Earthquake. For this analysis an event much more severe in consequences than would be expected from the design basis earthquake was examined. For some existing DOE facilities, the estimated seismic frequencies of beyond-design-basis events can be greater than 1.0×10^{-6} per year. The design basis for every building in the complex varies considerably depending on site specifics, including the type of construction used in the building. A damage assessment of the facility is further complicated by the fact that seismic considerations could also be incorporated in the glovebox design of the facility. In reality, such a catastrophic event may or may not demolish the building and the gloveboxes. However, for the purposes of illustrating a high-consequence accident, total demolition of the building is assumed. In this event, no credit is taken for the building, filters, or gloveboxes.

In the data report, an estimated frequency of 1.0×10^{-6} per year is cited as appropriate. To acknowledge the high degree of uncertainty in assessing a frequency of this scenario, a range of extremely unlikely to beyond extremely unlikely has been assigned to this event.

The source term for the beyond-design-basis earthquake includes a contribution from the plutonium storage vault, the assumed DR being 5 percent. The values used for the ARF, RF and vault DR—1.0×10^{-3}, 0.3, and

0, respectively—derive from adjustments consistent with the analysis of the corresponding scenario in the MOX facility data report. This results in a reduction of the source term for this accident by a factor of 2, to 11 g (0.39 oz) plutonium.

Extensive analyses have been performed on the seismic hazard at LLNL and the response of the plutonium facility, Building 332, to that hazard. According to the geology and seismology studies characterizing the nature and magnitude of the seismic threat, there is no physiographic basis for postulating earthquake magnitudes and ground accelerations higher than Richter magnitude 6.9 and 1.1g, respectively. Building 332, Increment III, has been evaluated for resistance to earthquakes and ground accelerations of these magnitudes and found to be adequate. Events of significantly higher magnitude and ground acceleration would be required to collapse Increment III. The frequency of these larger events would most likely be extremely low (1.0×10^{-6} per year or less), as the physiography of the dominant fault systems is such that they are thought incapable of producing the required magnitudes of ground accelerations (Coats 1998). Results of a number of reviews of Increment III indicate that the actual ground motion needed to cause collapse of the structure is above 1.5g. Based on the current LLNL hazard curve and various estimates of the fragility curves for collapse of Increment III, the frequency of collapse is estimated at 1.0×10^{-7} per year or less (Murray 1998). The frequency of a total collapse of Building 332 at LLNL is thus considered sufficiently low that additional examination is deemed unnecessary.

Explosion. An explosion event was postulated in the sintering furnace in the lead assembly fabrication facility. A nonexplosive mixture of 6 percent hydrogen and 94 percent argon is used in the furnace. Multiple equipment and operator errors would have to occur to enable the buildup of an explosive mixture of hydrogen and air in the box. It is assumed that green pellets are subjected to the direct force of the shock waves resulting from such an explosion. It is further assumed that the gloveboxes involved in powder blending are damaged indirectly by the explosion. It is not expected that the shock wave impacting this area would be severe enough to significantly damage all of the storage inventory because interim storage containers would provide some mitigation.

Fire. A moderate-size room fire is assumed. Combustible material such as hydraulic fluid, alcohol, or contaminated combustibles is assumed to be present in the room. Adjoining facilities such as offices conceivably add to the risk of fires in the building. The gloveboxes are assumed to fail in the fire. The MOX powder in interim storage is assumed to be at risk and subjected to the thermal stress of the fire, given failure of the gloveboxes. Because of the limited combustible material and mitigation features such as fire protection systems and a firefighting unit, the event is assumed to be terminated. This fire is not severe enough to jeopardize the overall confinement characteristics of the building.

The source term for the design basis fire analyzed in the lead assembly data reports is dominated by the explosive release of high pressure from two plutonium oxide cans as they are heated to the point of failure. The ARF and RF values for this phenomenon are 0.1 and 0.7, respectively, and reflect burst pressures on the order of 25 to 500 psig. The potential for this kind of release is highly uncertain, and a valid design basis fire may be defined without including it, as is the case with the data reports for the other facilities. Therefore, for greater consistency between the design basis fire for the lead assembly and those for the other facilities, it is assumed that the two plutonium oxide cans are already open and vulnerable to the same phenomena as the rest of the analyzed powder. This results in a reduction of the data report source term by a factor of 38.

It is noteworthy that the lead assembly data report assumes a room fire, and the other data reports, a process fire. This is not considered inconsistent: the lead assembly processes are expected to be closer to one another other than the MOX processes, so the potential for propagation of fire may be somewhat greater.

Beyond-Design-Basis Fire. Fuel-manufacturing operations do not involve the use of significant amounts of combustible material. For the purpose of analysis, the lead assembly data reports define a beyond-design-basis fire that results in building collapse, the breach of material in the plutonium storage vault, and a lofted plume. These assumptions, however, are inconsistent with the beyond-design-basis fires analyzed for the other facilities. The beyond-design-basis fire has therefore been modified to reflect a room fire or building fire that clogs the building HEPA filters, resulting in a ground-level, unfiltered release. The assumed LPF is 1.4×10^{-2} (Smith, Wilkey, and Siebe 1996), consistent with the other analyses. Additionally, it is assumed that the fire does not involve the vault or that the storage canisters in the vault provide adequate protection for the duration of the fire.

Next Section

K.2 FACILITY ACCIDENT IMPACTS AT HANFORD

The potential source terms and consequences of postulated bounding facility accidents for each facility option at Hanford are presented in Tables K–3 through K–9. Accident scenarios and source terms were developed from data reports prepared for each technology. Consequences were estimated using the MACCS2 computer code and local population and meteorology data. The consequences are presented for mean and 95th percentile meteorological conditions.

Meteorological data are based on 10-m (33-ft) weather readings at Hanford for the 1996 calendar year.[5] In accordance with the MACCS2 format requirements, the data set consists of 8,760 consecutive hourly readings of windspeed, wind direction, Pasquill-Gifford stability class, and accumulated rainfall.

Population estimates for Hanford are for the year 2010, are based on the *Census of Population and Housing, 1990* (DOC 1992), and are identical to the estimates used for the analysis of normal operations in this SPD EIS. Population values are formatted into 16 sectors centered around the 16 standard compass directions, which are further subdivided into 10 radial distance intervals out to 80 km (50 mi).

[5] The choice of calendar year was based primarily on data quality. For some combinations of site and calendar year, the data set contains significant gaps, making that data undesirable for use in dispersion modeling. As a result, not all sites were analyzed using meteorological data for the same calendar year.

Table K–3. Accident Impacts of Pit Conversion Facility in FMEF at Hanford

Accident	Source Term (g)	Frequency (per year)	Meteorology	Dose to Noninvolved Worker (rem)	Probability of Cancer Fatality Given Dose to Noninvolved Worker[a]	Dose at Site Boundary (rem)	Probability of Cancer Fatality Given Dose at Site Boundary[a]	Population Dose Within 80 km (person-rem)	Latent Cancer Fatalities Within 80 km[b]
Fire	1.2×10^{-5}	Unlikely	Mean	2.8×10^{-6}	1.1×10^{-9}	5.2×10^{-7}	2.6×10^{-10}	8.7×10^{-4}	4.3×10^{-7}
			95th percentile	1.1×10^{-5}	4.3×10^{-9}	1.6×10^{-6}	8.1×10^{-10}	5.3×10^{-3}	2.6×10^{-6}
Explosion	3.2×10^{-3}	Unlikely	Mean	7.3×10^{-4}	2.9×10^{-7}	1.4×10^{-4}	6.8×10^{-8}	2.3×10^{-1}	1.1×10^{-4}
			95th percentile	2.8×10^{-3}	1.1×10^{-6}	4.2×10^{-4}	2.1×10^{-7}	1.4	6.8×10^{-4}
Leaks/spills of nuclear material	4.4×10^{-6}	Extremely unlikely	Mean	1.0×10^{-6}	4.1×10^{-10}	1.9×10^{-7}	9.6×10^{-11}	3.2×10^{-4}	1.6×10^{-7}
			95th percentile	3.9×10^{-6}	1.6×10^{-9}	5.9×10^{-7}	3.0×10^{-10}	1.9×10^{-3}	9.5×10^{-7}
Tritium release	2.0×10^{1}	Extremely unlikely	Mean	7.8×10^{-2}	3.1×10^{-5}	1.5×10^{-2}	7.3×10^{-6}	2.4×10^{1}	1.2×10^{-2}
			95th percentile	3.0×10^{-1}	1.2×10^{-4}	4.5×10^{-2}	2.3×10^{-5}	1.5×10^{2}	7.3×10^{-2}
Criticality	1.0×10^{19} Fissions	Extremely unlikely	Mean	1.1×10^{-2}	4.4×10^{-6}	1.2×10^{-3}	6.0×10^{-7}	8.5×10^{-1}	4.3×10^{-4}
			95th percentile	3.3×10^{-2}	1.3×10^{-5}	3.4×10^{-3}	1.7×10^{-6}	5.4	2.7×10^{-3}
Design basis earthquake	3.9×10^{-4}	Unlikely	Mean	9.0×10^{-5}	3.6×10^{-8}	1.7×10^{-5}	8.4×10^{-9}	2.8×10^{-2}	1.4×10^{-5}
			95th percentile	3.5×10^{-4}	1.4×10^{-7}	5.2×10^{-5}	2.6×10^{-8}	1.7×10^{-1}	8.4×10^{-5}
Beyond-design-basis fire	1.7×10^{-2}	Beyond extremely unlikely	Mean	2.9×10^{-2}	1.1×10^{-5}	1.1×10^{-3}	5.6×10^{-7}	1.5	7.7×10^{-4}
			95th percentile	1.1×10^{-1}	4.3×10^{-5}	4.1×10^{-3}	2.0×10^{-6}	9.9	4.3×10^{-3}
Beyond-design-basis earthquake	3.9×10^{1}	Extremely unlikely to beyond extremely unlikely	Mean	6.6×10^{1}	2.6×10^{-2}	2.6	1.3×10^{-3}	3.6×10^{3}	1.8
			95th percentile	2.5×10^{2}	9.9×10^{-2}	9.4	4.7×10^{-3}	2.3×10^{4}	9.8

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Key: FMEF, Fuels and Materials Examination Facility.

Note: Calculated using the source terms in the pit conversion data report, as modified in Section K.1.5.1, site meteorology, projected regional population, and the MACCS2 computer code.

Table K–4. Accident Impacts of Ceramic Immobilization Facility in FMEF and HLWVF at Hanford (Hybrid Case)

Accident	Source Term (g)	Frequency (per year)	Meteorology	Dose to Noninvolved Worker (rem)	Probability of Cancer Fatality Given Dose to Noninvolved Worker[a]	Dose at Site Boundary (rem)	Probability of Cancer Fatality Given Dose at Site Boundary[a]	Population Dose Within 80 km (person-rem)	Latent Cancer Fatalities Within 80 km[b]
Criticality	1.0×10^{19} fissions	Extremely unlikely	Mean	1.1×10^{-2}	4.4×10^{-6}	1.2×10^{-3}	6.0×10^{-7}	8.5×10^{-1}	4.3×10^{-4}
			95th percentile	3.3×10^{-2}	1.3×10^{-5}	3.4×10^{-3}	1.7×10^{-6}	5.4	2.7×10^{-3}
Explosion in HYDOX furnace	3.4×10^{-3}	Unlikely	Mean	1.0×10^{-3}	4.0×10^{-7}	1.9×10^{-4}	9.4×10^{-8}	3.1×10^{-1}	1.6×10^{-4}
			95th percentile	3.8×10^{-3}	1.5×10^{-6}	5.8×10^{-4}	2.9×10^{-7}	1.9	9.4×10^{-4}
Glovebox fire (calcining furnace)	2.7×10^{-7}	Extremely unlikely	Mean	8.0×10^{-8}	3.2×10^{-11}	1.5×10^{-8}	7.4×10^{-12}	2.5×10^{-5}	1.2×10^{-8}
			95th percentile	3.0×10^{-7}	1.2×10^{-10}	4.6×10^{-8}	2.3×10^{-11}	1.5×10^{-4}	7.4×10^{-8}
Hydrogen explosion	3.8×10^{-4}	Unlikely	Mean	1.1×10^{-4}	4.4×10^{-8}	2.1×10^{-5}	1.0×10^{-8}	3.4×10^{-2}	1.7×10^{-5}
			95th percentile	4.2×10^{-4}	1.7×10^{-7}	6.4×10^{-5}	3.2×10^{-8}	2.1×10^{-1}	1.0×10^{-4}
Glovebox fire (sintering furnace)	1.5×10^{-6}	Extremely unlikely	Mean	4.4×10^{-7}	1.8×10^{-10}	8.3×10^{-8}	4.1×10^{-11}	1.4×10^{-4}	6.9×10^{-8}
			95th percentile	1.7×10^{-6}	6.8×10^{-10}	2.6×10^{-7}	1.3×10^{-10}	8.3×10^{-4}	4.1×10^{-7}
Design basis earthquake	3.8×10^{-4}	Unlikely	Mean	1.1×10^{-4}	4.5×10^{-8}	2.1×10^{-5}	1.0×10^{-8}	3.5×10^{-2}	1.7×10^{-5}
			95th percentile	4.3×10^{-4}	1.7×10^{-7}	6.4×10^{-5}	3.2×10^{-8}	2.1×10^{-1}	1.0×10^{-4}
Beyond-design-basis fire	2.1×10^{-3}	Beyond extremely unlikely	Mean	4.5×10^{-3}	1.8×10^{-6}	1.8×10^{-4}	8.9×10^{-8}	2.4×10^{-1}	1.2×10^{-4}
			95th percentile	1.7×10^{-2}	6.8×10^{-6}	6.5×10^{-4}	3.2×10^{-7}	1.6	6.8×10^{-4}
Beyond-design-basis earthquake	1.9×10^{1}	Extremely unlikely to beyond extremely unlikely	Mean	4.1×10^{1}	1.6×10^{-2}	1.6	8.1×10^{-4}	2.2×10^{3}	1.1
			95th percentile	1.5×10^{2}	1.6×10^{-2}	5.8	2.9×10^{-3}	1.4×10^{4}	6.1

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Key: FMEF, Fuels and Materials Examination Facility; HLWVF, high-level-waste vitrification facility, HYDOX, hydride oxidation.
Note: Calculated using the source terms in the immobilization data report, as modified in Section K.1.5.1, site meteorology, projected regional population, and the MACCS2 computer code.

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Note: Calculated using the source terms in the MOX data report, as modified in Section K.1.5.1, site meteorology, projected regional population, and the MACCS2 computer code.

K.3 FACILITY ACCIDENT IMPACTS AT INEEL

The potential source terms and consequences of postulated bounding facility accidents for each facility option for INEEL are presented in Tables K–10 and K–11. Accident scenarios and source terms were developed from data reports prepared for each technology. Consequences were estimated using the MACCS2 computer code and local population and meteorology data. The consequences are presented for mean and 95th percentile meteorological conditions.

Meteorological data are based on 10-m (33-ft) weather readings at INEEL for the 1993 calendar year.[6] In accordance with MACCS2 format requirements, the data set consists of 8,760 consecutive hourly readings of windspeed, wind direction, Pasquill-Gifford stability class, and accumulated rainfall.

Population estimates for INEEL are for the year 2010, are based on the *Census of Population and Housing, 1990* (DOC 1992), and are identical to the estimates used for the analysis of normal operations in this SPD EIS. Population values are formatted into 16 sectors centered around the 16 standard compass directions, which are further subdivided into 10 radial distance intervals out to 80 km (50 mi).

[6] The choice of calendar year was based primarily on data quality. For some combinations of site and calendar year, the data set contains significant gaps, making that data undesirable for use in dispersion modeling. As a result, not all sites were analyzed using meteorological data for the same calendar year.

K.4 FACILITY ACCIDENT IMPACTS AT PANTEX

The potential source terms and consequences of postulated bounding facility accidents for each facility option for Pantex are presented in Tables K–12 and K–13. Accident scenarios and source terms were developed from data reports prepared for each technology. Consequences were estimated using the MACCS2 computer code and local population and meteorology data. The consequences are presented for mean and 95th percentile meteorological conditions.

Meteorological data are based on 10-m (33-ft) weather readings from the Pantex Tower for the 1996 calendar year.[7] In accordance with MACCS2 format requirements, the data set consists of 8,760 consecutive hourly readings of windspeed, wind direction, Pasquill-Gifford stability class, and accumulated rainfall.

Population estimates for Pantex are for the year 2010, are based on the *Census of Population and Housing, 1990* (DOC 1992), and are identical to the estimates used for the analysis of normal operations in this SPD EIS. Population values are formatted into 16 sectors centered around the 16 standard compass directions, which are further subdivided into 10 radial distance intervals out to 80 km (50 mi).

[7] The choice of calendar year was based primarily on data quality. For some combinations of site and calendar year, the data set contains significant gaps, making that data undesirable for use in dispersion modeling. As a result, not all sites were analyzed using meteorological data for the same calendar year.

K.5 FACILITY ACCIDENT IMPACTS AT SRS

The potential source terms and consequences of postulated bounding facility accidents for each facility option for SRS are presented in Tables K–14 through K–23. Accident scenarios and source terms were developed from data reports prepared for each technology. Consequences were estimated using the MACCS2 computer code and local population and meteorology data. The consequences are presented for both mean and 95th percentile meteorological conditions.

Meteorological data are based on 10-m (33-ft) weather readings at SRS, are identical to the data used in *F-Canyon Plutonium Solutions Environmental Impact Statement*, (DOE 1994d), and included in Sample Problem D of the MACCS2 Users Guide. In accordance with MACCS2 format requirements, the data set consists of 8,760 consecutive hourly readings of windspeed, wind direction, Pasquill-Gifford stability class, and accumulated rainfall.

Population estimates for SRS are for the year 2010, are based on the *Census of Population and Housing, 1990* (DOC 1992), and are identical to the estimates used for the analysis of normal operations in the SPD EIS. Population values are formatted into 16 sectors centered around the 16 standard compass directions, which are further subdivided into 10 radial distance intervals out to 80 km (50 mi).

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] (or at the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Note: Calculated using the source terms in the pit conversion data report, as modified in Section K.1.5.1, site meteorology, projected regional population, and the MACCS2 computer code.

			95th percentile	$5.7\times10_{1}$	2.3×10^{-2}	2.2	1.1×10^{-3}	5.3×10^{3}	2.7

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Key: DWPF, Defense Waste Processing Facility; HYDOX, hydride oxidation.

Note: Calculated using the source terms in the immobilization data report, as modified in Section K.1.5.1, site meteorology, projected regional population, and the MACCS2 computer code.

[a] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m [3,281 ft] or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[b] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

			95th percentile	1.3×10^{-3}	5.3×10^{-7}	1.7×10^{-3}	8.5×10^{-7}	2.8×10^{-1}	1.5×10^{-4}
Design basis fire	1.7×10^{-5}	Unlikely	Mean	7.8×10^{-5}	3.1×10^{-8}	9.3×10^{-5}	4.7×10^{-8}	2.4×10^{-2}	1.2×10^{-5}
			95th percentile	5.7×10^{-4}	2.3×10^{-7}	7.4×10^{-4}	3.7×10^{-7}	1.2×10^{-1}	6.3×10^{-5}
Design basis explosion	2.7×10^{-4}	Extremely unlikely	Mean	1.3×10^{-3}	5.0×10^{-7}	1.5×10^{-3}	7.6×10^{-7}	3.9×10^{-1}	1.9×10^{-4}
			95th percentile	9.3×10^{-3}	3.7×10^{-6}	1.2×10^{-2}	6.0×10^{-6}	1.9	1.0×10^{-3}
Beyond-design-basis fire	2.4×10^{-2}	Beyond extremely unlikely	Mean	1.4×10^{-1}	5.7×10^{-5}	1.3×10^{-1}	6.7×10^{-5}	3.5×10^{1}	1.8×10^{-2}
			95th percentile	1.1	4.3×10^{-4}	1.1	5.3×10^{-4}	1.7×10^{2}	9.3×10^{-2}

[a] The closest point to the site boundary is 563 m (1,847 ft), which is less than 1,000 m (3,281 ft). Therefore, doses to the onsite worker are assessed at 1,000 m [3,281 ft] only in those directions where the site boundary is greater than 1,000 m (3,281 ft) away. For other directions, doses are assessed at the site boundary.

[b] Increased likelihood (or probability) of cancer fatality to a hypothetical individual (a single noninvolved worker at a distance of 1,000 m (3,281 ft) or the site boundary, whichever is smaller, or to a hypothetical individual in the offsite population located at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) if exposed to the indicated dose. The value assumes that the accident has occurred.

Key: LLNL, Lawrence Livermore National Laboratory.

Note: A beyond-design-basis earthquake was not evaluated for Building 332 at LLNL because extensive analyses of the seismic hazard at the site and the response of the building to those hazards indicate that the scenario is beyond the range of "reasonably foreseeable." Current estimates are that the frequency of collapse is on the order of 1.0×10^{-7} per year or less.

Appendix L
Evaluation of Human Health Effects From Transportation

L.1 INTRODUCTION

The overland transportation of any commodity involves a risk to both transportation crew members and members of the public. This risk results directly from transportation-related accidents and indirectly from the increased levels of pollution from vehicle emissions, regardless of the cargo. The transportation of certain materials, such as hazardous or radioactive waste, can pose an additional risk due to the unique nature of the material. In order to permit a complete appraisal of the environmental impacts of the proposed action and alternatives, the human health risks associated with the overland transportation of plutonium and uranium have been assessed.

This appendix provides an overview of the approach used to assess the human health risks that may result from the overland transportation. The appendix includes a discussion of the scope of the assessment, analytical methods used for the risk assessment (i.e., computer models), important assessment assumptions, and a determination of potential transportation routes. It also presents the results of the assessment. In addition, to aid in the understanding and interpretation of the results, specific areas of uncertainty are described, with an emphasis on how the uncertainties may affect comparisons of the alternatives.

The approach used in this appendix is modeled after that used in the *Storage and Disposition of Weapons-Usable Fissile Materials Final Programmatic Environmental Impact Statement* (PEIS) (DOE 1996a). The fundamental assumptions used in this analysis are consistent with those used in that PEIS, and the same computer codes and generic release and accident data are used.

The risk assessment results are presented in this appendix in terms of "per-shipment" risk factors, as well as for the total risks associated with each alternative. Per-shipment risk factors provide an estimate of the risk from a single hazardous material shipment between a specific origin and destination. The total risks for a given alternative are found by multiplying the expected number of shipments by the appropriate per-shipment risk factors.

L.2 SCOPE OF ASSESSMENT

The scope of the overland transportation human health risk assessment, including the alternatives and options, transportation activities, potential radiological and nonradiological impacts, and transportation modes considered, is described below. Additional details of the assessment are provided in the remaining sections of the appendix.

- Proposed Action and Alternatives—The transportation risk assessment conducted for the *Surplus Plutonium Disposition Environmental Impact Statement* (SPD EIS) estimates the human health risks associated with the transportation of plutonium and other hazardous materials for a number of disposition alternatives.

- Radiological Impacts—For each alternative, radiological risks (i.e., those risks that result from the radioactive nature of the plutonium and other hazardous materials are assessed for both incident-free (i.e., normal) and accident transportation conditions. The radiological risk associated with incident-free transportation conditions would result from the potential exposure of people to external radiation in the vicinity of a loaded shipment. The radiological risk from transportation accidents would come from the potential release and dispersal of radioactive material into the environment

during an accident and the subsequent exposure of people through multiple exposure pathways (i.e., exposure to contaminated ground or air, or ingestion of contaminated food).

All radiological impacts are calculated in terms of effective dose and associated health effects in the exposed populations. The radiation dose calculated is the total effective dose equivalent (NRC 1998), which is the sum of the effective dose equivalent from external radiation exposure and the 50-year committed effective dose equivalent from internal radiation exposure. Radiation doses are presented in units of roentgen equivalent man (rem) for individuals and person-rem for collective populations. The impacts are further expressed as health risks in terms of latent cancer fatalities (LCFs) and cancer incidence in exposed populations. The health risk conversion factors (expected health effects per dose absorbed) were taken from *International Commission on Radiological Protection Publication 60* (ICRP 1991).

- Nonradiological Impacts—In addition to the radiological risks posed by overland transportation activities, vehicle-related risks are also assessed for nonradiological causes (i.e., related to the transport vehicles and not the radioactive cargo) for the same transportation routes. The nonradiological transportation risks are independent of the radioactive nature of the cargo and would be incurred for similar shipments of any commodity. The nonradiological risks are assessed for both incident-free and accident conditions. Nonradiological risks during incident-free transportation conditions would be caused by potential exposure to increased vehicle exhaust emissions. The nonradiological accident risk refers to the potential occurrence of transportation accidents that directly result in fatalities unrelated to the cargo. State-specific transportation fatality rates are used in the assessment. Nonradiological risks are presented in terms of estimated fatalities.

- Transportation Modes—All overland shipments have been assumed to take place by truck transportation modes.

- Receptors—Transportation-related risks are calculated and presented separately for workers and members of the general public. The workers considered are truck crew members involved in the actual overland transportation. The general public includes all persons who could be exposed to a shipment while it is moving or stopped enroute. Potential risks are estimated for the collective populations of exposed people, as well as for the hypothetical maximally exposed individual. The collective population risk is a measure of the radiological risk posed to society as a whole by the alternative being considered. As such, the collective population risk is used as the primary means of comparing various alternatives.

L.3 PACKAGING AND REPRESENTATIVE SHIPMENT CONFIGURATIONS

Regulations that govern the transportation of radioactive materials are designed to protect the public from the potential loss or dispersal of radioactive materials as well as from routine radiation doses during transit. The primary regulatory approach to promote safety is through the specification of standards for the packaging of radioactive materials. Because packaging represents the primary barrier between the radioactive material being transported and radiation exposure to the public and the environment, packaging requirements are an important consideration for the transportation risk assessment. Regulatory packaging requirements are discussed briefly below and in Chapter 5. In addition, the representative packaging and shipment configurations assumed for the SPD EIS are described.

L.3.1 Packaging Overview

Although several Federal and State organizations are involved in the regulation of radioactive materials transportation, primary regulatory responsibility resides with the U.S. Department of Transportation (DOT)

and the U.S. Nuclear Regulatory Commission (NRC). All transportation activities must take place in accordance with the applicable regulations of these agencies specified in Title 49 of the Code of Federal Regulations (CFR) Part 173 (DOT 1992a) and 10 CFR 71 (NRC 1996).

Transportation packaging for small quantities of radioactive materials must be designed, constructed, and maintained to contain and shield their contents during normal transport conditions. For large quantities and for more highly radioactive material, such as spent nuclear fuel or plutonium, they must contain and shield their contents in the event of severe accident conditions. The type of packaging used is determined by the total radioactive hazard presented by the material within the packaging; 10 CFR 71 (NRC 1996) provides the rules for this determination. Four basic types of packaging are used: Excepted, Industrial, Type A, and Type B. Another packaging option, Strong and Tight, is still available for some domestic shipments.

Excepted packagings are limited to transporting materials with extremely low levels of radioactivity. Industrial packagings are used to transport materials that, because of their low concentration of radioactive materials, present a limited hazard to the public and the environment. Type A packagings are designed to protect and retain their contents under normal transport conditions and must maintain sufficient shielding to limit radiation exposure to handling personnel. These packagings are used to transport radioactive materials with higher concentrations or amounts of radioactivity than Excepted or Industrial packagings. Strong and Tight packagings are used in the United States for shipment of certain materials with low levels of radioactivity, such as natural uranium and rubble from the decommissioning of nuclear reactors. Type B packages are described in detail in Appendix L.3.1.6.

L.3.1.1 Uranium Hexafluoride Packaging

DOE would ship uranium hexafluoride from the Portsmouth Gaseous Diffusion Plant to a fuel fabrication facility in Model 30B cylinders, which are Type A packages (for the purposes of the SPD EIS). Uranium hexafluoride shipments are regulated under 49 CFR 173.420, which requires the packaging to be in accordance with ANSI N14.1, *Uranium Hexafluoride–Packaging for Transport*. Because uranium hexafluoride breaks down into hydrofluoric acid and uranyl fluoride when exposed to air, packages would be marked with the primary hazard label as "Radioactive Yellow-II" and a secondary hazard label as "Corrosive." The transport vehicle would be required to show the primary placard "Radioactive" and the secondary placard "Corrosive."

L.3.1.2 Uranium Dioxide Packaging

DOE would ship uranium oxide from the fuel fabrication facility to DOE's mixed oxide (MOX) facility in gasketed, open-head, 208-l (55-gal) drums with heavy plastic liners, which are Industrial Package Type 1 packages. Uranium oxide shipments are regulated under 49 CFR 173.425. Because uranium oxide is a low-specific activity material, no primary hazard label would be required, and because it is chemically stable, no secondary hazard label would be required. The transport vehicle would be required to show the primary placard "Radioactive" and no secondary placard.

L.3.1.3 Mixed Oxide Fuel Packaging

DOE will design the container for the MOX fuel assemblies. For analysis purposes, it is assumed that DOE would ship the unirradiated MOX fuel bundles to the reactor site(s) in Type B packages. Two conceptual packaging ideas are end-loading and lateral-loading packages (Ludwig et al. 1997). The fuel assembly weight per container is approximately 2800 kg (6,000 lb) for either pressurized water reactor (PWR) or boiling water reactor (BWR) fuel. The container could hold either four PWR or eight BWR assemblies.

L.3.1.4 Highly Enriched Uranium Packaging

DOE would ship highly enriched uranium (HEU) from the pit conversion facility to the Y–12 facility near Oak Ridge, Tennessee. The DOE-approved container type for these shipments is the DT–22.

L.3.1.5 Plutonium Packaging

DOE would ship all plutonium in Type B containers. DOE would ship nonpit plutonium from DOE sites (Hanford, Idaho National Engineering and Environmental Laboratory [INEEL], Los Alamos National Laboratory [LANL], Lawrence Livermore National Laboratory [LLNL], Rocky Flats Environmental Technology Site [RFETS], and Savannah River Site [SRS]) to the immobilization facility (Hanford or SRS) in a variety of containers, such as Type 3013, Type 2R, and Foodpac containers, which would be transported inside various casks, such as radial reflector, Model 60 FFTA DFA pins shipping or Specification 6M packages. DOE would ship plutonium pits from DOE sites to the pit conversion facility in DOE-approved FL containers and the piece parts resulting from pit disassembly in DOE-approved UC–609 and USA/9975 containers. Plutonium oxide produced at the pit disassembly and conversion facility (pit conversion facility) would be loaded into packaging that meets DOE-STD-3013-96, *Criteria for Safe Storage of Plutonium Metals and Oxides* (DOE 1996b) or equivalent. This package provides for safe storage of plutonium oxides for at least 50 years or until final disposition and serves as the primary containment vessel for shipping. DOE-STD-3013-96 specifies a design goal that the Type 3013 container could be shipped in a qualified shipping container without further reprocessing or repackaging. The Type 3013 primary containment vessel is designed for shipping and would be compatible with a Type B package. No Type B package has been specifically constructed or licensed for shipping DOE-STD-3013-96 primary containment vessels.

A Type B package is required when transporting commercial quantities of plutonium materials, including unirradiated MOX fuel assemblies. DOE is developing a conceptual design for a MOX container that optimizes safe, secure trailer (SST) load-carrying capacity and ensures compatibility with fuel-handling systems at commercial reactors (Ludwig et al. 1997).

L.3.1.6 Overview of Type B Containers

The transportation of highway-route controlled quantities of plutonium (more than a few grams, depending on activity level) requires the use of Type B packaging. In addition to meeting the standards for Type A packaging, Type B packaging must provide a high degree of assurance that, even in severe accidents, the integrity of the package will be maintained with essentially no loss of the radioactive contents or serious impairment of the shielding and maintain subcriticality capability. Type B packaging must satisfy stringent testing criteria specified in 10 CFR 71 (NRC 1996). The testing criteria were developed to simulate severe accident conditions, including impact, puncture, fire, and water immersion.

Beyond meeting DOT standards showing it can withstand normal conditions of transport without loss or dispersal of its radioactive contents or allowance of significant radiation fields, Type B packaging must also meet the 10 CFR 71 requirements administered by the NRC. The complete sequence of tests is listed below:

- Free-Drop Test—A 9-m (30-ft) free-drop onto a flat, essentially unyielding, horizontal surface, striking the surface in a position for which maximum damage to the package is expected.

- Puncture Test—A 1-m (40-in) drop onto the upper end of a 15-cm (6-in) diameter solid, vertical, cylindrical, mild steel bar (at least 20-cm [8-in] long) mounted on an essentially unyielding, horizontal surface.

- Thermal Test—Exposure to a heat flux of no less than that of a thermal radiation environment of 800 °C (1,475 °F) with an emissivity coefficient of at least 0.9 for a period of 30 minutes.

- Water Immersion Test—A separate, undamaged package specimen is subjected to water pressure equivalent to immersion under a head of water of at least 15-m (50-ft) for no less than 8 hours.

Effective April 1, 1996, 10 CFR 71 has been revised to require an additional immersion test in 200 m (660 ft) of water for Type B casks designed to contain material with activity levels greater than one million curies (Ci) (NRC 1996). Containers used for shipping plutonium will not necessarily be subject to this test because they will contain much less than one million curies. The packaging may also be required to undergo the crush test if it is considered a light-weight, low-density package as most drum-type packages are. The crush test consists of dropping a 500-kg (1100-lb) steel plate from 9 m (30 ft) onto the package, which is resting on an essentially unyielding surface.

Additional restrictions apply to package surface contamination levels, but these restrictions are not limiting for the transportation radiological risk assessment. For risk assessment purposes, it is important to note that all packaging of a given type is designed to meet the same performance criteria. Therefore, two different Type B designs would be expected to perform similarly during incident-free and accident transportation conditions. The specific containers selected, however, will determine the total number of shipments necessary to transport a given quantity of plutonium.

External radiation from a package must be below specified limits that minimize the exposure of the handling personnel and general public. For these types of shipments, the external radiation dose rate during normal transportation conditions must be maintained below the following limits of 49 CFR 173 (DOT 1992a):

- 10 mrem/hr at any point 2 m (6.6 ft) from the vertical planes projected by the outer lateral surfaces of the transport vehicle (referred to as the regulatory limit throughout this document)

- 2 mrem/hr in any normally occupied position in the transport vehicle

L.3.2 Safe, Secure Transportation

DOE anticipates that any transportation of plutonium pits, nonpit plutonium, plutonium oxide, MOX fuel, or HEU would be required to be made through use of the Transportation Safeguards System and shipped using SSTs. The SST is a fundamental component of the Transportation Safeguards System. The Transportation Safeguards System is operated by the DOE Transportation Safeguards Division of the Albuquerque Operations Office for the DOE Headquarters Office of Defense Programs. Based on operational experience between FY84 and FY93, the mean probability of an accident requiring the tow-away of the SST was 0.066 accident per million kilometers (0.11 accident per million miles). By contrast, the rate for commercial trucking in 1989 was about 0.3 accidents per million kilometers (0.5 accident per million miles). Commercial trucking accident rates (Saricks and Kvitek 1994) were used in the human health effects analysis. Since established in 1975, the Transportation Safeguards Division has accumulated more than 145 million km (90 million mi) of over-the-road experience transporting DOE-owned cargo with no accidents resulting in a fatality or release of radioactive material.

The SST is a specially designed component of an 18-wheel tractor-trailer vehicle. Although details of vehicle enhancements and some operational aspects are classified, key characteristics of the SST system include the following:

- Enhanced structural characteristics and a highly reliable tie-down system to protect cargo from impact
- Heightened thermal resistance to protect the cargo in case of fire
- Various deterrents to prevent unauthorized removal of cargo
- An armored tractor component that provides courier protection against attack and contains advanced communications equipment
- Specially designed escort vehicles containing advanced communications and additional couriers
- 24-hour-a-day real-time communications to monitor the location and status of all SST shipments via DOE's Security Communication system
- Couriers who are armed Federal Officers, receive rigorous specialized training, and who are closely monitored through DOE's Personnel Assurance Program
- Significantly more stringent maintenance standards than those for commercial transport equipment
- Conduct of periodic appraisals of the Transportation Safeguards System operations by the DOE Office of Defense Programs to ensure compliance with DOE orders and management directives.

L.3.3 Ground Transportation Route Selection Process

According to DOE guidelines, plutonium shipments must comply with both NRC and DOT regulatory requirements. Commercial shipments are also required by law to comply with both NRC and DOT requirements. NRC regulations cover the packaging and transport of plutonium, whereas DOT specifically regulates the carriers and the conditions of transport, such as routing, handling and storage, and vehicle and driver requirements. The highway routing of nuclear material is systematically determined according to DOT regulations 49 CFR 171–179 and 49 CFR 397 for commercial shipments. Specific routes cannot be publicly identified in advance for Transportation Safeguards Division shipments because they are classified to protect national security interests.

The DOT routing regulations require that shipment of a "highway route-controlled quantity" of radioactive material be transported over a preferred highway network including interstate highways, with preference toward interstate system bypasses around cities, and State-designated preferred routes. A State or Tribe may designate a preferred route to replace or supplement the interstate highway system in accordance with DOT guidelines (DOT 1992b).

Carriers of highway route-controlled quantities are required to use the preferred network, unless moving from origin to the nearest interstate or from the interstate to the destination, when making necessary repair or rest stops, or when emergency conditions render the interstate unsafe or impassible. The primary criterion for selecting the preferred route for a shipment is travel time. Preferred routing takes into consideration accident rate, transit time, population density, activities, time of day, and day of week.

The HIGHWAY computer code (Johnson et al. 1993) may be used for selecting highway routes in the United States. The HIGHWAY database is a computerized road atlas that currently describes about 386,400 km (240,000 mi) of roads. The Interstate System and all U.S. (U.S.-designated) highways are completely described in the database. In addition, most of the principal State highways and many local and community roads are also identified. The code is updated periodically to reflect current road conditions and has been benchmarked against reported mileages and observations of commercial truck firms. Features in the HIGHWAY code allow the user to select routes that conform to DOT regulations. Additionally, the HIGHWAY code contains data on the population densities along the routes. The distances and populations from the HIGHWAY code are part of the information used for the transportation impact analysis in the SPD EIS.

L.4 METHODS FOR CALCULATING TRANSPORTATION RISKS

The overland transportation risk assessment methodology is summarized in Figure L–1. After the alternatives were identified and goals of the shipping campaign were understood, the first step was to collect data on material characteristics and accident parameters. Physical, radiological, and packaging data were provided in reports from the DOE national laboratories. Accident parameters are largely based on the DOE-funded study of transportation accidents (Saricks and Kvitek 1994).

Representative routes that may be used for the shipment of plutonium were selected using the HIGHWAY code. These routes were selected for risk assessment purposes. They do not necessarily represent the actual routes that would be used to transport nuclear materials. Specific routes cannot be identified in advance because the routes would not be finalized until they had been reviewed and approved by NRC. The selection of the actual route would be responsive to environmental and other conditions that would be in effect or could be predicted at the time of shipment. Such conditions could include adverse weather conditions, road conditions, bridge closures, and local traffic problems. For security reasons, details about a route would not be publicized before the shipment.

The first analytic step in the ground transportation analysis was to determine the incident-free and accident risk factors, on a per-shipment basis, for transportation. Risk factors, as any risk estimate, are the product of the probability of exposure and the magnitude of the exposure. Accident risk factors were calculated for radiological and nonradiological traffic accidents. The probabilities, which are much lower than one, and the magnitudes of exposure were multiplied, yielding risk numbers. Incident-free risk factors were calculated for crew and public exposure to radiation emanating from the shipping container (cask) and public exposure to the chemical toxicity of the transportation vehicle exhaust. The probability of incident-free exposure is unity (one).

Radiological risk factors are expressed in units of rem. Later in the analysis, they will be multiplied by *International Commission on Radiation Protection Publication 60* (ICRP 1991) conversion factors and estimated number of shipments to give risk estimates in units of LCFs. The vehicle emission risk factors are calculated in latent fatalities, and the vehicle accident risk factors are calculated in fatalities.

For each alternative, risks were assessed for both incident-free transportation and accident conditions. For the incident-free assessment, risks were calculated for both collective populations of potentially exposed individuals and for maximally exposed individuals. The accident assessment consists of two components: (1) a probabilistic accident risk assessment that considers the probabilities and consequences of a range of possible transportation accident environments, including low-probability accidents that have high consequences and high-probability accidents that have low consequences, and (2) an accident consequence assessment that considers only the consequences of the most severe transportation accidents postulated.

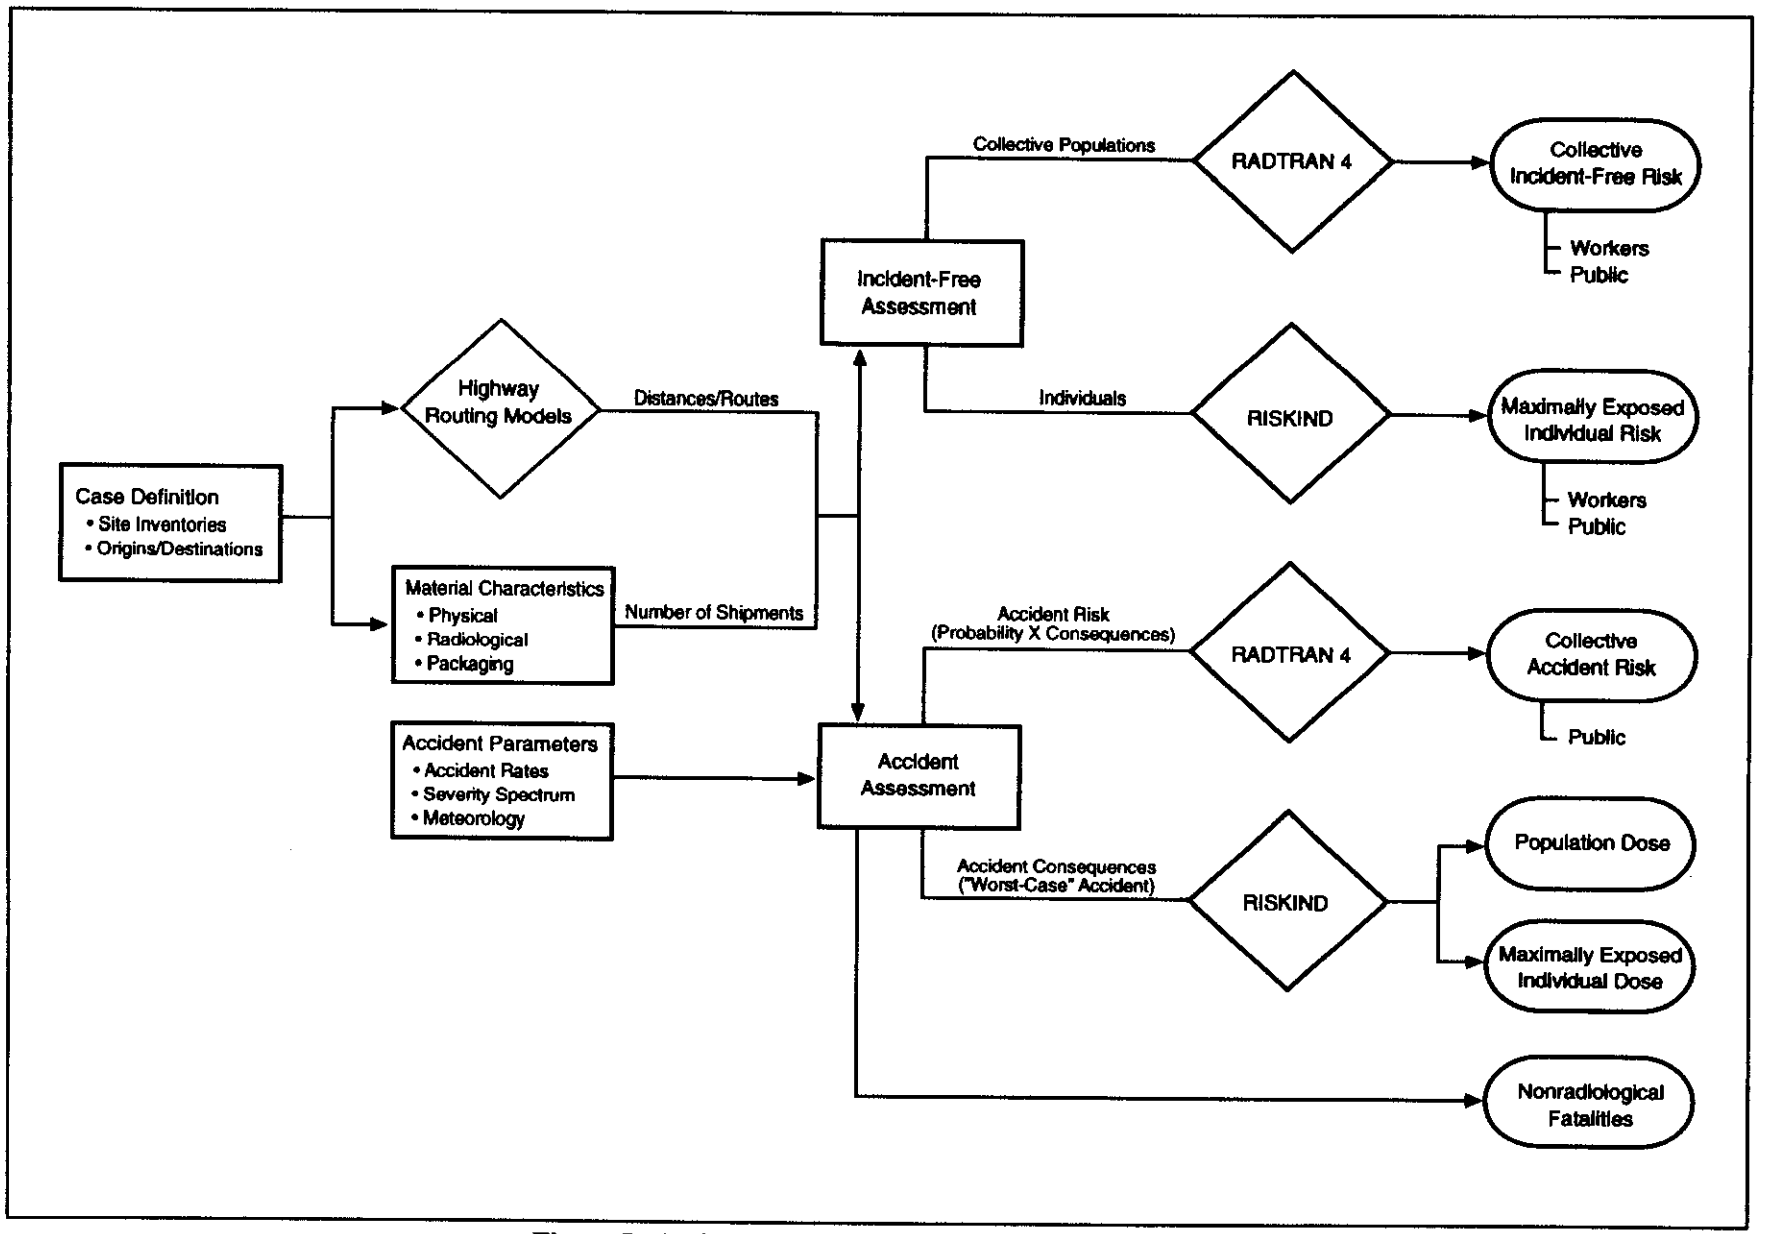

Figure L–1. Overland Transportation Risk Assessment

The RADTRAN 4 computer code (Neuhauser and Kanipe 1994) is used for incident-free and accident risk assessments to estimate the impacts on collective populations. RADTRAN 4 was developed by Sandia National Laboratories to calculate population risks associated with the transportation of radioactive materials by a variety of modes, including truck, rail, air, ship, and barge.

The RADTRAN 4 population risk calculations take into account both the consequences and probabilities of potential exposure events. The collective population risk is a measure of the total radiological risk posed to society as a whole by the alternative being considered. As such, the collective population risk is used as the primary means of comparing the various alternatives. The RISKIND computer code (Yuan et al. 1995) is used to estimate the incident-free doses to maximally exposed individuals and for estimating impacts for the accident consequence assessment. The RISKIND computer code was developed for DOE's Office of Civilian Radioactive Waste Management to analyze the exposure of individuals during incident-free transportation. In addition, the RISKIND code was designed to allow a detailed assessment of the consequences to individuals and population subgroups from severe transportation accidents under various environmental settings.

The RISKIND calculations were conducted to supplement the collective risk results calculated with RADTRAN 4. Whereas the collective risk results provide a measure of the overall risks of each alternative, the RISKIND calculations are meant to address areas of specific concern to individuals and population subgroups. Essentially, the RISKIND analyses are meant to address "What if" questions, such as "What if I live next to a site access road?" or "What if an accident happens near my town?"

If highly specialized analytic codes had been used to model SST behavior in an accident (*DOE-developed Analysis of Dispersal Risk Occurring in Transportation* [Claus et al. 1995:689–696] or ADROIT), the code would have provided a probabilistic risk analysis of special nuclear materials shipped in a SST. ADROIT is designed to provide a focused analysis of an energetic release caused by partial detonation of explosive material. The approach and the code could be tailored for the materials shipped in the SPD EIS. However, detailed thermal and mechanical models have not been created for most of the packages used in the SPD EIS.

L.5 ALTERNATIVES, PARAMETERS, AND ASSUMPTIONS

The transportation risk assessment is designed to ensure—through uniform and judicious selection of models, data, and assumptions—that relative comparisons of risk among the various alternatives are meaningful. The major input parameters and assumptions used in the transportation risk assessment are discussed below.

L.5.1 Transportation Alternatives

The proposed action would involve transporting plutonium and other nuclear materials between DOE and commercial sites. Except for the No Action Alternative, each alternative in the SPD EIS has extensive and unique requirements for the transportation of hazardous materials. In this section, the assumptions and logic used to model the intersite transportation requirements are described.

Alternatives 2 through 12 require transporting plutonium metal and pits from various DOE sites to the pit conversion facility at Hanford, INEEL, Pantex, or SRS. The pit conversion facility would disassemble pits and convert the plutonium metal into plutonium oxide. During the pit disassembly process, HEU would be recovered and shipped from the pit conversion facility to the Y–12 facility at Oak Ridge. In addition, some pit parts would be recovered and shipped to LANL. The plutonium oxide would be shipped to the MOX facility or the immobilization facility depending on the alternative. In many of the alternatives, the pit conversion facility is located on the same site as the MOX facility or immobilization facility, limiting the need for intersite transportation of the plutonium oxide. In these alternatives, the plutonium oxide would be transported between the facilities via a secure tunnel between the facilities.

In addition to reducing the number of trips required and the distance that would have to be traveled to transport surplus pits to the pit conversion facility, by placing the pit conversion facility at Pantex the dose associated with repackaging pits for intersite shipment could be reduced by nearly 40 percent. This is because pits can be transferred to the pit conversion facility at Pantex in their current storage containers (mainly the AL–R8 container) without having to be repackaged. If the pits are transported to another site, they have to be moved to a shipping container (e.g., FL-Type, 9975).

Based on estimates presented in the *Final EIS for the Continued Operation of Pantex,* 50 workers would be needed to repackage 12,000 pits from their current storage containers into containers that could also be used for shipping.[1] This effort would be completed over 10 years and the estimated annual dose received from repackaging activities would be about 50 mrem per worker. By locating the pit conversion facility at Pantex, it is expected that this dose could be reduced by approximately 20 mrem per worker to a level of 30 mrem per worker because the pits would not have to be repackaged for offsite shipment. The pits would be slowly moved from storage locations in storage containers on specially designed vehicles to the pit conversion facility. Over the 10-year operating life of the pit conversion facility, this would reduce the total estimated dose to involved Pantex workers by 10 person-rem from 25 person-rem to 15 person-rem. Under either scenario, the estimated number of excess cancer fatalities associated with repackaging activities would be 0.01 or less.

Alternatives 2 through 12 involve immobilization of nonpit plutonium at Hanford (Alternatives 2, 4, 8, 10, or 11) or SRS (Alternatives 3, 5, 6, 7, 9, or 12). This material would be transported from its current location at various DOE sites to the chosen immobilization facility. If the immobilization facility uses a ceramic process, uranium oxide would be required. One of the United States Enrichment Corporation's gaseous diffusion plants would fill cylinders with depleted uranium hexafluoride, which would be transported to a commercial facility for conversion to uranium oxide. (For the purpose of this analysis, the gaseous diffusion plant in Portsmouth, Ohio, and the nuclear fuel fabrication facility in Wilmington, North Carolina, have been chosen as representative sites for these activities.) The uranium oxide would be transported to the immobilization facility at Hanford or SRS. After the material is immobilized, it is assumed that the additional canisters of high level waste will be shipped to a geologic repository consistent with the assumptions made in the *Final Waste Management Programmatic Environmental Impact Statement for Managing Treatment, Storage, and Disposal of Radioactive and Hazardous Waste* (WM PEIS) (DOE 1997a). Figure L–2 shows the transportation requirements for immobilization.

The production of MOX fuel (Alternatives 2 through 10) requires transporting plutonium oxide from the pit conversion facility to the MOX facility at Hanford, INEEL, Pantex, or SRS. However, in every alternative except Alternatives 4 and 5, the pit conversion facility and MOX facility are collocated so there would not be any intersite transportation required for the plutonium oxide as discussed above. In the case of Alternative 4, the pit conversion facility would be located at Pantex and the plutonium oxide would be shipped to Hanford. Under Alternative 5, the pit conversion facility would also be at Pantex but the plutonium oxide would be shipped to SRS. Uranium oxide needed to produce MOX fuel would be converted from uranium hexafluoride, originally from Portsmouth, at Wilmington, and then transported to the MOX facility. If MOX fuel rods are bundled with low-enriched uranium fuel rods, the uranium fuel rods may come from a separate fabrication facility. Transportation of the uranium fuel rods to the MOX facility is equivalent to transportation of uranium fuel to a commercial reactor site. This transportation activity is covered under the *Final Environmental*

[1] In the analysis presented in the *Pantex EIS* (DOE 1996i), pits are assumed to be repackaged in AT–400A containers. The amount of effort involved in repackaging a pit in an AT–400A container is more intense than the effort needed to repackage a pit in a FL-type container; therefore, the doses would be expected to be higher. Since the *Pantex EIS* was completed, it has been decided that surplus pits would not be repackaged in AT–400A containers. As a result, the dose estimates associated with repackaging pits as presented in the *Pantex EIS* are conservatively high for the SPD EIS. No effort has been made to reestimate the dose associated with repackaging pits. The doses presented in the SPD EIS are based on using the AT–400A container, and therefore represent upper bounds on the expected dose to involved workers.

Statement on the Transportation of Radioactive Material by Air and Other Modes (NRC 1977). The MOX fuel would be transported to a U.S. nuclear reactor for power production. (For the purposes of this analysis, it is assumed that the reactor is 4,000 km (2,500 mi) from the MOX facility.) Figure L–3 shows the transportation requirements for MOX fuel fabrication.

Alternatives 2 through 10 include the production of MOX fuel. If this alternative is chosen by DOE, a lead fuel assembly campaign may precede the actual production of MOX. Plutonium oxide at LANL would be shipped to one of five DOE facilities (Argonne National Laboratory–West [ANL–W], Hanford, LLNL, LANL, or SRS). Low-enriched uranium (LEU) oxide would be produced from LEU hexafluoride, originally from Portsmouth, at Wilmington, and then transported to the lead assembly fabrication facility. From the fabrication facility, the MOX fuel lead assemblies would be transported overland to a U.S. reactor. After power production in the reactor, the spent MOX fuel lead assemblies would be transported to a DOE site (either ANL–W or Oak Ridge National Laboratory) for examination. Figure L–4 shows the transportation requirements for the lead assemblies.

L.5.2 Representative Routes and Populations

Representative overland truck routes have been selected for the origin and destination points identified in Figures L–2, L–3, and L–4 are shown in Table L–1. The routes (which were determined for risk assessment purposes) were selected consistent with current routing practices and all applicable routing regulations and guidelines. They do not necessarily represent the actual routes that would be used to transport plutonium and other hazardous materials in the future. Specific routes cannot be identified in advance, as explained in Appendix L.3.3.

Route characteristics that are important to the radiological risk assessment include the total shipment distance and the population distribution along the route. The specific route selected determines both the total potentially exposed population and the expected frequency of transportation-related accidents. Route characteristics are summarized in Table L–1. The population densities along each route are derived from 1990 U.S. Bureau of Census data and projected forward to the year 2010 using State-specific projections. Rural, suburban, and urban areas are characterized according to the following breakdown: rural population densities range from 0 to 54 persons per square kilometer (0 to 139 person per square mile); the suburban range is from 55 to 1,284 persons per square kilometer (140 to 3,326 persons per square mile); and the urban includes all population densities greater than 1,284 persons per square kilometer (3,326 persons per square mile). The exposed population includes all persons living within 800 m (0.5 mi) of each side of the road.

L.5.3 Distance Traveled by Alternative

Table L–2 shows the number of shipments, the total mileage traveled by the trucks carrying nuclear materials, and the affected populations. The affected population is designed to show the number of people actually or potentially exposed to nuclear material shipments. The measure is calculated by multiplying the number of shipments by the number of people living within 800 m (0.5 mi) of the route used to transport the material. The highest possible lead test assembly mileages and populations from Table L–2 are used in the alternative totals. The number of trips in Table L–2 comes from the SPD EIS data reports (UC 1998a through n).

Because the reactor sites are not identified in the SPD Draft EIS, a maximum possible distance between the PIE and MOX facilities, and the reactor site of 4000 km (2,486 mi) is assumed. If reactors near the PIE and MOX facilities are chosen to use MOX fuel, this number could be significantly lower. The rural, suburban, and urban density breakdown for this entirely hypothetical route is based on typical U.S. values (Neuhauser and Kanipe 1994).

L.5.4 Shipment External Dose Rates

The dose and corresponding risk to populations and maximally exposed individuals during incident-free transportation conditions are directly proportional to the assumed shipment external dose rate. The Federal regulations for maximum allowable dose rates for exclusive-use shipments were presented in Appendix L.3.1.

The actual shipment dose rate is a complex function of the composition and configuration of shielding and containment used in the cask, the geometry of the loaded shipments, and characteristics of the material shipped. DOE has years of experience handling the materials that would be required to be shipped under the alternatives assessed in the SPD EIS, and has regularly conducted radiation level measurements while handling these materials. The maximum predicted dose from individual packages, based on experience at DOE facilities, would yield a dose rate less than the Federal regulatory limit in every case. Spent nuclear fuel and nonpit plutonium were conservatively assumed to have dose rates equal to the regulatory limit of 10 mrem/hr at 2 m (6.6 ft) from the vehicle. This DOE experience was used in the preparation of the dose rates given in the data reports (UC 1998a through n) and used in the analysis.

L.5.5 Health Risk Conversion Factors

The health risk conversion factors used to estimate expected cancer fatalities were taken from *International Commission on Radiation Protection Publication 60* (ICRP 1991): 0.0005 and 0.0004 fatal cancer cases per person-rem for members of the public and workers, respectively. Cancer fatalities occur during the lifetimes of the exposed populations and, thus, are called latent cancer fatalities.

L.5.6 Accident Involvement Rates

For the calculation of accident risks, vehicle accident and fatality rates are taken from data provided in other reports (Saricks and Kvitek 1994). Accident rates are generically defined as the number of accident involvements (or fatalities) in a given year per unit of travel in that same year. Therefore, the rate is a fractional value, with the accident-involvement count as the numerator of the fraction and vehicular activity (total travel distance) as its denominator. Accident rates are generally determined for a multiyear period. For assessment purposes, the total number of expected accidents or fatalities is calculated by multiplying the total shipment distance for a specific case by the appropriate accident or fatality rate.

For truck transportation, the rates presented are specifically for heavy combination trucks involved in interstate commerce (Saricks and Kvitek 1994). Heavy combination trucks are rigs composed of a separable tractor unit containing the engine and one to three freight trailers connected to each other. Heavy combination trucks are typically used for radioactive waste shipments. The truck accident rates are computed for each State based on statistics compiled by the DOT Office of Motor Carriers for 1986 to 1988. Saricks and Kvitek present accident involvement and fatality counts; estimated kilometers of travel by State; and the corresponding average accident involvement, fatality, and injury rates for the 3 years investigated. Fatalities are deaths (including crew members) attributable to the accident or that occurred at any time within 30 days thereafter. SST accident rates are based on operational experience and influence factors (Phillips et al. 1994).

L.5.7 Container Accident Response Characteristics and Release Fractions

The transportation accident model assigns accident probabilities to a set of accident categories. Eight accident-severity categories defined in the NRC's *Final Environmental Impact Statement on the Transportation of Radioactive Material by Air and Other Modes,* NUREG-0170 (NRC 1977), were used. The least severe categories (Category I and II) represent low magnitudes of crush force, accident-impact velocity, fire duration, and/or puncture-impact speed. The most severe category (Category VIII) represents a large crush force, high accident-impact velocity, long fire duration, and a high puncture-impact speed. The fraction of material released and material aerosolized, and the fraction of that material that is respirable (particles smaller than 10 microns), was assigned based on the accident categories and container types. Because all plutonium shipments will use the previously described Type B containers and the SST system, even severe accidents release, at the most, a portion of the material being transported. The risks associated with other materials are significantly lower.

Next Section

L.6 RISK ANALYSIS RESULTS

L.6.1 Per-Shipment Risk Factors

Per-shipment risk factors have been calculated for the collective populations of exposed persons and for the crew for all anticipated routes and shipment configurations. The radiological risks are presented in doses per shipment for each unique route, material, and container combination. Doses are calculated for the crew, off-link public (i.e., people living along the route), on-link public (i.e., pedestrians and drivers along the route), and public at rest and fueling stops (i.e., stopped cars, buses and trucks, workers, and other bystanders). The accident risk factors are called "dose risk" because the values incorporate the spectrum of accident severity probabilities and associated consequences. Separate risk factors are provided for fatalities resulting from hydrocarbon emissions (known to contain carcinogens) and transportation accidents (fatalities resulting from impact).

L.6.2 Evaluation of Shipment Risks

Tables L–3 and L–4 show the risks and maximum risks, respectively, of transporting materials for the lead assemblies alternatives. As shown, the risks include the risk of transporting uranium dioxide, uranium hexafluoride, plutonium oxide, fuel assemblies and spent fuel. Table L–5 shows the results of similar calculations which give the risks for each alternative. The risk estimates in Table L–5 include the maximum risk for the lead assembly transportation (Alternatives 2 through 10), plutonium pit shipments, pit material shipments (HEU and nonplutonium bearing pit parts), uranium hexafluoride, uranium dioxide, fuel assemblies and nonpit plutonium. The data in Tables L–2 and L–5 are not presented in more detail because much of the shipping activity is classified. The risks are calculated by multiplying the per-shipment factors by the number of shipments and, in the case of the radiological doses, by the health risk conversion factors.

L.6.3 Maximally Exposed Individuals

The risks to maximally exposed individuals under incident-free transportation conditions have been estimated for hypothetical exposure scenarios. The estimated dose to inspectors and the public is presented in Table L–6 on a per-event basis (person-rem per event). Note that the potential exists for individual exposures if multiple exposure events occur. For instance, the dose to a person stuck in traffic next to a shipment for 30 minutes is calculated to be 11 mrem. (This conservatively assumes the person in a car is 1.2 m (4 ft) from the edge

Table L–6. Estimated Dose to Maximally Exposed Individuals During Incident-Free Transportation Conditions[a,b]

Receptor	Dose to Maximally Exposed Individual
Workers	
Crew member	0.1 rem/yr[c]
Inspector	0.0029 rem/event
Public	
Resident	4.0×10^{-7} rem/event
Person in traffic construction	0.011 rem/event
Person at service station	0.001 rem/event

[a] The exposure scenario assumptions are described in Appendix L.6.3.
[b] Doses are calculated assuming that the shipment external dose rate is equal to the maximum expected dose 10 mrem/hr at 2 m (6.6 ft) from the package.
[c] Dose to truck drivers could exceed the legal limit of 100 mrem/yr in the absence of administrative controls.

of the truck.) If the exposure duration was longer, the dose would rise proportionally. In addition, a person working at a truck service station could receive a significant dose if trucks were to use the same stops repeatedly. The dose to a person fueling a truck could be as much as 1 mrem. Administrative controls could be instituted to control the location and duration of truck stops if multiple exposures were to happen routinely. However, it is DOE's normal practice to have SST guard force members (trained, monitored radiation workers) perform fueling and routine on-road maintenance checks (i.e., check oil or windshield wiper fluid).

The cumulative dose to a resident was calculated assuming all shipments passed his or her home. The cumulative doses assume that the resident is present for every shipment and is unshielded at a distance of 30 m (98 ft) from the route. Therefore, the cumulative dose is only a function of the number of shipments passing a particular point and is independent of the actual route being considered. The maximum dose to this resident, would be about 1 mrem. The annual individual dose can be estimated by assuming that shipments would occur uniformly over a 15-year time period.

The accident consequence assessment is intended to provide an estimate of the maximum potential impacts posed by the most severe potential transportation accidents involving a shipment. The accident consequence results are presented in Table L–7 for the maximum severity accidents involving plutonium oxide shipments, and Table L–8 for maximum severity accidents involving plutonium pits. Table L–7 applies to alternatives in which the pit conversion facility is located at Pantex, and large amounts of plutonium oxides are shipped to a MOX or conversion facility. Table L–8 applies to alternatives in which plutonium pits and metals are shipped to a pit conversion facility at a site other than Pantex. In either table, the accident frequency in rural locations is about 1×10^{-7}/yr (once in 10 million years), and all other accidents are much less likely. The impacts represent the most severe accidents hypothesized.

The hypothetical accidents described in Tables L–7 and L–8 involve either a long-term fire, or tremendous impact or crushing forces. In the case of crushing forces, a fire would have to be burning in order to spread the plutonium as modeled. These accidents are more likely on rural interstates where speeds are higher, and where the vehicles spend most of their travel time. NUREG-0170 (NRC 1977) describes the analytic approach in more detail.

The population doses are for a uniform population density within an 80-km (50-mi) radius (Neuhauser and Kanipe 1994). The location of the maximally exposed individual is determined based on atmospheric conditions at the time of the accident and the buoyant characteristics of the released plume. The locations of maximum exposure would be 100 m (330 ft) and 500 m (1,650 ft) from the accident site for neutral (average)

Table L–7. Estimated Dose to the Population and to Maximally Exposed Individuals During the Most Severe Accident Conditions (Plutonium Oxide) [a, b]

	Neutral Conditions [c]				Stable Conditions [f]			
	Population [d]		Maximally Exposed Individual [e]		Population [d]		Maximally Exposed Individual [e]	
Mode and Accident Location	Dose (person-rem)	Consequences (Cancer Fatalities)	Dose (rem)	Consequences (Probability of Cancer Fatality)	Dose (person-rem)	Consequences (Cancer Fatalities)	Dose (rem)	Consequences (Probability of Cancer Fatality)
Truck								
Urban	53,200	27	159	0.08	9,400	4.7	5.4	0.003
Suburban	11,600	6	159	0.08	2,050	1	5.4	0.003
Rural	145	0.07	159	0.08	135	0.07	5.4	0.003

[a] The most severe accidents correspond to the NUREG-0170 accident severity category VIII (NRC 1977).
[b] Buoyant plume rise resulting from fire for a severe accident was included in the exposure model.
[c] Neutral weather conditions result in moderate dispersion and dilution of the release plume. Neutral conditions were taken to be Pasquill stability Class D with a wind speed of 4 m/sec (9 mph). Neutral conditions occur approximately 50 percent of the time in the United States.
[d] Populations extend at a uniform density to a radius of 80 km (50 mi) from the accident site. Population exposure pathways include acute inhalation, acute cloudshine, groundshine, resuspended inhalation, resuspended cloudshine, and ingestion of food, including initially contaminated food (RISKIND assumes that all food is grown in rural areas) (Yuan et al. 1995). It is assumed that decontamination or mitigative actions are taken.
[e] The maximally exposed individual is assumed to be at the location of maximum exposure. The locations of maximum exposure would be 100 m (330 ft) and 500 m (1650 ft) from the accident site under neutral and stable atmospheric conditions, respectively. Individual exposure pathways include acute inhalation, acute cloudshine, and groundshine during passage of the plume. No ingested dose is considered. Note that the maximally exposed individual receives more dose than the population in a rural location. This analytic phenomena is caused by probabilistic calculations. It is very unlikely that an individual will be nearby in a rural population zone.
[f] Stable weather conditions result in minimal dispersion and dilution of the release plume and are thus unfavorable. Stable conditions were taken to be Pasquill stability Class F with a wind speed of 1 m/sec (2.2 mph). Stable conditions occur approximately one-third of the time in the United States.

and stable conditions, respectively. The dose to the maximally exposed individual is independent of the location of the accident. No acute or early fatalities would be expected from radiological causes.

L.6.4 Waste Transportation

Under all of the alternatives being considered in the SPD EIS, some transportation would be required to support routine shipments of wastes from the proposed disposition facilities to treatment, storage, or disposal facilities located on the sites. All DOE sites have plans and procedures for handling and transporting waste. This transportation would be handled in the same manner as other site waste shipments, and would not represent a large increase in the amounts of waste already being generated at these sites and analyzed in the WM PEIS (DOE 1997a). The shipments would not represent any additional risks beyond the ordinary waste shipments at these sites, as analyzed in the WM PEIS (DOE 1997a).

However, in four specific cases, waste is being generated that is not covered in the WM PEIS (DOE 1997a): (1) transuranic (TRU) waste generated at Pantex from the pit conversion facility; (2) low-level waste (LLW) generated at Pantex from the pit conversion facility; (3) LLW generated at Pantex from the MOX facility, and (4) LLW generated at LLNL during fabrication of lead assemblies.

In the case of TRU waste generated at Pantex, this waste was not covered by the WM PEIS Record of Decision (ROD) because there was not any TRU waste at Pantex at the time the ROD was issued, and none was anticipated to be generated by ongoing site operations. Location of the pit conversion and MOX facilities at

Table L–8. Estimated Dose to the Population and to Maximally Exposed Individuals During the Most Severe Accident Conditions (Plutonium Pits)[a, b]

	Neutral Conditions [c]				Stable Conditions [f]

[a] The most severe accidents correspond to the NUREG-0170 accident severity category VIII (NRC 1977).

[b] Buoyant plume rise resulting from fire for a severe accident was included in the exposure model.

[c] Neutral weather conditions result in moderate dispersion and dilution of the release plume. Neutral conditions were taken to be Pasquill stability Class D with a wind speed of 4 m/sec (9 mph). Neutral conditions occur approximately 50 percent of the time in the United States.

[d] Populations extend at a uniform density to a radius of 80 km (50 mi) from the accident site. Population exposure pathways include acute inhalation, acute cloudshine, groundshine, resuspended inhalation, resuspended cloudshine, and ingestion of food, including initially contaminated food (RISKIND assumes that all food is frown in rural areas) (Yuan et al. 1995). It is assumed that decontamination or mitigative actions are taken.

[e] The maximally exposed individual is assumed to be at the location of maximum exposure. The locations of maximum exposure would be 100 m (330 ft) and 500 m (1650 ft) from the accident site under neutral and stable atmospheric conditions, respectively. Individual exposure pathways include acute inhalation, acute cloudshine, and groundshine during passage of the plume. No ingested dose is considered. Note that the maximally exposed individual receives more dose than the population in a rural location. This analytic phenomena is caused by probabilistic calculations. It is very unlikely that an individual will be nearby in a rural population zone.

[f] Stable weather conditions result in minimal dispersion and dilution of the release plume and are thus unfavorable. Stable conditions were taken to be Pasquill stability Class F with a wind speed of 1 m/sec (2.2 mph). Stable conditions occur approximately one-third of the time in the United States.

Pantex would result in the generation of TRU waste as described in Appendix 4.17.2.2. Shipment of TRU waste to WIPP was analyzed using the methodology and parameters found in Appendix E of the *Draft Waste Isolation Pilot Plant Disposal Phase Draft Supplemental Environmental Impact Statement* (DOE 1996c). In order to support the transportation of TRU waste from Pantex to WIPP, 76 additional shipments have been analyzed in the SPD EIS.

A fairly large increase in the amount of LLW at Pantex (i.e., 25 percent of the site's current storage capacity) would be expected if the pit conversion facility is located at Pantex. Currently, this type of waste is shipped to the Nevada Test Site (NTS) for disposal. In order to support the transportation of pit conversion facility LLW from Pantex to NTS, 21 additional shipments have been analyzed in the SPD EIS. The impacts have been calculated from LLW transportation impacts presented in the WM PEIS (DOE 1997a).

An additional increase in the amount of LLW at Pantex (i.e., 14 additional percent, for a total of 39 percent of the site's current storage capacity) would be expected if the pit conversion facility and MOX plant are located at Pantex. Currently, this type of waste is shipped to NTS for disposal. In order to support the transportation of MOX LLW from Pantex to NTS, 38 additional shipments have been analyzed in the SPD EIS. The impacts have been calculated from LLW transportation impacts presented in the WM PEIS (DOE 1997a).

Further, an increase in the LLW at LLNL would be expected if the lead assembly MOX assembly is done at LLNL. Currently, this type of waste is shipped to the NTS for disposal. In order to support transportation of

lead assembly LLW from LLNL to NTS, 44 additional shipments have been analyzed in the SPD EIS. The impacts have been calculated from LLW transportation impacts presented in the WM PEIS (DOE 1997a).

Table L–9 shows the impacts of transporting LLW and TRU waste. The radiological risks to the public are larger for TRU than for LLW because of the larger amount of radioactive material in the TRU. The dose to the crew are about the same, because the truck carrying TRU will require some shielding or spacing to ensure that the dose rate to the truck crew is less than 2 mrem/hr.

Table L–9. Impacts of Shipping Low-Level and Transuranic Waste

					Routine Transport Impacts				Accidental Risks
					Radiological		Nonradiological		Radiological
Waste Type	Origin	Destination	Trips	Kilometers Traveled	Crew	Public	Emission	Traffic	
TRU	Pantex, pit conversion facility	WIPP	76	54,000	0.0008	0.0025	0.00013	0.0015	1.1×10^{-6}
LLW	Pantex, pit conversion facility	NTS	38	76,000	0.0011	0.0015	0.00018	0.0029	5.8×10^{-7}
LLW	Pantex, MOX	NTS	21	42,000	0.0006	0.0008	0.00010	0.0016	3.2×10^{-7}
LLW	LLNL	NTS	44	50,000	0.0007	0.0010	0.00056	0.0020	3.9×10^{-7}

Key: LLNL, Lawrence Livermore National Laboratory; LLW, low-level waste; TRU, transuranic; WIPP, Waste Isolation Pilot Plant.
Note: All risks are expressed in latent cancer fatalities during the implementation of the proposed actions except for the Nonradiological Accidental Traffic column, which is a number of fatalities.

L.6.5 Consequences of Sabotage or Terrorist Attack During Transportation

This section provides an evaluation of impacts that could potentially result from a malicious act on a shipment of hazardous or radioactive material during shipment. In no instance, even in severe cases such as those discussed below, could a nuclear explosion or permanent contamination of the environment leading to condemnation of land occur. Because of the Transportation Safeguards System described in Appendix L.3.2, DOE considers sabotage or terrorist attack on an SST to be unlikely enough such that no further risk analysis is required.

The *Final Environmental Impact Statement on a Proposed Nuclear Weapons Nonproliferation Policy Concerning Foreign Research Reactor Spent Nuclear Fuel* (DOE 1996d) analyzed the spectrum of attacks on spent nuclear fuel casks. They fall into three categories or scenarios: (1) exploding a bomb near a shipping cask, (2) attacking a cask with a shaped charge, or an armor-piercing weapon (i.e., an antitank weapon), and (3) hijacking (stealing) a shipping cask. None of the scenarios considered would lead to a criticality accident. DOE determined that, due to the security measures that would be in place for any spent nuclear fuel shipments, such attacks would be unlikely to occur. At a minimum, the extent or effects of any such attacks, would be mitigated by the security measures. Additionally, the SPD EIS is considering a comparatively few shipments (if the lead assembly program is implemented) of spent nuclear fuel. Other materials, including uranium hexaflouride, uranium dioxide, TRU waste, and LLW, are commonly shipped, and do not represent particularly attractive targets for sabotage or terrorist attacks.

L.7 CUMULATIVE IMPACTS OF TRANSPORTATION

L.7.1 Radiological Impacts

The cumulative impacts of the transportation of radioactive material consist of impacts from (a) historical shipments of radioactive waste and spent nuclear, (b) reasonably foreseeable actions that include transportation of radioactive material, (c) general radioactive materials transportation that is not related to a particular action, and (d) the alternatives evaluated in the SPD EIS. The assessment of cumulative transportation impacts concentrates on the cumulative impacts of offsite transportation, because offsite transportation yields potential radiation doses to a greater portion of the general population than does onsite transportation. The collective dose to the general population and workers was the measure used to quantify cumulative transportation impacts. This measure of impact was chosen because it may be directly related to LCFs using a cancer risk coefficient, and because of the difficulty in identifying a maximally exposed individual for shipments throughout the United States spanning the period 1943 through 2048 (106 years). The year 1943 corresponds to the start of operations at the Hanford Site and the Oak Ridge Reservation.

Collective doses from historical shipments of spent nuclear fuel to NTS were summarized in (Jones and Maheras 1994). Data for these shipments were available for 1971 through 1993 and were linearly extrapolated back to 1951, the start of operations at NTS, because data before 1971 were not available. The results of this analysis are summarized in Table L–10. Collective doses from historical shipments of low-level waste, mixed low-level waste, and transuranic waste were also estimated (DOE 1996e). Over the time period 1974 through 1994, there were about 8,400 of these shipments; these shipments were estimated to result in a collective occupational dose of 82 person-rem and a collective dose for the general population of 100 person-rem.

Collective doses from other historical shipments of radioactive material were evaluated in the *Programmatic Spent Nuclear Fuel Management and Idaho National Engineering Laboratory Environmental Restoration and Waste Management Programs Final Environmental Impact Statement* (DOE 1995a). These include historical shipments associated with the INEEL, SRS, Hanford, Oak Ridge, and Naval spent nuclear fuel and test specimens.

There are considerable uncertainties in these historical estimates of collective dose. For example, the population densities and transportation routes used in the dose assessments were based on census data for 1990 and the U.S. highway and rail system as it existed in the 1990s. Using census data for 1990 tends to overestimate historical collective doses because the U.S. population has continuously increased over the time covered in these assessments. Basing collective dose estimates on the U.S. highway and rail system as it existed in the 1990s may slightly underestimate doses for shipments that occurred in the 1940s, 1950s, and 1960s, because a larger portion of the transport routes would have been on non-interstate highways where the population may have been closer to the road. Data were not available that correlated transportation routes and population densities for the 1940s, 1950s, 1960s, and 1970s; therefore, it was necessary to use more recent data to make dose estimates. By the 1970s, the structure of the interstate highway system was largely fixed and most shipments would have been made on interstates.

Shipment data were linearly extrapolated for years when data were unavailable, which also results in uncertainty. However, this technique was validated by linearly extrapolating the data in the *Historical Overview of Domestic Spent Fuel Shipments–Update* (SAIC 1991) for 1973 through 1989 to estimate the number of shipments that took place during the time period 1964 through 1972 (also contained in SAIC 1991). The data in the historical overview could not be used directly because only shipment counts are presented for 1964 through 1982, and no origins or destinations were listed for years before 1983. Based on the data in the historical overview, linearly extrapolating the data for 1973 through 1989 overestimates the shipments for 1964 through 1972 by 20 percent when compared to the actual shipment counts for 1964 through 1972.

Transportation impacts may also result from reasonably foreseeable projects, such as the transportation impacts contained in other DOE National Environmental Policy Act analyses. The results of these analyses are summarized in Table L–10. For some of these analyses, a preferred alternative was not identified or a ROD has not been issued. In those cases, the alternative that was estimated to result in the largest transportation impact was included in Table L–10.

There are also reasonably foreseeable projects that involve limited transportation of radioactive material: (a) shipment of submarine reactor compartments from the Puget Sound Naval Shipyard to Hanford for burial, (b) return of cesium 137 isotope capsules to Hanford, (c) shipment of uranium billets from Hanford to the United Kingdom, and (d) shipment of low specific activity nitric acid from Hanford to the United Kingdom. While this is not an exhaustive list of projects that may involve limited transportation of radioactive material, it does illustrate that the transportation impacts associated with these types of projects are extremely low when compared to major projects or general transportation.

There are also general transportation activities that take place that are unrelated to the alternatives evaluated in the SPD EIS or to reasonably foreseeable actions. Examples of these activities are shipments of radiopharmaceuticals to nuclear medicine laboratories and shipments of commercial low-level radioactive waste to commercial disposal facilities. The NRC evaluated these types of shipments based on a survey of radioactive materials transportation published in 1977 (NRC 1977). Categories of radioactive material evaluated in NRC 1977 included: (a) limited quantity shipments, (b) medical, (c) industrial, (d) fuel cycle, and (e) waste.

The NRC estimated that the annual collective worker dose for these shipments was 5,600 person-rem. The annual collective general population dose for these shipments was estimated to be 4,200 person-rem. Because comprehensive transportation doses were not available, these collective dose estimates were used to estimate transportation collective doses for 1943 through 1982 (40 years). These dose estimates included spent nuclear fuel and radioactive waste shipments made by truck and rail.

Based on the transportation dose assessments in NRC 1977, the cumulative transportation collective doses for 1943 through 1982 were estimated to be 220,000 person-rem for workers and 170,000 person-rem for the general population.

In 1983, another survey of radioactive materials transportation in the United States was conducted (Javitz et al. 1985). This survey included NRC and Agreement State licensees. Both spent nuclear fuel and radioactive waste shipments were included in the survey. Weiner, LaPlante, and Hageman (1991a:661–666, 1991b:665–660) used the survey by Javitz et al. (1985) to estimate collective doses from general transportation. The transportation dose assessments in Weiner, LaPlante, and Hageman: (1991a:661–666, 1991b:665–660) were used to estimate transportation doses for 1983 through 2048 (66 years). Weiner, LaPlante, and Hageman (1991a:661–666) evaluated eight categories of radioactive material shipments by truck: (a) industrial, (b) radiography, (c) medical, (d) fuel cycle, (e) research and development, (f) unknown, (g) waste, and (h) other. Based on a median external exposure rate, an annual collective worker dose of 1,400 person-rem and an annual collective general population dose of 1,400 person-rem were estimated. Over the 66-year time period from 1983 through 2048, both the collective worker and general population doses were estimated to be 92,000 person-rem.

Weiner, LaPlante, and Hageman (1991b:655–660) also evaluated six categories of radioactive material shipments by plane: (a) industrial, (b) radiography, (c) medical, (d) research and development, (e) unknown, and (f) waste. Based on a median external exposure rate, an annual collective worker dose of 290 person-rem and an annual collective general population dose of 450 person-rem were estimated. Over the 66-year time

Table L–10. Cumulative Transportation-Related Radiological Collective Doses and Latent Cancer Fatalities (1943 to 2048) (person-rem)

Category	Collective Dose	
	Occupational Dose	General Population Dose
Historical shipments (DOE 1995a)	**250**	**130**
Radioactive waste to Nevada Test Site (DOE 1996e)	82	100
Reasonably foreseeable actions		
Nevada Test Site expanded use (DOE 1996e)	–	150[b]
Spent nuclear fuel management (DOE 1995a, 1996d)	360	810
Waste Management PEIS (DOE 1997a)[a]	16,000	20,000
Waste Isolation Pilot Plant	790	5,900
Mo-99 production (DOE 1996f)	240	520
Tritium supply and recycling (DOE 1995b)	–	–
Surplus highly enriched uranium disposition (DOE 1996g)	400	520
Storage and Disposition of Fissile Materials (DOE 1996a)	–	2,400[b]
Stockpile Stewardship (DOE 1996h)	–	38[b]
Pantex (DOE 1996i)	250[c]	490[c]
West Valley (DOE 1996j)	1,400	12,000
S3G and D1G prototype reactor plant disposal (DOE 1997b)	2.9–6.8	2.2–5.4
S1C prototype reactor plant disposal (DOE 1996k)	6.7	1.9
Container system for naval spent nuclear fuel (USN 1996a)	11	15
Cruiser and submarine reactor plant disposal (USN 1996b)	5.8	5.8
Submarine reactor compartment disposal (USN 1984)	–	0.053
Return of cesium 137 capsules (DOE 1994)	0.42	5.7
Uranium billets (DOE 1992)	0.50	0.014
Nitric acid (DOE 1995c)	0.43	3.1
General transportation		
1943 to 1982 (NRC 1977)	220,000	170,000
1983 to 2048 (Weiner, LaPlante, and Hageman 1991a:661–666; 1991b:655–660)	110,000	120,000
Shipments for alternatives evaluated in the SPD EIS	10	50
Summary		
Historical	330	230
Reasonably foreseeable actions	19,000	43,000
General transportation (1943 to 2048)	330,000	290,000
Shipments for alternatives evaluated in the SPD EIS	10	50
Total collective dose (rounded to nearest thousand)	349,000	333,000
Total latent cancer fatalities	140	170

[a] Includes mixed low-level waste and low-level waste; transuranic waste included in DOE 1997a.
[b] Includes public and occupational collective doses.
[c] Includes all highly enriched uranium shipped to Y–12.

period from 1983 through 2048, the collective worker dose was estimated to be 19,000 person-rem and the general population collective dose was estimated to be 30,000 person-rem.

Like the historical transportation dose assessments, the estimates of collective doses because of general transportation also exhibit considerable uncertainty. For example, data for 1975 were applied to general transportation activities from 1943 through 1982. This approach probably overestimates doses because the amount of radioactive material that was transported in the 1950s and 1960s was less than the amount shipped in the 1970s. For example, in 1968, the shipping rate for radioactive material packages was estimated to be 300,000 packages per year (Patterson 1968:199–209); in 1975 this rate was estimated to be 2,000,000 packages per year (NRC 1977). However, because comprehensive data that would enable a more realistic transportation dose assessment are not available, the dose estimates developed by NRC were used.

Total collective worker doses from all types of shipments (historical, reasonably foreseeable actions, and general transportation) were estimated to be approximately 350,000 person-rem (140 LCFs), for the period of time 1943 through 2048 (106 years). Total general population collective doses were also estimated to be 330,000 person-rem (170 LCFs). The majority of the collective dose for workers and the general population was because of general transportation of radioactive material. The total number of LCFs over the time period 1943 through 2048 was estimated to be 310. Over this same period of time (106 years), about 54,060,000 people would die from cancer, based on 510,000 LCFs per year (*DOC* 1993). It should be noted that the estimated number of transportation-related LCFs would be indistinguishable from other LCFs, and the transportation-related LCFs would be 0.0000057 percent of the total number of expected LCFs during this timeframe.

L.7.2 Accident Impacts

For transportation accidents involving radioactive material, the dominant risk is from accidents that are unrelated to the cargo (i.e., traffic or vehicular accidents). Fatalities involving the shipment of radioactive materials were surveyed for 1971 through 1993 using the Radioactive Material Incident Report database. For 1971 through 1993, 21 vehicular accidents involving 36 fatalities occurred. These fatalities resulted from vehicular accidents and were not associated with the radioactive nature of the cargo; no radiological fatalities because of transportation accidents have ever occurred in the United States. During the same period of time, over 1,100,000 persons were killed in vehicular accidents in the United States (National Safety Council 1994). About 100 additional vehicular accident fatalities were estimated to result from the transportation of radioactive material (i.e., the transportation associated with reasonably foreseeable actions and general radioactive materials transportation). During the 39-year time period from 2010 through 2048, approximately 1,600,000 people would be expected to be killed in vehicular accidents in the United States. The vehicular accident fatalities associated with radioactive materials transportation would be expected to be 0.006 percent of the total number of vehicular accident fatalities

L.8 UNCERTAINTY AND CONSERVATISM IN ESTIMATED IMPACTS

The sequence of analyses performed to generate the estimates of radiological risk for the transportation includes: (1) determination of the inventory and characteristics, (2) estimation of shipment requirements, (3) determination of route characteristics, (4) calculation of radiation doses to exposed individuals (including estimation of environmental transport and uptake of radionuclides), and (5) estimation of health effects. Uncertainties are associated with each of these steps. Uncertainties exist in the way that the physical systems being analyzed are represented by the computational models, in the data required to exercise the models (due to measurement errors, sampling errors, natural variability, or unknowns simply caused by the future nature of the actions being analyzed), and in the calculations themselves (e.g., approximate algorithms used by the computers).

In principle, one can estimate the uncertainty associated with each input or computational source and predict the resultant uncertainty in each set of calculations. Thus, one can propagate the uncertainties from one set of calculations to the next and estimate the uncertainty in the final, or absolute, result; however, conducting such a full-scale quantitative uncertainty analysis is often impractical and sometimes impossible, especially for actions to be initiated at an unspecified time in the future. Instead, the risk analysis is designed to ensure, through uniform and judicious selection of scenarios, models, and input parameters, that relative comparisons of risk among the various alternatives are meaningful. In the transportation risk assessment, this design is accomplished by uniformly applying common input parameters and assumptions to each alternative. Therefore, although considerable uncertainty is inherent in the absolute magnitude of the transportation risk for each alternative, much less uncertainty is associated with the relative differences among the alternatives in a given measure of risk.

In the following sections, areas of uncertainty are discussed for the assessment steps enumerated above. Special emphasis is placed on identifying whether the uncertainties affect relative or absolute measures of risk. The degree of conservatism of the assumption is addressed. Where practical, the parameters that most significantly affect the risk assessment results are identified.

L.8.1 Uncertainties in Material Inventory and Characterization

The inventories and the physical and radiological characteristics are important input parameters to the transportation risk assessment. The potential amount of transportation for any alternative is determined primarily by the projected nuclear material inventory and assumptions concerning shipment capacities. The physical and radiological characteristics are important in determining the amount of material released during accidents and the subsequent doses to exposed individuals through multiple environmental exposure pathways.

Uncertainties in the inventory and characterization will be reflected to some degree in the transportation risk results. If the inventory is overestimated (or underestimated), the resulting transportation risk estimates also will be overestimated (or underestimated) by roughly the same factor. However, the same inventory estimates are used to analyze the transportation impacts of each of the SPD EIS alternatives. Therefore, for comparative purposes, the observed differences in transportation risks among alternatives are believed to represent unbiased, reasonably accurate estimates from current information in terms of relative risk comparisons.

No detailed characterization of surplus nonpit plutonium was included in the evaluation of each shipment of this material. Such information typically would not be compiled until actual shipments were being planned. Only global, conservative assumptions were used in the impact analysis. DOE assumed a maximum of 4.5 kg (9.9 lb) of plutonium per package, and 40 packages per SST. This leads to a conservative estimate of radiological accident risks for shipment of surplus nonpit plutonium for each alternative. However, since such shipments have been shown to have lower radiological accident risks than shipments of either plutonium oxides from pits or lead assembly spent fuel, the overall effect would be very small.

L.8.2 Uncertainties in Containers, Shipment Capacities, and Number of Shipments

The amount of transportation required for each alternative is based, in part, on assumptions concerning the packaging characteristics and shipment capacities for commercial trucks and safe secure transports. Changes in loading, tiedown, or packaging practices could affect estimates. Representative shipment capacities have been defined for assessment purposes based on probable future shipment capacities. In reality, the actual shipment capacities may differ from the predicted capacities, so that the projected number of shipments, and

consequently the total transportation risk, would change. However, although the predicted transportation risks would increase or decrease accordingly, the relative differences in risks among alternatives would remain about the same. The maximum amount of material allowed in Type B containers is set by conservative safety analyses.

L.8.3 Uncertainties in Route Determination

Representative routes have been determined between all origin and destination sites considered in the SPD EIS. The routes have been determined consistent with current guidelines, regulations, and practices, but may not be the actual routes that would be used in the future. In reality, the actual routes could differ from the representative ones in terms of distances and total population along the routes. Moreover, since radioactive materials could be transported over an extended period of time starting at some time in the future, the highway infrastructures and the demographics along routes could change. These effects have not been accounted for in the transportation assessment; however, it is not anticipated that these changes would significantly affect relative comparisons of risk among the alternatives considered in the SPD EIS. Specific routes cannot be identified in advance for the Transportation Safeguards Division shipments because the routes are classified to protect national security interests.

L.8.4 Uncertainties in the Calculation of Radiation Doses

The models used to calculate radiation doses from transportation activities introduce a further uncertainty in the risk assessment process. It is generally difficult to estimate the accuracy or absolute uncertainty of the risk assessment results. The accuracy of the calculated results is closely related to the limitations of the computational models and to the uncertainties in each of the input parameters that the model requires. The single greatest limitation facing users of RADTRAN, or any computer code of this type, is the scarcity of data for certain input parameters.

Uncertainties associated with the computational models are minimized by using state-of-the-art computer codes that have undergone extensive review. Because there are numerous uncertainties that are recognized but difficult to quantify, assumptions are made at each step of the risk assessment process that are intended to produce conservative results (i.e., overestimate the calculated dose and radiological risk). Because parameters and assumptions are applied to all alternatives, this model bias is not expected to affect the meaningfulness of relative comparisons of risk; however, the results may not represent risks in an absolute sense.

The single largest contributor to the collective population doses calculated with RADTRAN was found to be the dose to members of the public at truck stops. Currently, RADTRAN uses a simple point-source approximation for truck-stop exposures and assumes that the total stop time for a shipment is proportional to the shipment distance. The parameters used in the stop model were based on a survey of a very limited number of radioactive material shipments that examined a variety of shipment types in different areas of the country. It was assumed that stops occur as a function of distance, with a stop rate of 0.011 hr/km (0.018 hr/mi). For non-SST shipments, was further assumed that an average of 50 people at each stop are exposed at a distance of 20 m (66 ft). In RADTRAN, the population dose is directly proportional to the external shipment dose rate and the number of people exposed, and inversely proportional to the square of the distance. For this assessment, it was assumed that many shipments (nonpit plutonium and spent nuclear fuel) would have external dose rates at the regulatory limit of 10 mrem/hr at 2 m (6.6 ft). In practice, the external dose rates would vary from shipment to shipment. The stop rate assumed results in an hour of stop time per 100 km (62 mi) of travel.

Based upon the qualitative discussion with shippers, the parameter values used in the assessment appear to be conservative. However, data do not exist to quantitatively assess the degree of control, the location, frequency,

and duration of truck stops. However, based on the regulatory requirements of 10 CFR 73 for continuous escort of the material and the requirement for two drivers, it is clear that the trucks would be on the move much of the time until arrival at the destination. Therefore, the calculated impacts are extremely conservative. By using these conservative parameters, the calculations in the SPD EIS are consistent with the RADTRAN published values.

Shielding of exposed populations is not considered. For all incident-free exposure scenarios, no credit has been taken for shielding of exposed individuals. In reality, shielding would be afforded by trucks and cars sharing the transport routes, rural topography, and the houses and buildings in which people reside. Incident-free exposure to external radiation could be reduced significantly depending on the type of shielding present. For residential houses, shielding factors (i.e., the ratio of shielded to unshielded exposure rates) have been estimated to range from 0.02 to 0.7, with a recommended value of 0.33. If shielding were to be considered for the maximally exposed resident living near a transport route, the calculated doses and risks would be reduced by approximately 70 percent. Similar levels of shielding may be provided to individuals exposed in vehicles.

Postaccident mitigative actions are not considered for dispersal accidents. For severe accidents involving the release and dispersal of radioactive materials in the environment, no postaccident mitigative actions, such as interdiction of crops or evacuation of the accident vicinity, have been considered in this risk assessment. Postaccident mitigative measures to reduce groundshine doses (evacuation and/or decontamination) are assumed to occur 24 hours after the accident in RADTRAN analyses. Additionally, RADTRAN assumes that highly contaminated crops are not ingested (Neuhauser 1994). Since RISKIND is modeling the worst credible accident, these measures are not considered. In reality, mitigative actions would take place following an accident in accordance with U.S. Environmental Protection Agency (EPA) radiation protection guides for nuclear incidents (EPA 1991). The effects of mitigative actions on population accident doses are highly dependent upon the severity, location, and timing of the accident. For this risk assessment, ingestion doses are only calculated for accidents occurring in rural areas (the calculated ingestion doses, however, assumes all food grown on contaminated ground is consumed and is not limited to the rural population). Interdiction of foodstuffs would act to reduce, but not eliminate, this contribution.

Appendix M
Analysis of Environmental Justice

M.1 INTRODUCTION

Executive Order 12898, *Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations*, directs Federal agencies to identify and address, as appropriate, disproportionately high and adverse health or environmental effects of their programs, policies, and activities on minority and low-income populations.

The Council on Environmental Quality has oversight responsibility for documentation prepared in compliance with the National Environmental Policy Act (NEPA). In December 1997, the Council released guidance on environmental justice (CEQ 1997). The Council's guidance was adopted as the basis for the analysis of environmental justice contained in the *Surplus Plutonium Disposition Environmental Impact Statement* (EIS).

M.2 DEFINITIONS AND APPROACH

The following definitions were used in the analysis of environmental justice (CEQ 1997):

- Low-income population: Low-income populations in an affected area should be identified with the annual statistical poverty thresholds from the U.S. Bureau of the Census' Current Population Reports, Series P-60 on Income and Poverty. In identifying low-income populations, agencies may consider as a community either a group of individuals living in geographic proximity to one another, or set of individuals (such as migrant workers or Native Americans), where either type of group experiences common conditions of environmental exposure or effect.

- Minority: Individual(s) who are members of the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic.

- Minority population: Minority populations should be identified where either: (a) the minority population of the affected area exceeds 50 percent or (b) the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis. In identifying minority communities, agencies may consider as a community either a group of individuals living in geographic proximity to one another, or a geographically dispersed/transient set of individuals (such as migrant workers or American Indians), where either type of group experiences common conditions of environmental exposure or effect. The selection of the appropriate unit of geographic analysis may be a governing body's jurisdiction, a neighborhood, census tract, or other similar unit that is to be chosen so as to not artificially dilute or inflate the affected minority population. A minority population also exists if there is more than one minority group present and the minority percentage, as calculated by aggregating all minority persons, meets one of the above-stated thresholds.

- Disproportionately high and adverse human health effects: When determining whether human health effects are disproportionately high and adverse, agencies are to consider the following three factors to the extent practical:

    a. Whether the health effects, which may be measured in risks and rate, are significant (as employed by NEPA), or above generally accepted norms. Adverse health effects may include bodily impairment, infirmity, illness, or death; and

b. Whether the risk or rate of hazard exposure by a minority population or low-income population to an environmental hazard is significant (as employed by NEPA) and appreciably exceeds or is likely to appreciably exceed the risk or rate to the general population or other appropriate comparison group; and

c. Whether health effects occur in a minority or low-income population affected by cumulative or multiple adverse exposures from environmental hazards.

- Disproportionately high and adverse environmental effects: When determining whether environmental effects are disproportionately high and adverse, agencies are to consider the following three factors to the extent practical:

  a. Whether there is or will an impact on the natural or physical environment that significantly (as employed by NEPA) and adversely affects a minority or low-income population. Such effects may include ecological, cultural, human health, economic, or social impacts on minority communities or low-income communities, when those impacts are interrelated to impacts on the natural or physical environment; and

  b. Whether environmental effects are significant (as employed by NEPA) and are or may be having an adverse impact on minority populations or low-income populations that appreciably exceeds or is likely to appreciably exceed those on the general population or other appropriate comparison group; and

  c. Whether the environmental effects occur or would occur in a minority population or low-income population affected by cumulative or multiple adverse exposures from environmental hazards.

Data for the analysis of minorities were extracted from Table P12 of Summary Tape File 3A published on CD ROM by the United States Bureau of the Census (DOC 1992). Data for the analysis of low-income populations were extracted from Table P121 of Standard Tape File 3A.

Potentially affected areas examined in the SPD EIS include the areas surrounding proposed facilities for plutonium disposition located at four candidate sites: the Hanford Site (Hanford), Idaho National Engineering and Environmental Laboratory (INEEL), the Pantex Plant (Pantex), and the Savannah River Site (SRS). Minority and low-income populations residing within a 1.6-km (1-mi) corridor centered on representative transportation routes were also included in the evaluation of environmental justice.

M.3 SPATIAL RESOLUTION

For the purposes of enumeration and analysis, the Census Bureau has defined a variety of areal units (DOC 1992). Areal units of concern in this document include (in order of increasing spatial resolution): States, counties, census tracts, block groups, and blocks. The "block" is generally the smallest of these entities and offers the finest spatial resolution. This term refers to a relatively small geographical area bounded on all sides by visible features such as streets and streams, or by invisible boundaries such as city limits or property lines. During the 1990 census, the Census Bureau subdivided the United States and its territories into 7,017,425 blocks. For comparison, the number of counties, census tracts, and block groups used in the 1990 census were 3,248; 62,276; and 229,192; respectively. While blocks offer the finest spatial resolution, economic data required for identification of low-income populations are not available at the block-level of spatial resolution. In the analysis below, block groups are used throughout as the areal unit. Block groups generally contain between 250 and 500 housing units (DOC 1992:A-4).

During the decennial census, the Census Bureau collects data from individuals and then aggregates the data according to residence in geographical areas such as a counties or block groups. Boundaries of the areal units are selected to coincide with geographical features, such as streams and roads, or political boundaries, such as county and city borders. Boundaries used for aggregation of the census data usually do not coincide with boundaries used in the calculation of health effects. As discussed in Chapter 4 of the SPD EIS, radiological health effects due to an accident at one of the facilities for plutonium disposition are evaluated for persons residing within a distance of 80 km (50 mi) of the accident site. In general, the boundary of the circle with an 80-km (50-mi) radius centered at the accident site will not coincide with boundaries used by the Census Bureau for enumeration of the population in the potentially affected area. Some block groups lie completely inside or outside of the area included in the calculation of health effects. However, block groups intersecting the boundary of the potentially affected area are only partly included. Partial inclusion of block groups is illustrated in Figure M–1. This figure shows the block group structure near Idaho Falls, Idaho. The 80-km (50-mi) radius shown in this figure denotes the boundary used for calculation of health effects in the event of a radiological release at the Fuel and Materials Examination Facility (FMEF) at INEEL. Block groups that are unshaded in Figure M–1 lie within an 80-km (50-mi) radius centered at FMEF, and the total population of these block groups is included in the population count. Block groups shaded in gray lie outside of the circle, and the population of the shaded block groups is excluded from the population count. However, block groups such as those that are cross-hatched in Figure M–1 lie only partly within the circle. Because the geographical distribution of persons residing within a block group is not available from the census data, partial inclusions introduce uncertainties into the estimate of the population at risk.

In order to evaluate populations at risk in partially included block groups, it was assumed that residents are uniformly distributed throughout the area of each block group. For example, if 85 percent of the area of a block group lies within 80 km (50 mi) of the accident site, then it was assumed that 85 percent of the population residing in that block group would be at risk. An upper bound for the population at risk was obtained by including the total population of partially included block groups in the population at risk. Similarly, a lower bound for the population at risk was obtained by excluding the population of partially included blocks from the population at risk. As a general rule, if the areas of geographic units defined by the Census Bureau are small in comparison with the potentially affected area, then the uncertainties due to partial inclusions will be relatively small. Uncertainties in the estimates of populations surrounding facilities for plutonium disposition are described in Appendix M.5.1 below.

M.4 POPULATION PROJECTIONS

In Chapter 4 and Appendixes J, K, and L of the SPD EIS, health effects were calculated for populations projected to reside in potentially affected areas during the year 2010. Extrapolations of the total population for individual States are available from both the Census Bureau and various State agencies (Campbell 1996). The Census Bureau also projects populations by ethnic and racial classification in 1-year intervals for the years from 1995 to 2025. Data used to project minority populations in the SPD EIS were extracted from the Census Bureau's web site (www.census.gov/population/www/projections/stproj.html). Minority populations determined from the 1990 census data were taken as a baseline. Then it was assumed that percentage changes in the minority and majority populations of each block group for a given year (compared with the 1990 baseline data) will be the same as percentage changes in the State minority and majority populations projected for the same year. An advantage to this assumption is that the projected populations are obtained with consistent methodology regardless of the State and associated block group involved in the calculation. A disadvantage is that the methodology is insensitive to localized demographic changes that could alter the projection for a specific area.

The Census Bureau uses the cohort-component method to estimate future populations for each State (Campbell 1996). The set of cohorts is composed of: (1) age groups from 1 year or less to 85 years or more (in 1-year intervals), (2) male and female populations in each age group, and (3) the following racial and ethnic groups in each age group—Hispanic, non-Hispanic Asian, non-Hispanic Black, non-Hispanic Native American, and non-Hispanic White. Components of the population change used in the demographic accounting system are births, deaths, net State-to-State migration, and net international migration. If P(t) denotes the number of individuals in a given cohort at time "t", then:

$$P(t) = P(t_0) + B - D + DIM - DOM + IIM - IOM$$

where:

$P(t_0)$ = Cohort population at time $t_0 \leq t$, where t_0 denotes the year 1990.
B = Births expected during the period from t_0 to t.
D = Deaths expected during the period from t_0 to t.
DIM = Domestic migration expected into the State during the period from t_0 to t.
DOM = Domestic migration expected out of the State during the period from t_0 to t.
IIM = International migration expected into the State during the period from t_0 to t.
IOM = International migration expected out of the State during the period from t_0 to t.

Estimated values for the components shown on the right side of the equation are based on past data and various assumptions regarding changes in the rates for birth, mortality, and migration (Campbell 1996). The Census Bureau does not project populations of individuals who identified themselves as "Other Race" during the 1990 census. This population group is less than 2 percent of the total population in each of the States. In order to project total populations in the environmental justice analysis, population projections for the "Other Race" group were made under the assumption that the growth rate for the "Other Race" population will be identical to the growth rate for the combined minority and White (non-Hispanic) populations.

M.5 RESULTS FOR THE SITES

M.5.1 Population Estimates

Table M–1 shows total populations, minority populations, and percentage minority populations that resided within 80 km (50 mi) of the various sites at the time of the 1990 census. The 80-km (50-mi) distance defines

the radius of potential radiological effects for calculations of radiation dose to the general population (see Chapter 4 of the SPD EIS). Tables M–2 and M–3 show similar data for projected populations in 1997 and 2010. As discussed above, minority populations residing in potentially affected areas in 1990 were adopted as a baseline. Populations in 1997 and 2010 were then projected from the baseline data under the assumption that percentage changes in the majority and minority populations residing in the affected areas will be identical to those projected for State populations. The Census Bureau estimates that the national minority percentage will increase from approximately 24 percent in 1990 to 27 percent in 1997, and nearly 33 percent by 2010 (Campbell 1996). Percentage minority populations residing within 80 km (50 mi) of facilities at Hanford and SRS are projected to exceed the national percentage by year 2010. Percentage minority populations surrounding facilities at INEEL and Pantex were less than the national minority percentage in 1990 and are projected to remain so through the year 2010. In Tables M–1 through M–3, the sum of percentages shown in even-numbered columns beginning in column 6 may total slightly more or less than 100 percent due to roundoff.

Table M–4 illustrates the uncertainties in the population estimates for the year 2010 due to the partial inclusion of block groups within the boundaries of potentially affected areas. Column 2 of the table lists the number of block groups that are partly within the circle of 80-km (50-mi) radius centered at the various facilities. Column 3 shows the number of block groups that lie completely within the circle. Potentially affected areas surrounding Hanford and SRS include two States. Columns 2 and 3 show the number of partial or total inclusions for the affected States. Column 4 of the table, denoted as "T/P," shows the number of totally included block groups divided by the number of partially included block groups. In order to minimize the uncertainties in the population estimate, it is desirable that this ratio be as large as possible. Column 5 shows upper bounds for the estimates of the total population listed in column 6. As discussed above, upper bounds were obtained by including the total population of all block groups that lie at least partially within the affected area. Lower bounds for the estimate of total population shown in column 7 were obtained by including only the populations of totally included block groups. Analogous statements apply to columns 8 through 10.

As would be expected from the value of T/P shown in column 4, uncertainties in the total population estimate for Pantex were the smallest among the four sites (+2.4 percent and -2.7 percent), as were the uncertainties in the estimate of the minority population at risk near Pantex (+1.9 percent and -1.9 percent). Uncertainties in the population estimates for INEEL were the largest among the four sites (+17.2 percent and -15.2 percent for total population; +17.3 percent and -15.0 percent for minority population). None of the uncertainties shown in Table M–4 are large enough to noticeably affect the conclusions regarding radiological health effects or environmental justice.

M.5.2 Geographical Dispersion of Minority and Low-Income Populations

Figures M–2 through M–9 show the geographical distributions of minority and low-income populations at risk in the vicinity of the various candidate sites. Distributions shown in these figures are based on baseline population data for 1990. Even-numbered figures show the geographical distribution of minority populations in potentially affected areas within a distance of 80 km (50 mi) of candidate facilities. Block groups are shaded to indicate the percentage of the total population comprised of minorities. According to the decennial census of 1990, minorities comprised 24.2 percent of the total population of the contiguous United States. Block groups unshaded in the even-numbered figures are those for which the percentage of minority residents is less than the national percentage minority population. Areas shaded in gray show block groups for which the percentage of minority residents exceeds the national minority percentage by less than a factor of two. Diagonally hatched block groups shown in the even-numbered figures are those for which the percentage of minority residents exceeds the national minority percentage by a factor of two or more.

Table M–1. Racial and Ethnic Composition of Minority Populations Residing Within 80 km of Candidate Sites in 1990

Candidate Site	Total Pop.	Minority Pop.	Percent Minority Pop.	Asian or Pacific Islander Pop.	Percent Asian or Pacific Islander Pop.	Black Pop.	Percent Black Pop	Hispanic Pop.	Percent Hispanic Pop. Odd-numbered figures show the geographical distribution of low-income populations potentially at risk from implementation of the proposed action or alternatives. According to the decennial census of 1990, 13.4 percent of the population of the contiguous United States reported incomes less than the poverty threshold. Block groups unshaded in Figures M–1, M–5, M–7, and M–9 are those for which the percentage of low-income residents is less than the national percentage of persons reporting an income less than the poverty threshold. Areas shaded in gray show block groups for which the percentage of low-income residents exceeds the national low-income percentage by less than a factor of two. Diagonally hatched block groups shown in the odd-numbered figures are those for which the percentage of low-income residents exceeds the national low-income percentage by a factor of two or more.

M.5.3 Environmental Effects on Minority and Low-Income Populations Residing Near Candidate Sites

The analysis of environmental effects on populations residing within 80 km (50 mi) of proposed facilities is presented in Chapter 4 of the SPD EIS. This analysis shows that no radiological fatalities are likely to result from implementation of the proposed action or alternatives. Radiological risks to the public are small regardless of the racial and ethnic composition of the population, and regardless of the economic status of individuals comprising the population. Nonradiological risks to the general population are also small regardless of the racial and ethnic composition or economic status of the population. Thus, disproportionately high and adverse impacts on minority and low-income populations residing near the various facilities are not likely to result from implementation of the proposed action or alternatives.

M.6 RESULTS FOR TRANSPORTATION ROUTES

Table M–5 shows minority populations residing along 1.6-km (1-mi) corridors centered on routes that are representative of those that could be used for the transportation of nuclear materials under the proposed action or alternatives. Table M–6 shows similar data for low-income populations. Population data for Tables M–5 and M–6 were extracted from Tables P–12 and P–121 of the STF–3A files (DOC 1992). Distances from a given origin to a given destination are similar but not identical to corresponding distances shown in Appendix L. This is because distances listed in Appendix L were calculated with the HIGHWAY computer code, while distances shown in Tables M–5 and M–6 were obtained from a Geographical Information System analysis using TigerLine data and STF3A files prepared by the Census Bureau. Both techniques use block group spatial resolution, and the differences are generally less than 5 percent.

Total and minority populations residing in the highway corridors are listed in Columns 4 and 5, respectively, of Table M–5. Column 6 shows minority populations residing within highway corridors as a percentage of the total population. Although total and minority populations residing within the corridors generally tend to increase with increasing distance, the relationship is clearly route-dependent.

As discussed in Appendix L of the SPD EIS, implementation of the proposed action or alternatives would not result in significant radiological or nonradiological risks to populations residing along highway transportation routes. Although the percentage minority or low-income populations residing along highway routes can vary by as much as a factor of four, results of the analysis presented in Chapter 4 are independent of the racial and ethnic composition of populations within the corridors, as well as the economic status of populations at risk within the corridors. Implementation of the proposed action or alternatives is not likely to result in disproportionately high and adverse effects on minority or low-income populations residing within representative transportation corridors.

Appendix N
Plutonium Polishing

N.1 PLUTONIUM-POLISHING PROCESS

This appendix describes a polishing process by which impurities, in particular gallium, could be removed from the plutonium feed for mixed oxide (MOX) fuel fabrication. DOE has not proposed implementing this polishing process; it is considered only a contingency at this time subject to inclusion only if scheduled research and development activities demonstrate that the plutonium dioxide powder produced in the pit conversion process would not consistently be able to meet specifications for MOX fuel. If additional purification were needed, either solvent extraction or ion exchange would be the technology selected, and this capability would be incorporated into either the pit conversion or MOX facility. Therefore, both purification methods; and the additional support steps of plutonium dissolution and conversion back to an oxide powder, which would be the same regardless of whether solvent extraction or ion exchange would be used for purification, are evaluated in this appendix. If implemented, the plutonium-polishing module would be an integrated step in either the pit conversion or MOX facility, and all of the plutonium dioxide would be processed through the module.

N.2 PLUTONIUM-POLISHING MODULE SPACE REQUIREMENTS

The plutonium-polishing module would require about 1,950 m^2 (21,000 ft^2) on two levels. This processing area would be built in a hardened space of thick-walled concrete that would meet the standards for processing special nuclear materials. Because the plutonium-polishing module would be adjacent to or integrated in either the pit conversion or the MOX facility, major utility additions would not be required. However, an additional space of about 500 m^2 (5,400 ft^2) would be required for utilities; heating, ventilation, and air conditioning systems; and the control room and an analytical laboratory. About 315 m^2 (3,400 ft^2) of nonhardened space would be needed for offices, change rooms, and support facilities to accommodate the additional staff.

Process activities would be performed in gloveboxes, with inert atmospheres where required. All powder handling would be performed in enclosed equipment to contain the oxide dust. Batch loading between equipment would be done through powder valves, thereby isolating the equipment from the atmosphere of the process containment glovebox.

N.3 PROCESS DESCRIPTION

Figure N–1 is a flow diagram for the plutonium-polishing process. This process would include three elements: dissolution of the plutonium in nitric acid; removal of impurities by means of chemical separation (solvent extraction or ion exchange); and conversion of the plutonium back to an oxide powder by precipitation. The plutonium-polishing module would also include acid recovery steps by which nearly all the nitric acid would be recovered and reused in the process.

N.3.1 Dissolution

To begin the process, plutonium dioxide feedstock would be placed inside a feed preparation glovebox, weighed, and transferred in small quantities to one of the dissolver glovebox lines, where it would be dissolved in near-boiling, concentrated nitric acid with a hydrofluoric acid catalyst. After the plutonium dioxide was dissolved, the solution would be cooled, chemically treated and filtered, then transferred to the impurity removal step, either solvent extraction or ion exchange.

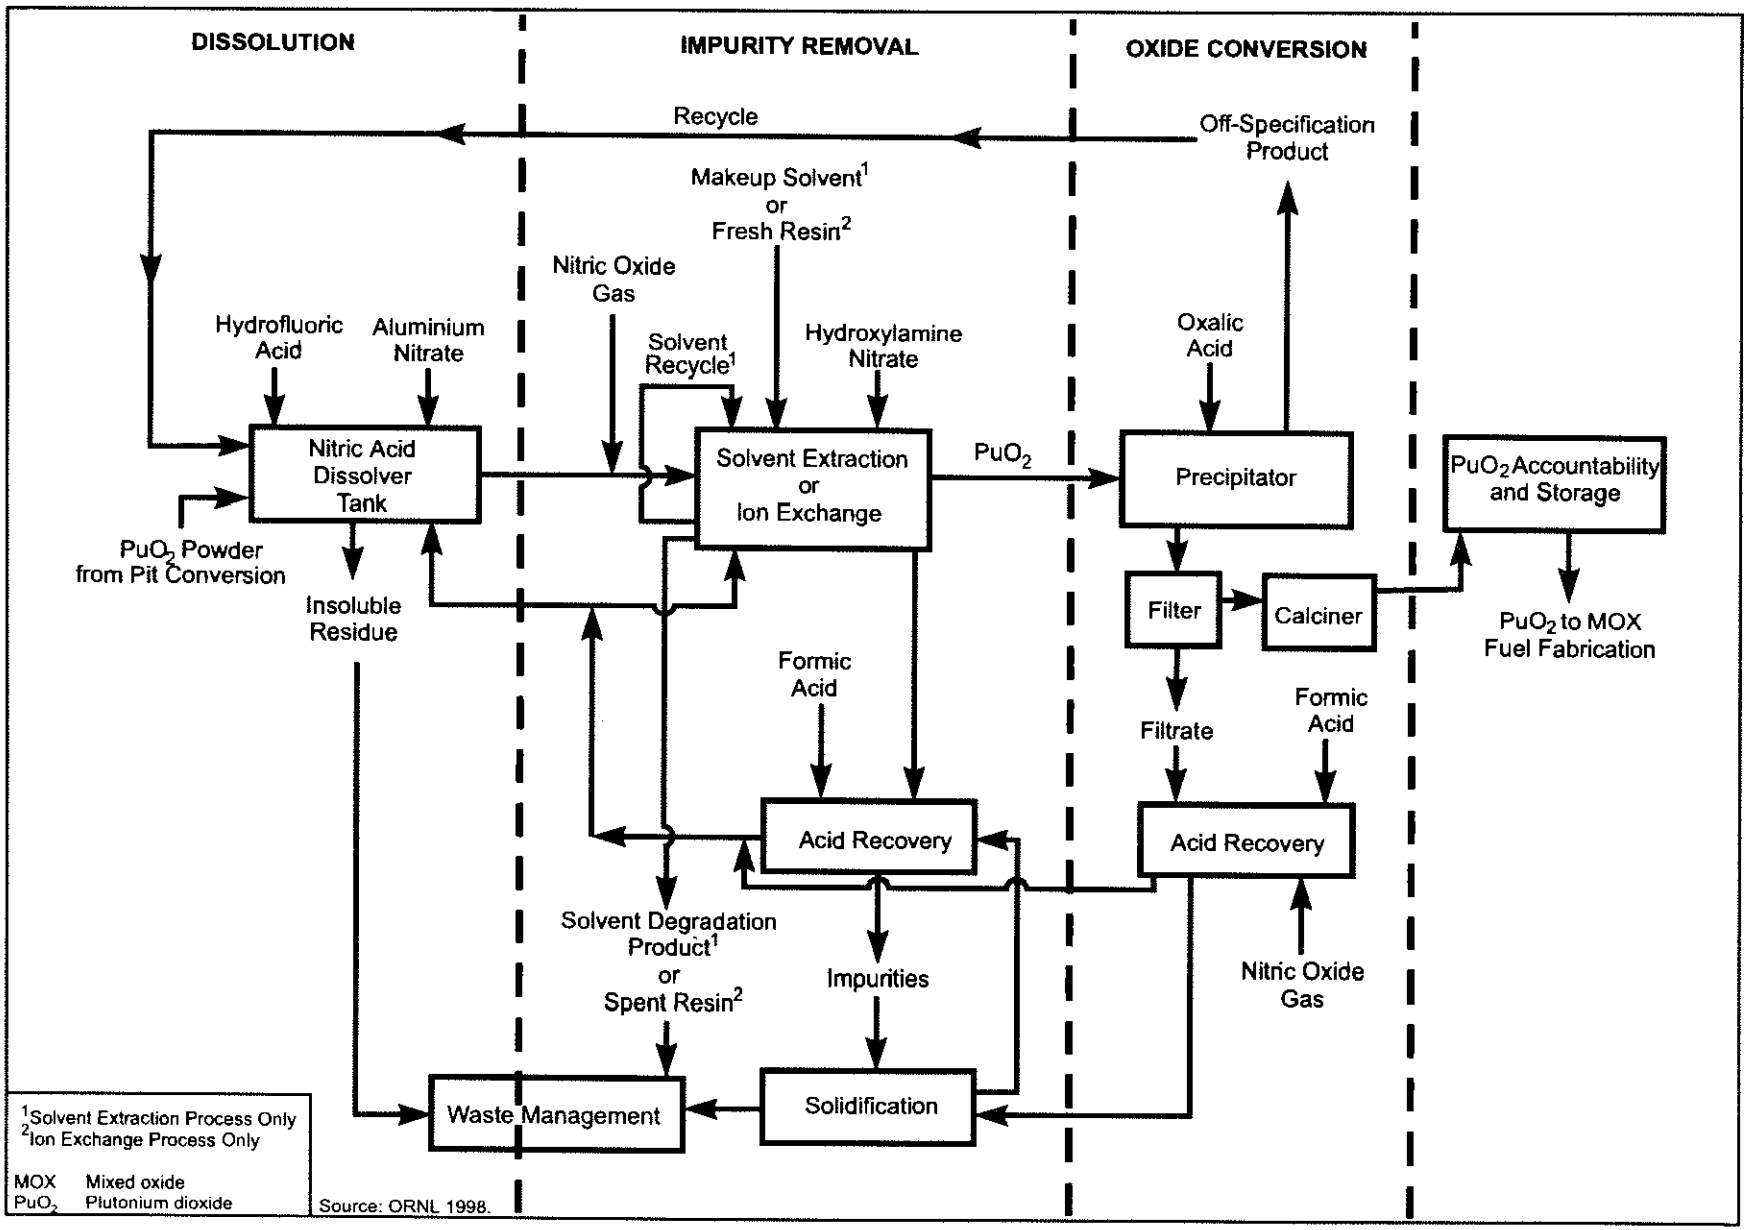

Figure N–1. Plutonium-Polishing Process

N.3.2 Impurity Removal

N.3.2.1 Solvent Extraction

Solvent extraction involves separating materials in solution according to their different preferences for a water-based (aqueous) or a hydrocarbon-based (solvent) solution. When the two solutions come into contact under the right physical and chemical conditions, one of the substances migrates from the solution in which they coexist (the feed solution) into the other (the solvent). After separation, the desired material (i.e., the product) is removed from its solution (either the feed stream or the solvent stream, depending on its preference). In this case, the plutonium would migrate from the feed solution (concentrated nitric acid) into the hydrocarbon solvent, while the gallium and other impurities would remain in the feed stream. The plutonium would then be removed from the solvent stream by contact with a second aqueous solution (dilute nitric acid), into which it would once again migrate. This process would occur in a series of centrifugal contactors, chambers which are designed to contain the materials and facilitate the contact between the aqueous and solvent streams. The dilute nitric acid stream containing the plutonium would be collected in a holding tank pending conversion. The impurities would be removed from the processed feed solution, solidified, and disposed of as waste. The solvent would be cleaned, and both it and the purified feed solution would be returned to the process for reuse.

N.3.2.2 Ion Exchange

Ion exchange operates on a similar principle: separation of substances by migration of one substance out of a solution containing both the substance of interest and impurities. In ion exchange, however, the solution is passed through columns filled with minute resin beads. Either the substance of interest or the impurities attach to the resin. In this case, the impurities would remain in solution in the feed stream, while the plutonium ions would attach themselves to the resin. The plutonium would then be removed from the resin by passing a second solution through the resin column. This stream would move on for the conversion step. The impurities remaining in the feed stream would be removed, solidified, and disposed of as waste; the purified feed stream would be returned to the process for reuse.

To begin this process, the feed solution (concentrated nitric acid containing the dissolved plutonium dioxide) would be transferred to the ion exchange glovebox for processing. The feed solution would be passed through parallel ion exchange columns to load the plutonium. Dilute nitric acid would subsequently be used to remove the plutonium from the resin columns. The stream containing the plutonium would be transferred to a holding tank to await the conversion step. The impurities would be removed from the used acids, solidified, and disposed of as waste, the purified acid stream would be returned to the process for reuse.

N.3.3 Oxide Conversion

Following impurity removal, the plutonium would be converted from a nitrate solution to an oxide powder through an oxalate precipitation, filtration, and calcination process. The plutonium-bearing dilute nitric acid solution would be transferred from the impurity removal holding tank to precipitation feed adjustment tanks, then fed into one of several precipitation tanks, where oxalic acid would be added. The resulting slurry would be mixed and allowed to settle, then would be transferred through mesh filters to filter boats.

The wet cake in the filter boats would be washed with a dilute oxalic/nitric acid solution. The filter boats would be transferred to a furnace for air drying, then calcining (heating at high temperatures, but below 700 °C [1,292 °F]). The resulting plutonium dioxide would then be transferred into storage containers, and stored pending transfer to MOX fuel fabrication.

N.3.4 Waste Management

Both the solvent extraction and ion exchange processes produce an aqueous acidic waste solution containing the separated impurities (e.g., gallium, americium, aluminum, and fluorides). This waste stream is treated by evaporation to recover nitric acid, and the concentrated impurities are solidified for disposal. The liquid wastes from the various impurity removal processes would be transferred to a waste feed tank for evaporation and chemical treatment as required. The evaporator condensate would be treated to produce concentrated acid and acidified water for process reuse. The evaporator concentrate would be chemically denitrated, and the off-gas from the denitrator scrubbed to produce concentrated nitric acid.

Solid wastes generated from process operations would include glovebox gloves, failed equipment, tools, wipes, and glovebox and high-efficiency particulate air (HEPA) filters. These materials would be removed from the process glovebox lines and transferred to a waste packaging glovebox. Nonprocess materials would be decontaminated to remove residual plutonium. The waste materials would then be packaged, assayed, and disposed of as appropriate.

N.4 POTENTIAL IMPACTS OF CONSTRUCTION AND OPERATION OF A PLUTONIUM-POLISHING MODULE

Because the plutonium-polishing module, if needed, would be added to either the pit conversion or MOX facility, impacts of its implementation would be an increment above those contributed by the facility to which it would be added. Although identified and evaluated as if the plutonium-polishing module were a discrete unit, these impacts would occur only if this module were actually added to one of the facilities. If added, the module would be completely integrated into facility operations, sharing security, services, common spaces, and other site and facility infrastructure. The impacts of the plutonium-polishing module presented in this appendix would bound the impacts of a polishing capability integrated with either of the disposition facilities. The resource areas evaluated are those where the greatest potential exists for effects on the environment. Other resource areas, such as geology and soils, and ecological resources, are not included in this appendix because the evaluations for the disposition facilities indicate that there would be little or no impact at the candidate sites on these resources, regardless of the disposition alternative being considered; and any incremental impact of the plutonium-polishing module would be negligible. Data tables are provided in Attachment 1 of this appendix.

N.4.1 Construction

The need for plutonium polishing would be identified prior to initiation of disposition facility construction, so the polishing capability would be an integral part of that construction. More building materials, fuel for equipment and vehicles, and water would be required to build the larger facility, and additional construction workers would be needed over the 3-year construction period. Water usage for sanitary and construction-related purposes could increase by as much as 2.2 million l/yr (580,000 gal/yr) during construction. As many as 112 additional construction workers would be needed annually, with the greatest total number of workers present during the second year of construction.

The volume of hazardous and nonhazardous solid wastes generated during construction of a pit conversion or MOX facility with plutonium-polishing capability would be approximately 20 percent greater than the volume of wastes which would be generated by construction of either of these facilities without plutonium polishing. These wastes would be typical of those generated during construction of an industrial facility, and would be managed largely at offsite facilities. It is unlikely that this additional waste load would have a major impact on the waste management systems at any of the candidate sites.

Nonhazardous liquid waste would primarily be sanitary wastewater, and would be managed as part of the overall facility wastewater. Including the plutonium-polishing capability in new construction would increase the wastewater generation by 8 to 20 percent, depending on the site and facility. This wastewater would be collected either in portable toilets that would be emptied and managed offsite through a contracted service, or would be processed in the existing onsite wastewater treatment facilities. As discussed in Chapter 4, existing site wastewater treatment facilities at all candidate sites have sufficient capacity to accept this additional volume of wastewater.

N.4.2 Operations

Analysis of the incremental impacts of operation of the plutonium-polishing module at each candidate site was based on the bounding plutonium disposition alternative (i.e., the alternative involving the most disposition activity, absent polishing) for that site. For the Hanford Site (Hanford) and the Savannah River Site (SRS), this would be the collocation of all three proposed disposition facilities; for the Idaho National Engineering and Environmental Laboratory (INEEL) and the Pantex Plant (Pantex), collocation of the pit conversion and MOX facilities. These are the same alternatives that were analyzed for Cumulative Impacts in Section 4.32 of the SPD EIS.

N.4.2.1 Resource Requirements

A staff of 85 would be required to support operation of the plutonium-polishing module. This additional direct employment would result in 152 to 288 indirect jobs at the candidate sites; the fewest at SRS and the most at Pantex. This additional employment would likely be filled from the existing community at each of the sites; however, community resources would be sufficient to absorb any potential in-migration.

Plutonium-polishing activities would increase electrical consumption at the candidate sites by about 5,500 MWh/yr. This would result in a 9 percent increase in the projected disposition facility needs at Hanford and SRS, and a 20 percent increase in facility demand at INEEL and Pantex. Water usage would not be appreciably increased. As discussed in Chapter 4 of the SPD EIS, sufficient electrical capacity is available at all candidate sites to support all disposition activities, including plutonium polishing.

The 930 m^2 (10,000 ft^2) that would be added to the footprint of the disposition facilities would not appreciably increase the amount of land disturbed at any of the candidate sites. However, areas of archaeological significance at SRS could be impacted. Section 4.26 of the SPD EIS describes the potential impacts of siting the disposition facilities at SRS and associated mitigation activities. Tables N–1 through N–4 present the impacts on resource use of disposition operations, including plutonium polishing, at the four candidate disposition sites.

Table N–1. Potential Impacts on Resource Use at Hanford From Operation of Disposition Facilities With Plutonium Polishing

Resource	Disposition Alternative 2	Polishing Increment	Alternative 2 With Polishing
Facility employment	1,014	85	1099
Electrical consumption (MWh/yr)	63,700	5,520	69,220
Water usage (million l/yr)	132	1.4	133
Developed land (ha)	15	0.09	15

Table N–2. Potential Impacts on Resource Use at INEEL From Operation of Disposition Facilities With Plutonium Polishing

Resource	Disposition Alternative 7A	Polishing Increment	Alternative 7A With Polishing
Facility employment	750	85	835
Electrical consumption (MWh/yr)	27,000	5,520	32,520
Water usage (million l/yr)	92	1.4	93
Developed land (ha)	13	0.09	13

Table N–3. Potential Impacts on Resource Use at Pantex From Operation of Disposition Facilities With Plutonium Polishing

Resource	Disposition Alternative 9A	Polishing Increment	Alternative 9A With Polishing
Facility employment	750	85	835
Electrical consumption (MWh/yr)	28,000	5,520	33,520
Water usage (million l/yr)	91	1.4	92
Developed land (ha)	16	0.09	16

Table N–4. Potential Impacts on Resource Use at SRS From Operation of Disposition Facilities With Plutonium Polishing

Resource	Disposition Alternative 3	Polishing Increment	Alternative 3 With Polishing
Facility employment	1,022	85	1,107
Electrical consumption (MWh/yr)	36,500	5,520	42,020
Water usage (million l/yr)	138	1.4	139
Developed land (ha)	31	0.09	31

N.4.2.2 Human Health Risk

As indicated in Tables N–5 through N–8, the additional processing steps required to implement the plutonium-polishing capability would not discernibly increase the dose or latent cancer fatality risk to members of the public, nor appreciably increase the dose or number of potential fatal cancers within the site workforce. The values in these tables are calculated for a 15-year period, including construction, startup, and facility operation.

Table N–5. Potential Impacts on Radiation Exposures at Hanford From Disposition Facilities With Plutonium Polishing

	Population Within 80 km		Badged Facility Workforce	
Impact	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Alternative 2	7.0×10^{1}	4×10^{-2}	5.6×10^{3}	2.2
Polishing	1.25×10^{-3}	6.3×10^{-7}	3.0×10^{2}	1.2×10^{-1}
Alternative 2 with polishing	7.0×10^{1}	4×10^{-2}	5.9×10^{3}	2.3

[a] Based on projected population of 387,800 in 2010.

Table N–6. Potential Impacts on Radiation Exposures at INEEL From Disposition Facilities With Plutonium Polishing

	Population Within 80 km		Badged Facility Workforce	
Impact	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Alternative 7A	2.2×10^{1}	1.1×10^{-2}	3.4×10^{3}	1.4
Polishing	1.35×10^{-3}	6.3×10^{-7}	3.1×10^{2}	1.2×10^{-1}
Alternative 7A with polishing	2.2×10^{1}	1.1×10^{-2}	3.8×10^{3}	1.5

[a] Based on projected population of 182,800 in 2010.

Table N–7. Potential Impacts on Radiation Exposures at Pantex From Disposition Facilities With Plutonium Polishing

	Population Within 80 km		Badged Facility Workforce	
Impact	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Alternative 9A	5.9	2.9×10^{-3}	3.7×10^{3}	1.5
Polishing	1.25×10^{-3}	6.3×10^{-7}	3.0×10^{2}	1.2×10^{-1}
Alternative 9A with polishing	5.9	2.9×10^{-3}	4.0×10^{3}	1.6

[a] Based on projected population of 299,000 in 2010.

Table N–8. Potential Impacts on Radiation Exposures at SRS From Disposition Facilities With Plutonium Polishing

	Population Within 80 km		Badged Facility Workforce	
Impact	Dose (person-rem)	Number of Fatal Cancers	Dose (person-rem)	Number of Fatal Cancers
Alternative 3	1.6×10^{1}	8×10^{-3}	5.6×10^{3}	2.3
Polishing	1.25×10^{-3}	6.3×10^{-7}	3.2×10^{2}	1.3×10^{-1}
Alternative 3 with polishing	1.6×10^{1}	8×10^{-3}	6.0×10^{3}	2.4

[a] Based on projected population of 387,800 in 2010.

Doses to involved workers from normal operations are provided in Table N–9. These workers are defined as those directly associated with process activities. The annual average dose to plutonium-polishing module workers would be 500 mrem, and the latent cancer fatality risk from 10 years of operation would be 2×10^{-3}, regardless of whether the module were added to either the pit conversion or MOX facility.

Table N–9. Potential Radiological Impacts on Involved Workers From Operation of Plutonium-Polishing Module

Impact	Estimate
Number of badged workers	60
Total dose (person-rem/yr)	30
10-year latent fatal cancers	0.12
Average worker dose (mrem/yr)	500
10-year latent fatal cancer risk	2.0×10^{-3}

N.4.2.3 Waste Management

Potential impacts of the additional waste that would be generated by the plutonium-polishing module at the candidate sites are presented in Tables N–10 through N–13. As indicated in these tables, waste could be a fairly large percentage of the total waste generated by the disposition facilities. With the exception of the storage of transuranic (TRU) waste at Pantex, however, it would be within the waste management capabilities of the sites. As discussed in Section 4.17 of the SPD EIS, TRU waste is not currently stored at Pantex, so TRU waste storage space would be provided in the pit conversion and MOX facilities. Although the addition of plutonium polishing would increase the TRU waste requiring storage by 210 m^3 (275 yd^3), additional TRU waste storage would be needed at Pantex under Alternative 9A with or without the plutonium-polishing module.

Table N–10. Potential Impacts on Waste Management at Hanford From Operation of Disposition Facilities With Plutonium Polishing (m^3)

Waste Type	Disposition Alternative 2[a]	Polishing Increment	Alternative 2 with Polishing	Site Capacity[b]		
				Treatment	Storage	Disposal
TRU	1,700	210	1,900	1,130,000	16,800	168,500[c]
LLW	2,200	600	2,800	2,000,000	24,000	1,970,000
Mixed LLW	44	10	54	2,400,000	24,500	14,200
Hazardous	414	17	431	NA	NA	NA

[c] Current disposal capacity at the Waste Isolation Pilot Plant.
Key: LLW, low-level waste; NA, not applicable (i.e., the majority of the waste is not routinely treated, stored, or disposed of on the site); TRU, transuranic.

N.4.2.4 Air Quality

Tables N–14 through N–17 demonstrate that only oxides of nitrogen and hydrocarbon emissions (solvent extraction only) would result from the additional processing steps required to implement the plutonium-polishing capability. As shown in these tables, however, none of the emissions from the disposition facilities at any of the candidate sites, even with the additional nitrogen dioxide and hydrocarbon contributions, would amount to even 1 percent of the regulatory standard or guideline.

Table N–14. Potential Impacts on Air Pollutant Emissions at Hanford From Operation of Disposition Facilities With Plutonium Polishing

Pollutant	Averaging Period	Most Stringent Standard or Guideline[a] ($\mu g/m^3$)	Disposition Alternative 2 Increment ($\mu g/m^3$)	Polishing Increment ($\mu g/m^3$)	Alternative 2 with Polishing ($\mu g/m^3$)	Percent of Standard or Guideline

N.4.2.5 Facility Accidents

A set of bounding accidents were identified for liquid phase operations of the plutonium-polishing process. Accidents involving dry powder handling were analyzed and determined to be bounded by similar accidents associated with the pit conversion and MOX facilities without polishing. Table N–18 summarizes the set of bounding design basis and beyond-design-basis accidents for the plutonium-polishing module.

For the bounding beyond-design-basis accidents, consequences were developed for the noninvolved worker, the maximally exposed member of the public, and the public within 80 km (50 mi). The design-basis-accident with the greatest consequences is criticality. The beyond-design-basis accident with the greatest consequences is the beyond-design-basis earthquake. Impacts from criticality and beyond-design-basis earthquake are summarized in Table N–19 for each of the candidate sites. The beyond-design-basis earthquake impacts are for the plutonium-polishing module only, and increase the postulated impacts from the pit conversion and MOX facilities by 15 and 6.8 percent, respectively.

Table N–18. Summary of Bounding Accidents for the Plutonium-Polishing Module

Postulated Accident	Material at Risk (Plutonium [g])	ARF/RF	Frequency	Material Released (Plutonium [g]) [a]
Spill (with release outside facility)	5,000 (in concentrated acid)	$2\times10^{-4}/0.5$	Extremely unlikely	5×10^{-6}
Fire in glovebox[b]	40 (in organic solvent)	$1\times10^{-2}/1.0$	Unlikely	4×10^{-6}
Uncontrolled reaction/explosion:				
Thermal excursion in ion exchange column[c]	1,000 (resin) 246 (solution)	9×10^{-3} 6×10^{-3}	Unlikely	2.4×10^{-5} [d]
Nitric acid reactant events	2.75 (in dilute acid)	$2\times10^{-3}/1.0$	Extremely unlikely	5.5×10^{-8}
Criticality (1×10^{19} fissions)[e]	4,200 (in dilute acid)	1.3×10^{-4} [f]	Extremely unlikely	5.3×10^{-6} [g]
Beyond-design-basis earthquake	24,000 (in dilute acid)	$2\times10^{-5}/1.0$ $1\times10^{-4}/1.0$ 1.9×10^{-4} [h]	Extremely unlikely to beyond extremely unlikely	6.0

[a] Including an LPF of 1×10^{-5} on particulates for all design basis accidents.
[b] Solvent extraction process only.
[c] Ion exchange process only.
[d] Assuming a DR of 0.1 for anion exchange column resin.
[e] For consistency, the criticality source term has been modified from that reported in *Environmental Data Report for Generic Site Add-On Facility for Plutonium Polishing* (ORNL 1998), a is based on the criticality in plutonium dioxide powder postulated in the body of the SPD EIS, adjusted to reflect the release potential of fission products from solution.
[f] Based on 0.05 percent converted to an aerosol and 25 percent evaporated.
[g] Plus fission product gases.
[h] Half of the material has an ARF/RF value of $2\times10^{-5}/1.0$, the other half, a value of $1\times10^{-4}/1.0$. Resuspension is 1.9×10^{-4}.

Key: ARF, airborne release fraction; DR, damage ratio; LPF, leak path factor; RF, respirable fraction.

Table N–19. Accident Impacts of the Plutonium-Polishing Module

Accident	Frequency	Impacts on Noninvolved Worker: Dose (rem)[a]	Impacts on Noninvolved Worker: Probability of Cancer Fatality[b]	Impacts at Site Boundary: Dose (rem)[a]	Impacts at Site Boundary: Probability of Cancer Fatality[b]	Impacts on Population Within 80 km: Dose (person-rem)[a]	Impacts on Population Within 80 km: Latent Cancer Fatalities[c]

Criticality at pit conversion facility	Extremely unlikely	8.7×10^{-2}	3.5×10^{-5}	9.4×10^{-3}	4.7×10^{-6}	1.4×10^{1}	7.0×10^{-3}
Criticality at MOX facility	Extremely unlikely	3.0×10^{-1}	1.2×10^{-4}	1.6×10^{-2}	8.0×10^{-6}	1.6×10^{1}	8.0×10^{-3}
Beyond-design-basis earthquake[e]	Extremely unlikely to beyond extremely unlikely	1.4×10^{1}	5.6×10^{-3}	5.5×10^{-1}	2.8×10^{-4}	1.3×10^{3}	6.5×10^{-1}

[a] For 95th percentile meteorological conditions. With the exception of doses due to criticality, the stated doses are from the inhalation of plutonium, and represent dose commitments that would be received over the lifetime of the impacted individual. Criticality doses also have a component from shine.

[b] Increased likelihood (or probability) of cancer fatality for a hypothetical individual (a single onsite worker at a distance of 1,000 m [3,281 ft] or at the site boundary, whichever is smaller, or for a hypothetical individual in the offsite population at the site boundary) if exposed to the indicated dose. The value assumes that the accident has occurred.

[c] Estimated number of cancer fatalities in the entire offsite population out to a distance of 80 km (50 mi) given exposure to the indicated dose. The value assumes that the accident has occurred.

[d] Impacts of a criticality accident occurring in FMEF would be the same whether the plutonium-polishing module were added to the pit conversion or MOX facility.

[e] Impacts of the design basis earthquake would be the same whether the plutonium-polishing module were added to the pit conversion or MOX facility.

Based on the frequency analysis documented in Appendix K of the SPD EIS, aircraft crash scenarios have been evaluated for the proposed disposition facilities at Pantex. The crash of an aircraft into the plutonium-polishing module was examined as a potential bounding beyond-design-basis accident.

The analysis of aircraft crash assumes that a plutonium inventory of 12 kg (26 lb) in a concentrated acid solution and 12 kg (26 lb) in a dilute acid solution is impacted by aircraft debris or building rubble. The bounding airborne release fractions and respirable fractions for free-fall spill of the concentrated solution are 2×10^{-5} and 1.0, respectively, and for the dilute solution, 2×10^{-4} and 0.5 (DOE 1994). These values have been used historically to model the collapse of building rubble onto plutonium solutions. It can be argued, however, that the energetics of the aircraft crash exceed the scope of these values, so that higher values must be used. For perspective, the bounding values for high-pressure release (>0.35 MPa_g) such as might result from the crushing and rupturing of a process vessel directly hit by aircraft debris, are 20 times greater than those for a free-fall spill. While it is unrealistic to assume that all process inventory would be impacted in this manner, it is conceivable that this type of phenomenology might play a part in the release. It is therefore assumed that half the inventory is subject to free-fall spill, and half to high-pressure release, for combined airborne release fraction/respirable fraction (ARF×RF) values of 2×10^{-4} and 1×10^{-3} for the concentrated and dilute solutions, respectively. This results in a plutonium source term of 14 g (0.5 oz).

For analysis purposes, it is also assumed that a jet fuel fire ensues, releasing additional plutonium into the air. DOE-HDBK-3010-94 presents two bounding estimates; a combined ARF×RF of 3×10^{-5} for heating without boiling, and 2×10^{-3} for boiling. It is highly unlikely that a fire would be of sufficient magnitude to involve the entire inventory in a boiling release. Moreover, the larger the fire, the greater the lofting of the resultant plume, tending to lower the doses for the noninvolved worker, the maximally exposed member of the public, and population within 80 km (50 mi). Consequently, the geometric mean value of 2×10^{-4} has been selected, along with the assumption of a nonlofted plume. This results in an additional plutonium release of 4.8 g, for a total of 19 g. This scenario results in less plutonium being released than would be released by an aircraft crash into the power storage areas of the pit conversion or MOX facilities, or from a beyond-design-basis earthquake at either of these facilities. Because the potential impacts of an aircraft crash are bounded by these other scenarios, this accident was not analyzed further.

No major consequences for the maximally exposed involved workers would be expected from leaks, spills, and smaller fires. These accidents are such that involved workers would either be able to evacuate immediately or would not be affected by the events. Explosions, on the other hand, could result in immediate injuries from flying debris, as well as the uptake of plutonium and uranium particulates through inhalation. If a criticality were to occur, workers within tens of meters could receive very high to fatal radiation exposures from the initial burst. The dose would strongly depend on the magnitude of the criticality (number of fissions), the distance from the criticality, and the amount of shielding provided by the structures and equipment between the workers and the criticality. The design basis and beyond-design-basis earthquakes would also have substantial consequences, ranging from workers being killed by debris from collapsing equipment and structures to high radiation exposures and uptakes of radionuclides. For most accidents, immediate emergency response actions should reduce the consequences to workers near the accident.

ATTACHMENT 1. PLUTONIUM-POLISHING DATA TABLES

1.1 Construction

Table 1–1. Average Annual Resource Requirements for Construction of Plutonium-Polishing Module

Resource	Requirement
Electricity	
Annual consumption (MWh)	890
Peak hourly demand (MW)	< 0.35
Fuel (l)	50,160
Water (l)	
Annual consumption	2,200,000
Peak daily demand	8,600
Concrete (m^3)	750
Steel (t)	300

Table 1–2. Estimated Waste Generation From Construction of Plutonium-Polishing Module

Waste Type	Estimated Additional Waste Generation
Hazardous	
Liquid (l)	2,940
Solid (m^3)	12
Nonhazardous	
Liquid (l)	3,260,000
Solid (m^3)	93,600

Table 1–3. Air Emissions From Construction of Plutonium-Polishing Module

Pollutant	Emissions (t/yr)
Carbon monoxide	2.7
Nitrogen dioxide	4.3
PM_{10}	2.7
Sulfur dioxide	0.29
Volatile organic compounds	0.62
Total suspended particulates	6.3
Hazardous and other toxic compounds (e.g., lead, benzene, hexane)	< 1

Table 1–4. Estimated Air Pollutant Concentrations From Construction of Plutonium-Polishing Module

Pollutant	Averaging Period[a]	Concentration ($\mu g/m^3$)
Carbon monoxide	8 hours	0.53
	1 hour	3.3
Nitrogen dioxide	Annual	0.07
PM_{10}	Annual	0.049
	24 hours	1.3
Sulfur dioxide	Annual	0.0046
	24 hours	0.055
	3 hours	0.24
	30 minutes	0.98
Total suspended particulates	3 hours	10.1
	1 hour	41
Hazardous and other toxic compounds (e.g., lead benzene, hexane)[b]	24 hours	0.002
	1 hour	0.0036

[a] The more stringent of the Federal and State standards is presented if both exist for the averaging period.

[b] Various toxic air pollutants may be emitted during construction. Figures here represent analysis for benzene.

1.2 Operations

Table 1–5. Average Annual Resource Requirements for Operation of Plutonium-Polishing Module

Process Chemical	Requirement
Nitric oxide (gas) (m^3/yr)[a]	850
Solvent (tri-butyl phosphate in n-Paraffin hydrocarbon) (l/yr)[b]	15
Hydrofluoric acid (l/yr)	90
Formic acid (l/yr)	81,140
Hydroxylamine nitrate (kg/yr)	656
Aluminum nitrate nanohydrate (kg/yr)	1,238
Oxalic acid dihydrate (kg/yr)	6,970
Reillex HPQ resin (wet basis) (kg/yr)[c]	163

[a] Makeup for nitric acid in processes.

[b] Solvent extraction process only.

[c] Ion exchange process only.

Table 1–6. Potential Radiological Impacts on the Public of Operation of Plutonium-Polishing Module

Impact	Estimate
Population within 80 km	
Dose (person-rem/yr)	1.2×10^{-4}
10-year latent fatal cancers	6.3×10^{-7}
Maximally exposed individual	
Annual dose (mrem)	5.3×10^{-5}
10-year latent fatal cancer risk	2.7×10^{-10}
Average exposed individual within 80 km	
Annual dose (mrem)	4.2×10^{-7}
10-year latent fatal cancer risk	2.1×10^{-12}

Table 1–7. Radiological Emissions From Operation of Plutonium-Polishing Module

Stream	Plutonium Release	Average Release Height
Air	1.65×10^{-8} g/yr (2μCi/yr)	Base facility stack height
Water	Not Applicable	Not Applicable

Table 1–8. Potential Waste Generation From Operation of Plutonium-Polishing Module

Waste Type	Estimate
TRU (m^3/yr)	21
LLW (m^3/yr)	60
Mixed LLW (m^3/yr)	1.0
Hazardous	
Liquid (l/yr)	740
Solid (m^3/yr)	1.0
Nonhazardous	
Liquid (l/yr)	1,380
Solid (m^3/yr)	290

Key: LLW, low-level waste; TRU, transuranic.

Table 1–9. Estimated Air Emissions (t) From Operation of Plutonium-Polishing Module

Pollutant	Annual Emissions
Nitrogen dioxide	0.86
Hazardous air pollutants (n-Paraffin hydrocarbon)[a]	<0.01

[a] Solvent extraction process only.
