12 concentration levels after the phaseout of leaded gasoline. The highest background
13 concentrations of criteria pollutants at these stations for the period 2004 to 2008 are presented
14 in Table 11.5.13.1-2 (EPA 2010b). Except for 8-hour O₃ and 24-hour PM₁₀, which approach
15 their respective standards, the highest concentration levels were lower than their respective
16 standards (up to 82%).

17
18 The PSD regulations (see 40 CFR 52.21), which are designed to limit the growth of air
19 pollution in clean areas, apply to a major new source or modification of an existing major source
20 within an attainment or unclassified area (see Section 4.11.2.3). As a matter of policy, the EPA
21 recommends that the permitting authority notify the Federal Land Managers when a proposed
22 PSD source would locate within 62 mi (100 km) of a sensitive Class I area. Several Class I areas
23 are located in Arizona and Utah; two of these are within 62 mi (100 km) of the proposed SEZ.
24 The nearest is Grand Canyon NP in Arizona (40 CFR 81.403), about 58 mi (93 km) southeast of
25 the East Mormon Mountain SEZ. This Class I area is not located downwind of prevailing winds
26 at the East Mormon Mountain SEZ (Figure 11.5.13.1-1). The next nearest Class I areas include
27 Zion and Bryce Canyon NPs in Utah, which are located about 62 mi (100 km) and 111 mi
28 (178 km) east-northeast of the SEZ, respectively.

31 **11.5.13.2 Impacts**

32
33 Potential impacts on ambient air quality associated with a solar project would be of
34 most concern during the construction phase. Impacts on ambient air quality from fugitive dust
35 emissions resulting from soil disturbances are anticipated, but they would be of short duration.
36 During the operations phase, only a few sources with generally low levels of emissions would
37 exist for any of the four types of solar technologies evaluated. A solar facility would either
38 not burn fossil fuels or burn only small amounts during operation. (For facilities using HTFs,
39 fuel could be used to maintain the temperature of the HTFs for more efficient daily start up.)
40 Conversely, use of solar facilities to generate electricity could offset air emissions that would
41 otherwise be released from fossil fuel power plants.

42
43 Air quality impacts shared by all solar technologies are discussed in detail in
44 Section 5.11.1, and technology-specific impacts are discussed in Section 5.11.2. Impacts specific
45 to the proposed East Mormon Mountain SEZ are presented in the following sections. Any such
46 impacts would be minimized through the implementation of required programmatic design

features described in Appendix A, Section A.2.2, and through any additional mitigation applied. Section 11.5.13.3 below identifies SEZ-specific design features of particular relevance to the East Mormon Mountain SEZ.

11.5.13.2.1 Construction

The East Mormon Mountain SEZ site has a relatively flat terrain; thus, only a minimum number of site preparation activities, perhaps with no large-scale earthmoving operations, would be required. However, fugitive dust emissions from soil disturbances during the entire construction phase would be a major concern because of the large areas that would be disturbed in a region that experiences windblown dust problems. Fugitive dusts, which are released near ground level, typically have more localized impacts than similar emissions from an elevated stack with additional plume rise induced by buoyancy and momentum effects.

Methods and Assumptions

Air quality modeling for PM₁₀ and PM_{2.5} emissions associated with construction activities was performed using the EPA-recommended AERMOD model (EPA 2009b). Details for emissions estimation, the description of AERMOD, input data processing procedures, and modeling assumption are described in Section M.13 of Appendix M. Estimated air concentrations were compared with the applicable NAAQS/SAAQS levels at the site boundaries and nearby communities and with Prevention of Significant Deterioration (PSD) increment levels at nearby Class I areas.⁹ However, no receptors were modeled for PSD analysis at the nearest Class I areas, Grand Canyon NP in Arizona and Zion NP in Utah, because they are about 58 mi (93 km) and 62 mi (100 km) from the SEZ, respectively, which is over the maximum modeling distance of 31 mi (50 km) for the AERMOD. Instead, several regularly spaced receptors in the direction of the Grand Canyon NP and Zion NP were selected as surrogates for the PSD analysis. For the East Mormon Mountain SEZ, the modeling was conducted based on the following assumptions and input:

- Emissions of 3,000 acres (12.1 km²) total were uniformly distributed in the southern portion of the SEZ, close to the nearest residences and towns such Bunkerville and Mesquite;
- Surface hourly meteorological data came from the Las Vegas McCarran International Airport and upper air sounding data came from the Mercury/Desert Rock Airport for the 2005 to 2009 period; and

⁹ To provide a quantitative assessment, the modeled air impacts of construction were compared to the NAAQS/SAAQS levels and the PSD Class I increment levels. Although the Clean Air Act exempts construction activities from PSD requirements, a comparison with the Class I increment levels was used to quantify potential impacts. Only monitored data can be used to determine the attainment status. Modeled data are used to assess potential problems and as a consideration in the permitting process.

- A receptor grid was regularly spaced over a modeling domain of 62 mi × 62 mi (100 km × 100 km), centered on the proposed SEZ, and there were additional discrete receptors at the SEZ boundaries.

Results

Modeling results are summarized in Table 11.5.13.2-1 for concentration increments and total concentrations (modeled plus background concentrations) of both PM₁₀ and PM_{2.5} that would result from construction-related fugitive emissions. Maximum 24-hour PM₁₀ concentration increments modeled to occur at the site boundaries would be an estimated 567 µg/m³, which far exceeds the relevant standard level of 150 µg/m³. Total 24-hour PM₁₀ concentrations of 709 µg/m³ would also exceed the standard level at the SEZ boundary. However, high PM₁₀ concentrations would be limited to the immediate areas surrounding the SEZ boundary and would decrease quickly with distance. Predicted maximum 24-hour PM₁₀ concentration increments would be about 10 µg/m³ at Mesquite (closest town, about 12 mi [19 km] southeast of the SEZ), about 5 µg/m³ at Bunkerville, and less than 4 µg/m³ at Moapa Valley towns such as Moapa Valley and Overton. Annual average modeled concentration increments and total concentrations (increment plus background) for PM₁₀ at the SEZ boundary would be about 63.7 µg/m³ and 89.7 µg/m³, respectively, which are higher than the SAAQS level of 50 µg/m³. Annual PM₁₀ increments would be much lower, about 0.1 µg/m³ or less, at all aforementioned towns.

Total 24-hour PM_{2.5} concentrations would be 47.8 µg/m³ at the SEZ boundary, which is higher than the NAAQS level of 35 µg/m³; modeled increments contribute more than three times the amount of background concentration to this total. The total annual average PM_{2.5} concentration would be 10.4 µg/m³, which is lower than the NAAQS level of 15.0 µg/m³. At Mesquite, predicted maximum 24-hour and annual PM_{2.5} concentration increments would be about 0.1 and 0.01 µg/m³, respectively.

Predicted 24-hour and annual PM₁₀ concentration increments at the surrogate receptors for the nearby Class I Area—Zion NP, Utah—would be about 10.8 µg/m³ and 0.17 µg/m³, or 135% and 4.2% of the PSD increments for the Class I area, respectively. These surrogate receptors are more than 33 mi (54 km) from the Zion NP; thus, predicted concentrations in Zion NP would be lower than the above values (about 66% of the PSD increments for 24-hour PM₁₀), considering the same decay ratio with distance.

In conclusion, predicted 24-hour and annual PM₁₀ and 24-hour PM_{2.5} concentration levels could exceed the standard levels at the SEZ boundaries and in the immediate surrounding areas during the construction of solar facilities. To reduce potential impacts on ambient air quality and in compliance with programmatic design features, aggressive dust control measures would be used. Potential air quality impacts on nearby communities would be much lower. Annual PM_{2.5} concentration levels are predicted to be lower than its standard level. Modeling indicates that emissions from construction activities are not anticipated to exceed Class I PSD PM₁₀ increments at the nearby federal Class I areas (Grand Canyon NP and Zion NP). Construction activities are not subject to the PSD program, and the comparison provides only a

TABLE 11.5.13.2-1 Maximum Air Quality Impacts from Emissions Associated with Construction Activities for the Proposed East Mormon Mountain SEZ

Pollutant ^a	Averaging Time	Rank ^b	Concentration (µg/m ³)				Percentage of NAAQS/SAAQS	
			Maximum Increment ^b	Background ^c	Total	NAAQS/SAAQS	Increment	Total
PM ₁₀	24 hours	H6H	567	142	709	150	378	473
	Annual	— ^d	63.7	26.0	89.7	50	127	179
PM _{2.5}	24 hours	H8H	37.6	10.2	47.8	35	107	136
	Annual	—	6.4	4.1	10.4	15.0	42	69

^a PM_{2.5} = particulate matter with a diameter of ≤2.5 µm; PM₁₀ = particulate matter with a diameter of ≤10 µm.

^b Concentrations for attainment demonstration are presented. H6H = highest of the sixth-highest concentrations at each receptor over the 5-year period. H8H = highest of the multiyear average of the eighth-highest concentrations at each receptor over the 5-year period. For the annual average, multiyear averages of annual means over the 5-year period are presented. Maximum concentrations are predicted to occur at the site boundaries.

^c See Table 11.5.13.1-2.

^d A dash indicates not applicable.

screen for gauging the magnitude of the impact. Accordingly, it is anticipated that impacts of construction activities on ambient air quality would be moderate and temporary.

Emissions from the engine exhaust of heavy construction equipment and vehicles have the potential to cause impacts on AQRVs (e.g., visibility and acid deposition) at the nearby federal Class I areas. However, SO_x emissions from engine exhaust would be very low, because programmatic design features would require ultra-low-sulfur fuel with a sulfur content of 15 ppm. NO_x emissions from engine exhaust would be the primary contributors to potential impacts on AQRVs. Construction-related emissions are temporary in nature, and thus would cause some unavoidable but short-term impacts.

For this analysis, the impacts of construction and operation of transmission lines outside of the SEZ were not assessed, assuming that the existing regional 500-kV transmission line might be used to connect some new solar facilities to load centers, and that additional project-specific analysis would be done for new transmission construction or line upgrades. However, some construction of transmission lines could occur within the SEZ and over a short distance (about 0.25 mi [0.4 km]) to the regional grid. Potential impacts on ambient air quality would be a minor component of construction impacts in comparison to solar facility construction, and would be temporary in nature.

11.5.13.2.2 Operations

Emission sources associated with the operation of a solar facility would include auxiliary boilers; vehicle (commuter, visitor, support, and delivery) traffic; maintenance (e.g., mirror cleaning and repair and replacement of damaged mirrors); and drift from cooling towers for the parabolic trough or power-tower technology, if wet cooling were implemented (drift constitutes low-level PM emissions).

The type of emission sources caused by and offset by operation of a solar facility are discussed in Section M.13.4 of Appendix M.

Estimates of potential air emissions displaced by solar project development at the East Mormon Mountain SEZ are presented in Table 11.5.13.2-2. Total power generation capacity ranging from 797 to 1,435 MW is estimated for the East Mormon Mountain SEZ for various solar technologies (see Section 11.5.2). The estimated amount of emissions avoided for the solar technologies evaluated depends only on the megawatts of conventional fossil fuel-generated power displaced, because a composite emission factor per megawatt-hour of power by conventional technologies is assumed (EPA 2009c). It is estimated that if the East Mormon Mountain SEZ would eventually have development on 80% of its land, emissions avoided could range from 3.7 to 6.6% of total emissions of SO₂, NO_x, Hg, and CO₂ from electric power systems in the state of Nevada (EPA 2009c). Avoided emissions could be up to 1.4% of total emissions from electric power systems in the six-state study area. When compared to all source categories, power production from the same solar facilities could displace up to 5.4% of SO₂, 2.0% of NO_x, and 3.6% of CO₂ emissions in the state of Nevada (EPA 2009a; WRAP 2009). These emissions could be up to 0.75% of total emissions from all source categories in the six-state study area. Power generation from fossil fuel-fired power plants accounts for about 93% of the total electric power generated in Nevada (EPA 2009c). The contribution of natural gas combustion is about 47%, followed by coal combustion of about 45%. Thus, solar facilities built in the East Mormon Mountain SEZ could displace relatively more fossil fuel emissions than those built in other states that rely less on fossil fuel-generated power.

As discussed in Section 5.11.1.5, the operation of associated transmission lines would generate some air pollutants from activities such as periodic site inspections and maintenance. However, these activities would occur infrequently, and the amount of emissions would be small. In addition, transmission lines could produce minute amounts of O₃ and its precursor NO_x associated with corona discharge (i.e., the breakdown of air near high-voltage conductors), which is most noticeable for high-voltage lines during rain or very humid conditions. Since the proposed East Mormon Mountain SEZ is located in an arid desert environment, these emissions would be small, and potential impacts on ambient air quality associated with transmission lines would be negligible, considering the infrequent occurrences and small amount of emissions from corona discharges.

TABLE 11.5.13.2-2 Annual Emissions from Combustion-Related Power Generation Avoided by Full Solar Development of the Proposed East Mormon Mountain SEZ

Area Size (acres)	Capacity (MW) ^a	Power Generation (GWh/yr) ^b	Emissions Displaced (tons/yr; 10 ³ tons/yr for CO ₂) ^c			
			SO ₂	NO _x	Hg	CO ₂
8,968	797–1,435	1,397–2,514	1,970–3,547	1,690–3,042	0.011–0.020	1,085–1,952
Percentage of total emissions from electric power systems in Nevada ^d			3.7–6.6%	3.7–6.6%	3.7–6.6%	3.7–6.6%
Percentage of total emissions from all source categories in Nevada ^e			3.0–5.4%	1.1–2.0%	– ^f	2.0–3.6%
Percentage of total emissions from electric power systems in the six-state study area ^d			0.79–1.4%	0.46–0.82%	0.38–0.69%	0.41–0.74%
Percentage of total emissions from all source categories in the six-state study area ^e			0.42–0.75%	0.06–0.11%	–	0.13–0.23%

^a It is assumed that the SEZ would eventually have development on 80% of the lands and that a range of 5 acres (0.020 km²) per MW (for parabolic trough technology) to 9 acres (0.036 km²) per MW (power tower, dish engine, and PV technologies) would be required.

^b A capacity factor of 20% was assumed.

^c Composite combustion-related emission factors for SO₂, NO_x, Hg, and CO₂ of 2.82, 2.42, 1.6 × 10⁻⁵, and 1,553 lb/MWh, respectively, were used for the state of Nevada.

^d Emission data for all air pollutants are for 2005.

^e Emission data for SO₂ and NO_x are for 2002, while those for CO₂ are for 2005.

^f A dash indicates not estimated.

Sources: EPA (2009a,c); WRAP (2009).

11.5.13.2.3 Decommissioning/Reclamation

As discussed in Section 5.11.1.4, decommissioning/reclamation activities are similar to construction activities but occur on a more limited scale and are of shorter duration. Potential impacts on ambient air quality would be correspondingly smaller than those from construction activities. Decommissioning activities would last for a short period, and their potential impacts would be moderate and temporary. The same mitigation measures adopted during the construction phase would also be implemented during the decommissioning phase (Section 5.11.5).

11.5.13.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features are required. Limiting dust generation during construction and operations at the proposed East Mormon Mountain SEZ (such as increased watering frequency or road paving or treatment) is a required design feature under BLM's Solar Energy Program. These extensive fugitive dust control measures would keep off-site PM levels as low as possible during construction.

11.5.14 Visual Resources

11.5.14.1 Affected Environment

The proposed East Mormon Mountain SEZ is located in Lincoln County in southeastern Nevada. It is located 9.3 mi (15.0 km) west of the Arizona and Utah state borders. The SEZ occupies 8,968 acres (36.29 km²) and extends approximately 5.1 mi (8.2 km) in a north–south direction and is approximately 3.0 mi (4.8 km) wide. The SEZ ranges in elevation from 2,568 ft (782.7 m) in the southeastern portion to 2,840 ft (865.6 m) in the northeastern portion.

The SEZ lies within the Mojave Basin and Range Level III ecoregion, which consists of broad basins and scattered mountains. Heavy use of OHVs and motorcycles in some areas has caused soil erosion, and there is relatively little grazing activity because of the lack of water and forage for livestock. Most land is federally owned. The East Mormon Mountain SEZ is located within the Creosotebush-Dominated Basins Level IV ecoregion, which includes valleys that lie between scattered mountain ranges. These valleys contain stream terraces, floodplains, alluvial fans, isolated hills, mesas, buttes, and eroded washes (Bryce et al. 2003).

The SEZ is located in a valley east of the East Mormon Mountains and south of the Tule Springs Hills. These nearby mountains add significantly to the scenic value of the SEZ. These mountains range in elevation from 3,000 ft (900 m) to more than 5,000 ft (1,500 m). The mountain slopes and peaks surrounding the SEZ generally are visually pristine. The SEZ and surrounding mountain ranges are shown in Figure 11.5.14.1-1.

The SEZ is located within a relatively flat desert floor, with the strong horizon line and surrounding mountain ranges being the dominant visual features. Light-colored, unvegetated playas provide strong color and texture contrast. Toquop Wash is a large, deep wash that roughly bisects the SEZ, running from northwest to southeast, and is a prominent visual feature in some locations within the SEZ. Other washes that generally run from northwest to southeast also add some vertical relief to the SEZ. The surrounding mountains are generally red to brown in color, with distant mountains appearing blue to purple. In contrast, pink to tan gravels dominate the desert floor, which is sparsely dotted with the greens of vegetation. No permanent surface water is present within the SEZ.

Vegetation is generally sparse in much of the SEZ, with widely spaced shrubs growing on more or less barren gravel flats. Vegetation within the SEZ is predominantly scrubland, with creosotebush and other low shrubs dominating the desert floor within the SEZ. Small Joshua trees add short vertical accents and color contrasts that add visual interest to portions of the SEZ. During an August 2009 site visit, the vegetation presented a range of greens (mostly the olive green of creosotebushes) with some grays and tans (from lower shrubs), with medium to coarse textures. Visual interest within the SEZ is generally low.

Other than a few roads and a visually prominent (500-kV) transmission line located outside the SEZ, but within 0.3 mi (0.5 km) of its southeast corner, the area is relatively free of cultural modifications that would detract from scenic qualities of the landscape.

FIGURE 11.5.14.1-1 Proposed East Mormon Mountain SEZ and Surrounding Lands

1 The general lack of topographic relief, water, and physical variety results in low scenic
2 value within the SEZ itself; however, because of the flatness of the landscape, the lack of trees,
3 and the breadth of the open desert, the SEZ presents a vast panoramic landscape with sweeping
4 views of the surrounding mountains that add significantly to the scenic values within the SEZ
5 viewshed. In general, the mountains appear to be devoid of vegetation; their varied and irregular
6 forms and red to brown colors provide visual contrasts to the strong horizontal line, green
7 vegetation, and pink to tan gravels of the valley floor, particularly when viewed from nearby
8 locations within the SEZ. Panoramic views of the SEZ are shown in Figures 11.5.14.1-2 and
9 11.5.14.1-3.

10
11 The BLM conducted a visual resource inventory (VRI) for the SEZ and surrounding
12 lands in 2007 (BLM 2009d). The VRI evaluates BLM-administered lands based on scenic
13 quality; sensitivity level, in terms of public concern for preservation of scenic values in the
14 evaluated lands; and distance from travel routes or KOPs. Based on these three factors, BLM-
15 administered lands are placed into one of four VRI Classes, which represent the relative value of
16 the visual resources. Classes I and II are the most valued; Class III represents a moderate value;
17 and Class IV represents the least value. Class I is reserved for specially designated areas, such as
18 national wildernesses and other congressionally and administratively designated areas where
19 decisions have been made to preserve a natural landscape. Class II is the highest rating for lands
20 without special designation. More information about VRI methodology is presented in
21 Section 5.12 and in *Visual Resource Inventory*, BLM Manual Handbook 8410-1 (BLM 1986a).

22
23 The VRI values for the SEZ are VRI Class III, indicating moderate visual values.
24 Immediately to the west of the SEZ, in the Mormon Mountains, the values are VRI Class II;
25 east of the SEZ, the values are VRI Class IV. The BLM conducted a new VRI for the SEZ and
26 surrounding lands in 2010; however, the VRI was not completed in time for the new data to be
27 included in the draft PEIS. The new VRI data will be incorporated into the analyses presented in
28 the final PEIS.

29
30 The *Proposed Las Vegas Resource Management Plan and Final Environmental Impact*
31 *Statement* (BLM 1998b) indicates that the SEZ is managed as VRM Classes III and IV. VRM
32 Class III objectives include partial retention of landscape character and permit moderate
33 modification of the existing character of the landscape. VRM Class IV permits major
34 modification of the existing character of the landscape. More information about the BLM VRM
35 program is presented in Section 5.12 and in *Visual Resource Management*, BLM Manual
36 Handbook 8400 (BLM 1984).

37 38 39 **11.5.14.2 Impacts**

40
41 The potential for impacts from utility-scale solar energy development on visual resources
42 within the proposed East Mormon Mountain SEZ and surrounding lands, and the impacts of
43 related developments (e.g., access roads and transmission lines) outside of the SEZ, are
44 presented in this section.
45

8

1 Site-specific impact assessment is needed to systematically and thoroughly assess visual
2 impact levels for a particular project. Without precise information about the location of a project,
3 a relatively complete and accurate description of its major components, and their layout, it is not
4 possible to precisely assess the visual impacts associated with the facility. However, if the
5 general nature and location of a facility are known, a more generalized assessment of potential
6 visual impacts can be made by describing the range of expected visual changes and discussing
7 contrasts typically associated with these changes. In addition, a general analysis can identify
8 sensitive resources that may be at risk if a future project is sited in a particular area. Detailed
9 information about the methodology employed for the visual impact assessment used in this
10 PEIS, including assumptions and limitations, is presented in Appendix M.

11
12
13 *Potential Glint and Glare Impacts.* Similarly, the nature and magnitude of potential glint-
14 and glare-related visual impacts for a given solar facility is highly dependent on viewer position,
15 sun angle, the nature of the reflective surface and its orientation relative to the sun and the
16 viewer, atmospheric conditions and other variables. The determination of potential impacts from
17 glint and glare from solar facilities within a given proposed SEZ would require precise
18 knowledge of these variables, and is not possible given the scope of the PEIS. Therefore, the
19 following analysis does not describe or suggest potential contrast levels arising from glint and
20 glare for facilities that might be developed within the SEZ; however, it should be assumed that
21 glint and glare are possible visual impacts from *any* utility-scale solar facility, regardless of size,
22 landscape setting, or technology type. The occurrence of glint and glare at solar facilities could
23 potentially cause large though temporary increases in brightness and visibility of the facilities.
24 The visual contrast levels projected for sensitive visual resource areas discussed in the following
25 analysis do not account for potential glint and glare effects; however, these effects would be
26 incorporated into a future site-and project-specific assessment that would be conducted for
27 specific proposed utility-scale solar energy projects. For more information about potential glint
28 and glare impacts associated with utility-scale solar energy facilities, see Section 5.12 of this
29 PEIS.

30 31 32 ***11.5.14.2.1 Impacts on the Proposed East Mormon Mountain SEZ***

33
34 Some or all of the SEZ could be developed for one or more utility-scale solar energy
35 projects, utilizing one or more of the solar energy technologies described in Appendix F.
36 Because of the industrial nature and large size of utility-scale solar energy facilities large visual
37 impacts on the SEZ would occur as a result of the construction, operation, and decommissioning
38 of solar energy projects. In addition, large impacts could occur at solar facilities utilizing highly
39 reflective surfaces or major light-emitting components (solar dish, parabolic trough, and power
40 tower technologies), with lesser impacts associated with reflective surfaces expected from PV
41 facilities. These impacts would be expected to involve major modification of the existing
42 character of the landscape and would likely dominate the views nearby. Additional, and
43 potentially large impacts would occur as a result of the construction, operation, and
44 decommissioning of related facilities, such as access roads and electric transmission lines. While
45 the primary visual impacts associated with solar energy development within the SEZ would

1 occur during daylight hours, lighting required for utility-scale solar energy facilities would be a
2 potential source of visual impacts at night, both within the SEZ and on surrounding lands.

3
4 Common and technology-specific visual impacts from utility-scale solar energy
5 development, as well as impacts associated with electric transmission lines, are discussed in
6 Section 5.12 of this PEIS. Impacts would last throughout construction, operation, and
7 decommissioning, and some impacts could continue after project decommissioning. Visual
8 impacts resulting from solar energy development in the SEZ would be in addition to impacts
9 from solar energy development and other development that may occur on other public or private
10 lands within the SEZ viewshed, and are subject to cumulative effects. For discussion of
11 cumulative impacts, see Section 11.5.22.4.13.

12
13 The changes described above would be expected to be consistent with BLM VRM
14 objectives for VRM Class IV, as seen from nearby KOPs. More information about impact
15 determination using the BLM VRM program is presented in Section 5.12 and in *Visual Resource*
16 *Contrast Rating*, BLM Manual Handbook 8431-1 (BLM 1986b).

17
18 Implementation of the programmatic design features intended to reduce visual impacts
19 (described in Appendix A, Section A.2.2) would be expected to reduce visual impacts associated
20 with utility-scale solar energy development within the SEZ; however, the degree of effectiveness
21 of these design features could be assessed only at the site- and project-specific level. Given the
22 large scale, reflective surfaces, and strong regular geometry of utility-scale solar energy facilities
23 and the lack of screening vegetation and landforms within the SEZ viewshed, siting the facilities
24 away from sensitive visual resource areas and other sensitive viewing areas would be the primary
25 means of mitigating visual impacts. The effectiveness of other visual impact mitigation measures
26 would generally be limited, but would be important to reduce visual contrasts to the greatest
27 extent possible.

28 29 30 **11.5.14.2.2 Impacts on Lands Surrounding the Proposed East Mormon Mountain SEZ**

31
32 Because of the large size of utility-scale solar energy facilities and the generally flat,
33 open nature of the proposed SEZ, lands outside the SEZ would be subjected to visual impacts
34 related to construction, operation, and decommissioning of utility-scale solar energy facilities.
35 The affected areas and extent of impacts would depend on a number of visibility factors and
36 viewer distance (for a detailed discussion of visibility and related factors, see Section 5.12).
37 A key component in determining impact levels is the intervisibility between the project and
38 potentially affected lands; if topography, vegetation, or structures screen the project from
39 viewer locations, there is no impact.

40
41 Preliminary viewshed analyses were conducted to identify which lands surrounding
42 the proposed SEZ would have views of solar facilities in at least some portion of the SEZ
43 (see Appendix M for information on the assumptions and limitations of the methods used).
44 Four viewshed analyses were conducted, assuming four different heights representative of
45 project elements associated with potential solar energy technologies: PV and parabolic trough
46 arrays (24.6 ft [7.5 m]), solar dishes and power blocks for CSP technologies (38 ft [11.6 m]),

1 transmission towers and short solar power towers (150 ft [45.7 m]), and tall solar power towers
2 (650 ft [198.1 m]). Viewshed maps for the SEZ for all four solar technology heights are
3 presented in Appendix N.
4

5 Figure 11.5.14.2-1 shows the combined results of the viewshed analyses for all four solar
6 technologies. The colored segments indicate areas with clear lines of sight to one or more areas
7 within the SEZ and from which solar facilities within these areas of the SEZ would be expected
8 to be visible, assuming the absence of screening vegetation or structures and adequate lighting
9 and other atmospheric conditions. The light brown areas are locations from which PV and
10 parabolic trough arrays located in the SEZ could be visible. Solar dishes and power blocks for
11 CSP technologies would be visible from the areas shaded in light brown and the additional areas
12 shaded in light purple. Transmission towers and short solar power towers would be visible from
13 the areas shaded light brown, light purple, and the additional areas shaded in dark purple. Power
14 tower facilities located in the SEZ could be visible from areas shaded light brown, light purple,
15 and dark purple, and at least the upper portions of power tower receivers could be visible from
16 the additional areas shaded in medium brown.
17

18 For the following visual impact discussion, the tall solar power tower (650 ft [198.1 m])
19 and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds are shown in the figures and
20 discussed in the text. These heights represent the maximum and minimum landscape visibility
21 for solar energy technologies analyzed in this PEIS. Viewsheds for solar dish and CSP
22 technology power blocks (38 ft [11.6 m]), and for transmission towers and short solar power
23 towers (150 ft [45.7 m]) are presented in Appendix N. The visibility of these facilities would fall
24 between that for tall power towers and PV and parabolic trough arrays.
25
26

27 **Impacts on Selected Federal-, State-, and BLM-Designated Sensitive Visual** 28 **Resource Areas** 29

30 Figure 11.5.14.2-2 shows the results of a GIS analysis that overlays selected federal,
31 state, and BLM-designated sensitive visual resource areas onto the combined tall solar power
32 tower (650 ft [198.1 m]) and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds in order
33 to illustrate which of these sensitive visual resource areas would have views of solar facilities
34 within the SEZ and therefore potentially would be subject to visual impacts from those facilities.
35 Distance zones that correspond with BLM's VRM system-specified foreground-middleground
36 distance (5 mi [8 km]), background distance (15 mi [24 km]), and a 25-mi (40-km) distance zone
37 are shown as well, in order to indicate the effect of distance from the SEZ on impact levels,
38 which are highly dependent on distance.
39

40 The scenic resources included in the analyses were as follows:
41

- 42 • National Parks, National Monuments, National Recreation Areas, National
43 Preserves, National Wildlife Refuges, National Reserves, National
44 Conservation Areas, National Historic Sites;
45
46

FIGURE 11.5.14.2-1 Viewshed Analyses for the Proposed East Mormon Mountain SEZ and Surrounding Lands, Assuming Solar Technology Heights of 24.6 ft (7.5 m), 38 ft (11.6 m), 150 ft (45.7 m), and 650 ft (198.1 m) (shaded areas indicate lands from which solar development within the SEZ could be visible)

- Congressionally authorized Wilderness Areas;
- Wilderness Study Areas;
- National Wild and Scenic Rivers;
- Congressionally authorized Wild and Scenic Study Rivers;
- National Scenic Trails and National Historic Trails;
- National Historic Landmarks and National Natural Landmarks;
- All-American Roads, National Scenic Byways, State Scenic Highways, and BLM- and USFS-designated scenic highways/byways;
- BLM-designated Special Recreation Management Areas; and
- ACECs designated because of outstanding scenic qualities.

Potential impacts on specific sensitive resource areas visible from and within 25 mi (40 km) of the proposed East Mormon Mountain SEZ are discussed below. The results of this analysis are also summarized in Table 11.5.14.2-1. Further discussion of impacts on these areas is presented in Sections 11.5.3 (Specially Designated Areas and Lands with Wilderness Character) and Section 11.5.17 (Cultural Resources).

The following visual impact analysis describes *visual contrast levels* rather than *visual impact levels*. *Visual contrasts* are changes in the landscape as seen by viewers, including changes in the forms, lines, colors, and textures of objects seen in the landscape. A measure of *visual impact* includes potential human reactions to the visual contrasts arising from a development activity, based on viewer characteristics, including attitudes and values, expectations, and other characteristics that are viewer- and situation-specific. Accurate assessment of visual impacts requires knowledge of the potential types and numbers of viewers for a given development and their characteristics and expectations, specific locations from which the project might be viewed, and other variables that were not available or not feasible to incorporate in the PEIS analysis. These variables would be incorporated into a future site- and project-specific assessment that would be conducted for specific proposed utility-scale solar energy projects. For more discussion of visual contrasts and impacts, see Section 5.12.

GOOGLE EARTH™ VISUALIZATIONS

The visual impact analysis discussion in this section utilizes three-dimensional Google Earth™ perspective visualizations of hypothetical solar facilities placed within the SEZ. The visualizations include simplified wireframe models of a hypothetical solar power tower facility. The models were placed at various locations within the SEZ as visual aids for assessing the approximate size and viewing angle of utility-scale solar facilities. The visualizations are intended to show the apparent size, distance, and configuration of the SEZ, as well as the apparent size of a typical utility-scale solar power tower project and its relationship to the surrounding landscape, as viewed from potentially sensitive visual resource areas within the viewshed of the SEZ.

The visualizations are not intended to be realistic simulations of the actual appearance of the landscape or of proposed utility-scale solar energy projects. The placement of models within the SEZ did not reflect any actual planned or proposed projects within the SEZ, and did not take into account engineering or other constraints that would affect the siting or choice of facilities for this particular SEZ. The number of facility models placed in the SEZ does not reflect the 80% development scenario analyzed in the PEIS, but it should be noted that the discussion of expected visual contrast levels does account for the 80% development scenario. A solar power tower was chosen for the models because the unique height characteristics of power tower facilities make their visual impact potential extend beyond other solar technology types.

National Monument

- *Grand Canyon-Parashant*—Grand Canyon-Parashant National Monument occupies 1,045,789 acres (4,232 km²) and is located about 22 mi (35 km) southeast of the SEZ at the point of closest approach. The National Monument is located on the northern edge of the Grand Canyon, and is jointly managed by the National Park Service (NPS) and the BLM. The National Monument is remote and undeveloped, providing opportunities for solitude. There are no paved roads into the monument and no visitor services.

As shown in Figure 11.5.14.2-2, within the National Monument, visibility of solar facilities within the SEZ would be limited to the most northwestern portion of the park. The area with views of the SEZ includes about 447 acres (1.8 km²) in the 650-ft (198.1-m) viewshed, or 0.04% of the total national monument acreage, and 427 acres (1.7 km²), 0.04%, are within the 24.6-ft (7.5-m) viewshed. The visible area of the National Monument is from the point of closest approach, and a small portion extends to beyond 25 mi (40 km) from the southeastern boundary of the SEZ.

Within the 25-mi (40- km) SEZ viewshed, solar development in the SEZ could be visible from a number of small areas of land, the largest of which covers approximately 145 acres (0.6 km²), and the rest are much smaller in size. These areas are located on the peaks and northwest-facing slopes of Virgin Peak Ridge, Lime Kiln Mountain, the Virgin Mountains, and the ridge immediately northwest of Hatchet Valley.

TABLE 11.5.14.2-1 Selected Potentially Affected Sensitive Visual Resources within a 25-mi (40-km) Viewshed of the Proposed East Mormon Mountain SEZ, Assuming a Target Height of 650 ft (198.1 m)

Feature Type	Feature Name (Total Acreage/Highway Length) ^a	Feature Area or Linear Distance ^b		
		Visible within 5 mi	Visible between	
			5 and 15 mi	15 and 25 mi
National Monument	Grand Canyon-Parashant, Arizona (1,045,789 acres)	0 acres	0 acres	447 acres (0.04%)
National Recreation Area	Lake Mead National Recreation Area	0 acres	0 acres	558 acres (0.05%)
National Conservation Area	Beaver Dam Wash, Utah (20,667 acres)	0 acres	329 acres (2%)	11,631 acres (56%)
	Beaver Dam Wash Designated Road Area, Utah (51,373 acres)	0 acres	12,335 acres (24%)	9,565 acres (19%)
WAs	Beaver Dam Mountains, Arizona (18,635 acres)	0 acres	0 acres	2,748 acres (15%)
	Clover Mountains (85,621 acres)	0 acres	0 acres	3,471 acres (4%)
	Meadow Valley Range (123,481 acres)	0 acres	0 acres	1,477 acres (1%)
	Mormon Mountains (157,645 acres)	3,143 acres (2%)	12,166 acres (10%)	0 acres
	Pauite, Arizona (87,908 acres)	0 acres	0 acres	15,359 acres (18%)
National Natural Landmark and ISA	Joshua Tree, Utah (1,047 acres)	0 acres	0 acres	744 acres (71%)
National Historic Trail	Old Spanish	0 mi	0.5 mi	15.1 mi (+2.4 mi high potential)
ACECs	Virgin Mountains (35,826 acres)	0 acres	0 acres	6,257 acres (18%)
Scenic Byways	Gold Butte Backcountry (62 mi)	0 mi	0 mi	1.8 mi

^a To convert acres to km², multiply by 0.004047. To convert mi to km, multiply by 1.609.

^b Percentage of total feature or road length viewable.

1 Because of the very long distance to the SEZ, the SEZ would occupy a small
2 amount of the horizontal field of view, and the vertical angle of view would
3 be very low, which would reduce the visible area of solar facilities within the
4 SEZ, tending to reduce visual contrasts. Figure 11.5.14.2-3 is a Google Earth
5 visualization of the SEZ as seen from a point on the ridge immediately
6 northwest of Hatchet Valley in the far northwestern portion of the National
7 Monument, about 23 mi (37 km) from the southeastern corners of the SEZ.
8 The visualization includes simplified wireframe models of a hypothetical solar
9 power tower facility. The models were placed within the SEZ as a visual aid
10 for assessing the approximate size and viewing angle of utility-scale solar
11 facilities. The receiver towers depicted in the visualization are properly scaled
12 models of a 459-ft (140-m) power tower with an 867-acre (3.5-km²) field of
13 12-ft (3.7-m) heliostats, and the tower/heliostat system represents about
14 100 MW of electric generating capacity. Four power tower models were
15 placed in the SEZ for this and other visualizations shown in this section of this
16 PEIS. In the visualization, the SEZ area is depicted in orange, the heliostat
17 fields in blue.

18
19 The viewpoint in the visualization is about 2,400 ft (730 m) higher in
20 elevation than the SEZ. Despite the elevated viewpoint, collector/reflector
21 arrays for solar facilities within the SEZ would be seen nearly edge-on
22 because of the long distance to the SEZ, and they would repeat the line of the
23 valley floor in which the SEZ is located, tending to reduce visual contrast. The
24 SEZ is viewed along its narrower south to north axis, and is far enough away
25 from the viewpoint that it would occupy a very small portion of the horizontal
26 field of view. Operating power tower receivers within the SEZ would likely
27 appear as distant points of light against the floor of the valley in which the
28 SEZ is located, or against the base of the East Mormon Mountains and/or the
29 Tule Hills. If more than 200 ft (61 m) tall, the power towers could have red or
30 white flashing hazard navigation lighting that would likely be visible from this
31 location at night. Despite the distance, the lighting could be noticeable, given
32 the dark night skies typical of the remote SEZ location.

33
34 Visual contrasts associated with solar facilities within the SEZ would depend
35 on the numbers, types, sizes and locations of solar facilities in the SEZ, and
36 other visibility factors. Depending on project location within the SEZ, the
37 types of solar facilities and their designs, and other visibility factors, weak
38 visual contrasts from solar energy development within the SEZ could be
39 expected at this viewpoint. Weak levels of visual contrast would also be
40 expected for the other areas in the National Monument contained within the
41 SEZ 25-mi (40-km) viewshed.

FIGURE 11.5.14.2-3 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint with blue, at center background only) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Grand Canyon-Parashant National Monument

National Recreation Area

- *Lake Mead National Recreation Area*—Lake Mead NRA contains 1,105,951 acres (4,476 km²) and is located about 24 mi (38 km) south of the SEZ at the point of closest approach. The Lake Mead NRA offers year-round recreational opportunities for boaters, swimmers, and fishermen as well as hikers, wildlife photographers, and roadside sightseers.

As shown in Figure 11.5.14.2-2, within the NRA, visibility of solar facilities within the SEZ would be limited to the most northern portion of the park. The area within the NRA with views of the SEZ includes about 558 acres (2.3 km²) in the 650-ft (198.1-m) viewshed, or 0.05% of the total NRA acreage. None of the NRA is within the 24.6-ft (7.5-m) viewshed. The visible area of the NRA extends from the point of closest approach to beyond 25 mi (40 km) from the southern boundary of the SEZ.

The viewshed analysis indicates that the upper portions of tall power towers located within the SEZ could be visible from the farthest northern sections of the Lake Mead NRA, on and along the Virgin River; however, the river valley is about 1,500 ft (460 m) lower in elevation than the SEZ, and at nearly 24 mi (38 km), the angle of view would be extremely low. If power towers were visible within the SEZ, at most they could span only a very small amount of the horizontal field of view. Furthermore, much of the river valley is heavily vegetated, and some views toward the SEZ are likely screened by vegetation. If visible at all, operating power towers in the SEZ would be seen as distant points of light on the northern horizon. If more than 200 ft (61 m) tall, power towers would have navigation warning lights that could potentially be visible from the NRA at night. Under the 80% development scenario analyzed in the PEIS, visual contrast levels from solar energy development within the SEZ would be expected to be minimal for viewpoints within the Lake Mead NRA.

National Conservation Area

- *Beaver Dam Wash*—The Beaver Dam Wash National Conservation Area (NCA) was designated by Congress through the Omnibus Public Land Management Act of 2009. It is located in southwestern Utah, along the Nevada and Arizona state lines, and is 9.2 mi (14.8 km) from the SEZ at the point of closest approach. The NCA is within an ecological transition zone between the Mojave Desert and the Great Basin. At this time, there are no developed recreational facilities within the NCA.

The NCA contains 20,667 acres (83.6 km²), with an additional 51,373 acres (208 km²) as designated road area. Portions of the Beaver Dam Wash NCA within the 650-ft (198.1-m) viewshed for the East Mormon Mountain SEZ include approximately 11,960 acres (48.4 km²), or 58% of the total NCA

acres. Portions of the NCA within the 24.6-ft (7.5-m) viewshed encompass about 10,212 acres (41.3 km²), or 49% of the total NCA acreage. Portions of the Beaver Dam Wash NCA designated road area within the 650-ft (198.1-m) viewshed for the East Mormon Mountain SEZ include approximately 21,900 acres (88.6 km²), or 43% of the total NCA acreage. Portions of the NCA designated road area within the 24.6-ft (7.5-m) viewshed encompass about 10,845 acres (43.9 km²), or 21% of the total NCA acreage. The visible area of the NCA extends from the point of closest approach to about 22 mi (35 km) east of the SEZ.

The NCA consists of low-elevation lands in and along Beaver Dam Wash and on the bajada of the Beaver Dam Mountains on the western side of the NCA, and higher-elevation lands in the Beaver Dam Mountains on the eastern side of the NCA. Near Beaver Dam Wash, elevations are similar to or a few hundred feet lower than the SEZ, so the vertical angles of view are very low, and many views are partially or completely screened by intervening topography. In the Beaver Dam Mountains within the NCA, viewpoints are up to 2,300 ft (700 m) or more higher in elevation than the SEZ, with more open views, and slightly higher vertical angles of view, though farther from the SEZ.

Figure 11.5.14.2-4 is a Google Earth visualization of the SEZ as seen from a road on the Beaver Dam Mountains bajada in the western portion of the NCA, on the boundary between the designated road area and the rest of the NCA, about 15 mi (24 km) east–northeast of the SEZ. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 750 ft (240 m) higher in elevation than the SEZ. Because of the long distance to the SEZ, the SEZ would be seen at a very low angle, and solar facilities within the SEZ would be seen in a thin band at the base of the East Mormon and Mormon Mountains. The northern portion of the SEZ would be partially screened by the intervening Tule Hills. Where visible, the collector/reflector arrays of solar facilities within the SEZ would appear edge-on, which would reduce their apparent size, conceal their strong regular geometry, and cause them to appear to repeat the line of the valley floor in which the SEZ is located, all of which would tend to reduce visual contrast. The SEZ is far enough away from the viewpoint that it would occupy a very small portion of the horizontal field of view, especially given the partial screening by the Tule Hills. Taller ancillary facilities, such as buildings, transmission structures, and cooling towers, and plumes (if present), could be visible projecting above the collector/reflector arrays, but depending on visibility factors might not be noticed by casual observers.

At a distance of 15 mi (32 km) or more, operating power tower receivers within the SEZ would likely appear as points of light against the backdrop of the East Mormon and Mormon Mountains. If sufficiently tall, the power

FIGURE 11.5.14.2-4 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint on a Road in the Beaver Dam Wash NCA

towers could have red or white flashing hazard navigation lighting that would likely be visible from this location at night. Despite the distance, the lighting could be noticeable, given the dark night skies typical of the remote SEZ location.

Given the very low angle of view to the SEZ, the relatively long distance to the SEZ, and partial screening of solar facilities within the SEZ, weak visual contrasts from solar energy development within the SEZ could be expected at this viewpoint.

Figure 11.5.14.2-5 is a Google Earth visualization of the SEZ as seen from an unnamed peak in the eastern portion of the NCA, about 19 mi (31 km) east of the SEZ. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 2,400 ft (730 m) higher in elevation than the SEZ, with a slightly elevated and open view of all but the most northern portion of the SEZ. Because of the long distance to the SEZ, the SEZ would be seen at a very low angle, and solar facilities within the SEZ would be seen in a thin band at the base of the East Mormon and Mormon Mountains. The collector/reflector arrays of solar facilities within the SEZ would appear almost edge-on, which would reduce their apparent size, conceal their strong regular geometry, and cause them to appear to repeat the line of the valley floor in which the SEZ is located, all of which would tend to reduce visual contrast. The SEZ is far enough away from the viewpoint that it would occupy a small portion of the horizontal field of view.

At a distance of 19 mi (31 km) or more, operating power tower receivers within the SEZ would likely appear as distant points of light against the floor of the valley in which the SEZ is located. If sufficiently tall, the power towers could have red or white flashing hazard navigation lighting that would likely be visible from this location at night. Despite the distance, the lighting could be noticeable, given the dark night skies typical of the remote SEZ location.

Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, weak visual contrasts from solar energy development within the SEZ could be expected at this viewpoint. In general, under the 80% development scenario analyzed in this PEIS, given the long distance to the SEZ, weak visual contrasts from solar energy development within the SEZ could be expected for viewpoints in the NCA located within the SEZ 25-mi (40-km) viewshed.

FIGURE 11.5.14.2-5 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Beaver Dam Mountains in Beaver Dam Wash NCA

Wilderness Areas

- *Beaver Dam Mountains*—Beaver Dam Mountains is a 18,635-acre (75.4-km²) congressionally designated WA located in Arizona, 19 mi (31 km) east of the SEZ. The WA is an increasingly popular destination for primitive recreation. There are no maintained or developed trails within the WA.

As shown in Figure 11.5.14.2-2, within 25 mi (40 km) of the SEZ, solar energy facilities within the SEZ could be visible from the western portions of the WA (about 2,748 acres [11.1 km²] in the 650-ft [198.1-m] viewshed, or 15% of the total WA acreage, and 2,539 acres [10.3 km²] in the 25-ft [7.5-m] viewshed, or 14% of the total WA acreage). The visible area of the WA extends from the point of closest approach to a small portion beyond 25 mi (40 km) from the eastern boundary of the SEZ.

Within the WA, many peaks and west-facing slopes within the Beaver Dam Mountains would have open views of the proposed SEZ. Figure 11.5.14.2-6 is a Google Earth visualization of the SEZ as seen from an unnamed peak in the western portion of the WA, about 20 mi (32 km) east of the SEZ. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 800 ft (240 m) higher in elevation than the SEZ. Because of the long distance to the SEZ, the SEZ would be seen at a very low angle, and solar facilities within the SEZ would be seen in a thin band at the base of the East Mormon and Mormon Mountains. The collector/reflector arrays of solar facilities within the SEZ would appear edge-on, which would reduce their apparent size, conceal their strong regular geometry, and cause them to appear to repeat the line of the valley floor in which the SEZ is located, all of which would tend to reduce visual contrast. The SEZ is far enough away from the viewpoint that it would occupy a small portion of the horizontal field of view.

At a distance of 20 mi (32 km) or more, operating power tower receivers within the SEZ would likely appear as distant points of light against the floor of the valley in which the SEZ is located. If sufficiently tall, the power towers could have red or white flashing hazard navigation lighting that would likely be visible from this location at night. Despite the distance, the lighting could be noticeable, given the dark night skies typical of the remote SEZ location.

Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, weak visual contrasts from solar energy development within the SEZ could be expected at this viewpoint. In general, under the 80% development scenario analyzed in the PEIS, given the long distance to the SEZ, weak visual contrasts from solar energy development within the SEZ could be expected for viewpoints in the WA located within the SEZ 25-mi (40-km) viewshed.

FIGURE 11.5.14.2-6 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Beaver Dam Mountains WA

- *Clover Mountains*—Clover Mountains is a 85,621-acre (346.5-km²) congressionally designated WA located 19 mi (31 km) north to northwest of the SEZ at the point of closest approach. Opportunities for hiking, camping, climbing, and rock scrambling, as well as horseback riding within the WA are outstanding due to the variety of scenic topography.

As shown in Figure 11.5.14.2-2, within 25 mi (40 km), solar energy facilities within the SEZ could be visible from scattered areas in the southern portion of the WA. Visible areas of the WA within the 25-mi (40-km) radius of analysis total about 3,471 acres (14.1 km²) in the 650-ft (198.1-m) viewshed, or 4% of the total WA acreage, and 2,396 acres (9.7 km²), or 3% of the total WA acreage, are visible within the 24.6-ft (7.5-m) viewshed. The visible area of the WA extends from the point of closest approach to beyond 25 mi (40 km) from the northern boundary of the SEZ.

Except for the highest elevations in the Clover Mountains, solar facilities within the SEZ would be viewed through narrow gaps in the Tule Hills and would be largely screened from view. In some areas, only the upper portions of tall power towers could be visible, while in a few areas, the upper portions of transmission towers and other taller solar facilities might be seen. Because of the screening, only a very small portion of the SEZ would be visible from these areas; at the long distance to the SEZ, expected visual contrasts would be minimal to weak.

At higher elevations in the Clover Mountains within the SEZ 25-mi (40-km) viewshed, more of the SEZ would be visible, though much of it would still be screened by the Tule Hills. Figure 11.5.14.2-7 is a Google Earth visualization of the SEZ as seen from an unnamed peak in the southern portion of the WA, about 23 mi (37 km) from the northwest corner of the SEZ. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 4,300 ft (1,300 m) higher in elevation than the SEZ. The mountain top is pinyon-juniper forest, which could partially screen views from this location and other nearby viewpoints. Where visible, solar facilities within the SEZ would be seen just above the Tule Hills. Because of the elevated viewpoint, the tops of collector/reflector arrays of solar facilities within the SEZ would be visible, but because of the very long distance to the SEZ, the facilities would be seen at a very low angle, which would reduce their apparent size and cause them to appear to repeat the line of the valley floor in which the SEZ is located, tending to reduce visual contrast. The SEZ is far enough away from the viewpoint that it would occupy a very small portion of the horizontal field of view, particularly in view of the partial screening of the SEZ by the Tule Hills.

FIGURE 11.5.14.2-7 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint with blue) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Clover Mountains WA

At a distance of 23 mi (37 km) or more, operating power tower receivers within the SEZ would likely appear as distant points of light against the floor of the valley in which the SEZ is located. If sufficiently tall, the power towers could have red or white flashing hazard navigation lighting that would likely be visible from this location at night. Despite the distance, the lighting could be noticeable, given the dark night skies typical of the remote SEZ location.

Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, weak visual contrasts from solar energy development within the SEZ could be expected at this viewpoint. In general, under the 80% development scenario analyzed in this PEIS, given the partial screening of solar facilities within the SEZ and the long distance to the SEZ, weak visual contrasts from solar energy development within the SEZ could be expected for viewpoints in the WA located within the SEZ 25-mi (40-km) viewshed.

- *Meadow Valley Range*—Meadow Valley Range is a 123,481-acre (499.7-km²) congressionally designated WA located 17 mi (27 km) west to northwest of the SEZ at the point of closest approach. The long ridgeline offers many peaks, narrow canyons and passes to explore.

As shown in Figure 11.5.14.2-2, within 25 mi (40 km), solar energy facilities within the SEZ could be visible from scattered areas in the far northern portion of the WA, on the southeast-facing slopes of the Meadow Valley Range. Visible areas of the WA within the 25-mi (40-km) radius of analysis total about 1,477 acres (6.0 km²) in the 650-ft (198.1-m) viewshed, or 1% of the total WA acreage, and 91 acres (0.37 km²), or 0.07%, are visible in the 24.6-ft (7.5-m) viewshed. The visible area of the WA extends from 23 mi (37 km) northwest of the SEZ, to just within 25 mi (40 km) from the northwestern boundary of the SEZ.

Views of solar facilities within the SEZ would largely be screened by intervening mountains. In more than 93% of the area within the SEZ 25-mi (40-km) viewshed in the WA, views of low-height solar facilities such as parabolic trough and PV arrays, would be screened from view. In most of these areas, only the upper portions of tall power towers could be visible, although the upper portions of transmission towers and other taller solar facilities might be seen in a few areas. In 12 very small areas totaling 91 acres (0.37 km²), low-height solar facilities within the SEZ could be visible, but even at these locations, most of the SEZ is screened from view by the Mormon Mountains and East Mormon Mountains, and as a result, the SEZ would occupy a very small portion of the horizontal field of view.

Despite the elevated viewpoints in the WA, because of the long distance to the SEZ, collector/reflector arrays for solar facilities within the SEZ would be seen nearly edge on, which would reduce their apparent size, and would also

1 cause them to appear to repeat the line of the valley floor in which the SEZ is
2 located, tending to reduce visual contrast. At more than 17 mi (27 km) away,
3 operating power tower receivers within the SEZ would likely appear as distant
4 points of light against the floor of the valley in which the SEZ is located, or
5 against the base of the Virgin Mountains. If sufficiently tall, the power towers
6 could have red or white flashing hazard navigation lighting that would likely
7 be visible from this location at night. Despite the distance, the lighting could
8 be noticeable, given the dark night skies typical of the remote SEZ location.
9

10 Given the partial screening of solar facilities within the SEZ and the long
11 distance to the SEZ, weak visual contrasts from solar energy development
12 within the SEZ could be expected for viewpoints in the WA located within the
13 SEZ 25-mi (40-km) viewshed.
14

- 15 • *Mormon Mountains*—Mormon Mountains is a 157,645-acre (638.0-km²)
16 congressionally designated WA located 2.4 mi (3.9 km) west of the SEZ at
17 the point of closest approach. The rocky cliffs, narrow drainages, and rolling
18 bajadas provide numerous opportunities for solitude in the Mormon
19 Mountains WA. Recreational opportunities include camping, hiking,
20 backpacking, hunting, and horseback riding.
21

22 As shown in Figure 11.5.14.2-2, visible areas of the WA within the 25-mi
23 (40-km) radius of analysis total about 15,304 acres (61.9 km²) in the 650-ft
24 (198.1-m) viewshed, or 10% of the total WA acreage, and 7,803 acres
25 (31.6 km²) in the 24.6-ft (7.5-m) viewshed, or 5% of the total WA acreage.
26 The visible area of the WA extends from 3.1 mi (5.0 km) to 11 mi (18 km)
27 west of the SEZ's western boundary.
28

29 Solar facilities within the SEZ could be visible from the summits and east-
30 facing slopes of some of the mountains in the eastern part of the WA, at
31 distances from about 3 to 11 mi (5 to 18 km) west of the SEZ's western
32 boundary. From many locations within the WA, views of solar facilities
33 within the SEZ would be largely screened by the intervening East Mormon
34 Mountains, or limited to views of taller solar facilities, or both, but there is a
35 substantial portion of the WA with open or nearly open views of the SEZ.
36 These views are generally through two gaps in the East Mormon Mountains,
37 one directly west of the central portion of the SEZ, and another northwest of
38 the northwest corner of the SEZ.
39

40 Figure 11.5.14.2-8 is a Google Earth visualization of the SEZ as seen through
41 the gap west of the SEZ from a low-elevation viewpoint in the eastern portion
42 of the WA, about 3.9 mi (6.2 km) from the western boundary of the SEZ
43 where visible through the gap. In the visualization, the SEZ area is depicted in
44 orange, the heliostat fields in blue.
45

FIGURE 11.5.14.2-8 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in blue) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Low-Elevation Viewpoint in Mormon Mountain WA

1 The viewpoint in the visualization is about 800 ft (240 m) higher in elevation
2 than the SEZ. Solar facilities within the SEZ could be visible through the gap
3 in the East Mormon Mountains, but most of the SEZ would be completely
4 screened from view. Where visible through the gap, collector/reflector arrays
5 of solar facilities within the SEZ would be seen at a very low angle, which
6 would reduce their apparent size, and would also cause them to appear to
7 repeat the line of the valley floor in which the SEZ is located, tending to
8 reduce visual contrast. However, at 3.9 mi (6.2 km) from the SEZ, if ancillary
9 facilities such as buildings, transmission structures, cooling towers, and
10 plumes (if present) were visible through the gap, they would project above the
11 collector arrays and could create strong visual contrasts with the surrounding
12 landscape in form, line, and color. Furthermore, the view of the SEZ would be
13 “framed” by the gap, which would tend to focus views on the solar facilities
14 within the SEZ, highlighting the contrasts. If operating power towers were
15 visible through the gap, the receivers could appear as brilliant white non-point
16 light sources atop discernable tower structures, viewed against the backdrop
17 of the Virgin Mountains east of the SEZ. They would command visual
18 attention, particularly because of the framed view through the gap. If
19 sufficiently tall, the power towers could have red or white flashing hazard
20 navigation lighting that would likely be conspicuous from this location at
21 night; they would command visual attention, especially given the dark night
22 skies typical of the remote SEZ location. Other lighting associated with solar
23 facilities in the SEZ would likely be visible as well.

24
25 Depending on project location within the SEZ, the types of solar facilities and
26 their designs, and other visibility factors, moderate visual contrasts from solar
27 energy development within the SEZ could occur at this viewpoint despite the
28 screening by the East Mormon Mountains if one or more power towers were
29 visible through the gap in the East Mormon Mountains.

30
31 Figure 11.5.14.2-9 is a Google Earth visualization of the SEZ as seen from an
32 unnamed peak in the eastern portion of the WA, about 5.6 mi (9.1 km) from
33 the western boundary of the SEZ. In the visualization, the SEZ area is
34 depicted in orange, the heliostat fields in blue.

35
36 The viewpoint in the visualization is about 2,500 ft (760 m) higher in
37 elevation than the SEZ. Solar facilities within the SEZ could be visible
38 through and over the gap in the East Mormon Mountains, and only the
39 southern part of the SEZ would be completely screened from view. From this
40 viewpoint, the SEZ would occupy much of the horizontal field of view. Where
41 visible through and over the gap, collector/reflector arrays of solar facilities
42 within the SEZ would be seen at a relatively high vertical angle, so that the
43 tops of the arrays would be visible, which would make their large areal extent
44 and strong regular geometry more apparent, tending to increase visual
45 contrast. At 5.6 mi (9.1 km) from the SEZ, ancillary facilities such as
46 buildings, transmission structures, cooling towers, and plumes (if present)

FIGURE 11.5.14.2-9 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from High-Elevation Viewpoint in Mormon Mountain WA

would be visible, and could create strong visual contrasts in form, line, and color with the surrounding landscape, and the strongly horizontal collector/reflector arrays. If operating power towers were visible through the gap, the receivers could appear as very bright non-point light sources atop discernable tower structures, viewed against the backdrop of the valley floor in which the SEZ is located. They would likely strongly command visual attention. If sufficiently tall, the power towers could have red or white flashing hazard navigation lighting that would likely be conspicuous from this location at night; they would command visual attention, especially given the dark night skies typical of the remote SEZ location. Other lighting associated with solar facilities in the SEZ would likely be visible as well.

Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, under the 80% development scenario analyzed in this PEIS, strong visual contrasts from solar energy development within the SEZ could occur at this viewpoint.

In general, visual contrast levels from solar facilities within the SEZ as seen from viewpoints within the WA would be highly dependent on viewpoint elevation. For low-elevation viewpoints, partial screening and low-angle views would tend to cause weak levels of visual contrast, except where clear views of power towers or highly reflective surfaces were visible through gaps in the East Mormon Mountains; where these views occurred, contrasts could rise to moderate levels. Higher elevation viewpoints on some peaks and high ridges within the WA have clearer views of the SEZ and from higher viewing angles, which would be expected to result in moderate to strong visual contrast levels.

- *Pauite*—Pauite is a 87,908-acre (355.8 km²) congressionally designated WA located in Arizona, 19 mi (30 km) southeast of the SEZ at the point of closest approach. Mt. Bangs, the highest peak at 8,012 ft (2,442 m), provides a commanding view of the Basin and Range province to the west and the Colorado Plateau to the east (BLM 1990).

As shown in Figure 11.5.14.2-2, visible areas of the WA within the 25-mi (40-km) radius of analysis total about 15,359 acres (62.2 km²) in the 650-ft (198.1-m) viewshed, or 18% of the total WA acreage, and 15,087 acres (61.1 km²) in the 24.6-ft (7.5-m) viewshed, or 17% of the total WA acreage. The visible area of the WA extends from the point of closest approach to beyond 25 mi (40 km) of the SEZ's eastern boundary.

Within the WA, many peaks and west- and northwest-facing slopes within the Virgin Mountains would have open views of the proposed SEZ. Figure 11.5.14.2-10 is a Google Earth visualization of the SEZ as seen from an unnamed peak in the northern portion of the WA, just east of Hedrick's Canyon, and about 22 mi (35 km) east-southeast of the SEZ.

FIGURE 11.5.14.2-10 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Paiute WA

1 In the visualization, the SEZ area is depicted in orange, the heliostat fields
2 in blue.

3
4 The viewpoint in the visualization is about 3,800 ft (1,200 m) higher in
5 elevation than the SEZ. Because of the long distance to the SEZ, the SEZ
6 would be seen at a very low angle, and solar facilities within the SEZ would
7 be seen in a thin band at the base of the East Mormon and Mormon
8 Mountains. The collector/reflector arrays of solar facilities within the SEZ
9 would appear nearly edge-on, which would reduce their apparent size, conceal
10 their strong regular geometry, and would also cause them to appear to repeat
11 the line of the valley floor in which the SEZ is located, tending to reduce
12 visual contrast. The SEZ is far enough away from the viewpoint that it would
13 occupy a small portion of the horizontal field of view.

14
15 At a distance of 22 mi (35 km), operating power tower receivers within the
16 SEZ would likely appear as distant points of light against the floor of the
17 valley in which the SEZ is located. If sufficiently tall, the power towers could
18 have red or white flashing hazard navigation lighting that would likely be
19 visible from this location at night. Despite the distance, the lighting could be
20 noticeable, given the dark night skies typical of the remote SEZ location.

21
22 Depending on project location within the SEZ, the types of solar facilities and
23 their designs, and other visibility factors, weak visual contrasts from solar
24 energy development within the SEZ could be expected at this viewpoint.
25 There are higher elevation viewpoints within the WA that would have higher-
26 angle views of solar facilities within the SEZ, and lower elevation viewpoints
27 that are slightly closer to the SEZ, but in general, because of the long distance
28 to the SEZ, under the 80% development scenario analyzed in this PEIS, weak
29 visual contrasts from solar energy development within the SEZ could be
30 expected for viewpoints in the WA located within the SEZ 25-mi (40-km)
31 viewshed.

32 33 34 ***Instant Study Area***

- 35
36 • *Joshua Tree ISA*—Joshua Tree is a 1,047-acre (4.2-km²) congressionally
37 designated ISA located 19 mi (31 km) east of the SEZ at the point of closest
38 approach, on the upper slopes of the Beaver Dam Mountains.

39
40 As shown in Figure 11.5.14.2-2, visible areas of the ISA within the 25-mi
41 (40-km) radius of analysis total about 744 acres (3.0 km²) in the 650-ft
42 (198.1-m) viewshed, or 71% of the total ISA acreage, and 715 acres (2.9 km²)
43 in the 24.6-ft (7.5-m) viewshed, or 68% of the total ISA acreage. The visible
44 area of the ISA extends about 21 mi (33 km) from the northeastern boundary
45 of the SEZ.

1 Much of the ISA would have open views of the distant SEZ, but despite
2 elevations more than 2,800 ft (850 m) higher than the SEZ in some locations,
3 because of the long distance to the SEZ the vertical angle of view is low, and
4 the SEZ would occupy only a small portion of the horizontal field of view.

5
6 At a distance of 19 mi (31 km) or more, operating power tower receivers
7 within the SEZ would likely appear as distant points of light against the floor
8 of the valley in which the SEZ is located. If sufficiently tall, the power towers
9 could have red or white flashing hazard navigation lighting that would likely
10 be visible from this location at night. Despite the distance, the lighting could
11 be noticeable, given the dark night skies typical of the remote SEZ location.

12
13 In general, visual contrasts associated with solar facilities within the SEZ would depend on
14 viewer location, the numbers, types, sizes and locations of solar facilities in the SEZ, and other
15 project- and site-specific factors. Under the 80% development scenario analyzed in the PEIS,
16 where there were unobstructed views, contrasts would be expected to be weak.

17 18 19 ***National Historic Trail***

- 20
21 • *Old Spanish National Historic Trail*—The Old Spanish National Historic
22 Trail is a congressionally designated multi-state historic trail that passes
23 within 12 mi (19 km) of the SEZ at the point of closest approach on the east
24 side of the SEZ. A high potential segment of the trail is located about 18 mi
25 (29 km) south of the SEZ. Nearly 18 mi (29 km) of the trail are within the
26 viewshed to the south and east of the SEZ, including 2.4 mi (3.9 km) of the
27 high-potential segment.

28
29 For about 13 mi (21 km) of the trail within the SEZ 25-mi (40 km) viewshed,
30 including the entirety of the high-potential segment, visibility of solar
31 facilities within the SEZ would be limited to the upper portions of taller power
32 towers. Low-height facility components, such as parabolic trough arrays,
33 heliostats, and PV panels would be potentially visible from about 5 mi (8 km)
34 of the trail, but this section of the trail ranges from about 17 to 22 mi (27 to
35 35 km) from the SEZ, so the views would be from relatively long distances.

36
37 Solar facilities within the SEZ could be visible from the trail in a number of
38 places. The largest segment with visibility is a 12-mi (19-km) stretch closely
39 paralleling U.S. 91 in a north–south direction between 16 and 19 mi (26 and
40 31 km) east of the SEZ, after the trail leaves the Virgin Valley and before it
41 enters the Beaver Dam Mountains. Within the southernmost 7 mi (11 km) of
42 this trail segment, visibility would be limited to the upper portions of
43 sufficiently tall power towers within the SEZ, and expected visual contrast
44 levels in this portion of the segment would be minimal. The northern 5 mi
45 (8 km) of the segment would have more or less open views of the SEZ, but at
46 distances exceeding 16 mi (26 km), the SEZ would occupy a very small

1 portion of the horizontal field of view, and the vertical angle of view would be
2 very low. Figure 11.5.14.2-11 is a Google Earth visualization of the SEZ as
3 seen from a point on the trail along U.S. 91 on the bajada of the Beaver Dam
4 Mountains about 18 mi (29 km) east-northeast of the SEZ. In the
5 visualization, the SEZ area is depicted in orange, the heliostat fields in blue.
6

7 The viewpoint in the visualization is about 560 ft (170 m) higher in elevation
8 than the SEZ. Because of the long distance to the SEZ, the SEZ would be seen
9 at a very low angle, and solar facilities within the SEZ would be seen in a very
10 thin band at the base of the East Mormon and Mormon Mountains. The
11 collector/reflector arrays of solar facilities within the SEZ would appear edge-
12 on, which would greatly reduce their apparent size, conceal their strong
13 regular geometry, and would also cause them to appear to repeat the line of
14 the valley floor in which the SEZ is located, tending to reduce visual contrast.
15 The SEZ is far enough away from the viewpoint that it would occupy a small
16 portion of the horizontal field of view.
17

18 At a distance of 18 mi (29 km), operating power tower receivers within the
19 SEZ would likely appear as distant points of light against the backdrop of the
20 East Mormon and Mormon Mountains. If sufficiently tall, the power towers
21 could have red or white flashing hazard navigation lighting that would likely
22 be visible from this location at night. Despite the distance, the lighting could
23 be noticeable, given the dark night skies typical of the remote SEZ location.
24 Depending on project location within the SEZ, the types of solar facilities and
25 their designs, and other visibility factors, weak visual contrasts from solar
26 energy development within the SEZ could be expected at this viewpoint.
27

28 North of this viewpoint on the trail, viewpoint elevations would be slightly
29 higher, but the viewpoints are farther from the SEZ, and in addition, the trail
30 enters a canyon, the walls of which would screen portions of the SEZ from
31 view. Expected visual contrast levels from solar facilities within the SEZ
32 would not be expected to increase.
33

34 South of this viewpoint on the trail, the elevation drops, and views of the SEZ
35 are gradually screened by terrain east of Beaver Dam Wash, resulting in lower
36 visual contrast levels. East of Beaver Dam Wash, the trail elevation drops to
37 900 to 1,300 ft (280 to 400 m) lower in elevation than the SEZ, greatly
38 limiting visibility of solar facilities in the SEZ and causing the angle of view
39 to be extremely low. Only the upper portions of tall power towers could
40 potentially be visible as distant points of light on the northern horizon. For the
41 13 mi of the trail within the viewshed where visibility is thus limited, and
42 including the high-potential segment of the trail, the expected visual contrast
43 levels would be minimal. In general, under the 80% development scenario
44 analyzed in this PEIS, minimal to weak visual contrasts would be expected for
45 viewpoints on the Old Spanish National Historic Trail within the SEZ 25-mi
46 (40-km) viewshed.

FIGURE 11.5.14.2-11 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint on Old Spanish National Historic Trail

National Natural Landmark

- *Joshua Tree*—Joshua Tree NNL is about 20 mi (33 km) east of the SEZ, on the upper slopes of the Beaver Dam Mountains. The NNL is located within the Joshua Tree ISA (see analysis above), and where the SEZ is visible within the NNL, expected visual contrasts would be the same as expected for the ISA. Some portions of the NNL may have open views of the distant SEZ, but despite elevations more than 2,800 ft (853 m) higher than the SEZ in some locations, the vertical angle of view is low because of the long distance to the SEZ, and the SEZ would occupy only a small portion of the horizontal field of view. Weak contrast levels would be expected from solar facilities within the SEZ as viewed from the NNL.

Scenic Byway

- *Gold Butte Backcountry Byway*—The Gold Butte Backcountry Byway is a BLM-designated scenic byway that begins approximately 14 mi (23 km) south of the SEZ. As shown in Figure 11.5.14.2-2, approximately 1.8 mi (2.9 km) are within the 650-ft (198.1-m) viewshed of the SEZ, and 0.2 mi (0.3 km) of the byway are within the 24.6-ft (7.5-m) viewshed.

As the Gold Butte Backcountry Byway traverses the lower slopes of the Virgin Mountains near the Virgin River, there are four short stretches of road where solar facilities within the SEZ could be visible. The longest stretch of the byway with visibility is 1.1 mi (1.7 km) long; in this stretch, visibility would be limited to the upper portions of power towers in the SEZ. If visible, operating power towers would likely appear as points of light against the backdrop of the Tule Hills. Total visibility would not last more than a few minutes, and because the viewpoint is nearly 1,000 ft (304 m) lower in elevation than the SEZ, the angle of view would be extremely low, and the lights would not likely be noticed by the casual viewer. Under the 80% development scenario analyzed in the PEIS, visual contrast levels from solar energy development within the SEZ would be expected to be minimal for viewpoints on the Gold Butte Backcountry Byway.

ACEC Designated because of Outstanding Scenic Qualities

- *Virgin Mountains*—The 35,826-acre (145.0-km²) Virgin Mountains ACEC is located 19 mi (31 km) southeast of the SEZ at the closest point of approach. The resource values under protection within the Virgin Mountains ACEC include wildlife habitat, scenic, and botanical values (BLM 1998a).

As shown in Figure 11.5.14.2-2, approximately 6,257 acres (25.32 km²), or 18% of the ACEC, is within the 650-ft (198.1-m) viewshed of the SEZ, and

6,082 acres (24.6 km²) is in the 24.6-ft (7.5-m) viewshed, or 17% of the total ACEC acreage. The visible area of the ACEC extends from the point of closest approach to approximately 24 mi (39 km) from the southeastern boundary of the SEZ.

Figure 11.5.14.2-12 is a Google Earth visualization of the SEZ as seen from an unnamed ridge in the far northern portion of the ACEC, about 19 mi (31 km) from the southeast corner of the SEZ. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 1,300 ft (400 m) higher in elevation than the SEZ. Solar facilities within the SEZ would be seen just below the Tule Hills. Despite the elevated viewpoint, because of the long distance to the SEZ, collector/reflector arrays for solar facilities within the SEZ would be seen nearly edge on, which would reduce their apparent size, and would also cause them to appear to repeat the line of the valley floor in which the SEZ is located, tending to reduce visual contrast. The SEZ is far enough away from the viewpoint that it would occupy a small portion of the horizontal field of view. Operating power tower receivers within the SEZ would likely appear as distant points of light against the floor of the valley in which the SEZ is located, or against the base of the Tule Hills. If sufficiently tall, the power towers could have red or white flashing hazard navigation lighting that would likely be visible from this location at night. Despite the distance, the lighting could be noticeable, given the dark night skies typical of the remote SEZ location.

Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, weak visual contrasts from solar energy development within the SEZ could be expected at this viewpoint. Farther south from this viewpoint within the ACEC, the elevation rises rapidly, so that views of the SEZ would be elevated, which would tend to increase visual contrasts from solar facilities within the SEZ; however, the potentially increased contrast from increased viewing angle is offset by the increased distance to the SEZ, such that expected contrasts would not rise above weak levels for the higher elevation viewpoints. In general, under the 80% development scenario analyzed in this PEIS, weak levels of visual contrast would also be expected for viewpoints in the ACEC located within the SEZ 25-mi (40-km) viewshed.

Additional scenic resources exist at the national, state, and local levels, and impacts may occur on both federal and nonfederal lands, including sensitive traditional cultural properties important to Tribes. Note that in addition to the resource types and specific resources analyzed in this PEIS, future site-specific NEPA analyses would include state and local parks, recreation areas, other sensitive visual resources, and communities close enough to the proposed project to be affected by visual impacts. Selected other lands and resources are included in the discussion below.

FIGURE 11.5.14.2-12 Google Earth Visualization of the Proposed East Mormon Mountain SEZ (shown in orange tint with blue, at center background only) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Viewpoint in Virgin Mountains ACEC

1 In addition to impacts associated with the solar energy facilities themselves, sensitive
2 visual resources could be affected by facilities that would be built and operated in conjunction
3 with the solar facilities. With respect to visual impacts, the most important associated facilities
4 would be access roads and transmission lines, the precise location of which cannot be determined
5 until a specific solar energy project is proposed. There is currently a 500-kV transmission line
6 adjacent to the proposed SEZ, so construction and operation of a transmission line outside the
7 proposed SEZ would not be required; however, transmission lines to connect facilities to the
8 existing line would be required. For this analysis, the impacts of construction and operation of
9 transmission lines outside of the SEZ were not assessed, assuming that the existing 500-kV
10 transmission line might be used to connect some new solar facilities to load centers, and that
11 additional project-specific analysis would be done for new transmission construction or line
12 upgrades. Note that depending on project- and site-specific conditions, visual impacts associated
13 with access roads, and particularly transmission lines, could be large. Detailed information about
14 visual impacts associated with transmission lines is presented in Section 5.7.1. A detailed site-
15 specific NEPA analysis would be required to determine visibility and associated impacts
16 precisely for any future solar projects, based on more precise knowledge of facility location and
17 characteristics.

20 **Impacts on Selected Other Lands and Resources**

23 **I-15.** About 4 mi (6.4 km) of I-15 are within the SEZ viewshed in two segments. One
24 segment a little more than 1 mi (1.6 km) long is located about 11 mi (18 km) south of the SEZ.
25 Visibility of solar facilities within the SEZ in this segment would be limited to the upper portions
26 of tall power towers; views would last less than 1 minute at highway speeds, and expected visual
27 contrast levels would be minimal. The other segment (about 3 mi [5 km] in length) is located
28 about 18 to 20 mi (29 to 32 km) east of the SEZ, east of Littlefield but west of the Beaver Dam
29 Mountains. Visibility of solar facilities within the SEZ in this segment would also be limited to
30 the upper portions of tall power towers. Views would last less than 3 minutes at highway speeds,
31 and expected visual contrast levels would be minimal.

34 **U.S. 91.** Almost 11 mi (18 km) of U.S. 91 are within the SEZ viewshed to the east of the
35 SEZ in a stretch running north–south between 16 and 19 mi (26 and 31 km) east of the SEZ,
36 between Littlefield and the Beaver Dam Mountains. Within the southernmost 6 mi (10 km) of the
37 roadway within the viewshed, visibility would be limited to the upper portions of sufficiently tall
38 power towers within the SEZ, and expected visual contrast levels in this portion of the segment
39 would be minimal. The northern 5 mi (8 km) of the segment would have more or less open views
40 of the SEZ, but at distances exceeding 16 mi (26 km) the SEZ would occupy a very small portion
41 of the horizontal field of view, and the vertical angle of view would be very low. Visual contrast
42 levels would be expected to be weak.

45 **Other Impacts.** In addition to the impacts described for the resource areas above, nearby
46 residents and visitors to the area may experience visual impacts from solar energy facilities

1 located within the SEZ (as well as any associated access roads and transmission lines) from their
2 residences, or as they travel area roads. The range of impacts experienced would be highly
3 dependent on viewer location, project types, locations, sizes, and layouts, as well as the presence
4 of screening, but under the 80% development scenario analyzed in the PEIS, from some
5 locations, strong visual contrasts from solar development within the SEZ could potentially be
6 observed.

7 8 9 **11.5.14.2.3 Summary of Visual Resource Impacts for the Proposed East Mormon** 10 **Mountain SEZ**

11
12 Under the 80% development scenario analyzed in the PEIS, the SEZ would contain
13 multiple solar facilities utilizing differing solar technologies, as well as a variety of roads and
14 ancillary facilities. The array of facilities could create a visually complex landscape that would
15 contrast strongly with the strongly horizontal, relatively uncluttered, and generally natural
16 appearing landscape of the flat valley in which the SEZ is located. Large visual impacts on the
17 SEZ and surrounding lands within the SEZ viewshed would be associated with solar energy
18 development within the proposed East Mormon Mountain SEZ because of major modification of
19 the character of the existing landscape. There is the potential for additional impacts from
20 construction and operation of transmission lines and access roads within and outside the SEZ.

21
22 Under the 80% development scenario analyzed in this PEIS, utility-scale solar energy
23 development within the proposed East Mormon Mountain SEZ is likely to result in strong visual
24 contrasts for some viewpoints within the Mormon Mountains WA, which is within 2.4 mi
25 (3.9 km) of the SEZ at the point of closest approach. Minimal to weak visual contrasts would be
26 expected for some viewpoints within other sensitive visual resource areas within the SEZ 25-mi
27 (40 km) viewshed.

28
29 Visitors to the area, workers, and residents of nearby communities may experience visual
30 impacts from solar energy facilities located within the SEZ (as well as any associated access
31 roads and transmission lines) as they travel other area roads.

32 33 34 **11.5.14.3 SEZ-Specific Design Features and Design Feature Effectiveness**

35
36 The presence and operation of large-scale solar energy facilities and equipment would
37 introduce major visual changes into non-industrialized landscapes and could create strong visual
38 contrasts in line, form, color, and texture that could not easily be mitigated substantially.
39 Implementation of programmatic design features intended to reduce visual impacts (described in
40 Appendix A, Section A.2.2) would be expected to reduce visual impacts associated with utility-
41 scale solar energy development within the SEZ; however, the degree of effectiveness of these
42 design features could be assessed only at the site- and project-specific level. Given the large
43 scale, reflective surfaces, strong regular geometry of utility-scale solar energy facilities, and the
44 lack of screening vegetation and landforms within the SEZ viewshed, siting the facilities away
45 from sensitive visual resource areas and other sensitive viewing areas is the primary means of

1 mitigating visual impacts. The effectiveness of other visual impact mitigation measures would
2 generally be limited.

3
4 While the applicability and appropriateness of some design features would depend on
5 site- and project- specific information that would only be available after a specific solar energy
6 project had been proposed, there is an SEZ-specific design feature that can be identified for the
7 East Mormon Mountains SEZ at this time.

- 8
9 • The development of power tower facilities should be prohibited within the
10 SEZ.

11
12 Application of the SEZ-specific design feature above would substantially reduce visual
13 impacts associated with solar energy development within the SEZ and would substantially also
14 reduce potential visual impacts on Mormon Mountains WA. Application of the SEZ-specific
15 design feature would also reduce impacts on the other sensitive visual resource areas listed
16 above.

11.5.15 Acoustic Environment

11.5.15.1 Affected Environment

The proposed East Mormon Mountain SEZ is located in the southeast corner of Lincoln County in southeastern Nevada. Neither the State of Nevada nor Lincoln County has established quantitative noise-limit regulations applicable to solar energy development.

The proposed East Mormon Mountain SEZ is generally isolated and undeveloped, and its overall character is considered wilderness to rural. No major roads are in proximity to the SEZ. I-15 runs east–west as close as 10 mi (16 km) to the south, and several dirt roads exist in and around the SEZ. A railroad runs north–south 14 mi (23 km) to the northwest. The nearest airport is Mesquite Airport, which is located about 12 mi (19 km) southeast of the SEZ, is under military airspace. The next nearest airport is Overton Municipal Airport, which is located about 27 mi (43 km) south-southwest of the SEZ. There are no agricultural activities in or around the SEZ, but cattle grazing occurs within the SEZ. A local transmission corridor with three large power transmission lines and at least one pipeline runs adjacent to the southeast side of the SEZ. No recreational land use is evident within the SEZ, but some quail and antelope hunting may occur. No sensitive receptors (e.g., residences, hospitals, schools, or nursing homes) exist close to the proposed East Mormon Mountain SEZ. The nearest residences lie about 9 mi (14.5 km) southeast of the SEZ, near Mesquite. Nearby towns include Bunkerville and Mesquite, which are located about 12 mi (19 km) south-southeast and southeast of the SEZ, respectively. Accordingly, noise sources around the SEZ include infrequent road traffic, aircraft flyover, cattle grazing, and possibly hunting. Considering noise sources in and around the SEZ, background noise levels are anticipated to be low.¹⁰ An environmental noise survey has been conducted in the proposed SEZ, and noise levels range from 25 to 50 dBA (BLM 2009f). On the basis of the population density, the day–night average noise level (L_{dn} or DNL) is estimated to be 18 dBA for Lincoln County, well below the range of 33 to 47 dBA L_{dn} typical of a rural area (Eldred 1982; Miller 2002).¹¹

11.5.15.2 Impacts

Potential noise impacts associated with solar projects in the East Mormon Mountain SEZ would occur during all phases of the projects. During the construction phase, potential noise impacts on the nearest residences (about 9 mi [14.5 km] to the southeast of the SEZ boundary) associated with operation of heavy equipment would be minimal because of the considerable separation distance. During the operations phase, potential impacts on the nearest residences

¹⁰ The Toquop natural gas–fired power plant is proposed within the southeastern corner of the SEZ (BLM 2009f). If this facility were built and operated, the noise level around the southeast corner of the SEZ would be industrial in character.

¹¹ Rural and undeveloped areas have sound levels in the range of 33 to 47 dBA as L_{dn} (Eldred 1982). Typically, the nighttime level is 10 dBA lower than the daytime level. This can be interpreted as 33 to 47 dBA (mean 40 dBA) during daytime hours and 23 to 37 dBA (mean 30 dBA) during nighttime hours.

1 would be anticipated to be minimal as well. If the proposed East Mormon Mountain SEZ were
2 fully developed, potential noise impacts on residences along the roads from commuter, visitor,
3 support, and delivery vehicular traffic to and from the SEZ would be minimal, compared with
4 the current heavy traffic volume along I-15. However, some potential noise impacts on
5 residences along local roads leading to the SEZ would be anticipated if construction-related
6 vehicles travel through either Bunkerville or Mesquite. Noise impacts shared by all solar
7 technologies are discussed in detail in Section 5.13.1, and technology-specific impacts are
8 presented in Section 5.13.2. Impacts specific to the proposed East Mormon Mountain SEZ are
9 presented in this section. Any such impacts would be minimized through the implementation of
10 required programmatic design features described in Appendix A, Section A.2.2, and through any
11 additional SEZ-specific design features applied (see Section 11.5.15.3 below). This section
12 primarily addresses potential noise impacts on humans, although potential impacts on wildlife at
13 nearby sensitive areas are discussed. Additional discussion on potential noise impacts on wildlife
14 is presented in Section 5.10.2.

15 16 17 **11.5.15.2.1 Construction** 18

19 The proposed East Mormon Mountain SEZ has a relatively flat terrain; thus, minimal site
20 preparation activities would be required, and associated noise levels would be lower than those
21 during general construction (e.g., erecting building structures and installing equipment, piping,
22 and electrical).

23
24 For the parabolic trough and power tower technologies, the highest construction noise
25 levels would occur at the power block area, where key components (e.g., steam turbine/
26 generator) needed to generate electricity are located; a maximum of 95 dBA at a distance of
27 50 ft (15 m) is assumed, if impact equipment such as pile drivers or rock drills is not being used.
28 Typically, the power block area is located in the center of the solar facility, at a distance of more
29 than 0.5 mi (0.8 km) from the facility boundary. Noise levels from construction of the solar array
30 would be lower than 95 dBA. When geometric spreading and ground effects are considered, as
31 explained in Section 4.13.1, noise levels would attenuate to about 40 dBA at a distance of
32 1.2 mi (1.9 km) from the power block area. This noise level is typical of daytime mean rural
33 background levels. In addition, mid- and high-frequency noise from construction activities is
34 significantly attenuated by atmospheric absorption under the low-humidity conditions typical of
35 an arid desert environment, and by temperature lapse conditions typical of daytime hours; thus,
36 noise attenuation to a 40-dBA level would occur at distances somewhat shorter than 1.2 mi
37 (1.9 km). If a 10-hour daytime work schedule is considered, the EPA guideline level of 55 dBA
38 L_{dn} for residential areas (EPA 1974) would occur about 1,200 ft (370 m) from the power block
39 area, which would be well within the facility boundary. For construction activities occurring
40 near the residences closest to the southern SEZ boundary, estimated noise levels at the nearest
41 residences would be about 17 dBA, which is well below the typical daytime mean rural
42 background level of 40 dBA. In addition, an estimated 40 dBA L_{dn} at these residences¹² (i.e., no

¹² For this analysis, background levels of 40 and 30 dBA for daytime and nighttime hours, respectively, are assumed, which result in a day-night average noise level (L_{dn}) of 40 dBA.

1 contribution from construction activities) is well below the EPA guidance of 55 dBA L_{dn} for
2 residential areas.

3
4 In addition, noise levels were estimated at the specially designated areas within a 5-mi
5 (8-km) range of the East Mormon Mountain SEZ, which is the farthest distance at which noise,
6 other than extremely loud noise, would be discernable. There are three specially designated areas
7 within the range where noise might be an issue: Mormon Mesa ACEC, adjacent to the SEZ's
8 southern boundary; Beaver Dam Slope ACEC, about 0.7 mi (1.1 km) east of the SEZ; and
9 Mormon Mountains WA, about 2.3 mi (3.8 km) west of the SEZ. For construction activities
10 occurring near the SEZ boundary close to the specially designated areas, noise levels are
11 estimated to be approximately 74 and 47 dBA at the boundaries of the Mormon Mesa ACEC and
12 Beaver Dam Slope ACEC, respectively, both of which are higher levels than the typical daytime
13 mean rural background level of 40 dBA. As discussed in Section 5.10.2, sound levels above
14 90 dB are likely to adversely affect wildlife (Manci et al. 1988). Thus, construction noise from
15 the SEZ is not likely to adversely affect wildlife at nearby specially designated areas, except in
16 areas within Mormon Mesa ACEC directly adjacent to the construction site.

17
18 Depending on soil conditions, pile driving might be required for installation of solar dish
19 engines. However, the pile drivers used, such as vibratory or sonic drivers, would be relatively
20 small and quiet, in contrast to the impulsive impact pile drivers frequently used at large-scale
21 construction sites. Potential impacts on the nearest residences would be anticipated to be
22 negligible, considering the distance to the nearest residences (about 9 mi [14.5 km] from the
23 southern SEZ boundary).

24
25 It is assumed that most construction activities would occur during the day, when noise is
26 better tolerated than at night because of the masking effects of background noise. In addition,
27 construction activities for a utility-scale facility are temporary in nature (typically a few years).
28 Construction within the proposed East Mormon Mountain SEZ would cause negligible
29 unavoidable, but localized, short-term noise impacts on neighboring communities, even when
30 construction activities occurred near the southern SEZ boundary, close to the nearest residences.

31
32 Construction activities could result in various degrees of ground vibration, depending
33 on the equipment used and construction methods employed. All construction equipment causes
34 ground vibration to some degree, but activities that typically generate the most severe vibrations
35 are high-explosive detonations and impact pile driving. As is the case for noise, vibration would
36 diminish in strength with distance. For example, vibration levels at receptors beyond 140 ft
37 (43 m) from a large bulldozer (87 VdB at 25 ft [7.6 m]) would diminish below the threshold of
38 perception for humans, which is about 65 VdB (Hanson et al. 2006). During the construction
39 phase, no major construction equipment that can cause ground vibration would be used, and no
40 residences or sensitive structures are located in close proximity. Therefore, no adverse vibration
41 impacts are anticipated from construction activities, including pile driving for dish engines.

42
43 For this analysis, the impacts of construction and operation of transmission lines outside
44 of the SEZ were not assessed, assuming that the existing regional 500-kV transmission line
45 might be used to connect some new solar facilities to load centers, and that additional project-
46 specific analysis would be done for new transmission construction or line upgrades. However,

1 some construction of transmission lines could occur within the SEZ and over a short distance
2 (about 0.25 mi [0.4 km]) to the regional grid. Potential noise impacts on nearby residences would
3 be a minor component of construction impacts in comparison to solar facility construction, and
4 would be temporary in nature.

7 **11.5.15.2.2 Operations**

9 Noise sources common to all or most types of solar technologies include equipment
10 motion from solar tracking, maintenance and repair activities (e.g., washing mirrors or
11 replacing broken mirrors) at the solar array area, commuter/visitor/support/delivery traffic
12 within and around the solar facility, and control/administrative buildings, warehouses, and
13 other auxiliary buildings/structures. Diesel-fired emergency power generators and firewater
14 pump engines would be additional sources of noise, but their operation would be limited to
15 several hours per month (for preventive maintenance testing).

17 With respect to the main solar energy technologies, noise-generating activities in the
18 PV solar array area would be minimal, related mainly to solar tracking, if used. On the other
19 hand, dish engine technology, which employs collector and converter devices in a single unit,
20 generally has the strongest noise sources.

22 For parabolic trough and power tower technologies, most noise sources during operations
23 would be in the power block area, including the turbine generator (typically in an enclosure),
24 pumps, boilers, and dry- or wet-cooling systems. The power block is typically located in the
25 center of the facility. On the basis of a 250-MW parabolic trough facility with a cooling tower
26 (Beacon Solar, LLC 2008), simple noise modeling indicates that noise levels around the power
27 block would be more than 85 dBA, but about 51 dBA at the facility boundary, about 0.5 mi
28 (0.8 km) from the power block area. For a facility located near the southern SEZ boundary, the
29 predicted noise level would be about 22 dBA at the nearest residences, located about 9 mi
30 (14.5 km) from the SEZ boundary, which is well below the typical daytime mean rural
31 background level of 40 dBA. If TES were not used (i.e., if the operation were limited to daytime,
32 12 hours only¹³), the EPA guideline level of 55 dBA (as L_{dn} for residential areas) would occur at
33 about 1,370 ft (420 m) from the power block area, and thus would not be exceeded outside of the
34 proposed SEZ boundary. At the nearest residences, about 40 dBA L_{dn} (i.e., no contribution from
35 facility operation) would be estimated, which is well below the EPA guideline of 55 dBA L_{dn} for
36 residential areas. However, day–night average noise levels higher than those estimated above by
37 using simple noise modeling would be anticipated if TES were used during nighttime hours, as
38 explained below and in Section 4.13.1.

40 On a calm, clear night typical of the proposed East Mormon Mountain SEZ setting, the
41 air temperature would likely increase with height (temperature inversion) because of strong
42 radiative cooling. Such a temperature profile tends to focus noise downward toward the ground.
43 There would be little, if any, shadow zone¹⁴ within 1 or 2 mi (1.6 or 3 km) of the noise source in

¹³ Maximum possible operating hours at the summer solstice, but limited to 7 to 8 hours at the winter solstice.

¹⁴ A shadow zone is defined as the region in which direct sound does not penetrate because of upward diffraction.

1 the presence of a strong temperature inversion (Beranek 1988). In particular, such conditions
2 add to the effect of noise being more discernable during nighttime hours, when the background
3 noise levels are lowest. To estimate the day–night average noise level (L_{dn}), 6-hour nighttime
4 generation with TES is assumed after 12-hour daytime generation. For nighttime hours under
5 temperature inversion, 10 dB is added to noise levels estimated from the uniform atmosphere
6 (see Section 4.13.1). On the basis of these assumptions, the estimated nighttime noise level at the
7 nearest residences (about 9 mi [14.5 km] from the SEZ boundary) would be 32 dBA, which is
8 somewhat higher than the typical nighttime mean rural background level of 30 dBA. The day–
9 night average noise level is estimated to be about 41 dBA L_{dn} , which is still well below the EPA
10 guideline of 55 dBA L_{dn} for residential areas. The assumptions are conservative in terms of
11 operating hours, and no credit was given to other attenuation mechanisms, so it is likely that
12 noise levels would be lower than 41 dBA L_{dn} at the nearest residences, even if TES were used at
13 a solar facility. Consequently, operating parabolic trough or power tower facilities using TES
14 and located near the southern SEZ boundary would result in minimal adverse noise impacts on
15 the nearest residences, depending on background noise levels and meteorological conditions
16

17 Associated with operation of solar facilities located near the southern SEZ boundary and
18 using TES, the estimated daytime level of 51 dBA at the boundary of the Mormon Mesa ACEC
19 is higher than the typical daytime mean rural background level of 40 dBA, while the estimated
20 nighttime level of 61 dBA is much higher than the typical nighttime mean rural background level
21 of 30 dBA. For a solar facility located near the eastern SEZ boundary, daytime and nighttime
22 noise levels at the Beaver Dam Slope ACEC are estimated to be 43 and 53 dBA, respectively.
23 However, sound levels above 90 dB are likely to adversely affect wildlife (Manci et al. 1988);
24 thus, operations noise from solar facilities with TES is not likely to adversely affect wildlife at
25 the nearby specially designated areas.
26

27 In the permitting process, refined noise propagation modeling might be warranted, along
28 with measurement of background noise levels.
29

30 The solar dish engine is unique among CSP technologies because it generates electricity
31 directly and does not require a power block. A single, large solar dish engine has relatively
32 low noise levels, but a solar facility might employ tens of thousands of dish engines, which
33 would cause high noise levels around such a facility. For example, the proposed 750-MW SES
34 Solar Two dish engine facility in California would employ as many as 30,000 dish engines
35 (SES Solar Two, LLC 2008). At the proposed East Mormon Mountain SEZ, on the basis of the
36 assumption of dish engine facilities of up to 797-MW total capacity (covering 80% of the total
37 area, or 7,174 acres [29.0 km²]), up to 31,890 25-kW dish engines could be employed. For a
38 large dish engine facility, several hundred step-up transformers would be embedded in the dish
39 engine solar field, along with a substation; however, the noise from these sources would be
40 masked by dish engine noise.
41

42 The composite noise level of a single dish engine would be about 88 dBA at a distance of
43 3 ft (0.9 m) (SES Solar Two, LLC 2008). This noise level would be attenuated to about 40 dBA
44 (typical of the mean rural daytime environment) within 330 ft (100 m). However, the combined
45 noise level from tens of thousands of dish engines operating simultaneously would be high in the
46 immediate vicinity of the facility, about 50 dBA at 1.0 mi (1.6 km) and 46 dBA at 2 mi (3 km)

1 from the boundary of the square-shaped dish engine solar field, for example; both values are
2 higher than the typical daytime mean rural background level of 40 dBA. However, these levels
3 would occur at somewhat shorter distances than the aforementioned distances, considering noise
4 attenuation by atmospheric absorption and temperature lapse during daytime hours. To estimate
5 noise levels at the nearest residences, it was assumed dish engines were placed all over the East
6 Mormon Mountain SEZ at intervals of 98 ft (30 m). Under these assumptions, the estimated
7 noise level at the nearest residences, about 9 mi (14.5 km) southeast of the SEZ boundary, would
8 be about 33 dBA, which is below the typical daytime mean rural background level of 40 dBA.
9 On the basis of 12-hr daytime operation, the estimated 40 dBA L_{dn} at these residences (i.e., no
10 contribution from dish engines) is well below the EPA guideline of 55 dBA L_{dn} for residential
11 areas. On the basis of other noise attenuation mechanisms, noise levels at the nearest residences
12 would be lower than the values estimated above. Accordingly, noise from dish engines is not
13 anticipated to cause adverse impacts on the nearest residences, irrespective of background noise
14 levels and meteorological conditions.

15
16 For dish engines placed all over the SEZ, estimated noise levels would be about 59 and
17 50 dBA at the boundaries of the Mormon Mesa ACEC and Beaver Dam Slope ACEC,
18 respectively, both of which are higher levels than the typical daytime mean rural background
19 level of 40 dBA. However, dish engine noise from the SEZ is not likely to adversely affect
20 wildlife at the nearby specially designated areas (Manci et al. 1988), as mentioned above.

21
22 During operations, no major ground-vibrating equipment would be used. In addition,
23 no sensitive structures are located close enough to the proposed East Mormon Mountain SEZ to
24 experience physical damage. Therefore, during operation of any solar facility, potential vibration
25 impacts on surrounding communities and vibration-sensitive structures would be negligible.

26
27 Transformer-generated humming noise and switchyard impulsive noises would be
28 generated during the operation of solar facilities. These noise sources would be located near the
29 power block area, typically near the center of a solar facility. Noise from these sources would
30 generally be limited within the facility boundary and not be heard at the nearest residences,
31 assuming a 9.5-mi (15-km) distance (at least 0.5 mi [0.8 km] to the facility boundary and 9 mi
32 [14.5 km] to the nearest residences). Accordingly, potential impacts of these noise sources on the
33 nearest residences would be negligible.

34
35 For impacts from transmission line corona discharge noise during rainfall events
36 (Section 5.13.1.5), the noise level at 50 ft (15 m) and 300 ft (91 m) from the center of a 230-kV
37 transmission line tower would be about 39 dBA and 31 dBA (Lee et al. 1996), respectively,
38 typical of daytime and nighttime mean background noise levels in rural environments. The noise
39 levels at 65 ft (20 m) and 300 ft (91 m) from the center of 500-kV transmission line towers
40 would be about 49 dBA and 42 dBA, typical of high-end and mean, respectively, daytime
41 background noise levels in rural environments. Corona noise includes high-frequency
42 components, which may be judged to be more annoying than other environmental noises.
43 However, corona noise would not likely cause impacts, unless a residence were located close to
44 the source (e.g., within 500 ft [152 m] of a 230-kV transmission line and 0.5 mi [0.8 km] of a
45 500-kV transmission line). The proposed East Mormon Mountain SEZ is located in an arid

1 desert environment, and incidents of corona discharge would be infrequent. Therefore, potential
2 impacts on nearby residents along the transmission line ROW would be negligible.
3
4

5 **11.5.15.2.3 Decommissioning/Reclamation**

6

7 Decommissioning/reclamation requires many of the same procedures and equipment
8 used in traditional construction. Decommissioning/reclamation would include dismantling of
9 solar facilities and support facilities such as buildings/structures and mechanical/electrical
10 installations, as well as disposal of debris, grading, and revegetation as needed. Activities for
11 decommissioning would be similar to those for construction, but more limited. Potential
12 noise impacts on surrounding communities would be correspondingly lower than those for
13 construction activities. Decommissioning activities would be of short duration, and their
14 potential impacts would be minimal and temporary in nature. The same mitigation measures
15 adopted during the construction phase could also be implemented during the decommissioning
16 phase.
17

18 Similarly, potential vibration impacts on surrounding communities and vibration-
19 sensitive structures during decommissioning of any solar facility would be lower than those
20 during construction and thus negligible.
21
22

23 **11.5.15.3 SEZ-Specific Design Features and Design Feature Effectiveness**

24

25 The implementation of required programmatic design features described in Appendix A,
26 Section A.2.2, would greatly reduce or eliminate the potential for noise impacts from
27 development and operation of solar energy facilities. Due to the considerable separation
28 distances, activities within the proposed East Mormon Mountain SEZ during construction and
29 operation would be anticipated to cause only minimal increases in noise levels at the nearest
30 residences and to have minor impacts on nearby specially designated areas. Accordingly, SEZ-
31 specific design features are not required.

11.5.16 Paleontological Resources

11.5.16.1 Affected Environment

The surface geology of the proposed East Mormon Mountain SEZ is predominantly thick alluvial deposits (more than 100 ft [30 m] thick), ranging in age from the Pliocene to Holocene, with some discontinuous residual deposits developed in sedimentary rocks in the eastern portion of the SEZ. The total acreage of the alluvial deposits include 8,736 acres (35 km²), or more than 97% of the proposed SEZ, and the total acreage of the residual materials is 228 acres (0.9 km²), or 2.5% of the SEZ. Minimal deposits of residual materials developed in fine-grained sedimentary rocks and in igneous and metamorphic rocks occur in the northeast and southwest corners of the SEZ, respectively. These deposits total no more than 2 acres (0.008 km²) each. In the absence of a PFYC map for Nevada, a preliminary classification of PFYC Class 2 is assumed for the young Quaternary alluvial deposits and the residual materials in sedimentary rocks, similar to that assumed for the Amargosa Valley SEZ (Section 11.1.16; see Section 4.14 for a discussion of the PFYC system). Class 2 indicates a low potential for the occurrence of significant fossil material. Volcanic deposits are typically PFYC Class 1, which indicates that the occurrence of significant fossil materials is nonexistent or extremely rare.

11.5.16.2 Impacts

Few, if any, impacts on significant paleontological resources are likely to occur in the proposed East Mormon Mountain SEZ. However, a more detailed look at the geological deposits of the SEZ is needed to determine whether a paleontological survey is warranted. If the geological deposits are determined to be as described above and are classified as PFYC Class 2 or lower, further assessment of paleontological resources in the SEZ is not likely to be necessary. Important resources could exist; if identified, they would need to be managed on a case-by-case basis. Section 5.14 discusses the types of impacts that could occur on any significant paleontological resources found to be present within the proposed East Mormon Mountain SEZ. Impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2.

Indirect impacts on paleontological resources outside of the SEZ, such as through looting or vandalism, are unknown but unlikely, because any such resources would be below the surface and not readily accessed. Programmatic design features for controlling water runoff and sedimentation would prevent erosion-related impacts on buried deposits outside of the SEZ.

No new transmission lines are currently anticipated for the proposed East Mormon Mountain SEZ, assuming an existing corridor would be used, but approximately 11 mi (18 km) of a new access road corridor to connect to the nearest interstate is assessed in this PEIS. Approximately 80 acres (0.3 km²) of disturbance is expected as a result of road construction. The access road corridor would likely be in thick alluvial deposits similar to the SEZ, and would be less likely to impact paleontological resources (preliminary classification of PFYC Class 2). However, depending on the exact location of the access road, some deposits of residual materials

1 developed in carbonate rocks are possible within the corridor, and the potential for
2 paleontological deposits is unknown in these areas. A preliminary classification of PFYC
3 Class 3b is assumed for the residual deposits. A more detailed investigation of the residual
4 deposits is needed prior to project approval. A paleontological survey will likely be needed
5 following consultation with the BLM. The appropriate course of action would be determined as
6 established in BLM IM2008-009 and IM2009-011 (BLM 2007a, 2008b). Impacts on
7 paleontological resources related to the creation of new corridors not assessed in this PEIS would
8 be evaluated at the project-specific level if new road or transmission construction or line
9 upgrades are to occur.

11.5.16.3 SEZ-Specific Design Features and Design Feature Effectiveness

14 Impacts would be minimized through the implementation of required programmatic
15 design features as described in Appendix A, Section A.2.2.

17 The need for and the nature of any SEZ-specific design features would depend on the
18 results of future paleontological investigations, especially along a potential new access road
19 corridor; however, based on the current level of information, a need for mitigation of areas
20 potentially classified as PFYC Class 2 or lower is not anticipated.

11.5.17 Cultural Resources

11.5.17.1 Affected Environment

11.5.17.1.1 Prehistory

The proposed East Mormon Mountain SEZ is located in the northeastern portion of the Mojave Desert, within the basin and range province in eastern Nevada. The earliest known human use of the area was likely during the Paleoindian Period, sometime between 12,000 and 10,000 years B.P. Surface finds of Paleoindian fluted projectile points, the hallmark of the Clovis culture, have been found in the area, but no sites with any stratigraphic context have been excavated. The Clovis culture is characterized by the aforementioned fluted projectile point and a hunting and gathering subsistence economy that followed migrating herds of Pleistocene mega fauna. The Iola site, located on the western side of the Meadow Valley Mountains in the Kane Spring Valley, about 26 mi (42 km) to the west, is one of the closest Paleoindian sites to the proposed East Mormon Mountain SEZ (BLM 2007c). The ephemeral nature of Paleoindian occupation in the Great Basin has given rise to the idea that Paleoindians may have been inclined to subsist off of the lake and marsh habitats provided by the ancient Pleistocene pluvial lakes that occupied a large portion of the Great Basin; consequently, the sites are difficult to find, because they have been buried by the ebb and flow of the pluvial lakes. This slightly later cultural material associated with the pluvial lake habitations is referred to as the Western Pluvial Lakes Tradition or Lake Mohave cultural complex. It is likely that people from this tradition did not rely entirely on marsh habitats, but were nomadic hunters and gatherers who relied on both wetland resources and those resources located in upland areas. The archaeological assemblage associated with this cultural tradition is characterized by stemmed projectile points, leaf-shaped bifaces, scrapers, crescents, and in some cases groundstone tools for milling plant material. Often the projectile points and tools were made from locally procured obsidian, sources of which were not far from the proposed East Mormon Mountain SEZ; two sources are in Kane Spring Valley and another source is in the Meadow Valley Mountains, about 20 mi (32 km) to the west. Collecting obsidian and other raw materials for tool manufacture, in addition to exploiting different ecological niches for various subsistence resources, was a part of a larger resource exploitation system, in which groups moved in seasonal rounds to take advantage of specific resources in different localities (Jones et al. 2003; Haarklau et al. 2005; Fowler and Madsen 1986).

The Archaic Period in the region began with the recession of most of the pluvial lakes in the area, around 8,000 to 6,000 B.P. Archaic Period groups likely still congregated around the marsh areas but also made use of the vast caves that can be found in the mountains of the Great Basin. The settlement system in some areas was likely based around a central base camp, with temporary camps located on the margins of the territory to exploit resources that were not in the immediate vicinity of the base camp. Other groups may not have had a central base, but were mobile “travelers” rather than “processors” (Jones et al. 2003). Some of the key Archaic sites in the area near the proposed East Mormon Mountain SEZ are Stuart Rockshelter in the lower Meadow Valley Wash area, and Etna Cave, Conaway Shelter, and O’Malley Shelter in the upper

1 portion of the Meadow Valley Wash area. The Archaic archaeological assemblages from these
2 sites maintain some cultural continuity with the previous period; they consist of Pinto points,
3 leaf-shaped bifaces, scrapers, drills, graters, and manos and metates (Fowler and Madsen 1986).
4

5 The Middle Archaic Period, 4,000 to 1,500 B.P., saw the climatic shift known as the
6 Little Pluvial, a wetter and cooler climate that caused some of the pluvial lakes to fill back up.
7 The cultural material of this time period is similar to the Early Archaic, with an increased
8 concentration of milling stones, mortars, and pestles, and the appearance of normally perishable
9 items, such as wicker baskets, split-twig figurines, duck decoys, and woven sandals (Neusius and
10 Gross 2007).
11

12 In the vicinity of the proposed East Mormon Mountain SEZ, the Late Archaic Period
13 began around 1,500 B.P. and extended until contact with European explorers. This period saw
14 major technological shifts, evidenced by changes in subsistence techniques, particularly in the
15 use of horticulture, and by smaller projectile points that were more useful because groups began
16 using bow-and-arrow technology instead of the atlatl. During this time period in the Muddy and
17 Virgin River valleys, most groups were a part of the Virgin Anasazi cultural group, an extension
18 of the Puebloan groups from the southwest into the Great Basin region. These groups brought
19 with them the knowledge of horticulture, which they practiced on the floodplains of the river
20 valleys they inhabited. Pueblo Grande de Nevada, located near Overton, Nevada, 31 mi (50 km)
21 south of the SEZ, is a prime example of the Virgin Anasazi culture in the vicinity of the SEZ.
22 The South Fork and Toquop Wash areas in the SEZ may have provided a locale that would have
23 been attractive to Virgin Anasazi groups. Characteristic of this period are Anasazi grey-ware
24 ceramics (sometimes decorated), rock art and intaglios, bedrock milling features, and turquoise
25 mining. Several prehistoric rock alignments have been documented in the proposed East
26 Mormon Mountain SEZ, and there are 9 additional rock alignment sites within 5 mi (8 km) of
27 the SEZ. The Virgin Anasazi groups left the region around 1,000 B.P., at which time Numic-
28 speaking groups migrated into the region, but the exact timing of these events is a subject for
29 further research. These Numic-speaking people were the descendents of the Southern Paiute, and
30 the archaeological assemblage associated with this time period consists of Desert series projectile
31 points, brown-ware ceramics, unshaped manos and milling stones, incised stones, mortars,
32 pestles, and shell beads. The following section describes the cultural history of the time period in
33 greater detail.
34
35

36 **11.5.17.1.2 Ethnohistory** 37

38 The proposed East Mormon Mountain SEZ is located in the heart of the traditional use
39 area of the Southern Paiute. It falls within the territory of the *Paranayi*, or western subtribe, but
40 is close to the lands of the *Yanawant*, or eastern subtribe (Stoffle et al. 1997). It is situated along
41 the Toquop Wash about 13 mi (21 km) upstream from the Virgin River. The Virgin River and its
42 tributaries form the single most important ribbon oasis in Southern Paiute Territory (Stoffle and
43 Dobyns 1983). The proposed SEZ lies in the area where the traditional ranges of the Moapa and
44 the Panaca Bands meet and is close to the territory of the St. George Band (Kelly 1934; Kelly
45 and Fowler 1986). Southern Paiute groups tended to be wide ranging and often shared resources.
46 It is thus likely that neighboring bands were familiar with the area as well. The core settlement

1 and activity areas of the Moapa Band were along the Moapa or Muddy River and the Virgin
2 River. The Panaca Band was centered in Meadow Valley, about 14 mi (23 km) northeast of the
3 proposed SEZ. The St. George Band was centered farther up the Virgin River and on the lower
4 reaches of Santa Clara Creek, about 33 mi (54 km) east-northeast of the proposed SEZ
5 (Kelly 1934).
6
7

8 **Southern Paiute** 9

10 A general account of the Southern Paiutes is given in Section 11.1.17.1.2. This section
11 deals primarily with those Southern Paiutes associated with the Moapa and Virgin Rivers and
12 their neighbors. The Southern Paiute practiced a mixed subsistence economy. They established
13 home bases along the ribbon oases formed by the few streams in the area, maintaining both
14 floodplain and irrigated agricultural fields. They also husbanded wild plants through
15 transplanting, pruning, burning, and irrigation (Stoffle and Dobyns 1983). Seasonally, these
16 groups left their base camps to seek wild plant resources as they became available (Kelly and
17 Fowler 1986). The Southern Paiute supplemented their food supply by hunting and fishing
18 (Kelly and Fowler 1986). Although there are springs in the adjacent hills, the proposed East
19 Mormon Mountain SEZ is arid and Toquop Wash is intermittent. Scatters of lithic and ceramic
20 artifacts, along with stone circles, suggest that Native Americans made use of the area for
21 temporary foraging activities.
22

23 The sixteenth-century arrival of Europeans in the southwest initially had indirect,
24 although serious, effects on the Southern Paiutes. The Southern Paiute bands suffered from the
25 spread of Old World diseases and the depredations of the slave trade that supplied Spanish and
26 Mexican markets. The Southern Paiutes retreated from areas such as those along the Old Spanish
27 Trail, where there was an increased presence of Euro-American travelers. In the mid-nineteenth
28 century, the Southern Paiute in Nevada were further displaced by Euro-American settlers, who
29 sought the same limited water supplies the southern Paiutes used. Mormon settlers established the
30 “Cotton Mission” on the Virgin River at St. George, Utah, in 1861. As Euro-American
31 settlements grew, the Southern Paiute were drawn into the new economy, often serving as
32 transient wage labor. Settlements or colonies of laborers grew up around Euro-American
33 settlements, farms, and mines, often including individuals from across the Southern Paiute
34 homeland (Kelly and Fowler 1986). A Southern Paiute group had formed around St. George by
35 1868 (Stoffle and Dobyns 1983).
36

37 In 1865, an initial attempt by the U.S. government to settle the Southern Paiutes in
38 northeastern Utah among their traditional enemies, the Utes, failed. The Moapa River
39 Reservation was established in 1875 with the intent of settling all Southern Paiutes there,
40 although the original reservation as authorized by President Ulysses S. Grant was severely
41 reduced by Congress to 1,000 acres (4 km²) of mostly unirrigable land. Nonetheless, limited
42 commercial farming was established. Though plagued by disease and poor water, the reservation
43 slowly became more prosperous, attracting Southern Paiutes from a variety of bands.
44 Capitalizing on its share of a judgment awarded by the Indian Claims Commission, and the
45 restoration in 1980 of part of the original reservation, Moapa River Reservation has continued
46 to develop into a center of Southern Paiute activity (Stoffle and Dobyns 1983). In 1891, a small

1 reservation was established southwest of St. George for the Shivwits Band. Members of the
2 St. George Band made their way there, and by the end of the century Southern Paiutes no
3 longer farmed along the Santa Clara River. In the first decades of the twentieth century, small
4 reservations were created for the Indian Peak, Koosharem, Kanosh, and Kaibab Bands, and the
5 Southern Paiute colony at Cedar City, Utah, had acquired a small land base. Members of the
6 Panaca Band tended to join the Indian Peak reservation. Where feasible, the Southern Paiute
7 farmed or ranched on these reservations, but mostly the Paiutes served as wage laborers,
8 sometimes travelling great distances. This mobile lifestyle allowed the various bands to retain
9 social and ceremonial ties with one another. In 1954, the four Utah reservations were terminated
10 by the Federal Government and their lands distributed among Tribal members, resulting in the
11 loss of much of the land. The Southern Paiute successfully filed claims with the Indian Claims
12 Commission in the same decade. In 1980, the Paiute Indian Tribe of Utah was created from the
13 terminated Utah bands and the Cedar City colony and restored to federal trust status (Stoffle and
14 Dobyns 1983; Kelly and Fowler 1986).

15 16 17 **11.5.17.1.3 History** 18

19 The earliest documented European presence in the Great Basin region was the
20 Dominguez-Escalante Expedition that began in July of 1776.¹⁵ Two Catholic priests, Fathers
21 Francisco Atanasio Dominguez and Silvestre Velez de Escalante, were looking for a route from
22 the Spanish capital city of Santa Fe to the Spanish settlement of Monterey on the California
23 coast. The group did not initially complete their goal of reaching California. They turned back to
24 Santa Fe when the weather got too bad; however, the maps and journals describing their travels
25 and encounters would prove valuable to later expeditions that traversed the area. These included
26 Spanish/New Mexican traders and Anglo-American fur trappers traveling the Old Spanish Trail
27 in the 1820s and 1830s (BLM 1976).

28
29 The Old Spanish National Historic Trail was an evolving trail system generally
30 established in the early nineteenth century. It tended to follow previously established paths
31 used by earlier explorers like Dominguez and Escalante, but also followed those established by
32 Native Americans. Due to a desire to avoid hostile Indian Tribes, as well as natural land
33 formations such as the Grand Canyon, the trail is not a direct route. Several forks and cutoffs
34 were established as more and more travelers made use of the trail system. The 2,700-mi
35 (4,345-km) trail network crosses through six states, and includes various paths between Santa Fe
36 and Los Angeles. It was used primarily between 1829 and 1848 by New Mexican traders
37 exchanging textiles for horses. In 1829, while following the Old Spanish Trail, Antonio Armijio
38 found an oasis that served as a crucial stopping point along the trail. This oasis was named
39 Las Vegas, Spanish for “The Meadows.” By utilizing this oasis, groups traveling on the trail
40 were able to significantly shorten their trip through the harsh desert (Fehner and Gosling 2000).
41 The Old Spanish National Historic Trail is a congressionally designated route; consequently, the
42 trail, trail resources, and setting must be managed in accordance with the National Trail System
43 Act. The closest section of the trail passes about 12 mi (19 km) to the south and east of the

¹⁵ Although it was technically illegal, traders from New Spain (New Mexico) would travel north to acquire Native American slaves for New Mexican settlers from at least the mid-1700s.

1 proposed East Mormon Mountain SEZ as it follows the Virgin River. A portion of the
2 congressionally designated trail about 15 mi (24 km) southwest of the SEZ near Littlefield, Utah,
3 has been designated a high-potential segment.
4

5 With the ratification of the Treaty of Guadalupe Hidalgo in 1848 closing out the
6 Mexican-American War, the area came under American control. In 1847, the first American
7 settlers arrived in the Great Basin, among them Mormon immigrants under the leadership of
8 Brigham Young, who settled in the Valley of the Great Salt Lake in Utah. They sought to bring
9 the entire Great Basin under their control, establishing an independent State of Deseret. From
10 its center in Salt Lake City, the church sent out colonizers to establish agricultural communities
11 in surrounding valleys and missions to acquire natural resources such as minerals and timber.
12 Relying on irrigation to support their farms, the Mormons often settled in the same places as the
13 Fremont and Virgin Anasazi centuries before. The result was a scattering of planned agricultural
14 communities from northern Arizona to southern Idaho and parts of Wyoming, Nevada, and
15 southern California. In 1855, Brigham Young sent 30 men, led by William Bringham, to the
16 Las Vegas valley, southwest of the proposed East Mormon Mountain SEZ, in an effort to
17 establish a mission in the southern portion of Nevada. They called their mission Las Vegas Fort,
18 but only stayed in the area for a few years before abandoning the mission because of the harsh
19 climate and the closing of the nearby Potosi mine that provided the majority of the income and
20 patronage at the mission. About 30 mi (48 km) north of the proposed East Mormon Mountains
21 SEZ was a small Mormon settlement, Clover Valley, where Mormons farmed and raised stock
22 beginning in the late 1860s. Neighboring Washington County in Utah was home to the Mormon
23 Cotton Mission, an area that was intensively cultivated for the procurement of cotton in the early
24 1860s in an effort to allow the Mormons to become more self-sufficient (Paher 1970; Fehner and
25 Gosling 2000).
26

27 Nevada's nickname is the "Silver State," so named for the Comstock Lode strike near
28 Virginia City in 1859, about 280 mi (451 km) northwest of the proposed East Mormon Mountain
29 SEZ. This was the first major silver discovery in the United States, and with the news of the
30 strike hopeful prospectors flocked to the area in an effort to capitalize on the possible wealth
31 under the surface of the earth. The discovery of the Comstock Lode led to the creation of
32 Virginia City and other nearby towns that served the burgeoning population. The population
33 increase due to mining was so dramatic that while in 1850 there were less than a dozen non-
34 native people in the State of Nevada, by 1860 there were 6,857, and by 1875 an estimated
35 75,000 people had settled in the state. The Comstock Lode strike is important to the history of
36 Nevada, not just because of the population growth and significant amount of money that was
37 consequently brought to the area, but also because of technological innovations that were
38 created and employed in the mines. The use of square-set timbering, which kept loose soil from
39 collapsing on miners, was one concept that was eventually employed in other mines around the
40 world (Paher 1970).
41

42 Mining for valuable deposits occurred in all regions of the state of Nevada, including in
43 the vicinity of the proposed East Mormon Mountain SEZ. The most notorious mining district in
44 Lincoln County was Pioche, about 65 mi (105 km) north of the proposed East Mormon Mountain
45 SEZ. Pioche was a violent, Wild West town that was one of the most prosperous districts in the
46 county. The closest mining district to the proposed SEZ was the Gourd Spring Mining District.

1 Located on the eastern slopes of the East Mormon Mountains, this mine produced tungsten,
2 barite, gypsum, and magnesium. Other notable mines near the SEZ were the Whitmore mine in
3 the Mormon Mountains to the west, the Key West Mine, a copper mine near Glendale, Nevada,
4 the Viola and Vigo Mining Districts in the Clover Mountains to the north of the SEZ, and the
5 Delamar Mine about 45 mi (72 km) northwest of the SEZ, which accounted for over half of the
6 state's ore output during the down years at the turn of the nineteenth century. Mining today is
7 not a major concern in the area, and the mineral production was never sufficient to attract large
8 numbers of miners to the area or allow them to construct any permanent camps; most of the
9 camps in the vicinity of the SEZ were temporary and short lived. The construction of railroads
10 in Nevada was often directly related to the mining activities that occurred in the state; the
11 San Pedro–Los Angeles–Salt Lake Railroad acted as a stimulant to the depraved mining
12 economy with its construction in 1905. The still-used railroad runs through the Meadow Valley
13 Wash area, about 20 mi (32 km) to the west of the proposed East Mormon Mountain SEZ
14 (Paher 1970; Tingley 1998; Rusco and Muñoz 1983).

15
16 Nevada's desert-mountain landscape has made it a prime region for use by the
17 U.S. government for several decades. In October of 1940, President Franklin D. Roosevelt
18 established the Las Vegas Bombing and Gunnery Range, a 3.5-million-acre (14,000-km²)
19 parcel of land northwest of Las Vegas, near Indian Springs, Nevada, 82 mi (132 km) southwest
20 of the SEZ. At the start of the Cold War in 1948, the range was renamed the Nellis Air Force
21 Base; three years later, the Nevada Test Site (NTS), a U.S. Department of Energy facility, was
22 established within Nellis Air Force Base. For the next 41 years, testing of nuclear weapons
23 occurred throughout regions of the NTS, in addition to regular Air Force training missions.
24 Although the proposed East Mormon Mountain SEZ does not fall within the specific boundaries
25 of these government installations, they are important contributors to the overall history and
26 context of the region.

27 28 29 **11.5.17.1.4 Traditional Cultural Properties—Landscape** 30

31 The Southern Paiutes have traditionally taken a holistic view of the world, in which the
32 sacred and profane are inextricably intertwined. According to their traditions, they were created
33 in their traditional use territory and have a divine right to the land, along with a responsibility to
34 manage and protect it. Landscapes as a whole are often culturally important. An adverse effect
35 on one part diminishes the rest (Stoffle 2001). From a Southern Paiute perspective, landscapes
36 include places of power. Among the most important such places are sources of water; peaks,
37 mountains, and elevated features; caves; distinctive rock formations; and panels of rock art.
38 Places of power are important to the religious beliefs of the Southern Paiute. They may be
39 sought out for individual vision quests or healing and may also be associated with culturally
40 important plant and animal species. The view from such a point of power or the ability to see
41 from one important place to another can be an important element of its integrity (Stoffle and
42 Zedeño 2001b). Landscapes as a whole are tied together by a network of culturally important
43 trails (Stoffle and Dobyns 1983; Stoffle and Zedeño 2001a).

44
45 The proposed East Mormon Mountain SEZ is located in an arid area bisected by Toiyup
46 Wash. Scattered archaeological remains of Native American activities within the SEZ suggest

1 that they foraged there. The area was in reach of Southern Paiute base camps, or rancherias,
2 located along the Virgin and Santa Clara Rivers and Meadow Valley Wash. Springs, rock
3 shelters, caves, petroglyphs, and pictographs have been found in the East Mormon Mountains to
4 the west of the proposed SEZ, forming a cultural landscape potentially important to the Southern
5 Paiute. The Salt Song Trail, ritually of great importance to the Southern Paiute, approaches this
6 part of Nevada (BLM 2009f). Consultation with affected Tribes will be necessary to determine
7 whether it will be affected by the development of solar facilities in the proposed SEZ.
8 Descendants of the Moapa, Panaca, and St. George Bands have placed high cultural importance
9 on springs, burial sites, religious sites, trails, shrines, and rock art (Stoffle and Dobyns 1983).

11.5.17.1.5 Cultural Surveys and Known Archaeological and Historical Resources

10
11
12
13
14 The proposed East Mormon Mountain SEZ has had seven surveys conducted within its
15 boundaries, encompassing 78 acres (0.31 km²) and covering 0.9% of the SEZ. An additional
16 41 surveys have been conducted within 5 mi (8 km) of the SEZ. These surveys have resulted in
17 the recording of four sites within the proposed East Mormon Mountain SEZ and 45 sites within
18 5 mi (8 km) of the SEZ boundary. The four sites located in the proposed East Mormon Mountain
19 SEZ are all prehistoric in nature; three of the sites are rock alignments and one is a lithic scatter;
20 the sites were determined not to be eligible for listing in the NRHP (de Dufour 2009).

21
22 Most of the sites (37 of 45) that have been documented within 5 mi (8 km) of the SEZ are
23 prehistoric, and the remaining eight sites are historic. At least 11 of these 45 sites are potentially
24 eligible for listing in the NRHP. Most of the prehistoric sites are rock shelters, roasting pits, or
25 rock alignments, and the historic sites are either trash scatters or road features (de Dufour 2009).

26
27 A portion of the congressionally designated Old Spanish National Historic Trail passes
28 about 12 mi (19 km) to the south of the proposed East Mormon Mountain SEZ, as the trail
29 follows the Virgin River. Some portions of this congressionally designated trail are high
30 potential segments; they are located approximately 15 mi (24 km) to the southeast of the
31 proposed SEZ.

32
33 The proposed East Mormon Mountain SEZ has the potential to contain significant
34 cultural resources, in addition to the four previously mentioned sites. The areas near the South
35 Fork and Toquop Wash could have provided temporary sources of water. Petroglyphs have been
36 documented on the eastern portion of the East Mormon Mountains and in the Toquop Gap area,
37 indicating that the area was used by indigenous groups throughout the course of the history of
38 the region.

39
40 The BLM has designated an ACEC in the vicinity of the proposed East Mormon
41 Mountain SEZ to protect cultural resource values. This is the Virgin River ACEC 12 mi (19 km)
42 to the south of the SEZ, portions of which are also located in nearby Arizona and maintained by
43 the Arizona Strip Field Office. There are several other ACECs with important cultural resources
44 in the area, but they are more than 25 mi (40 km) from the SEZ.

National Register of Historic Places

There are no sites listed in the NRHP in the proposed East Mormon Mountain SEZ, or within 5 mi (8 km); however, the aforementioned 11 sites that are located within 5 mi (8 km) of the SEZ are considered potentially eligible.

Several sites listed in the NRHP are located in the Mesquite and Bunkerville areas, communities situated about 12 mi (19 km) to the south of the proposed East Mormon Mountain SEZ, along the Virgin River in neighboring Clark County. These sites include the Desert Valley Museum and the Mesquite High School Gymnasium, in Mesquite, and the Hunt, Parley House and Levitt, Thomas House in Bunkerville, as well as the Old Spanish National Historic Trail. Lincoln County maintains nine properties in the NRHP, all of which are farther than 25 mi (40 km) away from the proposed SEZ. Three of the properties are archaeological sites between 45 and 75 mi (72 and 121 km) from the SEZ; the Black Canyon Petroglyph Site in the Pahrangat National Wildlife Refuge west of the SEZ, the Panaca Summit Archaeological District north of the SEZ, and the White River Narrows Archaeological District northwest of the SEZ. The other six properties are historic sites near the towns of Caliente and Pioche.

11.5.17.2 Impacts

Direct impacts on significant cultural resources could occur in the proposed East Mormon Mountain SEZ; however, further investigation is needed in a number of areas. A cultural resources survey of the entire APE of a proposed project would first need to be conducted to identify archaeological sites, historic structures and features, and traditional cultural properties, and an evaluation would need to follow to determine whether any are eligible for listing in the NRHP. The proposed East Mormon Mountain SEZ has a high potential for containing archaeological sites in the South Fork and Toquop Wash areas. Possible impacts from solar energy development on cultural resources that are encountered within the SEZ or along related ROWs are described in more detail in Section 5.15. Impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2. Programmatic design features assume that the necessary surveys, evaluations, and consultations will occur.

Programmatic design features to reduce water runoff and sedimentation would reduce the likelihood of indirect impacts on cultural resources resulting from erosion outside of the SEZ boundary (including along ROWs). No needs for new transmission lines have currently been identified, assuming an existing line would be used. An access road would need to be constructed to the SEZ, the closest road being I-15, about 11 mi (18 km) to the south. The construction of this road would result in the disturbance of approximately 80 acres (0.32 km²). Impacts on cultural resources are possible in areas related to the access road, since new areas of potential cultural significance could be directly impacted by construction or opened to increased access due to road construction and use. Indirect impacts are also possible from unauthorized collection of artifacts or vandalism, depending on the proximity of the road to historic properties. Impacts on cultural resources related to the creation of new corridors not assessed in this PEIS

1 would be evaluated at the project-specific level if new road or transmission construction or line
2 upgrades are to occur.

3
4 The congressionally designated Old Spanish National Historic Trail and aforementioned
5 NRHP sites in the Mesquite/Bunkerville area are located south of the proposed East Mormon
6 Mountain SEZ, and would likely not be physically affected by solar development in the SEZ.
7 However, these cultural resources could be affected from a visual standpoint, although the Flat
8 Top Mesa would probably screen or block the view of the solar development from the southeast
9 portion of the SEZ. The rock art sites that are located on the eastern portions of the East Mormon
10 Mountains and in the Toquop Gap area could potentially be affected. Depending on the
11 significance of these sites and whether they are considered sites of traditional cultural
12 importance, there is a potential for visual and auditory effects on these locations as a result of
13 solar energy development in the proposed SEZ.

14 15 16 **11.5.17.3 SEZ-Specific Design Features and Design Feature Effectiveness**

17
18 Programmatic design features to mitigate adverse effects on significant cultural
19 resources, such as avoidance of significant sites and features, cultural awareness training for the
20 workforce, and measures for addressing possible looting/vandalism issues through formalized
21 agreement documents, are provided in Appendix A, Section A.2.2.

22
23 SEZ-specific design features would be determined in consultation with the Nevada SHPO
24 and affected Tribes and would depend on the results of future investigations.

- 25
26 • Avoidance of the South Fork and Toquop Wash areas is recommended
27 because these areas have a higher potential for containing significant sites.
- 28
29 • Coordination with the Trail Administration for the Old Spanish Trail and Old
30 Spanish Trail Association is recommended to identify potential mitigation
31 strategies for avoiding or minimizing potential impacts, if impacts are
32 identified in future studies, on the congressionally designated Old Spanish
33 National Historic Trail.

11.5.18 Native American Concerns

Native Americans share many environmental and socioeconomic concerns with other ethnic groups. This section focuses on concerns that are specific to Native Americans or to which Native Americans bring a distinct perspective. For a discussion of issues of possible Native American concern shared with the population as a whole, several sections in this PEIS should be consulted. Topics of general concern are addressed in Section 4.16. Specifically for the proposed East Mormon Mountain SEZ, Section 11.5.17 discusses archaeological sites, structures, landscapes, trails, and traditional cultural properties; Section 11.5.8 discusses mineral resources; Section 11.5.9.1.3 discusses water rights and water use; Section 11.5.10 discusses plant species; 11.5.11 discusses wildlife species, including wildlife migration patterns; Section 11.5.13 discusses air quality; Section 11.5.14 discusses visual resources; Sections 11.5.19 and 11.5.20 discuss socioeconomics and environmental justice, respectively. Issues of human health and safety are discussed in Section 5.21.

11.5.18.1 Affected Environment

The proposed East Mormon Mountain SEZ is within the Tribal traditional use area generally attributed to the Southern Paiute (Kelly and Fowler 1986). All federally recognized Tribes with Southern Paiute roots have been contacted and provided an opportunity to comment or consult regarding this PEIS. They are listed in Table 11.5.18.1-1. Details of government-to-government consultation efforts are presented in Chapter 14; a listing of all federally recognized Tribes contacted for this PEIS is provided in Appendix K.

TABLE 11.5.18.1-1 Federally Recognized Tribes with Traditional Ties to the Proposed East Mormon Mountain SEZ

Tribes	Location	State
Chemehuevi Indian Tribe	Lake Havasu	California
Kaibab Paiute Tribe	Fredonia	Arizona
Las Vegas Paiute Tribe	Las Vegas	Nevada
Moapa Band of Paiutes	Moapa	Nevada
Pahrump Paiute Tribe	Pahrump	Nevada
Paiute Indian Tribe of Utah	Cedar City	Utah
Cedar Band	Cedar City	Utah
Indian Peak Band	Cedar City	Utah
Kanosh Band	Kanosh	Utah
Koosharem Band	Cedar City	Utah
Shivwits Band	Ivins	Utah
San Juan Southern Paiute Tribe	Tuba City	Arizona

11.5.18.1.1 Southern Paiute Territorial Boundaries

The traditional territory of the Southern Paiute lies mainly in the Mojave Desert, stretching from California to the Colorado Plateau. It generally follows the northern and western banks of the Colorado River, including its tributary streams and canyons in southern Nevada and Utah. It includes most of Clark and Lincoln Counties in Nevada and extends as far north as Beaver County in Utah (Kelly and Fowler 1986). Most of their traditional range, including the lands for the proposed East Mormon Mountain SEZ, has been judicially recognized as the traditional use area of the Southern Paiute by the Indian Claims Commission (Royster 2008).

11.5.18.1.2 Plant Resources

The Southern Paiutes continue to make use of a wide range of indigenous plants for food, medicine, construction materials, and other uses. The vegetation present at the proposed East Mormon Mountain SEZ is described in Section 11.5.10. The cover type present at the SEZ is almost entirely Sonora–Mojave Creosotebush–White Bursage Desert Shrub, with small pockets of North American Warm Desert Playa (USGS 2005a). The proposed SEZ is sparsely vegetated, at least in part because much of it burned in 2005. The deeply cut Toquop Wash runs diagonally from northwest to southeast across the proposed SEZ. Smaller tributary washes cross much of the SEZ. Creosotebush and white bursage are the dominant species; of these, creosotebush has Native American medicinal uses. As shown in Table 11.5.18.1-2, there are likely to be some plants used by Native Americans for food in the SEZ (Stoffle et al. 1999; Stoffle and Dobyns 1983). Project-specific analyses will be needed to determine the presence of these plants at any proposed building site. Traditional plant knowledge is found most abundantly among Tribal elders, especially female elders (Stoffle et al. 1999).

11.5.18.1.3 Other Resources

Members of the Moapa Band of the Southern Paiutes rate springs as the most important cultural resource in their cultural landscape. Water is an essential prerequisite for life in the arid areas of the Great Basin. As a result, water is a keystone of desert cultures' religion. They consider all water sacred and a purifying agent. Water sources are often associated with rock art. Springs are often associated with powerful beings, and hot springs in particular figure in Southern Paiute creation stories. Water sources are seen as connected, so damage to one damages all (Fowler 1991; Stoffle and Zedeño 2001a). Tribes are also sensitive regarding the use of scarce local water supplies for the benefit of far-distant communities and recommend determination of adequate water supplies as a primary consideration in determining whether a site is suitable for the development of a utility-scale solar energy facility (Moose 2009).

Wildlife likely to be found in the proposed East Mormon Mountain SEZ is described in Section 11.5.11. Although now restricted, in the past, the hunting of sheep was an important part of Southern Paiute culture and had religious significance, as reflected in the many panels of sheep petroglyphs found throughout Southern Paiute territory. Bighorn sheep are present in the East Mormon Mountains and Mormon Mountains of the SEZ and in the Tule Spring Hills to the

TABLE 11.5.18.1-2 Plant Species Important to Native Americans Observed or Likely To Be Present in the Proposed East Mormon Mountain SEZ

Common Name	Scientific Name	Status
Food		
Desert trumpet (buckwheat)	<i>Eriogonum inflatum</i>	Observed
Dropseed	<i>Sporobolus</i> spp.	Possible
Indian rice grass	<i>Oryzopsis hymenoides</i>	Observed
Iodine bush	<i>Allenrolfea occidentalis</i>	Possible
Joshua tree	<i>Yucca brevifolia</i>	Observed
Prickly pear cactus	<i>Opuntia</i> spp.	Possible
Saltbush	<i>Atriplex canescens</i>	Observed
Seablite	<i>Suaeda diffusa</i>	Possible
Wolfberry	<i>Lycium andersonii</i>	Possible
Medicine		
Creosotebush	<i>Larrea tridentata</i>	Observed
Mormon tea	<i>Ephedra nevadaensis</i>	Possible
Palmer's phacelia	<i>Phacelia palermi</i>	Possible

Sources: Field visit; USGS (2005a); Fowler (1986); Stoffle and Dobyns (1983); Stoffle et al. (1999).

north. Mule deer habitat occurs in the Mormon Mountains about 5 mi (8 km) west (BLM 2009f). The desert tortoise was once a food source for the Moapa Band, but it is now often mentioned by the Moapa Band as a species that should be protected (Stoffle and Dobyns 1983). The SEZ is desert tortoise habitat and borders critical habitat to the south (BLM 2009f). Because of the general aridity of the SEZ, few game species traditionally important to Native Americans occur within the SEZ (see Table 11.5.18.1-3). Among the most important is the black-tailed jack rabbit (*Lepus californicus*) (Stoffle and Dobyns 1983; Kelly and Fowler 1986). Other small game species important to Native Americans that can be found in the SEZ include desert cottontails (*Sylvilagus audubonii*) and woodrats (*Neotoma lepida*). Other animals traditionally important to the Southern Paiute include lizards, which are likely to occur in the SEZ, and the golden eagle (*Aquila chrysaetos*).

Other natural resources traditionally important to Native Americans include clay for pottery, salt, naturally occurring mineral pigments for the decoration and protection of the skin, and turquoise for ritual purposes (Stoffle and Dobyns 1983)

11.5.18.2 Impacts

The Southern Paiutes tend to take a holistic view of their traditional homeland. For them, cultural and natural features are inextricably bound together. Effects on one part have ripple effects on the whole. Western distinctions between the sacred and the secular have no meaning

TABLE 11.5.18.1-3 Animal Species Used by Native Americans as Food with Ranges That Include the Proposed East Mormon Mountain SEZ

Common Name	Scientific Name	Status
Mammals		
Badger	<i>Taxidea taxus</i>	All year
Black-tailed jackrabbit	<i>Lepus californicus</i>	All year
Bobcat	<i>Lynx rufus</i>	All year

in their traditional worldview (Stoffle and Dobyns 1983). While no comments specific to the proposed East Mormon Mountain SEZ have been received from Native American Tribes to date, the Paiute Indian Tribe of Utah has asked to be kept informed of PEIS developments. Typically, the Southern Paiute have concerns over adverse effects on a wide range of resources. They consider springs and burial grounds of highest importance (Stoffle and Dobyns 1983). Other sites and features are often seen as important because they are the location of or have ready access to a range of plant, animal, and mineral resources (Stoffle et al. 1997). Resources considered important include plants used for food, medicine, basketry, and in construction; large and small game animals; birds; and sources of clay, salt, and pigments (Stoffle and Dobyns 1983). Those resources likely to occur within the proposed East Mormon Mountain SEZ are discussed in Section 11.5.18.1.2. Geophysical features and physical cultural remains are discussed in Section 11.5.17.1.4.

The development and operation of utility-scale solar energy facilities in the proposed East Mormon Mountain SEZ would require tapping into the water resources at Tule Spring just north

1 of the SEZ. Other springs are located in the Tule Springs Hills and East Mormon Mountains.
2 Significant drawdown from Tule Springs or groundwater could affect these culturally important
3 traditional resources. However, implementation of programmatic design features, as discussed in
4 Section A.2.2, should eliminate impacts on Tribes' reserved water rights and the potential for
5 groundwater contamination issues.
6

7 The most likely traditional use of the lands proposed for the East Mormon Mountain SEZ
8 is foraging. The development of a solar energy facility would result in the loss of some plants
9 traditionally used by Native Americans. However, vegetation is sparse in the proposed SEZ. The
10 state would require that the developer allow any Joshua trees that would be uprooted to be
11 transplanted prior to the start of development. The same vegetation cover types are wide-spread
12 in the surrounding area. It is therefore likely that effects on these resources would be minimal
13 (see Section 11.5.10). Similarly, although the habitat of traditionally important animal species,
14 such as the black-tailed jackrabbit, would be disturbed, there likewise is an abundance of similar
15 habitat in the area (see Section 11.5.11). This should be confirmed by consultation with affected
16 Native American Tribes when specific projects are proposed.
17

18 As consultation with the Tribes continues and project-specific analyses are undertaken, it
19 is possible that Native Americans will express additional concerns over potential visual, acoustic
20 and other effects on specific resources and any culturally important landscapes within or adjacent
21 to the proposed SEZ.
22
23

24 **11.5.18.3 SEZ-Specific Design Features and Design Feature Effectiveness**

25

26 Programmatic design features that would address impacts of potential concern to Native
27 Americans, such as avoidance of sacred sites, water sources, and tribally important plant and
28 animal species, are provided in Appendix A, Section A.2.2. Mitigation of impacts on
29 archaeological sites and traditional cultural properties is discussed in Section 11.5.17.3, in
30 addition to the programmatic design features for historic properties presented in Section A.2.2 in
31 Appendix A.
32

33 The need for and nature of SEZ-specific design features addressing issues of potential
34 concern would be determined during government-to-government consultation with affected
35 Tribes listed in Table 11.5.18.1-1.

11.5.19 Socioeconomics

11.5.19.1 Affected Environment

This section describes current socioeconomic conditions and local community services within the ROI surrounding the proposed East Mormon Mountain SEZ. The ROI is a three-county area comprising Clark and Lincoln Counties in Nevada and Washington County in Utah. It encompasses the area in which workers are expected to spend most of their salaries and in which a portion of site purchases and nonpayroll expenditures from the construction, operation, and decommissioning phases of the proposed SEZ facility are expected to take place.

11.5.19.1.1 ROI Employment

In 2008, employment in the ROI stood at 984,248 (Table 11.5.19.1-1). Over the period 1999 to 2008, the annual average employment growth rate was higher in Lincoln County (5.1%) than in Washington County (4.8%) and Clark County (3.2%). At 3.3%, the growth rate in the ROI as a whole was higher than the average rate for Nevada (2.7%) and Utah (2.1%).

In the ROI in 2006, the services sector provided the highest percentage of employment at 58.7%, followed by wholesale and retail trade at 15.1% and construction at 11.9% (Table 11.5.19.1-2). Within the three counties in the ROI, the distribution of employment across

TABLE 11.5.19.1-1 ROI Employment in the Proposed East Mormon Mountain SEZ

Location	1999	2008	Average Annual Growth Rate, 1999–2008 (%)

sectors is different from that of the ROI as a whole, with employment in services (59.6%) and construction (11.6%) higher in Clark County than in the other two counties in the ROI, while employment in transportation and public utilities (4.4%), and agriculture (0.0%) were lower than in the other counties in the ROI.

11.5.19.1.2 ROI Unemployment

The average rate in Lincoln County over the period over the period 1999 to 2008 was 5.2%, slightly higher than the rate in Clark County (5.0%), and higher than the rate for Washington County (Table 11.5.19.1-3). The average rate in the ROI over this period was 5.0%, the same as the average rate for Nevada. Unemployment rates for the first 11 months of 2009 contrast with rates for 2008 as a whole; in Clark County the unemployment rate increased to 11.1%, while in Lincoln County the rate reached 8.0%, and in Washington County it increased to 7.1%. The average rates for the ROI (10.8%) and for Nevada (11.0%) and Utah (5.2%) as a whole were also higher during this period than the corresponding average rates for 2008.

11.5.19.1.3 ROI Urban Population

The population of the ROI in 2008 was 59% urban. The largest city, Las Vegas, had an estimated population of 562,849; other large cities in Clark County are Henderson (253,693) and North Las Vegas (217,975) (Table 11.5.19.1-4). In addition, there are two smaller cities in the county, Mesquite (16,528) and Boulder City (14,954). There are a number of unincorporated urban areas in Clark County that are not included in the urban population, meaning that the percentage of the county population not living in urban areas is overstated. The largest urban area in Washington County, St. George, had an estimated 2008 population of 71,702; other

TABLE 11.5.19.1-3 ROI Unemployment Rates for the Proposed East Mormon Mountain SEZ (%)

Washington	8,816	17,452	9.9	45,502	NA	NA

^a Data are averages for the period 2006 to 2008.

^b NA = data not available.

Sources: U.S. Bureau of the Census (2009b–d).

urban areas in the county are Washington (17,452) and Hurricane (13,149) (Table 11.5.19.1-4). In addition, there are 12 other urban areas in the county. Most of these cities are less than 100 mi (160 km) from the site of the proposed SEZ.

Population growth rates in the ROI have varied over the period 2000 to 2008 (Table 11.5.19.1-4). Washington grew at an annual rate of 9.9% during this period, with higher-than-average growth also experienced in North Las Vegas (8.3%), Mesquite (7.3%), Ivins (7.1%) Hurricane (6.0%), and Henderson (4.7%). The cities of Las Vegas (2.1%), Caliente (0.7%), and others experienced a lower growth rate, while Boulder City (0.0%) experienced a static growth rate between 2000 and 2008.

11.5.19.1.4 ROI Urban Income

Median household incomes vary across urban areas in the ROI. Of the four cities for which data are available for 2006 to 2008, Henderson (\$67,886) and North Las Vegas (\$60,506) had median incomes higher than the average for Nevada (\$56,348), while median incomes in Las Vegas (\$55,113) were slightly lower than the state average. Median incomes in St. George (\$47,308) were also lower than the state average for Utah (\$56,484) (Table 11.5.19.1-4).

Growth rates between 1999 and 2006 to 2008 were small in North Las Vegas (0.2%), and St. George (0.1%), and negative in Henderson (−0.7%), and Las Vegas (−0.3%). The average median household income growth rate as a whole over this period was −0.2% for Nevada, and −0.5% in Utah.

11.5.19.1.5 ROI Population

Table 11.5.19.1-5 presents recent and projected populations in the ROI and for the two states as a whole. Population in the ROI stood at 2,019,414 in 2008, having grown at an average annual rate of 4.0% since 2000. Growth rates for ROI were higher than those in Nevada (3.4%) and Utah (2.5%) over the same period.

Each county in the ROI experienced growth in population between 2000 and 2008; population in Clark County grew at an annual rate of 4.0%, while population in Washington County grew by 5.2% and 1.4% in Lincoln County. The ROI population is expected to increase to 2,977,752 by 2021 and to 3,079,077 by 2023.

TABLE 11.5.19.1-5 ROI Population for the Proposed East Mormon Mountain SEZ

Location	2000	2008	Average Annual Growth Rate, 2000–2008 (%)	2021	2023

Sources: U.S. Bureau of the Census (2009e,f); Nevada State Demographers Office (2008).

11.5.19.1.6 ROI Income

Total personal income in the ROI stood at \$77.5 billion in 2007 and has grown at an annual average rate of 5.0% over the period 1998 to 2007 (Table 11.5.19.1-6). Per-capita income also rose over the same period at a rate of 0.7%, increasing from \$35,664 to \$38,327.

Per-capita incomes were higher in Clark County (\$40,307) than in Lincoln County (\$24,121) and Washington County (\$23,499) in 2007. Growth rates in total personal income have been higher in Clark County (5.0%) and Washington County (5.1%) than in Lincoln

County (0.7%). Personal income growth rates were higher in the ROI (5.0%) than in Nevada (4.3%) and Utah (2.9%), but per-capita income growth rate in Clark and Lincoln Counties were the same, or slightly less than in Nevada (1.0%) and in Utah (0.8%). The per-capita income growth rates for Lincoln County (-0.2%) and Washington County (-0.1%) were both negative.

Median household income in 2006 to 2008 varied from \$41,173 in Lincoln County, to \$49,747 in Washington County, to \$56,954 in Clark County (U.S. Bureau of the Census 2009d).

11.5.19.1.7 ROI Housing

In 2007, more than 808,400 housing units were located in the three ROI counties; about 93% of these were in Clark County (Table 11.5.19.1-7). Owner-occupied units compose approximately 60% of the occupied units in the three counties, with rental housing making up 40% of the total. Vacancy rates in 2007 were 29.3% in Lincoln County, 17.1% in Washington County, and 12.2% in Clark County; with an overall vacancy rate of 12.6% in the ROI. There were 101,695 vacant housing units in the ROI in 2007, of which 40,476 are estimated to be rental units that would be available to construction workers. There were 13,082 units in seasonal, recreational, or occasional use in the ROI at the time of the 2000 Census, with 1.5% of vacant housing units in Clark County, 12.0% in Washington County, and 14.0% in Lincoln County used for seasonal or recreational purposes.

Housing stock in the ROI as a whole grew at an annual rate of 4.4% over the period 2000 to 2007, with 209,990 new units added to the existing housing stock (Table 11.5.19.1-7).

The median value of owner-occupied housing in 2006 to 2008 varied from \$80,300 in Lincoln County, \$139,500 in Clark County to \$139,800 in Washington County (U.S. Bureau of the Census 2009g).

11.5.19.1.8 ROI Local Government Organizations

The various local and county government organizations in the ROI are listed in Table 11.5.19.1-8. In addition, three Tribal governments are located in the ROI; members of other Tribal groups are located in the county, but their Tribal governments are in adjacent counties or states.

11.5.19.1.9 ROI Community and Social Services

This section describes educational, health-care, law enforcement, and firefighting resources in the ROI.

Schools

In 2007, the three-county ROI had a total of 375 public and private elementary, middle, and high schools (NCES 2009). Table 11.5.19.1-9 provides summary statistics for enrollment and educational staffing and two indices of educational quality—student-teacher ratios and levels of service (number of teachers per 1,000 population). The student-teacher ratio in Washington County schools (22.1) is higher than that in Clark County (19.0) and Lincoln County schools (13.3), while the level of service is much higher in Lincoln County (18.2) than elsewhere in the ROI, where there are fewer teachers per 1,000 population (Clark County, 8.7; Washington County, 7.8).

1 **Health Care**

2
3 The total number of physicians and the number of physicians per 1,000 population is
4 higher in Clark County (4,220; 2.3) than in Washington County (277; 2.0) and in Lincoln County
5 (2; 0.4) (Table 11.5.19.1-10).
6

7
8 **Public Safety**

9
10 Several state, county, and local police departments provide law enforcement in the
11 ROI (Table 11.5.19.1-11). Lincoln County has 26 officers and would provide law enforcement
12 services to the SEZ; there are 3,214 officers in Clark County and 45 officers in Washington
13 County. Levels of service of police protection per 1,000 population are 5.8 in Lincoln County,
14 1.7 in Clark County, and 0.3 in Washington County. Currently, there are 1,002 professional
15 firefighters in the ROI (Table 11.5.19.1-11).
16

17
18 ***11.5.19.1.10 ROI Social Structure and Social Change***

19
20 Community social structures and other forms of social organization within the ROI are
21 related to various factors, including historical development, major economic activities and
22 sources of employment, income levels, race and ethnicity, and forms of local political
23 organization. Although an analysis of the character of community social structures is beyond the
24 scope of the current programmatic analysis, project-level NEPA analyses would include a
25 description of ROI social structures, contributing factors, their uniqueness, and consequently, the
26 susceptibility of local communities to various forms of social disruption and social change.
27

28 Various energy development studies have suggested that once the annual growth in
29 population is between 5 and 15% in smaller rural communities, alcoholism, depression, suicide,
30 social conflict, divorce, and delinquency would increase and levels of community satisfaction
31 would deteriorate (BLM 1980, 1983, 1996). Data on violent crime and property crime rates and
32 on alcoholism, illicit drug use, mental health, and divorce, which might be used as indicators of
33 social change, are presented in Tables 11.5.19.1-12 and 11.5.19.1-13, respectively.
34

35
36 There is some variation in the level of crime across the ROI, with higher rates of violent
37 crime in Clark County (8.3 per 1,000 population) than in Washington County (2.0) and Lincoln
38 County (1.3) (Table 11.5.19.1-12). Property-related crime rates are also higher in Clark County
39

(34.5) than in Washington County (23.6) and Lincoln County (7.3); overall crime rates in Clark County (42.5) were higher than in Washington County (25.6) and Lincoln County (8.6).

Other measures of social change—alcoholism, illicit drug use, and mental health—are not available at the county level and thus are presented for the SAMHSA region in which the ROI is located. There is slight variation across the three regions in which the three counties are located; rates for alcoholism and mental health are slightly higher in the region in which Clark County is located (Table 11.5.19.1-13).

1 **11.5.19.1.11 ROI Recreation**

2
3 Various areas in the vicinity of the proposed SEZ are used for recreational purposes, with
4 natural, ecological, and cultural resources in the ROI attracting visitors for a range of activities,
5 including hunting, fishing, boating, canoeing, wildlife watching, camping, hiking, horseback
6 riding, mountain climbing, and sightseeing. These activities are discussed in Section 11.5.5.
7

8 Because the number of visitors using state and federal lands for recreational activities is
9 not available from the various administering agencies, basing the value of recreational resources
10 in these areas solely on the number of recorded visitors is likely to be an underestimation. In
11 addition to visitation rates, the economic valuation of certain natural resources can also be
12 assessed in terms of the potential recreational destination for current and future users, that is,
13 their nonmarket value (see Section 5.17.1.1.1).
14

15 Another method is to estimate the economic impact of the various recreational activities
16 supported by natural resources on public land in the vicinity of the proposed solar facilities, by
17
18

TABLE 11.5.19.1-12 County and ROI Crime Rates for the Proposed East Mormon Mountain SEZ^a

	Violent Crime ^b		Property Crime ^c		All Crime	
	Offenses	Rate	Offenses	Rate	Offenses	Rate

Utah				3.6

^a Data for alcoholism and drug use represent percentage of the population over 12 years of age with dependence or abuse of alcohol, illicit drugs. Data are averages for 2004 to 2006.

^b Data for mental health represent percentage of the population over 18 years of age suffering from serious psychological distress. Data are averages for 2002 to 2004.

^c Divorce rates are the number of divorces per 1,000 population. Data are for 2007.

^d NA = data not available.

Sources: SAMHSA (2009); CDC (2009).

identifying sectors in the economy in which expenditures on recreational activities occur. Not all activities in these sectors are directly related to recreation on state and federal lands; some activity occurs on private land (e.g., dude ranches, golf courses, bowling alleys, and movie theaters). Expenditures associated with recreational activities form an important part of the economy of the ROI. In 2007, 248,507 people were employed in the ROI in the various sectors identified as recreation, constituting 25.8% of total ROI employment (Table 11.5.19.1-14). Recreation spending also produced more than \$9,552 million in income in the ROI in 2007. The primary sources of recreation-related employment were hotels and lodging places and eating and drinking places.

11.5.19.2 Impacts

The following analysis begins with a description of the common impacts of solar development, including those on recreation and on social change. These impacts would occur regardless of the solar technology developed in the SEZ. The impacts of facilities employing various solar energy technologies are analyzed in detail in subsequent sections.

11.5.19.2.1 Common Impacts

Construction and operation of a solar energy facility at the proposed SEZ would produce direct and indirect economic impacts. Direct impacts would occur as a result of expenditures on wages and salaries, procurement of goods and services required for project construction and

**TABLE 11.5.19.1-14 Recreation Sector Activity in
the Proposed East Mormon Mountain SEZ ROI, 2007**

ROI	Employment	Income (\$ million)
Amusement and recreation services	4,933	151.1
Automotive rental	2,927	119.9
Eating and drinking places	111,946	3,291.2
Hotels and lodging places	117,616	5,640.1
Museums and historic sites	315	18.7
Recreational vehicle parks and campsites	398	11.1
Scenic tours	5,519	224.0

Total ROI	248,507	9,552.3

Source: MIG, Inc. (2010).

operation, and the collection of state sales and income taxes. Indirect impacts would occur as project wages and salaries, procurement expenditures, and tax revenues subsequently circulate through the economy of each state, thereby creating additional employment, income, and tax revenues. Facility construction and operation would also require in-migration of workers and their families into the ROI surrounding the site, which would affect population, rental housing, health service employment, and public safety employment. Socioeconomic impacts common to all utility-scale solar energy facilities are discussed in detail in Section 5.17. These impacts will be minimized through the implementation of programmatic design features described in Section A.2.2 of Appendix A.

Recreation Impacts

Estimating the impact of solar facilities on recreation is problematic, because it is not clear how solar development in the SEZ would affect recreational visitation and nonmarket values (i.e., the value of recreational resources for potential or future visits; see Section 5.17.1.2.3). While it is clear that some land in the ROI would no longer be accessible for recreation, the majority of popular recreational locations would be precluded from solar development. It is also possible that solar facilities in the ROI would be visible from popular recreation locations, and that construction workers residing temporarily in the ROI would occupy accommodation otherwise used for recreational visits, thus reducing visitation and consequently affecting the economy of the ROI.

Social Change

Although an extensive literature in sociology documents the most significant components of social change in energy boomtowns, the nature and magnitude of the social impact of energy developments in small rural communities are still unclear (see Section 5.17.1.1.4). While some degree of social disruption is likely to accompany large scale in-migration during the boom phase, there is insufficient evidence to predict the extent to which specific communities are likely to be affected, which population groups within each community are likely to be most affected, and the extent to which social disruption is likely to persist beyond the end of the boom period (Smith et al. 2001). Accordingly, because of the lack of adequate social baseline data, it has been suggested that social disruption is likely to occur once an arbitrary population growth rate associated with solar energy projects has been reached, with an annual rate of between 5 and 10% growth in population assumed to result in a breakdown in social structures and a consequent increase in alcoholism, depression, suicide, social conflict, divorce, and delinquency, and deterioration in levels of community satisfaction (BLM 1980, 1983, 1996).

In overall terms, the in-migration of workers and their families into the ROI would represent an increase of less than 0.1% in regional population during construction of the trough technology, with smaller increases for the power tower, dish engine and PV technologies, and during the operation of each technology. While it is possible that some construction and operations workers will choose to locate in communities closer to the SEZ, because of the lack of available housing to accommodate all in-migrating workers and families in smaller rural communities in the ROI and insufficient range of housing choices to suit all solar occupations, many workers are likely to commute to the SEZ from larger communities elsewhere in the ROI, thereby reducing the potential impact of solar development on social change. Regardless of the pace of population growth associated with the commercial development of solar resources and the likely residential location of in-migrating workers and families in communities some distance from the SEZ itself, the number of new residents from outside the ROI is likely to lead to some demographic and social change in small rural communities in the ROI. Communities hosting solar facilities are likely to be required to adapt to a different quality of life, with a transition away from a more traditional lifestyle involving ranching and taking place in small, isolated, close-knit, homogenous communities with a strong orientation toward personal and family relationships, toward a more urban lifestyle, with increasing cultural and ethnic diversity and increasing dependence on formal social relationships within the community.

Livestock Grazing Impacts

Cattle ranching and farming supported 202 jobs, and \$1.3 million in income in the ROI in 2007 (MIG, Inc. 2010). The construction and operation of solar facilities in the East Mormon Mountain SEZ could result in a decline in the amount of land available for livestock grazing, resulting in total (direct plus indirect) impacts of the loss of seven jobs and less than \$0.1 million in income in the ROI. There would also be a decline in grazing fees payable to the BLM and to the USFS by individual permittees based on the number of AUMs required to support livestock on public land. Assuming the 2008 fee of \$1.35 per AUM, grazing fee losses would amount to \$667 annually on land dedicated to solar facilities in the SEZ.

Access Road Impacts

The impacts of construction of an access road connecting the SEZ could include the addition of 234 jobs in the ROI (including direct and indirect impacts) in the peak year of construction (Table 11.5.19.2-1). Construction activities in the peak year would constitute less than 1% of total ROI employment. Access road construction would also produce \$9.1 million in ROI income. Direct sales taxes would be \$0.3 million; direct income taxes in Utah would be less than \$0.1 million.

Total operations (maintenance) employment impacts in the ROI (including direct and indirect impacts) of an access road would be less than 1 job during the first year of operation (Table 11.5.19.2-1) and would also produce less than \$0.1 million in income. Direct sales taxes would be less than \$0.1 million in the first year; direct income taxes less than \$0.1 million.

Construction and operation of an access road would not require the in-migration of workers and their families from outside the ROI; consequently, no impacts on housing markets in the ROI would be expected, and no new community service employment would be required in order to meet existing levels of service in the ROI.

11.5.19.2.2 Technology-Specific Impacts

The economic impacts of solar energy development in the proposed SEZ were measured in terms of employment, income, state tax revenues (sales and income), BLM acreage rental and capacity payments, population in-migration, housing, and community service employment (education, health, and public safety). More information on the data and methods used in the analysis can be found in Appendix M.

The assessment of the impact of the construction and operation of each technology was based on SEZ acreage, assuming 80% of the area could be developed. To capture a range of possible impacts, solar facility size was estimated on the basis of the land requirements of various solar technologies, assuming that 9 acres/MW (0.04 km²/MW) would be required for power tower, dish engine, and PV technologies and 5 acres/MW (0.02 km²/MW) would be required for solar trough technologies. Impacts of multiple facilities employing a given technology at each SEZ were assumed to be the same as impacts for a single facility with the same total capacity. Construction impacts were assessed for a representative peak year of construction, assumed to be 2021 for each technology. Construction impacts assumed that a maximum of one project could be constructed within a given year, with a corresponding maximum land disturbance of up to 3,000 acres (12 km²). For operations impacts, a representative first year of operations was assumed to be 2023 for trough and power tower and 2022 for the minimum facility size and 2023 for the maximum facility size for dish engine and PV. The years of construction and operations were selected as representative of the entire 20-year study period, because they are the approximate midpoint; construction and operations could begin earlier.

**TABLE 11.5.19.2-1 ROI Socioeconomic
Impacts of an Access Road Connecting the
Proposed East Mormon Mountain SEZ^a**

Parameter	Construction	Operations
Employment (no.)		
Direct	134	<1
Total	234	<1
Income ^b		
Total	9.1	<0.1
Direct state taxes ^b		
Sales	0.3	<0.1
Income	<0.1	<0.1
In-migrants (no.)	0	0
Vacant housing ^c (no.)	0	0
Local community service employment		
Teachers (no.)	0	0
Physicians (no.)	0	0
Public safety (no.)	0	0

^a Construction impacts assume 11 mi (18 km) of access road is required for the East Mormon Mountain SEZ. Construction impacts are assessed for the peak year of construction. Although gravel surfacing might be used, the analysis assumes the access road will be paved.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada; data provided are for workers who would reside Utah.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

1
2
3

Solar Trough

Construction. Total construction employment impacts in the ROI (including direct and indirect impacts) from the use of solar trough technologies would be up to 4,438 jobs (Table 11.5.19.2-2). Construction activities would constitute 0.3% of total ROI employment. A solar facility would also produce \$268.7 million in income. Direct sales taxes would be \$8.7 million; direct income taxes in Utah would be \$1.0 million.

Given the scale of construction activities and the likelihood of local worker availability in the required occupational categories, construction of a solar facility would mean that some in-migration of workers and their families from outside the ROI would be required, with 743 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility construction on the number of vacant rental housing units would not be expected to be large, with 371 rental units expected to be occupied in the ROI. This occupancy rate would represent 0.6% of the vacant rental units expected to be available in the ROI.

In addition to the potential impact on housing markets, in-migration would affect community service employment (education, health, and public safety). An increase in such employment would be required to meet existing levels of service in the ROI. Accordingly, seven new teachers, two physicians, and two public safety employees (career firefighters and uniformed police officers) would be required in the ROI. These increases would represent less than 0.1% of total ROI employment expected in these occupations.

Operations. Total operations employment impacts in the ROI (including direct and indirect impacts) of a build-out using solar trough technologies would be 496 jobs (Table 11.5.19.2-2). Such a solar facility would also produce \$18.9 million in income. Direct sales taxes would be \$0.2 million; direct income taxes in Utah would be \$0.1 million. Based on fees established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), acreage rental payments would be \$0.6 million, and solar generating capacity payments at least \$9.4 million.

Given the likelihood of local worker availability in the required occupational categories, operation of a solar facility would mean that some in-migration of workers and their families from outside the ROI would be required, with 40 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility operation on the number of vacant owner-occupied housing units would not be expected to be large, with 36 owner-occupied units expected to be occupied in the ROI.

TABLE 11.5.19.2-2 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed East Mormon Mountain SEZ with Trough Facilities^a

Parameter	Maximum Annual Construction Impacts	Operations Impacts
Employment (no.)		
Direct	1,744	313
Total	4,438	496
Income ^b		
Total	268.7	18.9
Direct state taxes ^b		
Sales	8.7	0.2
Income	1.0	0.1
BLM payments ^b		
Rental	NA ^d	0.6
Capacity ^e	NA	9.4
In-migrants (no.)	743	40
Vacant housing ^c (no.)	371	36
Local community service employment		
Teachers (no.)	7	0
Physicians (no.)	2	0
Public safety (no.)	2	0

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 600 MW (corresponding to 3,000 acres [12 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 1,435 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada; data provided are for workers who would reside Utah.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d NA = data not available.

^e The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), assuming a solar facility with no storage capability and full build-out of the site. Projects with 3 or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 No new community service employment would be required to meet existing levels of
2 service in the ROI.

3 4 5 **Power Tower**

6
7
8 **Construction.** Total construction employment impacts in the ROI (including direct
9 and indirect impacts) from the use of power tower technologies would be up to 1,768 jobs
10 (Table 11.5.19.2-3). Construction activities would constitute 0.1% of total ROI employment.
11 Such a solar facility would also produce \$107.0 million in income. Direct sales taxes would
12 be \$3.5 million; direct income taxes in Utah would be \$0.4 million.
13

14 Given the scale of construction activities and the likelihood of local worker availability
15 in the required occupational categories, construction of a solar facility would mean that some
16 in-migration of workers and their families from outside the ROI would be required, with
17 296 persons in-migrating into the ROI. Although in-migration may potentially affect local
18 housing markets, the relatively small number of in-migrants and the availability of temporary
19 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
20 construction on the number of vacant rental housing units would not be expected to be large,
21 with 148 rental units expected to be occupied in the ROI. This occupancy rate would represent
22 0.2 % of the vacant rental units expected to be available in the ROI.
23

24 In addition to the potential impact on housing markets, in-migration would affect
25 community service (education, health, and public safety) employment. An increase in such
26 employment would be required to meet existing levels of service in the ROI. Accordingly,
27 three new teachers, one physician, and one public safety employee would be required in the
28 ROI. These increases would represent less than 0.1% of total ROI employment expected in
29 these occupations.
30

31
32 **Operations.** Total operations employment impacts in the ROI (including direct and
33 indirect impacts) of a build-out using power tower technologies would be 221 jobs
34 (Table 11.5.19.2-3). Such a solar facility would also produce \$7.6 million in income. Direct
35 sales taxes would be less than \$0.1 million; direct income taxes in Utah would be less than
36 \$0.1 million. Based on fees established by the BLM in its Solar Energy Interim Rental Policy
37 (BLM 2010c), acreage rental payments would be \$0.6 million, and solar generating capacity
38 payments would total at least \$5.2 million.
39

40 Given the likelihood of local worker availability in the required occupational categories,
41 operation of a solar facility means that some in-migration of workers and their families from
42 outside the ROI would be required, with 21 persons in-migrating into the ROI. Although
43 in-migration may potentially affect local housing markets, the relatively small number of
44 in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home
45 parks) mean that the impact of solar facility operation on the number of vacant owner-occupied
46

Vacant housing ^c (no.)		
	148	19
Local community service employment		
Teachers (no.)	3	0
Physicians (no.)	1	0
Public safety (no.)	1	0

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 333 MW (corresponding to 3,000 acres [12 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 797 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada; data provided are for workers who would reside in Utah.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d NA = data not available.

^e The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), assuming a solar facility with no storage capability and full build-out of the site. Projects with 3 or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 housing units would not be expected to be large, with 19 owner-occupied units expected to be
2 required in the ROI.

3
4 No new community service employment would be required to meet existing levels of
5 service in the ROI.

6 7 8 **Dish Engine**

9
10
11 **Construction.** Total construction employment impacts in the ROI (including direct
12 and indirect impacts) from the use of dish engine technologies would be up to 719 jobs
13 (Table 11.5.19.2-4). Construction activities would constitute less than 0.1% of total ROI
14 employment. Such a solar facility would also produce \$43.5 million in income. Direct sales
15 taxes would be \$1.4 million; direct income taxes in Utah would be \$0.2 million.

16
17 Given the scale of construction activities and the likelihood of local worker availability
18 in the required occupational categories, construction of a solar facility would mean that some
19 in-migration of workers and their families from outside the ROI would be required, with
20 120 persons in-migrating into the ROI. Although in-migration may potentially affect local
21 housing markets, the relatively small number of in-migrants and the availability of temporary
22 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
23 construction on the number of vacant rental housing units would not be expected to be large,
24 with 60 rental units expected to be occupied in the ROI. This occupancy rate would represent
25 0.1% of the vacant rental units expected to be available in the ROI.

26
27 In addition to the potential impact on housing markets, in-migration would affect
28 community service (education, health, and public safety) employment. An increase in such
29 employment would be required to meet existing levels of service in the ROI. Accordingly, one
30 new teacher would be required in the ROI. This increase would represent less than 0.1% of total
31 ROI employment expected in these occupations.

32
33
34 **Operations.** Total operations employment impacts in the ROI (including direct
35 and indirect impacts) of a build-out using dish engine technologies would be 214 jobs
36 (Table 11.5.19.2-4). Such a solar facility would also produce \$7.4 million in income.
37 Direct sales taxes would be less than \$0.1 million; direct income taxes in Utah would be less
38 than \$0.1 million. Based on fees established by the BLM in its Solar Energy Interim Rental
39 Policy (BLM 2010c), acreage rental payments would be \$0.6 million, and solar generating
40 capacity payments would total at least \$5.2 million.

41
42 Given the likelihood of local worker availability in the required occupational categories,
43 operation of a dish engine solar facility means that some in-migration of workers and their
44 families from outside the ROI would be required, with 20 persons in-migrating into the ROI.
45 Although in-migration may potentially affect local housing markets, the relatively small number
46

^d NA = data not available.

^e The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), assuming a solar facility with no storage capability and full build-out of the site. Projects with 3 or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile
2 home parks) mean that the impact of solar facility operation on the number of vacant owner-
3 occupied housing units would not be expected to be large, with 18 owner-occupied units
4 expected to be required in the ROI.

5
6 No new community service employment would be required to meet existing levels of
7 service in the ROI.

8 9 10 **Photovoltaic**

11
12
13 **Construction.** Total construction employment impacts in the ROI (including direct and
14 indirect impacts) from the use of PV technologies would be up to 444 jobs (Table 11.5.19.2-5).
15 Construction activities would constitute less than 0.1% of total ROI employment. Such solar
16 development would also produce \$28.1 million in income. Direct sales taxes would be
17 \$0.7 million; direct income taxes in Utah would be \$0.1 million.

18
19 Given the scale of construction activities and the likelihood of local worker availability
20 in the required occupational categories, construction of a solar facility would mean that some
21 in-migration of workers and their families from outside the ROI would be required, with
22 101 persons in-migrating into the ROI. Although in-migration may potentially affect local
23 housing markets, the relatively small number of in-migrants and the availability of temporary
24 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
25 construction on the number of vacant rental housing units would not be expected to be large,
26 with 50 rental units expected to be occupied in the ROI. This occupancy rate would represent
27 0.1% of the vacant rental units expected to be available in the ROI.

28
29 In addition to the potential impact on housing markets, in-migration would affect
30 community service (education, health, and public safety) employment. An increase in such
31 employment would be required to meet existing levels of service in the ROI. Accordingly,
32 one new teacher would be required in the ROI. This increase would represent less than 0.1%
33 of total ROI employment expected in this occupation.

34
35
36 **Operations.** Total operations employment impacts in the ROI (including direct and
37 indirect impacts) of a build-out using PV technologies would be 21 jobs (Table 11.5.19.2-5).
38 Such a solar facility would also produce \$0.7 million in income. Direct sales taxes would be
39 less than \$0.1 million; direct income taxes in Utah would be less than \$0.1 million. Based on
40 fees established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), acreage
41 rental payments would be \$0.6 million, and solar generating capacity payments would total at
42 least \$4.2 million.

43
44 Given the likelihood of local worker availability in the required occupational categories,
45 operation of a solar facility would mean that some in-migration of workers and their families
46 from outside the ROI would be required, with two persons in-migrating into the ROI. Although

9

10 **11.5.19.3 SEZ-Specific Design Features and Design Feature Effectiveness**

11
12
13 No SEZ-specific design features addressing socioeconomic impacts have been identified
14 for the proposed East Mormon Mountain SEZ. Implementing the programmatic design features
15 described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would
16 reduce the potential for socioeconomic impacts during all project phases.
17
18

11.5.20 Environmental Justice

11.5.20.1 Affected Environment

On February 11, 1994, the President signed Executive Order 12898, “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,” which formally requires federal agencies to incorporate environmental justice as part of their missions (*Federal Register*, Volume 59, page 76297, Feb. 11, 1994). Specifically, it directs them to address, as appropriate, any disproportionately high and adverse human health or environmental effects of their actions, programs, or policies on minority and low-income populations.

The analysis of the impacts of solar energy projects on environmental justice issues follows guidelines described in the CEQ’s *Environmental Justice Guidance under the National Environmental Policy Act* (CEQ 1997). The analysis method has three parts: (1) a description of the geographic distribution of low-income and minority populations in the affected area is undertaken; (2) an assessment is conducted to determine whether construction and operation would produce impacts that are high and adverse; and (3) if impacts are high and adverse, a determination is made as to whether these impacts disproportionately affect minority and low-income populations.

Construction and operation of solar energy projects in the proposed SEZ could affect environmental justice if any adverse health and environmental impacts resulting from either phase of development are significantly high and if these impacts disproportionately affect minority and low-income populations. If the analysis determines that health and environmental impacts are not significant, there can be no disproportionate impacts on minority and low-income populations. In the event impacts are significant, disproportionality would be determined by comparing the proximity of any high and adverse impacts with the location of low-income and minority populations.

The analysis of environmental justice issues associated with the development of solar facilities considered impacts within the SEZ and an associated 50-mi (80-km) radius around the boundary of the SEZ. A description of the geographic distribution of minority and low-income groups in the affected area was based on demographic data from the 2000 Census (U.S. Bureau of the Census 2009k,l). The following definitions were used to define minority and low-income population groups:

- **Minority.** Persons who identify themselves as belonging to any of the following racial groups: (1) Hispanic, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or Other Pacific Islander.

Beginning with the 2000 Census, where appropriate, the census form allows individuals to designate multiple population group categories to reflect their ethnic or racial origin. In addition, persons who classify themselves as being of multiple racial origins may choose up to six racial groups as the basis of

1 their racial origins. The term minority includes all persons, including those
2 classifying themselves in multiple racial categories, except those who classify
3 themselves as not of Hispanic origin and as White or “Other Race”
4 (U.S. Bureau of the Census 2009k).

5
6 The CEQ guidance proposed that minority populations should be identified
7 where either (1) the minority population of the affected area exceeds 50% or
8 (2) the minority population percentage of the affected area is meaningfully
9 greater than the minority population percentage in the general population or
10 other appropriate unit of geographic analysis.

11
12 This PEIS applies both criteria in using the Census data for census block
13 groups, wherein consideration is given to the minority population that is both
14 greater than 50% and 20 percentage points higher than in the state (the
15 reference geographic unit).

- 16
17 • **Low-Income.** Individuals who fall below the poverty line. The poverty line
18 takes into account family size and age of individuals in the family. In 1999,
19 for example, the poverty line for a family of five with three children below
20 the age of 18 was \$19,882. For any given family below the poverty line, all
21 family members are considered as being below the poverty line for the
22 purposes of analysis (U.S. Bureau of the Census 2009l).

23
24 The data in Table 11.5.20.1-1 show the minority and low-income composition of the
25 total population located in the proposed SEZ based on 2000 Census data and CEQ guidelines.
26 Individuals identifying themselves as Hispanic or Latino are included in the table as a separate
27 entry. However, because Hispanics can be of any race, this number also includes individuals
28 identifying themselves as being part of one or more of the population groups listed in the table.

29
30 Minority and low-income individuals are located in the 50-mi (80-km) area around the
31 boundary of the SEZ. Within the 50-mi (80-km) radius in Nevada, 26.4% of the population is
32 classified as minority, while 12.0% is classified as low-income. However, the number of
33 minority individuals does not exceed 50% of the total population in the area, and the number of
34 minority individuals does not exceed the state average by 20 percentage points or more; thus, in
35 aggregate, there is no minority population in the SEZ area based on 2000 Census data and CEQ
36 guidelines. The number of low-income individuals does not exceed the state average by
37 20 percentage points or more and does not exceed 50% of the total population in the area; thus,
38 in aggregate, there are no low-income populations in the SEZ.

39
40 In the Utah portion of the 50-mi (80-km) radius, 21.8% of the population is classified as
41 minority, while 10.2% is classified as low-income. The number of minority individuals does not
42 exceed 50% of the total population in the area and the number of minority individuals does not
43 exceed the state average by 20 percentage points or more; thus, in aggregate, there is no minority
44 population in the SEZ area based on 2000 Census data and CEQ guidelines. The number of low-
45 income individuals does not exceed the state average by 20 percentage points or more and does
46

TABLE 11.5.20.1-1 Minority and Low-Income Populations within the 50-mi (80-km) Radius Surrounding the Proposed East Mormon Mountain SEZ

Parameter	Arizona	Nevada	Utah
Total population	1,588	22,739	81,757
White, non-Hispanic	1,169	17,780	74,222
Hispanic or Latino	376	3,930	4,454
Non-Hispanic or Latino minorities	43	1,029	3,081
One race	22	747	2,128
Black or African American	0	159	168
American Indian or Alaskan Native	15	320	1,183
Asian	2	185	357
Native Hawaiian or Other Pacific Islander	1	42	348
Some other race	4	41	72
Two or more races	21	282	953
Total minority	419	4,959	7,535
Low-income	190	2,314	8,675
Percentage minority	26.4	21.8	9.2
State percentage minority	36.2	34.8	14.0
Percentage low-income	12.0	10.2	10.6
State percentage low-income	13.9	10.5	9.4

Source: U.S Bureau of the Census (2009k,l).

not exceed 50% of the total population in the area; thus, in aggregate, there are no low-income populations in the SEZ.

In the Arizona portion of the 50-mi (80-km) radius, 9.2% of the population is classified as minority, while 10.6% is classified as low-income. The number of minority individuals does not exceed 50% of the total population in the area and the number of minority individuals does not exceed the state average by 20 percentage points or more; thus, in aggregate, there is no minority population in the SEZ area based on 2000 Census data and CEQ guidelines. The number of low-income individuals does not exceed the state average by 20 percentage points or more and does not exceed 50% of the total population in the area; thus, in aggregate, there are no low-income populations in the SEZ.

Figures 11.5.20.1-1 and 11.5.20.1-2 show the locations of the low-income and minority population groups, respectively, within the 50-mi (80-km) radius around the boundary of the SEZ.

FIGURE 11.5.20.1-1 Low-Income Population Groups within the 50-mi (80-km) Radius Surrounding the Proposed East Mormon Mountain SEZ

FIGURE 11.5.20.1-2 Minority Population Groups within the 50-mi (80-km) Radius Surrounding the Proposed East Mormon Mountain SEZ

11.5.20.2 Impacts

Environmental justice concerns common to all utility-scale solar energy facilities are described in detail in Section 5.18. These impacts will be minimized through the implementation of the programmatic design features described in Section A.2.2 of Appendix A, which address the underlying environmental impacts contributing to the concerns. The potentially relevant environmental impacts associated with solar facilities within the proposed SEZ include noise and dust during the construction; noise and EMF effects associated with operations; visual impacts of solar generation and auxiliary facilities, including transmission lines; access to land used for economic, cultural, or religious purposes; and effects on property values as areas of concern that might potentially affect minority and low-income populations.

Potential impacts on low-income and minority populations could be incurred as a result of the construction and operation of solar facilities involving each of the four technologies. Although impacts are likely to be small, there are minority populations defined by CEQ guidelines (Section 11.5.20.1) within the 50-mi (80-km) radius around the boundary of the SEZ; this means that any adverse impacts of solar projects could disproportionately affect minority populations. Because there are low-income populations within the 50-mi (80-km) radius, there could also be impacts on low-income populations.

11.5.20.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features addressing environmental justice impacts have been identified for the proposed East Mormon Mountain SEZ. Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would reduce the potential for environmental justice impacts during all project phases.

11.5.21 Transportation

Although the region of the proposed East Mormon Mountain SEZ contains interstate highways, major railroads, and a major airport, these features are not readily accessible from the SEZ. The interstate highway is 11 mi (18 km) to the south of the SEZ. The nearest rail access is approximately 25 mi (40 km) southwest of the SEZ, and the nearest major airport is about 70 mi (113 km) to the southwest, although several smaller airports are located closer to the SEZ. General transportation considerations and impacts are discussed in Sections 3.4 and 5.19, respectively.

11.5.21.1 Affected Environment

I-15 runs southwest–northeast approximately 11 mi (18 km) to the southeast of the SEZ, as shown in Figure 11.5.21-1. The closest existing exits to the SEZ on I-15 are Exits 112 and 120, with Exit 120 serving the western edge of Mesquite. The Las Vegas metropolitan area is approximately 62 mi (100 km) southwest of the SEZ along I-15. In the opposite direction, Salt Lake City is approximately 340 mi (547 km) away along I-15. There are several local unimproved dirt roads in the vicinity of the SEZ. OHV use in the SEZ and surrounding area has been designated as “Limited to travel on designated roads and trails” (BLM 2008a). As listed in Table 11.5.21-1, I-15 carries an average traffic volume of about 17,000 vehicles per day in the vicinity of the East Mormon Mountain SEZ (NV DOT 2010).

The UP Railroad serves the region. The main line passes through Las Vegas on its way between Los Angeles and Salt Lake City; the railroad passes about 20 mi (32 km) west of the East Mormon Mountain SEZ. The nearest rail access is in Moapa, approximately 25 mi (40 km) southwest of the SEZ.

There are seven public use airports within a driving range of about 80 mi (129 km) of the East Mormon Mountain SEZ, as listed in Table 11.5.21-2. Five of these airports do not have scheduled passenger service; the nearest of these is the Mesquite Airport, a small airport near I-15. North Las Vegas Airport, 70 mi (113 km) to the southwest, does not have scheduled commercial passenger service, but caters to smaller private and business aircraft (Clark County Department of Aviation 2010). In 2008, 22,643 and 23,950 passengers arrived at and departed from North Las Vegas Airport, respectively (BTS 2009).

The nearest airport with scheduled passenger service is the St. George Municipal Airport, 43 mi (69 km) to the northeast in St. George, Utah. Passenger service is provided by Delta Airlines and its partners (City of St. George Airport 2010). In 2008, 47,086 and 46,613 passengers arrived at and departed from this airport, respectively (BTS 2009). In the same year, 485,000 lb (220,000 kg) and 506,000 lb (229,000 kg) of freight arrived at and departed from St. George Airport, respectively (BTS 2009). Farther away in the opposite direction, McCarran International Airport in Las Vegas is served by all major U.S. airlines. In 2008, 20.43 million and 20.48 million passengers arrived at and departed from McCarran International Airport, respectively (BTS 2009). About 83.2 million lb (37.7 million kg) of freight departed and 117 million lb (53.2 million kg) arrived at McCarran in 2008 (BTS 2009).

TABLE 11.5.21-1 AADT on Major Roads Near the Proposed East Mormon Mountain SEZ for 2009

Road	General Direction	Location	AADT

11.5.21.2 Impacts

As discussed in Section 5.19, the primary transportation impacts are anticipated to be from commuting worker traffic. Single projects could involve up to 1,000 workers each day, with an additional 2,000 vehicle trips per day (maximum). The volume of traffic on I-15 would represent an increase in traffic of about 12% in the area of the SEZ for one solar project. Because higher traffic volumes would be experienced during shift changes, traffic on I-15 could experience minor slowdowns during these time periods in the area of exits in the vicinity of the SEZ where a project is located. Local road improvements would be necessary in the vicinity of exits from I-15 so as not to overwhelm the local access roads near any site access point(s).

Solar development within the SEZ would affect public access along OHV routes designated open and available for public use. If there are any designated as open within the proposed SEZ, such open routes crossing areas issued ROWs for solar facilities would be re-designated as closed (see Section 5.5.1 for more details on how routes coinciding with proposed solar facilities would be treated).

11.5.21.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features have been identified related to impacts on transportation systems around the proposed East Mormon Mountain SEZ. The programmatic design features described in Appendix A, Section A.2.2, including local road improvements, multiple site access locations, staggered work schedules, and ride-sharing, would all provide some relief to traffic congestion on local roads leading to the site. Depending on the location of solar facilities within the SEZ, more specific access locations and local road improvements could be implemented.

11.5.22 Cumulative Impacts

The analysis presented in this section addresses the potential cumulative impacts in the vicinity of the proposed East Mormon Mountain SEZ in Lincoln County, Nevada. The CEQ guidelines for implementing NEPA define cumulative impacts as environmental impacts resulting from the incremental effects of an action when added to other past, present, and reasonably foreseeable future actions (40 CFR 1508.7). The impacts of other actions are considered without regard to the agency (federal or nonfederal), organization, or person that undertakes them. The time frame of this cumulative impacts assessment could appropriately include activities that would occur up to 20 years in the future (the general time frame for PEIS analyses), but little or no information is available for projects that could occur further than 5 to 10 years in the future.

The land surrounding the East Mormon Mountain SEZ is undeveloped with few permanent residents living in the area. The nearest population centers are the small communities of Mesquite (population 21,253) and Bunkerville (population 1,330), approximately 12 mi (19 km) southeast of the southern boundary of the SEZ. The Moab Valley National Wildlife Refuge is 30 mi (48 km) southwest of the SEZ; the Desert National Wildlife Range is 40 mi (64 km) west of the SEZ; the Lake Mead National Recreation Area is about 30 mi (48 km) south of the SEZ; Valley of Fire State Park is 30 mi (48 km) southwest of the SEZ; and Grand Canyon-Parashant National Monument in Arizona is 25 mi (40 km) southeast of the SEZ. The Mormon Mountains WA is a few miles west of the SEZ. Three other WAs are within 50 mi (80 km) of the SEZ. The BLM administers approximately 82% of the lands in the Ely District, which contains the East Mormon Mountain SEZ. In addition, the Delamar Valley SEZ is located about 40 mi (64 km) to the northwest of the East Mormon Mountain SEZ and the proposed Dry Lake SEZ is located about 40 mi (64 km) to the southwest, and for some resources, the geographic extents of impacts from multiple SEZs overlap.

The geographic extent of the cumulative impacts analysis for potentially affected resources near the East Mormon Mountain SEZ is identified in Section 11.5.22.1. An overview of ongoing and reasonably foreseeable future actions is presented in Section 11.5.22.2. General trends in population growth, energy demand, water availability, and climate change are discussed in Section 11.5.22.3. Cumulative impacts for each resource area are discussed in Section 11.5.22.4.

11.5.22.1 Geographic Extent of the Cumulative Impacts Analysis

The geographic extent of the cumulative impacts analysis for potentially affected resources evaluated near the East Mormon Mountain SEZ is provided in Table 11.5.22.1-1. These geographic areas define the boundaries encompassing potentially affected resources. Their extent may vary based on the nature of the resource being evaluated and the distance at which an impact may occur (e.g., the evaluation of air quality may have a greater regional extent of impact than visual resources). Most of the lands around the SEZ are administered by the BLM, the USFWS, or the NPS; there are also some Tribal Lands nearby: the Moapa River Indian Reservation, about 30 mi (48 km) southwest of the SEZ, and the Paiute Shivwits Reservation,

TABLE 11.5.22.1-1 Geographic Extent of the Cumulative Impacts Analysis by Resource Area: Proposed East Mormon Mountain SEZ

Resource Area	Geographic Extent
Land Use	Southeast Lincoln County
Specially Designated Areas and Lands with Wilderness Characteristics	Within a 25-mi (40-km) radius of the East Mormon Mountain SEZ
Rangeland Resources	
Grazing	Grazing allotments within 5 mi (8 km) of the East Mormon Mountain SEZ
Wild Horses and Burros	A 50-mi (80-km) radius from the Center of the East Mormon Mountain SEZ
Recreation	Southeast Lincoln County
Military and Civilian Aviation	Southeast Lincoln County
Soil Resources	Areas within and adjacent to the East Mormon Mountain SEZ
Minerals	Southeast Lincoln County
Water Resources	
Surface Water	Toquop Wash, South Fork Toquop Wash, and the Virgin River Valley basin
Groundwater	Lower Virgin River Valley and Tule Desert groundwater basins
Air Quality and Climate	A 31-mi (50-km) radius from the center of the East Mormon Mountain SEZ
Vegetation, Wildlife and Aquatic Biota, Special Status Species	A 50-mi (80-km) radius from the center of the East Mormon Mountain SEZ, including portions of Lincoln and Clark in Nevada, Washington County in Utah, and Mohave County in Arizona
Visual Resources	Viewshed within a 25-mi (40-km) radius of the East Mormon Mountain SEZ
Acoustic Environment (noise)	Areas adjacent to the East Mormon Mountain SEZ
Paleontological Resources	Areas within and adjacent to the East Mormon Mountain SEZ
Cultural Resources	Areas within and adjacent to the East Mormon Mountain SEZ for archaeological sites; viewshed within a 25-mi (40-km) radius of the East Mormon Mountain SEZ for other properties, such as traditional cultural properties
Native American Concerns	Areas within and adjacent to the East Mormon Mountain SEZ; viewshed within a 25-mi (40-km) radius of the East Mormon Mountain SEZ
Socioeconomics	A 50-mi (80-km) radius from the center of the East Mormon Mountain SEZ
Environmental Justice	A 50-mi (80-km) radius from the center of the East Mormon Mountain SEZ
Transportation	I-15

1 22 mi (35 km) northeast of the SEZ in Utah. The BLM administers approximately 78.3% of the
2 lands within a 50-mi (80-km) radius of the SEZ.

4

5 **11.5.22.2 Overview of Ongoing and Reasonably Foreseeable Future Actions**

6

7 The future actions described below are those that are “reasonably foreseeable”; that is,
8 they have already occurred, are ongoing, are funded for future implementation, or are included in
9 firm near-term plans. Types of proposals with firm near-term plans are as follows:
10

- 11 • Proposals for which NEPA documents are in preparation or finalized;
- 12
- 13 • Proposals in a detailed design phase;
- 14
- 15 • Proposals listed in formal NOIs published in the *Federal Register* or state
- 16 publications;
- 17
- 18 • Proposals for which enabling legislations has been passed; and
- 19
- 20 • Proposals that have been submitted to federal, state, or county regulators to
- 21 begin a permitting process.
- 22

23 Projects that are in the bidding or research phase or that have been put on hold were not included
24 in the cumulative impact analysis.
25

26 The ongoing and reasonably foreseeable future actions described below are grouped into
27 two categories: (1) actions that relate to renewable energy and energy distribution, including
28 potential solar energy projects under the proposed action (Section 11.5.22.2.1); and (2) other
29 ongoing and reasonably foreseeable actions, including those related to fossil energy production,
30 mining and mineral processing, pipelines, water management systems, communication systems,
31 and residential developments (Section 11.5.22.2.2). Together, these actions and trends have the
32 potential to affect human and environmental receptors within the geographic range of potential
33 impacts over the next 20 years.
34
35

36 **11.5.22.2.1 Energy Production and Distribution**

37

38 On February 16, 2007, Governor Gibbons signed an Executive Order to encourage the
39 development of renewable energy resources in Nevada (Gibbons 2007a). The Executive Order
40 requires all relevant state agencies to review their permitting processes to ensure the timely and
41 expeditious permitting of renewable energy projects. On May 9, 2007, and June 12, 2008, the
42 Governor signed Executive Orders creating the Nevada Renewable Energy Transmission Access
43 Advisory Committee Phase I and Phase II, which will propose recommendations for improved
44 access to the grid system for renewable energy industries (Gibbons 2007b, 2008). On May 28,
45 2009, the Nevada Legislature passed Senate Bill 358 modifying the Renewable Energy Portfolio

Standards. The bill requires that 25% of the electricity sold to be produced by renewable energy sources by 2025.

Reasonably foreseeable future actions related to renewable energy production and energy distribution within 50 mi (80 km) of the proposed East Mormon Mountain SEZ are identified in Table 11.5.22.2-1 and described in the following sections. Three foreseeable solar energy projects on private land were identified, but no solar, wind, or geothermal projects on public land were identified. Four proposed transmission line projects are also discussed.

Renewable Energy Development

Renewable energy applications are considered in two categories, fast-track and regular-track applications. Fast-track applications, which apply principally to solar and wind energy facilities, are those applications on public lands for which the environmental review and public participation process is under way and the applications could be approved by December 2010. A fast-track project would be considered foreseeable, because the permitting and environmental review processes would be under way. Regular-track proposals are considered potential future projects but not necessarily foreseeable projects, since not all applications would be expected to be carried to completion. These pending proposals are considered together as a general level of interest in development of renewable energy in the region.

No fast-track solar, wind, or geothermal projects on public land were identified. However, three reasonably foreseeable solar projects on private land within 50 mi (80 km) of the proposed SEZ were identified, as listed in Table 11.5.22.2-1 and described in the following sections.

BrightSource Energy Coyote Springs Project. BrightSource Energy is planning to build a 960-MW, solar, thermal-power facility on private land at the Coyote Springs Investment Planned Development Project at the junction of U.S. 93 and State Route 168. The facility would utilize the Luz Power Tower, which consists of thousands of mirrors that reflect sunlight onto a boiler filled with water sitting on top of a tower. The high-temperature steam produced would be piped to a conventional turbine that generates electricity. The station would utilize a dry-cooling system. The site, approximately 7,680 acres (31 km²), would be 38 mi (61 km) southwest of the SEZ (BrightSource Energy 2009).

BrightSource Energy Overton Project. BrightSource Energy is planning to build three 400-MW solar thermal power facilities on private land east of the airport at Overton, Nevada. The facility would utilize the Luz Power Tower, which consists of thousands of mirrors that reflect sunlight onto a boiler filled with water sitting on top of a tower. The high-temperature steam produced would be piped to a conventional turbine that generates electricity. The station would utilize a dry-cooling system. The site would be 30 mi (48 km) southwest of the SEZ. The plan is for initial operation in 2012 (Cleantech 2008).

TABLE 11.5.22.2-1 Reasonably Foreseeable Future Actions Related to Energy Development and Distribution near the Proposed East Mormon Mountain SEZ^a

Description	Status	Resources Affected	Primary Impact Location
<i>Renewable Energy Projects on Private Lands</i>			
BrightSource Coyote Springs Project, 960 MW, solar tower, 7,680 acres	Planning stage	Terrestrial habitats, vegetation, wildlife, soil, water, visual, cultural	38 mi (60 km) southwest of the SEZ
BrightSource Overton Project 1,200 MW, solar tower	Planning stage	Terrestrial habitats, vegetation, wildlife, soil, water, visual, cultural	30 mi (48 km) southwest of the SEZ
Sithe Global Flat Top Mesa Solar, 50 MW, PV, 450 acres	Proposed	Terrestrial habitats, wildlife, cultural, visual	10 mi (16 km) northeast of the SEZ
<i>Transmission and Distribution Systems</i>			
One Nevada Transmission Line Project	Draft Supplemental EIS Nov. 30, 2009	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes 40 mi (64 km) west of the SEZ
Southwest Intertie Project	FONSI issued July 30, 2008; in-service in 2010	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes 40 mi (64 km) west of the SEZ
TransWest Transmission Project	Permit Application Nov. 2009	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes southern boundary of SEZ
Zephyr and Chinook Transmission Line Project	Permit Applications in 2011/2012	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes about 40 mi (64 km) west of the SEZ

^a Projects in later stages of agency environmental review and project development.

1
2
3

1 **Sithe Global Flat Top Mesa Solar.** Sithe Global is planning to build a 50-MW solar PV
2 power plant. The 450-acre (1.8-km²) site would be located on private land 5 mi (8 km) west of
3 Mesquite Nevada and 10 mi (16 km) southeast of the SEZ. Approximately 200 workers would be
4 required during the 15-month construction period (Sithe Global 2010a).

5
6
7 ***Pending Solar and Wind ROW Applications on BLM-Administered Lands.***

8 Applications for ROW-way grants that have been submitted to the BLM include eight pending
9 solar projects, three pending authorizations for wind site testing, and two authorized projects for
10 wind testing that would be located within 50 mi (80 km) of the East Mormon Mountain SEZ
11 (BLM 2010a). No applications for geothermal projects have been submitted. Table 11.5.22.2-2
12 lists these applications and Figure 11.5.22.2-1 shows their locations.

13
14 The likelihood of any of the regular-track application projects actually being developed
15 is uncertain, but it is generally assumed to be less than that for fast-track applications. The
16 projects, listed in Table 11.5.22.2-2 for completeness, are an indication of the level of interest in
17 development of renewable energy in the region. Some number of these applications would be
18 expected to result in actual projects. Thus, the cumulative impacts of these potential projects are
19 analyzed in their aggregate effects.

20
21 Wind testing would involve some relatively minor activities that could have some
22 environmental effects, mainly, the erection of meteorological towers and monitoring of wind
23 conditions. These towers may or may not employ guy wires and may be 200 ft (60 m) high.

24
25
26 **Transmission and Distribution Systems**

27
28 Table 11.5.22.2-1 identifies four major new transmission projects, which are described
29 below.

30
31
32 ***One Nevada Transmission Line Project.*** NV Energy proposes to construct and operate a
33 236-mi (382-km) 500-kV transmission line with fiber optic telecommunication and appurtenant
34 facilities in White Pine, Nye, Lincoln, and Clark counties. It will consist of self-supporting, steel-
35 lattice and steel-pose H-frame structures, placed 900 to 1,600 ft (274 to 488 m) apart. The width
36 of the ROW is 200 ft (61 m). The proposed action includes new substations outside the ROI of
37 the East Mormon Mountain SEZ. The transmission line would be within the SWIP utility
38 corridor 40 mi (64 km) west of the SEZ. Construction could have potential impacts on the
39 Mojave Desert Tortoise (BLM 2009a).

40
41
42 ***Southwest Intertie Project (SWIP).*** The SWIP is a 520-mi (830-km) single-circuit,
43 overhead, 500-kV transmission line project. The first phase, the Southern Portion, is a 264-mi
44 (422-km) long transmission line that begins at the existing Harry Allen Substation in Dry Lake,
45 Nevada, and runs north to a proposed substation approximately 18 mi (29 km) northwest of Ely,
46 Nevada. The transmission line will pass 40 mi (64 km) west of the SEZ. It will consist of
47

FIGURE 11.5.22.2-1 Locations of Renewable Energy Project ROW Applications on Public Land within a 50-mi (80-km) Radius of the Proposed East Mormon Mountain SEZ

^a BLM (2010a).

^b Information for pending solar (BLM and USFS 2010c) and pending wind (BLM and USFS 2010d) energy projects downloaded from GeoCommunicator.

^c To convert acres to km², multiply by 0.004047.

^d A dash indicates data not available.

1 self-supporting, steel-lattice and steel-pole H-frame structures, placed 1,200 to 1,500 ft (366 to
2 457 m) apart. The SWIP is expected to be completed in 2010. Construction could have potential
3 impacts on the Mojave Desert Tortoise (BLM 2007b).

4
5
6 **TransWest Transmission Project.** TransWest Express proposes to construct a high-
7 voltage electric utility transmission line. The 600-kV direct current transmission line would
8 extend from south central Wyoming to southern Nevada. A terminal/converter station would be
9 located near Boulder, Nevada. A communication system for command and control will require a
10 fiber optic network and periodic regenerative sites. The proposed routes have been sited to
11 parallel existing facilities and occupy designated utility corridors to the extent practicable, and
12 will pass the southern boundary of the SEZ (TransWest Express 2009).

13
14
15 **Zephyr and Chinook Transmission Line Project.** TransCanada is proposing to construct
16 two 500-kV, high-voltage, direct current transmission lines. The Zephyr project would originate
17 in southeastern Wyoming. The Chinook project would originate in south central Montana. Both
18 would travel along the same corridor from northern Nevada, passing about 40 mi (64 km) west
19 of the SEZ, and terminate in the El Dorado Valley south of Las Vegas. Construction is expected
20 to be complete in 2015 or 2016 (TransCanada 2010).

21 22 23 **11.5.22.2.2 Other Actions**

24
25 There are a number of energy production facilities within a 50-mi (80-km) radius from
26 the center of the East Mormon Mountain SEZ, which includes portions of Clark and Lincoln
27 Counties in Nevada, Washington County in Utah, and Mohave County in Arizona. Other major
28 ongoing and foreseeable actions within 50 mi (80 km) of the proposed East Mormon Mountain
29 SEZ are listed in Table 11.5.22.2-3 and described in the following sections.

30 31 32 **Other Ongoing and Foreseeable Energy Projects**

33
34
35 **Apex Generating Station.** The Apex Generating Station is a 600-MW, combined-cycle,
36 natural gas-fired power plant, consisting of two combustion turbine generators, two heat
37 recovery steam generators, and one steam turbine generator. The plant is located within the
38 Apex Industrial Park near the intersection of I-15 and U.S. 93. The site is about 50 mi (80 km)
39 southwest of the SEZ (Mirant Las Vegas, LLC 2007).

40
41
42 **Chuck Lenzie Generating Station.** The Chuck Lenzie Generating Station is an
43 1,160-MW, combined-cycle, natural gas-fired electric generation facility, located approximately
44 50 mi (80 km) southwest of the SEZ; it consists of four combustion turbines, four heat recovery
45 steam generators and two steam turbines. The plant, owned by NV Energy, has been operating at
46 full power since 2006. The station utilizes a dry-cooling system (NV Energy 2010a).

TABLE 11.5.22.2-3 Other Major Actions near the Proposed East Mormon Mountain SEZ^a

Description	Status	Resources Affected	Primary Impact Location
<i>Energy Projects</i>			
Apex Generating Station	Operating since 2003	Terrestrial habitats, wildlife, water, air, cultural, visual	50 mi (80 km) southwest of the SEZ
Chuck Lenzie Generating Station	Operating since 2006	Terrestrial habitats, wildlife, water, air, cultural, visual	50 mi (80 km) southwest of the SEZ
Harry Allen Generating Station	Operating since early 1980s	Terrestrial habitats, wildlife, water, air, cultural, visual	50 mi (80 km) southwest of the SEZ
Harry Allen Generating Station Expansion	Under construction	Terrestrial habitats, wildlife, water, air, cultural, visual	50 mi (80 km) southwest of the SEZ
Reid Gardner Generating Station	Operating since 1965	Terrestrial habitats, wildlife, water, air, cultural, visual	30 mi (48 km) southwest of the SEZ
Reid Gardner Expansion	EA and FONSI March 2008	Terrestrial habitats, wildlife, soil, air, water	30 mi (48 km) southwest of the SEZ
Silverhawk Generating Station	Operating since 2004	Terrestrial habitats, wildlife, water, air, cultural, visual	50 mi (80 km) southwest of the SEZ
Toquop Energy Project	Coal-fired plant FEIS 2009, changed to natural gas in 2010	Terrestrial habitats, wildlife, soil, water, air, cultural, visual	Adjacent to SEZ
<i>Distribution Systems</i>			
Kern River Gas Transmission System	Operating since 1992	Disturbed areas, terrestrial habitats along pipeline ROW	Corridor passes just south of SEZ
UNEV Pipeline Project	FEIS April 2010	Disturbed areas, terrestrial habitats along pipeline ROW	Corridor passes just south of SEZ

Description	Status	Resources Affected	Primary Impact Location
Other Projects			
Clark, Lincoln and White Pine Counties Groundwater Development Project	DEIS expected in 2011	Terrestrial habitats, wildlife, groundwater	43 mi (69 km) northwest of the SEZ
Coyote Springs Investment Planned Development Project	FEIS issued Sept. 2008, ROD issued Oct. 2008	Terrestrial habitats, wildlife, water, socioeconomics	35 mi (56 km) west of the SEZ
East Mormon Mountain Groundwater Testing/Monitoring Wells	EA and FONSI issued Sept. 2009	Terrestrial habitats, wildlife cultural resources	Within the SEZ
Lincoln County Land Act Groundwater Development and Utility ROW	FEIS issued May 2009 ROD Jan. 2010	Terrestrial habitats, wildlife, groundwater	Passes through the SEZ
Caliente Rail Realignment	FEIS June 2008	Terrestrial habitats, wildlife cultural resources	Closest approach 44 mi (70 km) northwest of the SEZ
Meadow Valley Industrial Park	FEIS issued Jan. 2010	Terrestrial habitats, wildlife, socioeconomics	44 mi (70 km) northwest of the SEZ
Ash Canyon Sagebrush Restoration and Fuels Reduction Project	Preliminary EA issued May 2010	Terrestrial habitats, wildlife	38 mi (61 km) northwest of the SEZ
Meadow Valley Gypsum Project	EA and FONSI issued 2008	Terrestrial habitats, wildlife, soils, socioeconomics	10 mi (16 km) west of the SEZ
Mesquite Nevada General Aviation Replacement Airport	DEIS April 2008		10 mi (16 km) southeast of SEZ
NV Energy Microwave and Mobile Radio Project	Preliminary EA March 2010	Terrestrial habitats, wildlife cultural resources	Two of the sites 40 mi (64 km) west of SEZ; one site 50 mi (80 km) northwest of SEZ

^a Projects ongoing or in later stages of agency environmental review and project development.

1 **Harry Allen Generating Station.** The Harry Allen Generating Station is a 144-MW,
2 gas-fired power plant. The plant is located north of the intersection of I-15 and U.S. 93. The
3 site is about 50 mi (80 km) southwest of the SEZ (NV Energy 2010b).
4

5
6 **Harry Allen Generating Station Expansion.** The Harry Allen Generating Station
7 Expansion is a 484-MW, combined-cycle, natural gas-fired power plant, consisting of two
8 combustion turbine generators, two heat recovery steam generators, and one steam turbine
9 generator. The heat rejection system will utilize a cooling system composed of natural-draft
10 dry-cooling towers. The plant is located on the site of the existing 144-MW plant. The site is
11 about 50 mi (80 km) southwest of the SEZ (NV Energy 2010b).
12

13
14 **Reid Gardner Generating Station.** The Reid Gardner Generating Station is a four-unit,
15 557-MW coal-fired electric generating facility owned by NV Energy. The first unit went online
16 in 1965. All four units have been operating since 1983. The 480-acre (1.9-km²) site is located
17 near the town of Moapa, about 30 mi (48 km) southwest of the SEZ. The facility includes
18 evaporation ponds and fly ash, bottom ash, and solids landfills. Pollution control includes wet
19 scrubbers. The heat rejection system consists of wet-cooling towers. Coal is delivered by rail
20 (BLM 2008d).
21

22
23 **Reid Gardner Expansion Project.** The Reid Gardner Expansion Project will consist of
24 the construction of a 240-acre (0.97-km²) fly ash landfill and a 315-acre (1.27-km²) evaporation
25 pond to support the existing Reid Gardner Power Plant. The proposed expansion is located
26 adjacent to the southern boundary of the existing site near the town of Moapa, about 30 mi
27 (48 km) southwest of the SEZ (BLM 2008d).
28

29
30 **Silverhawk Generating Station.** The Silverhawk Generating Station is a 580-MW,
31 combined-cycle, natural gas-fired power plant, consisting of two combustion turbine generators,
32 two heat recovery steam generators, and one steam turbine generator. The plant is located within
33 the Apex Industrial Park near the intersection of I-15 and U.S. 93. The site is about 50 mi
34 (80 km) southwest of the SEZ. The station utilizes a dry-cooling system (NV Energy 2009b).
35

36
37 **Toquop Energy Project.** The Toquop Energy Project, originally proposed as a 750-MW,
38 coal-fired electric generation facility, is now planned as a 1,100-MW natural gas-fired combined-
39 cycle power plant, located on a 640-acre (2.59-km²) site 12 mi (19 km) northwest of the town of
40 Mesquite, Nevada, and adjacent to the SEZ. The project will be built in phases. Phase 1 will be a
41 nominal 550 to 600 MW combined-cycle plant. A water supply system, a gas pipeline
42 connecting the power plant to the Kern River pipeline, connection to the existing Navajo-
43 McCullogh transmission line, and road access to I-15 would be required. The heat rejection
44 system will utilize a hybrid cooling system composed of natural draft dry-cooling towers with
45 ability to apply water overspray on the heating surfaces to provide additional cooling at ambient
46 air temperatures greater than about 80°F (27°C). The proposed project would require 600

workers during construction, scheduled to begin in 2012 with commercial operation in 2015 (BLM 2009b; Sithe Global 2010b).

Ongoing and Foreseeable Distribution Systems

Kern River Gas Transmission System. The Kern River Gas Transmission system transports 1.7 billion ft³ per day (48 million m³) of natural gas from Wyoming to the Las Vegas area and then southwest as far as San Bernardino, California. The 1,680-mi (2,690-km) pipeline has been in operation since 1992. A two-pipeline delivery system exists along most of the pipeline route. The pipeline passes to the south of the SEZ (Kern River Gas Transmission Company 2010).

UNEV Pipeline Project. Holly Energy Partners proposes to construct and operate a 399-mi (640-km), 12-in. (30.5-cm) petroleum products pipeline that will originate at the Holly Corporation's Woods Cross, Utah, refinery near Salt Lake City and terminate near the Apex Industrial Park near the intersection of I-15 and U.S. 93. The pipeline would generally follow the Kern River ROW within Nevada and pass just south of the SEZ (BLM 2010b).

Other Ongoing and Foreseeable Projects

Clark, Lincoln, and White Pine Counties Groundwater Development Project. The Southern Nevada Water Authority (SNWA) proposes to construct a groundwater development project that would transport approximately 122,755 ac-ft/yr (151 million m³/yr) of groundwater under existing water rights and applications from several hydrographic basins in eastern Nevada and western Utah. The proposed facilities include production wells, 306 mi (490 km) of buried water pipelines, five pumping stations, six regulating tanks, three pressure reducing stations, a buried storage reservoir, a water treatment facility, and about 323 mi (517 km) of 230-kV overhead power lines, as well as two primary and five secondary substations. The project would develop groundwater in the following amounts in two hydraulically connected valleys that are about 35 mi (56 km) west of the East Mormon Mountain SEZ and in a separate hydrographic basin: Dry Lake Valley (11,584 ac-ft/yr [14.3 million m³/yr]) and Delamar Valley (2,493 ac-ft/yr [3.1 million m³/yr]). In addition, an undetermined amount of water could be developed and transferred from Coyote Spring Valley, which is down-gradient of the other two basins (SNWA 2010).

Coyote Springs Investment (CSI) Development Project. CSI intends to develop a new town in southern Lincoln County at the junction of U.S. 93 and State Route 168. The town would be a master-planned community on 21,454 acres (86.8 km²), and would include residential, commercial, and industrial land uses. Plans call for more than 111,000 residential dwelling units at a density of 5 units per acre (0.004047 km²). Also included in the community would be public

1 buildings, hotels, resorts, casinos, commercial and light industrial areas, roads, bridges, and a
2 heliport. Utilities and other infrastructure would be developed to serve the town, including power
3 facilities, sanitary sewer and wastewater treatment facilities, stormwater facilities, solid waste
4 disposal transfer stations, and telecommunications facilities. Water supply treatment facilities,
5 monitoring wells, production wells, storage facilities, and transmission and distribution facilities
6 would also be built. Approximately 70,000 ac-ft/yr (86 million m³/yr) of water would be needed
7 for the community at full build-out, which may occur over a period of about 40 years. Currently,
8 CSI and its affiliates hold approximately 36,000 ac-ft/yr (44.0 million m³/yr) in certificated
9 groundwater rights in various basins within Lincoln County. CSI currently owns the 21,454-acre
10 (86.82-km²) development area and holds leases on an additional 7,548 acres (30.6 km²) of BLM
11 land in Lincoln County and 6,219 acres (25.2 km²) of BLM land in Clark County within or next
12 to the privately held land. These adjacent areas would be managed by BLM for the protection of
13 federally listed threatened or endangered species; activities would be limited to non-motorized
14 recreation or scientific research. The development is 35 mi (56 km) west of the SEZ
15 (USFWS 2008).

16
17
18 **East Mormon Mountain Groundwater Testing/Monitoring Wells.** The SNWA
19 intends to construct two to four groundwater wells within two 2.5-acre (0.010-km²) (1.0-acre
20 [0.004-km²] long term and 1.5-acre [0.006-km²] short term) site locations in the East Mormon
21 Mountain SEZ. The dimensions for the long-term ROW would be 168 ft × 260 ft (51 m × 79 m),
22 and the dimensions for the short-term ROW would be 330 ft × 330 ft (100 m × 100 m). Two
23 12-in. (30.5-cm) and two 20-in. (50.8-cm) wells would be drilled to between 2,200 and 2,400 ft
24 (670 and 730 m) in depth. Access to the well sites would be from both existing roads and a new
25 809-ft (247-m) long access road. Water generated during the tests would be discharged into the
26 natural drainage network around the sites. At the completion of hydraulic testing, SNWA would
27 continue to record data to establish baseline ranges of the groundwater levels in the area.

28
29
30 **Lincoln County Land Act Groundwater Development and Utility ROW.** This project
31 involves the construction of the infrastructure required to pump and convey groundwater
32 resources in the Clover Valley and Tule Desert Hydrographic Areas. The construction includes
33 75 mi (122 km) of collection and transmission pipeline, 30 wells, 5 storage tanks, water pipeline
34 booster stations, transmission lines and substations, and a natural gas pipeline. A total of
35 240 acres (0.97 km²) will be permanently disturbed, and 1,878 acres (7.6 km²) temporarily
36 disturbed. The pipeline will pass through the SEZ (BLM 2009e).

37
38
39 **Caliente Rail Alignment.** The DOE proposes to construct and operate a railroad for the
40 shipment of spent nuclear fuel and high-level radioactive waste to the geologic repository at
41 Yucca Mountain, Nevada. The rail line would begin near Caliente, Nevada, and extend north,
42 then turn in a westerly direction, passing through the SEZ, to a location near the northwest corner
43 of the Nevada Test and Training Range, and then continue south-southwest to Yucca Mountain.
44 The rail line would range in length from approximately 328 mi (528 km) to 336 mi (541 km),
45 depending upon the exact location of the alignment. The rail line would be restricted to DOE
46 shipments. Over a 50-year period, 9500 casks containing spent nuclear fuel and high-level

1 radioactive waste, and approximately 29,000 rail cars of other materials, including construction
2 materials, would be shipped to the repository. An average of 17 one-way trains per week would
3 travel along the rail line. Construction of support facilities, interchange yard, staging yard,
4 maintenance-of-way facility, rail equipment maintenance yard, cask maintenance facility, and
5 Nevada Rail Control Center and National Transportation Operation Center would also be
6 required. Construction would take 4 to 10 years and cost \$2.57 billion. Construction activities
7 would occur inside a 1000 ft (300 m) wide ROW for a total footprint of 40,600 acres (164 km²)
8 (DOE 2008).

10
11 **Meadow Valley Industrial Park.** The BLM is planning to transfer a 103-acre (0.42-km²)
12 parcel to the City of Caliente, Nevada, for the construction of the Meadow Valley Industrial
13 Park. The site is located on a previously disturbed area used for agriculture and recreation at the
14 intersection of U.S. 93 and State Route 317, about 20 mi (32 km) northeast of the SEZ.
15 Improvements to the site would include construction of a rail spur, access roads, and water and
16 sewer extensions (USFWS 2010b).

17
18
19 **Ash Canyon Sagebrush Restoration and Fuels Reduction Project.** The BLM Caliente
20 Field Office is proposing to conduct a sagebrush improvement and fuels reduction project
21 adjacent to Ash Canyon, about 5 mi (8 km) southeast of Caliente, Nevada, and about 38 mi
22 (61 km) northwest of the SEZ. The size of the project area is 870 acres (3.5 km²). The goal is to
23 reduce pinyon and juniper in order to achieve a desired state where sagebrush is present along
24 with an understory of perennial species; to reduce risk of wild fires by reducing fuel loading; to
25 restore the historic disturbance regime; and to improve the available habitat for resident wildlife
26 (BLM 2010d).

27
28
29 **Meadow Valley Gypsum Project.** Meadow Valley Gypsum was issued a Finding of No
30 Significant Impact (BLM 2008c) following an Environmental Assessment of proposed mining,
31 processing, and transporting of gypsum on public lands. The project would be located 50 mi
32 (80 km) south of Caliente in Lincoln County, Nevada. The project would disturb 46.7 acres
33 (0.2 km²) and would consist of an open pit, processing plant, and a 1.5-mi (2.4-km) access road.

34
35
36 **Mesquite Nevada General Aviation Replacement Airport.** The City of Mesquite,
37 Nevada, is proposing to replace its existing airport with a new airport on Mormon Mesa, adjacent
38 to I-15 near Riverside, Nevada, and about 10 mi (16 km) south of the SEZ. The airport would
39 require BLM to release 2,560 acres (10.4 km²) of BLM land for acquisition by the City of
40 Mesquite. The airport would include a new runway with associated parallel taxiway and general
41 aviation support and maintenance facilities. The existing airport would be decommissioned, and
42 the site would be released for nonaeronautical uses (FAA 2008).

1 **NV Energy Microwave and Mobile Radio Project.** NV Energy is proposing to install a
2 new microwave and radio communications network at 13 sites. Two sites are located 40 mi
3 (64 km) west of the SEZ, and one is located 50 mi (80 km) northwest of the SEZ. The two
4 closest sites are small, about 0.1 acres (0.0004 km²). The further site is 0.6 acres (0.0024 km²)
5 but requires 57 acres (0.23 km²) of land disturbance for access and power line ROWs. Each site
6 would include a communication shelter, two propane tanks, and a generator. Two of the sites
7 have a 160-ft (50-m) self-supporting lattice tower and one, an 80-ft (25-m) tower (BLM 2010a).
8
9

10 **Grazing**

11
12 There are numerous grazing allotments within the BLM Ely District. Restrictions on
13 Season of Use have been placed upon the desert tortoise critical habitat portions of the Gourd
14 Springs and Summit Spring allotments in the Programmatic Biological Opinion for the Bureau of
15 Land Management's Ely District Resource Management Plan.
16
17

18 **Mining**

19
20 The Meadow Valley Gypsum Project is proposing to mine gypsum on public land
21 approximately 10 mi (16 km) west of the SEZ, as noted above. A total of 46.7 acres (0.19 km²)
22 would be disturbed during the 10-year lifetime of the project. A 1.5-mi (2.5-km) access road and
23 a 1.8-acre (0.0073-km²) railroad siding would be constructed.
24
25

26 **11.5.22.3 General Trends**

27
28 General trends of population growth, energy demand, water availability, and climate
29 change for the proposed East Mormon Mountain SEZ are presented in this section.
30 Table 11.5.22.3-1 lists the relevant impacting factors for the trends.
31
32

33 **11.5.22.3.1 Population Growth**

34
35 Over the period 2000 to 2008, the population in Lincoln County grew annually by 1.4%,
36 in Clark County, 4.0%, and in Washington County, Utah, 5.2%, portions of which make up the
37 ROI for the East Mormon Mountain SEZ (see Section 11.5.19.1.5). The annual growth rate for
38 Nevada as a whole was 3.4% and for Utah, 2.5%. The population of the ROI in 2008 was
39 2,019,414 and is projected to increase to 2,977,752 by 2021 and to 3,079,077 by 2023.
40
41

TABLE 11.5.22.3-1 General Trends Relevant to the Proposed SEZs in Nevada

General Trend	Impacting Factors
Population growth	Urbanization Increased use of roads and traffic Land use modification Employment Education and training Increased resource use (e.g., water and energy) Tax revenue
Energy demand	Increased resource use Energy development (including alternative energy sources) Energy transmission and distribution
Water availability	Drought conditions and water loss Conservation practices Changes in water distribution
Climate change	Water cycle changes Increased wildland fires Habitat changes Changes in farming production and costs

11.5.22.3.2 Energy Demand

The growth in energy demand is related to population growth through increases in housing, commercial floorspace, transportation, manufacturing, and services. Given that population growth is expected in seven SEZ areas in Nevada between 2006 and 2016, an increase in energy demand is also expected. However, the EIA projects a decline in per-capita energy use through 2030, mainly because of improvements in energy efficiency and the high cost of oil throughout the projection period. Primary energy consumption in the United States between 2007 and 2030 is expected to grow by about 0.5% each year, with the fastest growth projected for the commercial sector (at 1.1% each year). Transportation, residential, and industrial energy consumption are expected to grow by about 0.5, 0.4, and 0.1% each year, respectively (EIA 2009).

11.5.22.3.3 Water Availability

As described in Section 11.5.9.1.2, the proposed East Mormon Mountain SEZ is located within the Lower Virgin River Valley groundwater basin. Groundwater recharge from precipitation is estimated to be between 9,500 and 55,000 ac-ft/yr (12 million and 68 million m³/yr); evaporation from groundwater is estimated to be 30,000 to 70,000 ac-ft/yr (37 million to 86 million m³/yr); and outflow into Lake Mead is estimated at 29,000 to

1 40,000 ac-ft/yr (36 million to 49 million m³/yr). The estimated sustainable yield of the
2 groundwater basin in the three-state region near the SEZ is between 12,600 and 40,000 ac-ft/yr
3 (16 million and 49 million m³/yr), but is currently set by the NDWR as 3,600 ac-ft/yr
4 (4.4 million m³/yr) in the Nevada portion of the basin.
5

6 In 2005, water withdrawals from surface waters and groundwater in Lincoln County were
7 57,100 ac-ft/yr (70 million m³/yr), of which 11% came from surface waters and 89% from
8 groundwater. The largest water use category was irrigation at 55,100 ac-ft/yr (68 million m³/yr),
9 while public supply/domestic water uses accounted for 1,300 ac-ft/yr (1.6 million m³/yr). It is
10 estimated that a total of 12,000 ac-ft/yr (15 million m³/yr) are withdrawn from the Lower Virgin
11 Valley Groundwater basin.
12

13 The Lincoln County Water District has proposed a groundwater development and utility
14 ROW project (Lincoln County Land Act project described above) to pump and convey water
15 that is permitted or may be permitted for use by the Nevada State Engineer from the Clover
16 Valley and Tule Desert hydrographic areas for use by Lincoln County customers. The project
17 could pump up to 14,480 ac-ft/yr (17.9 million m³/yr) from 15 wells in Clover Valley and
18 9,340 ac-ft/yr (11.5 million m³/yr) from Tule Desert. A pipeline ROW on public land would
19 convey water to multiple storage tanks for use (BLM 2009e).
20

21 22 **11.5.22.3.4 Climate Change** 23

24 Governor Jim Gibbons' Nevada Climate Change Advisory committee (NCCAC)
25 conducted a study of climate change and its effects on Utah (NCCAC 2008). The report
26 summarized the present scientific understanding of climate change and its potential impacts on
27 Nevada. A report on global climate change in the United States prepared by the U.S. Global
28 Research Program (GCRP 2009) documents current temperature and precipitation conditions and
29 historic trends. Excerpts of the conclusions from these reports indicate the following:
30

- 31 • Precipitation will decrease, and a greater percentage of that precipitation will
32 come from rain, resulting in a greater likelihood of winter and spring flooding
33 and decreased stream flow in the summer.
34
- 35 • The average temperature in the Southwest has already increased by about
36 1.5°F compared to a 1960 to 1979 baseline, and by the end of the century, the
37 average annual temperature is projected to rise 4°F to 10°F.
38
- 39 • A warming climate and the related reduction in spring snowpack and soil
40 moisture have increased the length of the wildfire season and intensity of
41 forest fires.
42
- 43 • Later snow and less snow coverage in ski resort areas could force ski areas to
44 shut down before the season would otherwise end.
45

- Much of the Southwest has experienced drought conditions since 1999. This represents the most severe drought in the last 110 years. Projections indicate an increasing probability of drought in the region.
- As temperatures rise, landscape will be altered as species shift their ranges northward and upward to cooler climates.
- Temperature increases, when combined with urban heat island effects for major cities such as Las Vegas, present significant stress to health, electricity, and water supply.
- Increased minimum temperatures and warmer springs extend the range and lifetime of many pests that stress trees and crops, and lead to northward migration of weed species.

11.5.22.4 Cumulative Impacts on Resources

This section addresses potential cumulative impacts in the proposed East Mormon Mountain SEZ on the basis of the following assumptions: (1) because of the small size of the proposed SEZ (<10,000 acres [$<40.5 \text{ km}^2$]), only one project could be constructed at a time, and (2) maximum total disturbance over 20 years would be about 7,174 acres (29 km^2) (80% of the entire proposed SEZ). For purposes of analysis, it is also assumed that no more than 3,000 acres (12.1 km^2) would be disturbed per project annually and 250 acres (1.01 km^2) monthly on the basis of construction schedules planned in current applications. Since an existing 500-kV transmission line runs by the southeast corner of the SEZ, no analysis of impacts has been conducted for the construction of new transmission line outside of the SEZ that might be needed to connect solar facilities to the regional grid (see Section 11.5.1.2). The nearest major road is I-15, which lies 11 mi (18 km) south of the SEZ. It is assumed that a new access road disturbing an additional 80 acres (0.3 km^2) would be constructed to support solar development in the SEZ.

Cumulative impacts that would result from the construction, operation, and decommissioning of solar energy development projects within the proposed SEZ when added to other past, present, and reasonably foreseeable future actions described in the previous section in each resource area are discussed below. At this stage of development, because of the uncertain nature of the future projects in terms of size, number, location within the proposed SEZ, and the types of technology that would be employed, the impacts are discussed qualitatively or semi-quantitatively, with ranges given as appropriate. More detailed analyses of cumulative impacts would be performed in the environmental reviews for the specific projects in relation to all other existing and proposed projects in the geographic areas.

11.5.22.4.1 Lands and Realty

The proposed East Mormon Mountain SEZ is very isolated and is accessible only by dirt roads. There are no existing rights of way within the SEZ, but two designated 368b transmission

1 corridors pass adjacent to the SEZ and contain three major transmission lines and a natural gas
2 pipeline (Section 11.5.2.1).

3
4 Development of the SEZ for utility-scale solar energy production would establish a
5 large industrial area that would exclude many existing and potential uses of the land, perhaps
6 in perpetuity. Access to such areas by both the general public and much wildlife would be
7 eliminated. Traditional uses of public lands would no longer be allowed. Solar energy facilities
8 would become a dominating visual presence in the area due to their large size.

9
10 As presented in Section 11.5.22.2, foreseeable actions within a 50-mi (80-km) radius of
11 the proposed SEZ include the Toquop power plant, three solar facilities, four transmission lines,
12 two groundwater development projects, a petroleum pipeline project, the proposed 21,454-acre
13 (86.8-km²) Coyote Springs Investment residential development, and a proposed new community
14 airport. In addition, eight potential solar facilities with pending applications covering over
15 40,000 acres (160 km²) and five pending wind applications lie within this distance. Existing
16 facilities include several large gas-fired power plants located 30 to 50 mi (49 to 80 km) to the
17 southwest near the proposed Dry Lake SEZ. The proposed Dry Lake SEZ, located about 40 mi
18 (64 km) to the southwest, and the proposed Delamar Valley SEZ, located about 40 mi (64 km) to
19 the northwest, each lie within 50 mi (80 km) of the proposed East Mormon Mountain SEZ. The
20 number of solar applications, along with the two foreseeable solar energy projects within this
21 distance, indicates a fairly strong interest in solar energy development in the region.

22
23 The development of utility-scale solar projects in the proposed East Mormon Mountain
24 SEZ in combination with other ongoing, foreseeable, and potential actions within the 50-mi
25 (80-km) geographic extent of effects could have cumulative effects on land use in the vicinity of
26 the proposed SEZ. Cumulative impacts on accessibility of land for other purposes and on
27 groundwater and visual resources could result, among other resource impacts, depending in part
28 on where and how many potential solar and wind projects are actually built.

29 30 31 ***11.5.22.4.2 Specially Designated Areas and Lands with Wilderness Characteristics***

32
33 There are 20 specially designated areas within 25 mi (40 km) of the proposed East
34 Mormon Mountain SEZ in Nevada, Utah, and Arizona (Section 11.5.3.1). Potential exists for
35 cumulative visual impacts on these areas from the construction of utility-scale solar energy
36 facilities within the SEZ and other projects outside the SEZ. The exact nature of cumulative
37 visual impacts on the users of these areas would depend on the specific solar technologies
38 employed and the locations selected within the SEZ for solar facilities. Currently proposed
39 projects and potential solar and wind projects within the geographic extent of effects could
40 cumulatively affect sensitive areas through visual impacts and effects on wilderness
41 characteristics. In addition, projects would produce fugitive dust emissions, and could strain
42 water resources and reduce access to specially designated areas.

11.5.22.4.3 Rangeland Resources

Portions of two grazing allotments overlap the proposed SEZ; they would be reduced by less than 10% in size by solar energy development within the SEZ. One allotment has already been reduced by other factors, so SEZ impacts would result in a small cumulative impact on livestock grazing in this allotment, and the proposed adjacent Toquop power plant could further affect one or both of these allotments. However, the loss of approximately 315 AUMs within the proposed SEZ would be a negligible reduction in the over 54,199 AUMs authorized within the BLM Caliente Field Office (Section 11.5.4.1.2.1).

Because the East Mormon Mountain SEZ is 32 mi (51.5 km) or more from any wild horse and burro HMA managed by the BLM and more than 50 mi (80 km) from any wild horse and burro territory administered by the USFS, solar energy development within the SEZ would not directly or indirectly affect wild horses and burros that are managed by these agencies and would not contribute to cumulative impacts on these species (Section 11.5.4.2.2).

11.5.22.4.4 Recreation

Limited outdoor recreation (e.g., backcountry driving, OHV use, and some camping and hunting) occurs on or in the immediate vicinity of the SEZ. Construction of utility-scale solar projects on the SEZ would preclude recreational use of the affected lands for the duration of the projects. Road closures and access restrictions within the proposed SEZ would affect OHV use and access to undeveloped areas. Foreseeable and potential future actions would similarly affect areas of low recreational use and would have minimal effects on recreation. Thus, cumulative impacts on recreation within the geographic extent of effects are not expected.

11.5.22.4.5 Military and Civilian Aviation

The proposed East Mormon Mountain SEZ is located under two MTRs and 5 mi (8 km) east of a large MOA that extends across southern Nevada just north of Las Vegas. The area is also located within a mandatory DoD Consultation Area. The military has indicated that solar facility structures higher than 200 ft (61 m) would intrude into military airspace and would present safety concerns for military aircraft (Section 11.5.6.2). Foreseeable and potential solar facilities, communication towers, and transmission lines, and the proposed Toquop power plant adjacent to the SEZ, could present additional concerns for military aviation and could result in cumulative impacts on military aviation. The Mesquite and St. George Airports are located far enough away from the facility that there would be no effect on their operations.

11.5.22.4.6 Soil Resources

Ground-disturbing activities (e.g., grading, excavating, and drilling) during the construction phase of a solar project, including the construction of any associated transmission line connections and new roads, would contribute to soil loss due to wind erosion. Road use during construction, operations, and decommissioning of the solar facilities would further contribute to soil loss. Programmatic design features would be employed to minimize erosion and loss. Residual soil losses with mitigations in place would be in addition to losses from construction of the proposed Toquop power plant and nearby transmission lines and pipelines, and from recreational uses. Overall, small cumulative impacts on soil resources near the proposed SEZ could result with mitigations in place.

In addition to soil loss from erosion, landscaping of solar energy facilities and other future projects within and outside the SEZ could alter drainage patterns and lead to increased siltation of surface water streambeds. However, programmatic design features would be in place to minimize impacts from erosion.

11.5.22.4.7 Minerals (Fluids, Solids, and Geothermal Resources)

As discussed in Section 11.5.8, there are currently no active oil and gas leases within the proposed East Mormon Mountain SEZ, and there are no pending mining claims or proposals for geothermal energy development in the SEZ. Because of the generally low level of mineral production in the area and the expected low impact of other foreseeable actions on mineral accessibility within the geographic extent of effects, no cumulative impacts on mineral resources are expected.

11.5.22.4.8 Water Resources

Section 11.5.9.2 describes the water requirements for various technologies if they were to be employed on the proposed SEZ to develop utility-scale solar energy facilities. The amount of water needed during the peak construction year for all evaluated solar technologies would be 1,039 to 1,492 ac-ft (1.3 million to 1.8 million m³). During operations, with full development of the SEZ over 80% of its available land area, the amount of water needed for all evaluated solar technologies would range from 41 to 21,543 ac-ft/yr (51 thousand to 27 million m³). The amount of water needed during decommissioning would be similar to or less than the amount used during construction. As discussed in Section 11.5.22.2.3, water withdrawals in 2005 in Lincoln County were 57,100 ac-ft/yr (70 million m³/yr), of which 11% came from surface waters and 89% came from groundwater. The largest water use categories were irrigation at 55,100 ac-ft/yr (68 million m³/yr) and public supply/domestic supply at 1,300 ac-ft/yr (1.6 million m³/yr). Cumulatively, the additional water resources needed for solar facilities in the SEZ during operations would constitute from a very small (0.07%) to a large (38%) increment (the ratio of the annual operations water requirement to the annual amount withdrawn in Lincoln County) depending on the solar technology used (PV technology at the low end and wet-cooled parabolic trough technology at the high end).

1 Near the SEZ, the Lower Virgin River Valley groundwater basin has an estimated
2 sustainable yield of between 12,600 and 40,000 ac-ft/yr (16 and 49 million m³/yr) in the three-
3 state region near the SEZ (Section 11.5.9.1.2). Thus, solar developments on the SEZ would have
4 the capacity to use about half of the sustainable groundwater yield in the local basin using wet
5 cooling. Full development with dry-cooled solar trough technologies would require up to
6 2,172 ac-ft/yr (2.7 million m³/yr), or about 5% of this level (Section 11.5.9.2.2).
7

8 While solar development of the proposed SEZ with water-intensive technologies would
9 likely be infeasible due to impacts on groundwater supplies and existing demands on water
10 rights, excessive groundwater withdrawals could disrupt the existing groundwater supplies in the
11 Lower Virgin River Valley and in hydraulically connected basins. In addition, land disturbance
12 for solar facility construction could cause localized soil erosion and sedimentation of ephemeral
13 washes, degrade associated habitats, and alter groundwater recharge and discharge processes.
14 Thus, a significant increase in withdrawals from solar development within the proposed SEZ
15 could result in a major impact on groundwater, and further cumulative impacts could occur when
16 combined with other current and future uses in the region. These could include the foreseeable
17 Toquop power plant, which would be adjacent to the SEZ and tap the same groundwater
18 resources of the Tule Desert basin, which is adjacent to the Virgin River Valley basin to the
19 northwest and hydraulically connected. This plant was originally configured to produce 750 MW
20 from coal and use hybrid cooling as analyzed in the 2009 Final EIS (BLM 2009e), requiring an
21 estimated 2,500 ac-ft/yr (3.1 million m³/yr) of water. The Nevada State Engineer has already
22 permitted 2,100 ac-ft/yr for a power plant at this location; the remaining 400 ac-ft/yr
23 (494,000 m³/yr) is pending approval. In March 2010, however, project proponents announced
24 revised plans for a 1,100-MW gas-fired plant (Phase 1, 550 to 600 MW) supplemented by 50 to
25 100 MW of PV solar, which would use 60% less water than the coal-fired version
26 (Sithe Global 2010b). In addition, the proposed Lincoln County Land Act Groundwater
27 Development and Utility ROW project would pump and store groundwater from the Clover
28 Valley and Tule Desert hydrographic areas for use in Lincoln County, including potentially for
29 Toquop power plant. Other foreseeable and potential solar projects are more than 15 mi (24 km)
30 from the SEZ and would not likely affect the same groundwater resources (Section 11.5.22.2).
31

32 Small quantities of sanitary wastewater would be generated during the construction and
33 operation of the potential utility-scale solar energy facilities. The amount generated from solar
34 facilities would be in the range of 9 to 74 ac-ft (11,000 to 91,000 m³) during the peak
35 construction year and would range from less than 1 up to 20 ac-ft/yr (up to 25,000 m³/yr) during
36 operations. Because of the small quantity, the sanitary wastewater generated by the solar energy
37 facilities would not be expected to put undue strain on available sanitary wastewater treatment
38 facilities in the general area of the SEZ. For technologies that rely on conventional wet-cooling
39 systems, there would also be from 226 to 408 ac-ft/yr (0.28 to 0.50 million m³) of blowdown
40 water from cooling towers. Blowdown water would need to be either treated on-site or sent to an
41 off-site facility. Any on-site treatment of wastewater would have to ensure that treatment ponds
42 are effectively lined in order to prevent any groundwater contamination. Thus, blowdown water
43 would not contribute to cumulative effects on treatment systems or on groundwater.
44
45
46

11.5.22.4.9 Vegetation

The proposed East Mormon Mountain SEZ is located within the Creosotebush–Dominated Basins ecoregion, which is characterized by sparse creosotebush, white bursage, and big galleta grass, with cacti, yucca, ephedra, and Indian ricegrass also common. Sonora–Mojave Creosote–White Bursage Desert Scrub is the predominant cover type within the proposed SEZ. Sensitive habitats on the SEZ include desert dry wash, riparian, and playa habitats. Areas surrounding the SEZ include the Creosotebush–Dominated Basins and Arid Footslopes ecoregions. The dominant cover type in the 5-mi (8-km) area of indirect effects is Sonora–Mojave Creosote–White Bursage Desert Scrub. If utility-scale solar energy projects were to be constructed within the SEZ, all vegetation within the footprints of the facilities would likely be removed during land-clearing and land-grading operations. Full development of the SEZ over 80% of its area would result in small impacts on all cover types in the affected area (Section 11.5.10.2.1). Playa habitats, riparian habitats, or other intermittently flooded areas within or downgradient from solar projects, including riparian plant communities along Toquop Wash and the Virgin River, could be affected by ground-disturbing activities, and increased runoff from facilities could affect the hydrology of these areas. In addition, groundwater drawdown by solar facilities could affect wetland communities associated with springs, including Tule Spring, Abe Spring, Gourd Spring, and Peach Spring. A further concern in disturbed areas is the establishment and spread of noxious weeds and invasive species. An increase in invasive species such as red brome could increase fire frequency within native plant communities.

The fugitive dust generated during the construction of the solar facilities could increase the dust loading in habitats outside a solar project area, in combination with that from other construction, agriculture, recreation, and transportation. The cumulative dust loading could result in reduced productivity or changes in plant community composition. Similarly, surface runoff from project areas after heavy rains could increase sedimentation and siltation in areas downstream. Programmatic design features would be used to reduce the impacts from solar energy projects and thus reduce the overall cumulative impacts on plant communities and habitats.

Solar facilities within the SEZ in combination with other ongoing and reasonably foreseeable future actions would have a cumulative effect on both common and uncommon cover types within the 50-mi (80-km) geographic extent of effects. Sensitive habitats, including wetlands, would be of particular concern. The proposed Toquop power plant would draw on groundwater from the Tule Desert region, which would also serve facilities within the SEZ. Many other large-acreage developments exist or are proposed within this distance, including several large power plants, transmission line and pipeline projects, the 21,454-acre (86.8-km²) Coyote Springs Investment residential development, and a community airport (Section 11.5.22.2). However, many of these projects lie 30 to 50 mi (48 to 80 km) southwest of the proposed East Mormon Mountain SEZ, near the proposed Dry Lake SEZ, although some proposed transmission line and pipeline projects pass near the SEZ. Taken together, current and future projects could have small to moderate cumulative effects on vegetation in the region. The degree of such impacts would depend to some extent on the level of actual solar and wind development in the region. Eight pending solar and five pending wind project applications lie on public land within 50 mi (80 km) of the SEZ; most solar applications lie on or near the East

1 Mormon Mountain SEZ. The East Mormon Mountain SEZ would make a relatively small
2 contribution to cumulative effects, however, given its modest size in comparison to other
3 developments.

6 **11.5.22.4.10 Wildlife and Aquatic Biota**

8 Wildlife species that could potentially be affected by the development of utility-scale
9 solar energy facilities in the proposed SEZ include amphibians, reptiles, birds, and
10 mammals. The construction of utility-scale solar energy projects in the SEZ and any associated
11 transmission lines and roads in or near the SEZ would have an impact on wildlife through habitat
12 disturbance (i.e., habitat reduction, fragmentation, and alteration), wildlife disturbance, and
13 wildlife injury or mortality. In general, impacted species with broad distributions and a variety of
14 habitats would be less affected than species with a narrowly defined habitat within a restricted
15 area. The use of programmatic design features would reduce the severity of impacts on wildlife.
16 These design features may include pre-disturbance biological surveys to identify key habitat
17 areas used by wildlife, followed by avoidance or minimization of disturbance to those habitats.

18
19 As noted in Section 11.5.22.2, other ongoing, reasonably foreseeable, and potential future
20 actions within 50 mi (80 km) of the proposed SEZ include three foreseeable large solar facilities
21 on private land, four foreseeable transmission line projects, eight potential solar facilities with
22 pending applications covering over 40,000 acres (160 km²) on public land, five pending wind
23 applications, several existing large power plants, two pipeline projects, the proposed 21,454-acre
24 (86.8-km²) Coyote Springs Investment residential development, and a proposed new community
25 airport (Section 11.5.22.2). While impacts from full build-out over 80% of the proposed SEZ
26 would result in small impacts on amphibian, reptile, bird, and mammal species (Section 11.5.11),
27 impacts from foreseeable development within the 50-mi (80-km) geographic extent of effects
28 could be moderate. However, many of the wildlife species present within the proposed SEZ that
29 could be affected by other actions would still have extensive available habitat within the region,
30 while contributions to cumulative impacts from solar facilities within the proposed SEZ would
31 be relatively small due to its modest size.

32
33 There are no permanent streams or water bodies within the proposed East Mormon SEZ
34 or within the 5-mi (8-km) area of indirect effects. Toquop Wash is an intermittent stream located
35 within the SEZ, along with several large, unnamed ephemeral washes. Streams and washes
36 typically contain water only after substantial rainfall and carry water to the southeast and
37 eventually drain into the Virgin River. Ephemeral streams and washes in the SEZ may contain a
38 diverse seasonal community of invertebrates adapted to dry conditions, but are not expected to
39 contain permanent aquatic habitat or communities. No NWI-mapped wetlands are present within
40 the SEZ or within area of indirect effects (Section 11.5.11.4.1). Within the 50-mi (80-km)
41 geographic extent of effects, there are 7,372 acres (30 km²) of dry lakes, 19,963 acres (81 km²)
42 of perennial lakes, 319 mi (513 km) of perennial streams, and 402 mi (647 km) of intermittent
43 streams. The Virgin River is the nearest perennial surface stream and is located approximately
44 10 mi (16 km) south of the SEZ (Section 11.5.11.2). Soil disturbance from construction of solar
45 facilities in the SEZ could result in soil transport to surface streams via water and airborne
46 routes, but is expected to be low with mitigations in place. Groundwater drawdown by operating

1 solar facilities within the SEZ could affect aquatic habitats in springs supported by groundwater.
2 Cumulative impacts on aquatic biota from all ongoing and foreseeable development within the
3 50-mi (80-km) geographic extent of effects could be accrued, given the level of foreseen
4 development. However, most such impacts would occur away from the proposed East Mormon
5 Mountain SEZ, while any contributions to cumulative impacts on aquatic biota from solar
6 development within the proposed SEZ would be small. The proposed Toquop power plant would
7 combine with impacts from the SEZ.
8
9

10 **11.5.22.4.11 Special Status Species (Threatened, Endangered, Sensitive,** 11 **and Rare Species)** 12

13 On the basis of recorded occurrences or suitable habitat, as many as 32 special status
14 species could occur within the East Mormon Mountain SEZ. The following three special status
15 species are known to occur within the affected area of the SEZ: Las Vegas buckwheat, desert
16 tortoise, and Nelson's bighorn sheep. No groundwater-dependent special status species have
17 been identified in the affected area. Occurrences of the desert tortoise have been recorded near
18 the SEZ, while critical habitat for the desert tortoise lies with the 5-mi (8-km) area of indirect
19 affects outside the SEZ, adjacent to the eastern and southern boundaries. Numerous species that
20 occur on or in the vicinity of the SEZ are listed as threatened or endangered by the State of
21 Nevada or listed as a sensitive species by the BLM (Section 11.5.12.1). Avoidance of habitat and
22 minimization of erosion, sedimentation, and dust deposition are some of the programmatic
23 design features to be used to reduce or eliminate the potential for effects on these species from
24 the construction and operation of utility-scale solar energy projects in the SEZs and related
25 developments (e.g., access roads and transmission line connections) outside the SEZ. Special-
26 status species are also affected by ongoing actions within the 50-mi (80-km) geographic extent of
27 effects, including from residential areas, roads, transmission lines, and power plants within this
28 distance. Future developments, including the proposed Toquop power plant, two foreseeable
29 large solar facilities on private land, four foreseeable transmission line projects, eight potential
30 solar facilities with pending applications covering over 40,000 acres (160 km²) on public land,
31 five pending wind applications, the proposed 21,454-acre (86.8-km²) Coyote Springs Investment
32 residential development, and a proposed new community airport (Section 11.5.22.2), will add
33 further effects. Potential developments cover large areas and long linear distances and are likely
34 to affect special status species. Moderate total cumulative impacts on some species, such as the
35 desert tortoise, within the geographic extent of effects could result. However, contributions to
36 cumulative impacts from solar development with the proposed SEZ would be small. Future
37 projects would employ mitigation measures to limit effects.
38
39

40 **11.5.22.4.12 Air Quality and Climate** 41

42 While solar energy generates minimal emissions compared with fossil fuels, the site
43 preparation and construction activities associated with solar energy facilities would be
44 responsible for some amount of air pollutants. Most of the emissions would be particulate matter
45 (fugitive dust) and emissions from vehicles and construction equipment. When these emissions
46 are combined with those from other nearby projects outside the proposed SEZ, or when they are

1 added to natural dust generation from winds and windstorms, the air quality in the general
2 vicinity of the projects could be temporarily degraded. For example, the maximum 24-hour
3 PM₁₀ concentration at or near the SEZ boundaries could at times exceed the applicable standard
4 of 150 µg/m³. Dust generation from construction activities can be controlled by implementing
5 aggressive dust control measures, such as increased watering frequency, or road paving or
6 treatment.

7
8 Because operation of solar facilities within the SEZ would produce minimal contributions
9 of air emissions to those from operation of existing and future industrial sources in the area,
10 mainly gas-fired power plants, the only type of air pollutant of concern is dust generated during
11 construction of new facilities in addition to that produced by winds. Because there are relatively
12 few other foreseeable and potential actions that could produce fugitive dust emissions near the
13 SEZ, it is unlikely but possible that construction of two or more projects could overlap in both
14 time and affected area and produce small cumulative air quality effects due to dust emissions.

15
16 Over the long term and across the region, the development of solar energy may have
17 beneficial cumulative impacts on the air quality and atmospheric values by offsetting the need
18 for energy production that results in higher levels of emissions, such as methods using coal, oil,
19 and natural gas. As discussed in Section 11.5.13.2.2, air emissions from operating solar energy
20 facilities are relatively minor, while the displacement of criteria air pollutants, VOCs, TAPs, and
21 GHG emissions currently produced from fossil fuels could be significant. For example, if the
22 East Mormon Mountain SEZ were fully developed (80% of its acreage) with solar facilities, the
23 quantity of pollutants avoided could be as large as 6.6% of all emissions from the current electric
24 power systems in Nevada.

25 26 27 **11.5.22.4.13 Visual Resources**

28
29 The proposed East Mormon Mountain SEZ is located in a valley east of the East Mormon
30 Mountains and south of the Tule Hills. The area is rural with little cultural disturbance, mainly
31 roads and a 500-kV transmission line (Section 11.5.14.1). Construction of utility-scale solar
32 facilities in the SEZ would substantially alter the natural scenic quality of the area. Other
33 foreseeable actions near the proposed SEZ would cumulatively affect the visual resources in the
34 area. Because of the large size of utility-scale solar energy facilities and the generally flat, open
35 nature of the proposed SEZ, some lands outside the SEZ would also be subjected to visual
36 impacts related to the construction, operation, and decommissioning of utility-scale solar energy
37 facilities. Potential impacts would include night sky pollution, including increased skyglow, light
38 spillage, and glare.

39
40 Visual impacts resulting from solar energy development within the SEZ would be in
41 addition to impacts caused by other potential projects in the area. There are currently two
42 potential solar projects and one wind project with pending applications on public land lie within
43 the 25-mi (40 km) geographic extent for visual impacts, all near I-15 (Figure 11.5.22.2-1). In
44 addition, the proposed Toquop power plant would lie adjacent to the SEZ, while at least one
45 proposed transmission project and several pipeline projects would pass through or near the
46 proposed SEZ (Section 11.5.22.2). While the contribution to cumulative visual impacts of these

foreseeable and potential projects would depend on the location of facilities that are actually built, it may be concluded that the general visual character of the landscape within this distance would be significantly altered by the presence of these developments. Because of the topography of the region, such developments, located in basin flats, would be visible at great distances from surrounding mountains, which include sensitive viewsheds, such as the Mormon Mountains WA. Given the proximity of some current proposals, it is possible that two or more facilities would be viewable from a single location. In addition, some facilities would be located near major roads and thus would be viewable by motorists, who would also be viewing transmission lines, towns, and other infrastructure, as well as the road system itself.

As additional facilities are added, several projects might become visible from one location, or in succession, as viewers move through the landscape, as by driving on local roads. In general, the new developments would not be expected to be consistent in terms of their appearance and, depending on the number and type of facilities, the resulting visual disharmony could exceed the visual absorption capability of the landscape and add significantly to the cumulative visual impact. Considering the above, small to moderate cumulative visual impacts could occur within the geographic extent of effects from future solar, wind, and other existing and future developments.

11.5.22.4.14 Acoustic Environment

The areas around the proposed East Mormon Mountain SEZ are relatively quiet. The existing noise sources around the SEZ include infrequent road traffic, aircraft flyover, and cattle grazing, and possibly hunting. The construction of solar energy facilities could increase the noise levels periodically for up to 3 years per facility, and there would be increased noise during operation of solar facilities, notably from solar dish engine facilities and from parabolic trough or power tower facilities using TES. However, these noises would minimally affect nearby residences due to considerable separation distance.

Other ongoing and reasonably foreseeable and potential future activities in the general vicinity of the SEZs are described in Section 11.5.22.2. Because the nearest residents are relatively far from the SEZ and from other foreseeable projects with respect to noise impacts, cumulative noise effects during the construction or operation of solar facilities are unlikely.

11.5.22.4.15 Paleontological Resources

The proposed East Mormon Mountain SEZ has low potential for the occurrence of significant fossil material in nearly 100% of its area, which contains mainly alluvial deposits (Section 11.5.16.1). While impacts on significant paleontological resources are unlikely to occur in the SEZ, a review of the geological deposits in the specific sites selected for future projects would be needed to determine whether a paleontological survey was warranted. Any paleontological resources encountered would be mitigated to the extent possible. No significant contributions to cumulative impacts on paleontological resources are expected.

11.5.22.4.16 Cultural Resources

The area around East Mormon Mountain is rich in cultural history, with settlements dating as far back as 12,000 years. The area covered by the proposed East Mormon Mountain SEZ has the potential to contain significant cultural resources. Seven surveys have been conducted within the SEZ boundaries, covering 0.9% of the SEZ, while 41 surveys have been conducted within the 5-mi (8-km) area of indirect effects, recording four sites and 45 sites, respectively (Section 11.5.17.1). Areas with high potential for containing archaeological sites include the South Fork and Toquop Wash areas. It is possible that the development of utility-scale solar energy projects in the SEZ would contribute to cumulative impacts on cultural resources in the region. Such contributions would be small and overall cumulative effects within the 25-mi (40-km) geographic extent of effects would also be small, given relatively little ongoing and foreseeable development within this distance, except for the proposed adjacent Toquop power plant (Section 11.5.22.2). While any future solar projects would disturb large areas, the specific sites selected for future projects would be surveyed; historic properties encountered would be avoided or mitigated to the extent possible. Through ongoing consultation with the Nevada SHPO and appropriate Native American governments, it is likely that most adverse effects on significant resources in the region could be mitigated to some degree. It is unlikely that any sites recorded in the SEZ would be of such individual significance that, if properly mitigated, development would cumulatively cause an irretrievable loss of information about a significant resource type, but this would depend on the results of the future surveys and evaluations.

11.5.22.4.17 Native American Concerns

To date, no specific concerns have been raised to the BLM regarding the proposed East Mormon Mountain SEZ. However, the Paiute Indian Tribe of Utah has asked to be kept informed of PEIS developments (Section 11.5.18.2). It is possible that the development of utility-scale solar energy projects in the proposed SEZ would contribute to cumulative impacts on resources important to Native Americans. Significant drawdown of groundwater supporting Tule Springs by solar facilities in the SEZ and by the proposed Toquop power plant could affect culturally important traditional resources. In addition, the Moapa River Valley 25 mi (40 km) to the southeast is a core area of Southern Paiute population and culture and is the location of several proposed solar projects within the geographic extent of visual impacts of the SEZ (Figure 11.5.22.2-1). Continued discussions with the area Tribes through government-to-government consultation are necessary to effectively consider and address the Tribes' concerns about solar energy development in the proposed East Mormon Mountain SEZ.

11.5.22.4.18 Socioeconomics

Solar energy development projects in the proposed East Mormon Mountain SEZ could cumulatively contribute to socioeconomic effects in the immediate vicinity of the SEZs and in the surrounding ROI. The effects could be positive (e.g., creation of jobs and generation of extra income, increased revenues to local governmental organizations through additional taxes paid by

the developers and workers) or negative (e.g., added strain on social institutions such as schools, police protection, and health care facilities). Impacts from solar development would be most intense during facility construction, but of greatest duration during operations. Construction, in combination with temporary workers involved in other new developments in the area, including other renewable energy development, would temporarily increase the number of workers in the area needing housing and services. The number of workers involved in the construction of solar projects in the peak construction year (including the transmission lines) could range from about 240 to 1,700 depending on the technology being employed, with solar PV facilities at the low end and solar trough facilities at the high end. The total number of jobs created in the area could range from approximately 440 (solar PV) to as high as 4,400 (solar trough). Cumulative socioeconomic effects in the ROI from construction of solar facilities would occur to the extent that multiple construction projects of any type were ongoing at the same time. It is a reasonable expectation that this condition would occur within a 50-mi (80-km) radius of the SEZ occasionally over the 20-year or more solar development period.

Annual impacts during the operation of solar facilities would be less, but of 20- to 30-year duration, and could combine with those from other new developments in the area, including several foreseeable and potential solar and wind energy projects, several proposed transmission line and pipeline projects, and the proposed Toquop power plant project (Section 11.5.22.2). The number of workers needed at the SEZ solar facilities would be in the range of 16 to 310, with approximately 20 to 500 total jobs created in the region, assuming full build-out of the SEZ (Section 11.5.19.2.2). Population increases would contribute to general upward trends in the region in recent years. The socioeconomic impacts overall would be positive, through the creation of additional jobs and income. The negative impacts, including some short-term disruption of rural community quality of life, would not likely be considered large enough to require specific mitigation measures.

11.5.22.4.19 Environmental Justice

Any impacts from solar development could have cumulative impacts on minority and low-income populations within 50 mi (80 km) of the proposed SEZ in combination with other development in the area. Such impacts could be both positive, such as from increased economic activity, and negative, such as from visual impacts, noise, and exposure to fugitive dust. Actual impacts would depend on the geographic range of effects and on the location of low-income populations relative to solar and other proposed facilities. Overall, effects from facilities within the SEZ are expected to be small, while other foreseeable and potential actions could contribute additional small effects on minority and low-income populations. However, except for the proposed Toquop project, most foreseeable actions are more than 30 mi (48 km) from the proposed SEZ, and no minority or low-income populations are currently present within the 50-mi (80-km) ROI (Section 11.5.20.1). While future minority and low-income populations, if present, could experience small cumulative effects of some types, such as effects on visual resources or from fugitive dust from all actions within the geographic extent of effects, contributions from solar development in the proposed East Mormon Mountain SEZ would be small. If needed, mitigation measures could be employed to reduce the impacts on these populations in the vicinity of the SEZ.

1 **11.5.22.4.20 Transportation**
2

3 I-15 is the nearest major road and lies about 11 mi (18 km) southeast of the proposed East
4 Mormon Mountain SEZ. The Las Vegas metropolitan area lies approximately 62 mi (100 km) to
5 the southwest of the SEZ along I-15. The nearest airport with scheduled passenger service is the
6 St. George Municipal Airport, 43 mi (69 km) to the northeast in St. George, Utah. The closest
7 railroad access is in Moapa, about 25 mi (40 km) southwest of the SEZ. During construction of
8 utility-scale solar energy facilities, there could be up to 1,000 workers commuting to the
9 construction site at the SEZ, which could increase the AADT on these roads by 2,000 vehicle
10 trips for each facility under construction. With a single solar facility assumed to be under
11 construction at a given time, traffic on I-15 could experience minor slowdowns in the area near
12 access to the SEZ (Section 11.5.21.2). This increase in highway traffic from construction
13 workers could likewise have minor cumulative impacts on traffic flow in combination with
14 existing traffic levels and increases from additional future developments in the area, including
15 construction of the proposed Toquop power plant and facilities for the proposed Lincoln County
16 Land Act Groundwater Development and Utility ROW project in the vicinity of the proposed
17 SEZ, should project schedules overlap. Local road improvements may be necessary on portions
18 of I-15 near access to the SEZ. Any impacts during construction activities would be temporary.
19 The impacts can also be mitigated to some degree by staggered work schedules and ride-sharing
20 programs. Traffic increases during operation would be relatively small because of the low
21 number of workers needed to operate the solar facilities and would have little contribution to
22 cumulative impacts.

11.6 GOLD POINT

11.6.1 Background and Summary of Impacts

11.6.1.1 General Information

The proposed Gold Point SEZ is located in Esmeralda County in southwestern Nevada (Figure 11.6.1.1-1). The SEZ has a total area of 4,810 acres (19 km²). In 2008, the county population was 664, while adjacent Nye County to the east had a population of 44,175. There are no incorporated towns in close proximity to the SEZ. The town of Tonopah is approximately 50 mi (80 km) to the north, and the Las Vegas metropolitan area is approximately 180 mi (290 km) to the southeast of the SEZ.

The nearest major road access to the proposed Gold Point SEZ is State Route 774, which parallels the eastern edge of the SEZ; U.S. 95 runs north–south as it passes within 9 mi (14 km) to the east of the SEZ. The UP Railroad serves the region; the closest stop is in Thorne, 160 mi (257 km) northwest of the SEZ. The nearest public airport is Lida Junction Airport, a small BLM airport about 10 mi (16 km) from the SEZ. There are three additional airports in the vicinity, none of which have scheduled commercial passenger service. The nearest airport with scheduled passenger service is in Las Vegas, Nevada.

A 120-kV transmission line passes 22 mi (35 km) west of the SEZ. It is assumed that a new transmission line would be needed to provide access from the SEZ to the transmission grid (see Section 11.6.1.2).

Applications for ROWs that have been submitted to the BLM include one pending solar project, one pending authorization for wind site testing, two authorized projects for wind site testing, and one authorized geothermal project that would be located within 50 mi (80 km) of the Gold Point SEZ. These applications are discussed in Section 11.6.22.2.1.

The proposed Gold Point SEZ is in an undeveloped rural area. The SEZ is located in the Lida Valley, which lies between the Mount Jackson Ridge and Cuprite Hills to the north and Slate Ridge to the south. It is bounded on the west by the Palmetto Mountains and on the east by the Stonewell Mountains.

The proposed Gold Point SEZ and other relevant information are shown in Figure 11.6.1.1-1. The criteria used to identify the SEZ as an appropriate location for solar energy development included proximity to existing transmission lines or designated corridors, proximity to existing roads, a slope of generally less than 2%, and an area of more than 2,500 acres (10 km²). In addition, the area was identified as being relatively free of other types of conflicts, such as USFWS-designated critical habitat for threatened and endangered species, ACECs, SRMAs, and NLCS lands (see Section 2.2.2.2 for the complete list of exclusions). Although these classes of restricted lands were excluded from the proposed Gold Point SEZ, other restrictions might be appropriate. The analyses in the following sections address the

1

2 **FIGURE 11.6.1.1-1 Proposed Gold Point SEZ**

1 affected environment and potential impacts associated with utility-scale solar energy
2 development in the proposed SEZ for important environmental, cultural, and socioeconomic
3 resources.
4

5 As initially announced in the *Federal Register* on June 30, 2009, the proposed Gold
6 Point SEZ encompassed 5,830 acres (24 km²). Subsequent to the study area scoping period, the
7 boundaries of the proposed Gold Point SEZ were altered somewhat to facilitate the BLM's
8 administration of the SEZ area. Borders with irregularly shaped boundaries were adjusted to
9 match the section boundaries of the Public Lands Survey System (PLSS) (BLM and USFS
10 2010c). The revised SEZ is approximately 1,020 acres (4 km²) smaller than the original SEZ
11 area as published in June 2009.
12
13

14 **11.6.1.2 Development Assumptions for the Impact Analysis**

15

16 Maximum solar development of the Gold Point SEZ is assumed to be 80% of the SEZ
17 area over a period of 20 years, a maximum of 3,848 acres (16 km²). These values are shown in
18 Table 11.6.1.2-1, along with other development assumptions. Full development of the Gold Point
19 SEZ would allow development of facilities with an estimated total of 428 MW of electrical
20 power capacity if power tower, dish engine, or PV technologies were used, assuming
21 9 acres/MW (0.04 km²/MW) of land required, and an estimated 770 MW of power if solar
22 trough technologies were used, assuming 5 acres/MW (0.02 km²/MW) of land required.
23

24 Availability of transmission from SEZs to load centers will be an important consideration
25 for future development in SEZs. The nearest existing transmission line is a 120-kV line 22 mi
26 (35 km) west of the SEZ. It is possible that a new transmission line could be constructed from
27 the SEZ to this existing line, but the 120-kV capacity of that line would be inadequate for 428 to
28 770 MW of new capacity (note that a 500 kV line can accommodate approximately the load of
29 one 700-MW facility). At full build-out capacity, new transmission and/or upgrades of existing
30 transmission lines (in addition to or instead of construction of a connection to the nearest existing
31 line) might be required to bring electricity from the proposed Gold Point SEZ to load centers;
32 however, at this time the location and size of such new transmission facilities are unknown.
33 Generic impacts of transmission and associated infrastructure construction and of line upgrades
34 for various resources are discussed in Chapter 5. Project-specific analyses would need to identify
35 the specific impacts of new transmission construction and line upgrades for any projects
36 proposed within the SEZ.
37

38 For purposes of as complete an analysis of impacts of development in the SEZ as
39 possible, it was assumed that, at a minimum, a transmission line segment would be constructed
40 from the proposed Gold Point SEZ to the nearest existing transmission line to connect the SEZ to
41 the transmission grid. This assumption was made without additional information on whether the
42 nearest existing transmission line would actually be available for connection of future solar
43
44

TABLE 11.6.1.2-1 Proposed Gold Point SEZ—Assumed Development Acreages, Solar MW Output, Access Roads, and Transmission Line ROWs

Total Acreage and Assumed Developed Acreage (80% of Total)	Assumed Maximum SEZ Output for Various Solar Technologies	Distance to Nearest State, U.S., or Interstate Highway	Distance and Capacity of Nearest Existing Transmission Line	Assumed Area of Transmission Line and Road ROWs	Distance to Nearest Designated Corridor ^e
4,810 acres and 3,848 acres ^a	428 MW ^b and 770 MW ^c	State Route 774 0 mi	22 mi ^d and 120 kV	667 acres and 0 acres	6 mi

^a To convert acres to km², multiply by 0.004047.

^b Maximum power output if the SEZ were fully developed using power tower, dish engine, or PV technologies, assuming 9 acres/MW (0.04 km²/MW) of land required.

^c Maximum power output if the SEZ were fully developed using solar trough technologies, assuming 5 acres/MW (0.02 km²/MW) of land required.

^d To convert mi to km, multiply by 1.609.

^e BLM-designated corridors are developed for federal land use planning purposes only and are not applicable to state-owned or privately owned land.

facilities, and without assumptions about upgrades of the line. Establishing a connection to the line closest to the SEZ would involve the construction of about 22 mi (35 km) of new transmission line outside of the SEZ. The ROW for this transmission line would occupy approximately 667 acres (2.7 km²) of land, assuming a 250-ft (76-m) wide ROW, a typical width for such a ROW. If a connecting transmission line were constructed to a different offsite grid location in the future, site developers would need to determine the impacts from construction and operation of that line. In addition, developers would need to determine the impacts of line upgrades if they were needed.

Existing road access to the proposed Gold Point SEZ should be adequate to support construction and operation of solar facilities, because State Route 774 runs along the eastern border of the SEZ. Thus, no additional road construction outside of the SEZ is assumed to be required to support solar development, as summarized in Table 11.6.1.2-1.

11.6.1.3 Summary of Major Impacts and SEZ-Specific Design Features

In this section, the impacts and SEZ-specific design features assessed in Sections 11.6.2 through 11.6.21 for the proposed Gold Point SEZ are summarized in tabular form. Table 11.6.1.3-1 is a comprehensive list of impacts discussed in these sections; the reader may reference the applicable sections for detailed support of the impact assessment. Section 11.6.22 discusses potential cumulative impacts from solar energy development in the proposed SEZ.

TABLE 11.6.1.3-1 Summary of Impacts of Solar Energy Development within the Proposed Gold Point SEZ and SEZ-Specific Design Features

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Lands and Realty	Full development of the proposed Gold Point SEZ could disturb up to 3,848 acres (15.6 km ²). Development of the SEZ for utility-scale solar energy production would establish an isolated industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity.	None.
Specially Designated Areas and Lands with Wilderness Characteristics	Light from solar facilities could adversely affect night sky viewing in some specially designated areas. New transmission lines could cause visual impacts on specially designated areas.	None. Transmission line construction should be routed and constructed in such a way as to minimize visual impacts on specially designated areas.
Rangeland Resources: Livestock Grazing	None.	None.
Rangeland Resources: Wild Horses and Burros	Wild horses and burros in the Gold Mountain HMA could incur indirect impacts from solar energy development. Wild horses and burros would incur direct and indirect impacts from construction of the assumed transmission line in the Goldfield HMA. Direct impacts would be small as only 0.07% of the HMA would be impacted by construction. Following construction, wild horses and burros would be able to make use of the rangelands within the transmission line ROW.	None.
Recreation	Recreational use would be eliminated from portions of the SEZ that would be developed for solar energy production; the loss of use, however, is anticipated to be minimal. There are no anticipated adverse effects on recreation use of specially designated areas within 25 mi (40 km) of the SEZ.	None.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Military and Civilian Aviation	<i>Military:</i> The military has expressed serious concern over solar energy facilities being constructed within the SEZ. Nellis Air Force Base has indicated that solar technologies could interfere with flight operations on MTRs that cross the SEZ. The NTTR has indicated that structures higher than 50 ft (15 m) above ground level may present unacceptable electromagnetic compatibility concerns for the NTTR test mission. <i>Civilian:</i> There would be no effect on civilian aviation.	None. None.
Geologic Setting and Soil Resources	Impacts on soil resources would occur mainly as a result of ground-disturbing activities (e.g., grading, excavating, and drilling), especially during the construction phase. Impacts would include soil compaction, soil horizon mixing, soil erosion and deposition by wind, soil erosion by water and surface runoff, sedimentation, and soil contamination. These impacts may be impacting factors for other resources (e.g., air quality, water quality, and vegetation).	None.
Minerals (fluids, solids, and geothermal resources)	None.	None.
Water Resources	Ground-disturbance activities (affecting 62% of the total area in the peak construction year) could affect surface water quality due to surface runoff, sediment erosion, and contaminant spills. Construction activities may require up to 1,707 ac-ft (2.1 million m³) of water during the peak construction year. Construction activities would generate as high as 74 ac-ft (91,300 m³) of sanitary wastewater.	Water resource analysis indicates that wet-cooling options would not be feasible; other technologies should incorporate water conservation measures. Land disturbance activities should minimize impacts to the unnamed intermittent stream, the playa area in the northeast corner, and ephemeral washes on site.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Water Resources (Cont.)	Assuming full development of the SEZ, operations would use the following amounts of water: - For parabolic trough facilities (770-MW capacity), 550 to 1,166 ac-ft/yr (678,400 to 1.4 million m³/yr) for dry-cooled systems; water requirements for wet-cooled systems are more than 10 times the perennial yield of the basin. - For power tower facilities (428-MW capacity), 305 to 647 ac-ft/yr (376,200 to 798,000 m³/yr) for dry-cooled systems; water requirements for wet-cooled systems are more than 6 times the perennial yield of the basin. - For dish engine facilities (428-MW capacity), 219 ac-ft/yr (270,100 m³/yr). - For PV facilities (428-MW capacity), 22 ac-ft/yr (27,100 m³/yr). Assuming full development of the SEZ, operations would generate up to 11 ac-ft/yr (13,600 m³/yr) of sanitary wastewater and up to 219 ac-ft/yr (270,100 m³/yr) of blowdown water.	Siting of solar facilities and construction activities should avoid any areas identified as within a 100-year floodplain or jurisdictional waters. Groundwater supplies during the construction and operations phases would need to be secured through coordination of the NDWR in terms of obtaining groundwater rights with in the Lida Valley groundwater basin, and potentially from off-site sources and adjacent groundwater basins for the construction phase. Stormwater management plans and BMPs should comply with standards developed by the Nevada Division of Environmental Protection. Groundwater monitoring and production wells should be constructed in accordance with state standards. Water for potable uses would have to meet or be treated to meet water quality standards in accordance with the <i>Nevada Administrative Code</i>.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Vegetation ^b	Up to 80% of the SEZ (3,848 acres [15.6 km²]) would be cleared of vegetation; re-establishment of desert scrub communities in temporarily disturbed areas would likely be very difficult because of the arid conditions and might require extended periods of time. Noxious weeds could become established in disturbed areas and colonize adjacent undisturbed habitats, thus reducing restoration success and potentially resulting in widespread habitat degradation. The deposition of fugitive dust from large areas of disturbed soil onto habitats outside a solar project area could result in reduced productivity or changes in plant community composition. Vegetation communities associated with playa habitats, greasewood flats, riparian habitats, desert dry washes, or other intermittently flooded areas within or downgradient from solar projects could be affected by ground-disturbing activities. The use of groundwater within the proposed Gold Point SEZ for technologies with high water requirements, such as wet-cooling systems, could disrupt the groundwater flow pattern and adversely affect habitats associated with springs in the vicinity of the SEZ.	An Integrated Vegetation Management Plan, addressing invasive species control, and an Ecological Resources Mitigation and Monitoring Plan, addressing habitat restoration, should be approved and implemented to increase the potential for successful restoration of desert scrub, greasewood flat, and other affected habitats, and to minimize the potential for the spread of invasive species. Invasive species control should focus on biological and mechanical methods where possible to reduce the use of herbicides. All riparian, dry wash, and playa communities within the SEZ and transmission line corridor should be avoided to the extent practicable, and any impacts minimized and mitigated. Any Joshua tree or other <i>Yucca</i> species, cacti, or succulent plant species that cannot be avoided should be salvaged. A buffer area should be maintained around dry wash, riparian, and playa habitats to reduce the potential for impacts. Appropriate engineering controls should be used to minimize impacts on dry wash, playa, wetland, greasewood flat, and riparian habitats, including downstream occurrences, resulting from surface water runoff, erosion, sedimentation, altered hydrology, accidental spills, or fugitive dust deposition to these habitats. Appropriate buffers and engineering controls would be determined through agency consultation.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Vegetation (<i>Cont.</i>)		Groundwater withdrawals should be limited to reduce the potential for indirect impacts on habitats associated with springs. Potential impacts on springs should be determined through hydrological studies.
Wildlife: Amphibians and Reptiles ^b	Direct impacts on all representative amphibian and reptile species would be small (i.e., loss of 0.1% or less of potentially suitable habitats within the SEZ region). With the implementation of design features, indirect impacts would be expected to be negligible.	Development in wash and playa habitats should be avoided.
Wildlife: Birds ^b	Direct impacts on all representative bird species would be small (i.e., loss of 0.2% or less of potentially suitable habitats within the SEZ region). Other impacts on birds could result from collision with vehicles and infrastructure (e.g., buildings and fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment.	The requirements contained within the 2010 Memorandum of Understanding between the BLM and USFWS to promote the conservation of migratory birds will be followed. Take of golden eagles and other raptors should be avoided. Mitigation regarding the golden eagle should be developed in consultation with the USFWS and the NDOW. A permit may be required under the Bald and Golden Eagle Protection Act. Wash and playa habitats should be avoided.
Wildlife: Mammals ^b	Direct impacts on all representative mammal species would be small (i.e., loss of 0.1% or less of potentially suitable habitats within the SEZ region). Other impacts on mammals could result from collision with vehicles and infrastructure (e.g., fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment. These impacts are expected to be negligible with the implementation of design features.	The fencing around the solar energy development should not block the free movement of mammals, particularly big game species. Wash and playa habitats should be avoided.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Aquatic Biota ^b	There are no permanent water bodies, streams, or wetlands present within the area of direct or indirect effects of either the proposed Gold Point SEZ or the presumed new transmission line corridor. Intermittent and ephemeral streams are present in the area of direct and indirect effects, and ground disturbance could increase the transport of soil into these streams via waterborne and airborne pathways. In addition, contaminants such as fuels, lubricants, or pesticides/herbicides could enter intermittent streams near construction activities. However, these streams are not expected to contain aquatic habitat or biota and do not connect to perennial surface waters. Therefore, no impacts on aquatic habitat or biota are expected.	None.
Special Status Species ^b	Potentially suitable habitat for 21 special status species occurs in the affected area of the Gold Point SEZ. For most special status species, less than 1% of the potentially suitable habitat in the region occurs in the area of direct effects.	Pre-disturbance surveys should be conducted within the area of direct effects to determine the presence and abundance of special status species. Disturbance to occupied habitats for these species should be avoided or minimized to the extent practicable. If avoiding or minimizing impacts on occupied habitats is not possible for some species, translocation of individuals from areas of direct effects or compensatory mitigation of direct effects on occupied habitats could reduce impacts. A comprehensive mitigation strategy for special status species that uses one or more of these options to offset the impacts of development should be developed in coordination with the appropriate federal and state agencies. Avoiding or minimizing disturbance to desert wash, playa, and sagebrush habitats could reduce or eliminate impacts on two special status species.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Special Status Species ^b (Cont.)		Coordination with the USFWS and the NDOW should be conducted for the greater sage-grouse—a candidate species for listing under the ESA. Coordination would identify an appropriate survey protocol and mitigation requirements, which may include avoidance, minimization, translocation, or compensation. Harassment or disturbance of special status species and their habitats in the affected area should be avoided or minimized. This can be accomplished by identifying any additional sensitive areas and implementing necessary protection measures based upon consultation with the USFWS and NDOW.
Air Quality and Climate	<i>Construction:</i> Temporary exceedances of AAQS for 24-hour and annual PM₁₀ and 24-hour PM_{2.5} concentration levels at the SEZ boundaries and in the immediate surrounding areas during the construction of solar facilities. These concentrations would decrease quickly with distance. Modeling indicates that emissions from construction activities are not anticipated to exceed Class I PSD PM₁₀ increments at the nearest federal Class I area (John Muir WA, California). In addition, construction emissions from the engine exhaust of heavy equipment and vehicles could affect AQRVs (e.g., visibility and acid deposition) at nearby federal Class I areas. <i>Operations:</i> Positive impact due to avoided emissions of air pollutants from combustion-related power generation: 2.0 to 3.6% of total emissions of SO₂, NO_x, Hg, and CO₂ from electric power systems in the state of Nevada (up to 1,902 tons/yr SO₂, 1,632 tons/yr NO_x, 0.011 ton/yr Hg, and 1,047,000 tons/yr CO₂).	None.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Visual Resources	The SEZ is in an area of low scenic quality, but with few cultural disturbances already present. Residents, workers, and visitors to the area may experience visual impacts from solar energy facilities located within the SEZ (as well as any associated access roads and transmission lines) as they travel area roads. Solar development could produce large visual impacts on the SEZ and surrounding lands within the SEZ viewshed due to major modification of the character of the existing landscape. The SEZ is located 7.0 mi (13.5 km) from Queer Mountain WSA. Because of the elevated viewpoints in the WSA, moderate visual contrasts could be observed by WSA visitors. The SEZ is located 5.0 mi (8 km) from Magruder Mountain. Because of the close proximity and elevated viewpoints on Magruder Mountain, moderate visual contrasts could be observed by viewers on the mountain. Approximately 18 mi (29 km) of State Route 266 are within the SEZ viewshed. Because State Route 266 passes with 2 mi (3 km) of the SEZ, strong visual contrasts would be expected for nearby viewpoints on this highway. The community of Gold Point is located less than 2 mi (3 km) from the SEZ, although slight variations in topography and buildings could provide limited screening. Because of the close proximity of the SEZ to Gold Point, strong visual contrasts would be expected for viewpoints within the community of Gold Point.	None.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Acoustic Environment	<i>Construction:</i> For construction of a solar facility located near the southern SEZ boundary, estimated noise levels at the nearest residences located about 2 mi (3 km) from the SEZ boundary would be about 34 dBA, which is below the typical daytime mean rural background level of 40 dBA. In addition, an estimated 40 dBA L_{dn} at these residences (i.e., no contribution from construction activities) is well below the EPA guidance of 55 dBA L_{dn} for residential areas. <i>Operations:</i> For operation of a parabolic trough or power tower facility located near the southern SEZ boundary, the predicted noise level would be about 36 dBA at the nearest residences, which is below the typical daytime mean rural background level of 40 dBA. If the operation were limited to daytime, 12 hours only, a noise level of about 41 dBA L_{dn} (i.e., minimal contribution from facility operation) would be estimated for the nearest residences, which is well below the EPA guideline of 55 dBA L_{dn} for residential areas. However, in the case of 6-hour TES, the estimated noise level at the nearest residences would be 46 dBA, which is well above the typical nighttime mean rural background level of 30 dBA. The day-night average noise level is estimated to be about 48 dBA L_{dn}, which is below the EPA guideline of 55 dBA L_{dn} for residential areas. If 80% of the SEZ were developed with dish engine facilities, the estimated noise level at the nearest residences would be about 43 dBA, which is somewhat higher than the typical daytime mean rural background level of 40 dBA. On the basis of 12-hour daytime operation, the estimated 43 dBA L_{dn} at these residences would be well below the EPA guideline of 55 dBA L_{dn} for residential areas.	Noise levels from cooling systems equipped with TES should be managed so that levels at the nearby residences to the south of the SEZ are kept within applicable guidelines. This could be accomplished in several ways, for example, through placing the power block approximately 1 to 2 mi (1.6 to 3 km) or more from residences, limiting operations to a few hours after sunset, and/or installing fan silencers. Dish engine facilities within the Gold Point SEZ should be located more than 1 to 2 mi (1.6 to 3 km) from the nearby residences. Direct noise control measures applied to individual dish engine systems could also be used to reduce noise impacts at nearby residences.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Paleontological Resources	Few, if any, impacts on significant paleontological resources are likely in the proposed Gold Point SEZ. However, a more detailed look at the geological deposits of the SEZ is needed to determine whether a paleontological survey is warranted. The potential for impacts on significant paleontological resources in portions of the transmission line corridor is unknown. A paleontological survey may be needed prior to project approval.	The need for and nature of SEZ-specific design features would depend on the results of future paleontological investigations, especially along a potential new transmission corridor.
Cultural Resources	Direct impacts on significant cultural resources could occur in the proposed Gold Point SEZ; however, further investigation is needed. Sites related to historic mining in the region are possible. Visual impacts on the Gold Point Town Site are also likely. A cultural resource survey of the entire area of potential effect, including consultation with affected Native American Tribes, would first need to be conducted to identify archaeological sites, historic structures and features, and traditional cultural properties, and an evaluation would need to follow to determine whether any are eligible for listing in the NRHP. Impacts on several sites are possible along the transmission line route, depending on the specific location of the line. Visual impacts along the transmission corridor are also possible, potentially affecting the Goldfield Historic District.	SEZ-specific design features would be determined through consultation with the Nevada SHPO and affected Tribes and would depend on the results of future cultural investigations. General visual mitigation measures may need to be employed to reduce visual impacts on the Gold Point Town Site near the SEZ and along the possible transmission line near the Goldfield Historic District.
Native American Concerns	While no comments specific to the proposed Gold Point SEZ have been received from Native American Tribes to date, as consultation with the Tribes continues and project-specific analyses are undertaken, it is possible that Native Americans will express concern over potential visual and other effects of solar energy development within the SEZ on specific resources, including culturally important landscapes.	The need for and nature of SEZ-specific design features would be determined during government-to-government consultation with the affected Tribes.

TABLE 11.6.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Gold Point SEZ	SEZ-Specific Design Features
Socioeconomics	<i>Construction:</i> A total 173 to 2,287 jobs would be added; ROI income would increase by \$10.5 million to \$138.9 million. <i>Operations:</i> A total of 10 to 224 annual jobs would be added; ROI income would increase by \$0.3 million to \$7.6 million. Construction of new transmission line: 79 jobs; \$3.7 million income in ROI.	None.
Environmental Justice	As defined in CEQ guidelines, no minority or low-income populations occur within the 50-mi (80-km) radius around the boundary of the SEZ; thus, there would be no disproportionately high and adverse human health or environmental effects on low-income or minority populations.	None.
Transportation	The primary transportation impacts are anticipated to be from commuting worker traffic. Single projects could involve up to 1,000 workers each day, with an additional 2,000 vehicle trips per day (maximum). The increase in the volume of traffic on U.S. 95, State Route 266, and State Route 774 would represent an increase in traffic of about 100%, 1,000%, and 10,000%, respectively. Traffic on U.S. 95 could experience slowdowns, and local road improvements would be necessary on State Route 266 and on State Route 774.	None.

Abbreviations: AAQS = ambient air quality standards; ACEC = Area of Critical Environmental Concern; AQRV = air quality–related value; BLM = Bureau of Land Management; BMP = best management practice; CEQ = Council on Environmental Quality; CO₂ = carbon dioxide; dBA = A-weighted decibel; EPA = U.S. Environmental Protection Agency; ESA = Endangered Species Act; Hg = mercury; L_{dn} = day-night average sound level; MTR = military training route; NDOW = Nevada Department of Wildlife; NDWR = Nevada Division of Water Resources; NNHP = Nevada Natural Heritage Program; NO_x = nitrogen oxides; NP = National Park; NRHP = *National Register of Historic Places*; PEIS = programmatic environmental impact statement; PM_{2.5} = particulate matter with an aerodynamic diameter of 2.5 µm or less; PM₁₀ = particulate matter with an aerodynamic diameter of 10 µm or less; PSD = prevention of significant deterioration; PV = photovoltaic; ROI = region of influence; ROW = right-of-way; SEZ = solar energy zone; SHPO = State Historic Preservation Office; SO₂ = sulfur dioxide; SRMA = Special Recreation Management Area; TES = thermal energy storage; USFWS = U.S. Fish and Wildlife Service; WA = Wilderness Area.

11.6.2 Lands and Realty

11.6.2.1 Affected Environment

The proposed Gold Point SEZ is a small but well-blocked area of BLM-administered land that is isolated but accessible via U.S. 95 and connecting to State Routes 266 and 774. The latter highway is within 0.25 mi (0.4 km) of the eastern border of the SEZ. The SEZ is located about 180 mi (290 km) northwest from Las Vegas. The character of the land in the SEZ is undeveloped and rural with only a few dirt roads present within the area. There are no existing ROWs within the SEZ, but there is a designated 368b transmission corridor (of the Energy Policy Act of 2005) that passes about 6.5 mi (10 km) to the northeast of the area. There also is a proposed local corridor located just west of the 368b corridor.

As of February 2010, there were no ROW applications for solar energy facilities within the SEZ.

11.6.2.2 Impacts

11.6.2.2.1 Construction and Operations

Full development of the proposed Gold Point SEZ could disturb up to 3,848 acres (15.6 km²) (Table 11.6.1.2-1). Development of the SEZ for utility-scale solar energy production would establish an industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity. Since the SEZ is undeveloped and isolated, utility-scale solar energy development would be a new and highly discordant land use to the area.

Should the proposed area be identified as a solar energy zone in the ROD for this PEIS, the BLM would still have discretion to authorize additional ROWs in the area until solar energy development was authorized, and then future ROWs would be subject to the rights issued for solar energy development. Because the proposed SEZ is surrounded by BLM-administered lands, approval of solar energy development of the SEZ would not have any impact on the availability of land for future ROWs in the area.

11.6.2.2.2 Transmission Facilities and Other Off-Site Infrastructure

An existing 120 kV transmission line runs 22 mi (35 km) northeast of the SEZ. It is assumed that a new transmission line segment would be constructed from the proposed Gold Point SEZ to the nearest existing transmission line to connect the SEZ to the transmission grid. Construction of the line would result in the disturbance of 667 acres (2.7 km²) outside of the SEZ. If a connecting transmission line were constructed in a different location outside of the SEZ in the future, site developers would need to determine the impacts from construction and

1 operation of that line. In addition, developers would need to determine the impacts of line
2 upgrades if they were needed.

3
4 State Route 774 is adjacent to the SEZ, and it is assumed that no new roads would be
5 required to access the site.

6
7 Roads and transmission lines would be constructed within the SEZ as part of the
8 development of the area.

10 11 **11.6.2.3 SEZ-Specific Design Features and Design Feature Effectiveness**

12
13 No SEZ-specific design features would be required. Implementing the programmatic
14 design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy
15 Program, would provide adequate mitigation for some identified impacts. The exceptions would
16 be that the development of the SEZ would establish a large industrial area that would exclude
17 many existing and potential uses of the land, perhaps in perpetuity and utility-scale solar energy
18 development would be a new and discordant land use to the area.

11.6.3 Specially Designated Areas and Lands with Wilderness Characteristics

11.6.3.1 Affected Environment

There are 9 specially designated areas within 25 mi (40 km) of the proposed Gold Point SEZ that potentially could be affected by solar energy development within the SEZ, principally from impacts on scenic, recreation, and/or wilderness resources. The potential area of impact for the SEZ includes parts of Nevada and California. The specially designated areas that could be impacted from solar development within the SEZ include the following (see Figure 11.6.3.1-1):

- National Park
 - Death Valley
- National Conservation Area
 - California Desert
- Wilderness Areas
 - Death Valley
 - Piper Mountain
 - Sylvania Mountains
- Wilderness Study Areas
 - Pigeon Spring
 - Queer Mountain
 - Grapevine Mountains
- Special Recreation Management Area
 - Fish Lake Valley

Although they are within the 25-mi (40-km) radius of the visual analysis area, both the Piper Mountain and Sylvania Mountains WAs and the Grapevine Mountains WSA have no visibility of potential development within the SEZ; thus they are not considered further.

No lands near the SEZ and outside of designated WAs or WSAs have been identified by the BLM to be managed to protect wilderness characteristics.

11.6.3.2 Impacts

11.6.3.2.1 Construction and Operations

The primary potential impacts on specially designated areas generally are from visual impacts of solar energy development that could affect scenic, recreational, or wilderness characteristics of the areas. This visual impact is difficult to determine and would vary by solar technology employed, the specific area being affected, and the perception of individuals viewing

2 **FIGURE 11.6.3.1-1 Specially Designated Areas in the Vicinity of the Proposed Gold Point SEZ**

the development. From viewshed analysis, it appears that solar development of the proposed Gold Point SEZ would not be a significant factor in the viewshed of any of these specially designated areas, as summarized in Table 11.6.3.2-1. Five of the specially designated areas would have no significant acreage with visibility of development within the SEZ closer than 15 mi (24 km). The data provided in the table assume the use of 650-ft (98.1-m) power tower solar energy technology, which because of the potential height of these facilities, could be visible from the largest amount of land of the technologies being considered in the PEIS. (See Section 11.6.14 for more detail on all viewshed analysis discussed in this section). Assessment of the visual impact of solar energy projects must be conducted on a site-specific and technology-specific basis to accurately identify impacts.

In general, the closer a viewer is to solar development, the greater the impact on an individual's perception. From a visual analysis perspective, the most sensitive viewing distances generally are from 0 to 5 mi (0 to 8 km). The viewing height above a solar energy development area, the size of the solar development area, and the purpose for which a person is visiting an area are also important. Individuals seeking a wilderness or scenic experience within these areas

TABLE 11.6.3.2-1 Potentially Affected Specially Designated Areas within a 25-mi (40-km) Viewshed of the Proposed Gold Point SEZ^a

Feature Type	Feature Name (Total Acreage) ^b	Feature Area ^c		
		Visible within 5 mi	Visible between	
			5 mi and 15 mi	15 mi and 25 mi
National Park	Death Valley (3,397,062 acres)	0 acres	67 acres (0%)	3,814 acres (0.11%)
National Conservation Area	California Desert (25,919,319 acres)	0 acres	67 acres (0%)	4,265 acres (0.02%)
WAs	Death Valley (3,074,256 acres)	0 acres	67 acres (0%)	3,774 acres (0.12%)
WSAs	Pigeon Spring (3,651 acres)	0 acres	0 acres (0%)	8 acres (0.21%)
	Queer Mountain (85,294 acres)	0 acres	1,276 acres	1,276 acres (0.23%)
SRMA	Fish Lake Valley (196,811 acres)	0 acres	0 acres	460 (0.23%)

^a Assuming power tower solar technology with a height of 650 ft (198.1 m).

^b To convert acres to km², multiply by 0.004047. To convert mi to km, multiply by 1.609.

^c Percentage of total feature acreage viewable.

1 could be expected to be more adversely affected than those simply traveling along a highway
2 with another destination in mind.

3
4 The occurrence of glint and glare at solar facilities could potentially cause large though
5 temporary increases in brightness and visibility of the facilities. The visual contrast levels
6 projected for sensitive visual resource areas that were used to assess potential impacts on
7 specially designated areas do not account for potential glint and glare effects; however, these
8 effects would be incorporated into a future site-and project-specific assessment that would be
9 conducted for specific proposed utility-scale solar energy projects.

10
11
12 ***California Desert Conservation Area (CDCA), Death Valley National Park,***
13 ***and Death Valley Wilderness Area.***
14

15 These areas are all located in California, and the state line is about 12.5 mi (20 km)
16 southwest of the SEZ. The three areas overlap one another in this area; the WA is within the
17 National Park, which is within the CDCA.

18
19 Solar facilities within the SEZ could be visible from the summits and northeast-facing
20 slopes of higher peaks in the area surrounding Last Chance Mountain in the northern portion of
21 Death Valley NP, at a distance of about 16 to 18 mi (26 to 29 km) from the SEZ. This area with
22 visibility encompasses about 4,000 acres (16 km²); however, visibility in about one-third of the
23 area would be restricted only to taller solar facility components, such as transmission towers and
24 power towers. Some viewpoints would have clear, but long-distance, views of the SEZ, but the
25 SEZ would occupy only a very small part of the horizontal field of view, and the vertical viewing
26 angle would be very low, despite the elevated viewpoints. Furthermore, most of the area has
27 scattered vegetation, and some views of the SEZ could therefore be subject to screening. Three
28 additional small areas with visibility of the SEZ exist at distances from 14 to 20 mi (23 to 30 km)
29 from the SEZ. The largest of these areas is less than 200 acres (0.8 km²) in size, and in these
30 smaller areas, visibility would be limited to the upper portions of tall power towers in the SEZ.
31 Visual contrast levels caused by solar facilities within the SEZ for viewpoints within all of the
32 areas described would not be expected to exceed very weak levels. For that reason, it is
33 anticipated that there would be no adverse impacts on wilderness, scenic, or recreational
34 resources within these three specially designated areas.

35
36 Because of the lack of development in the immediate region of the SEZ, the night sky
37 is very dark. The NPS has identified the concern that solar facility development in the region
38 adjacent to Death Valley NP could adversely affect the quality of the night sky environment as
39 viewed from the park. The amount of light that could emanate from this relatively small SEZ is
40 not known, but it could adversely affect night sky viewing from limited portions of the National
41 Park and the adjoining wilderness and other specially designated areas.

42
43
44 ***Queer Mountain WSA***
45

46 The boundary of this WSA is directly south of the SEZ at a distance of 7 mi (11 km) at
47 the closest point of approach. At a distance of about 10 mi (16 km) from the SEZ, solar facilities

1 in the SEZ could be visible from about 1,400 acres (5.7 km²) within the WSA on summits and
2 north-facing slopes of Gold Mountain and some ridges to the west of Gold Mountain in the
3 northern portion of the area. From the highest peaks and ridges in those portions of the WSA
4 that have views of the SEZ, the ridges of Slate Ridge screen portions of the SEZ from view;
5 however, from some viewpoints most of the SEZ would be visible, and the SEZ would occupy a
6 moderate amount of the horizontal field of view. The vertical angle of view is low, but high
7 enough that the tops of collector/reflector arrays within the SEZ would likely be visible. From
8 these very high-elevation viewpoints, visual contrast levels from solar facilities could potentially
9 reach moderate levels; for lower-elevation viewpoints, very weak or weak levels of visual
10 contrast would be expected. Because of these levels of contrast and the distance from the SEZ, it
11 is anticipated that there would be no adverse impact on wilderness characteristics in the WSA.

14 ***Pigeon Spring WSA***

15
16 This WSA is 15 mi (24 km) west of the SEZ. Because of topographic screening, only a
17 very small area within the WSA about 16 mi (26 km) from the westernmost boundary of the SEZ
18 would have any visibility of development in the SEZ. Because of the long distance view and
19 very low contrast levels from solar energy facilities, it is anticipated that there would be no
20 impact on wilderness characteristics within the WSA.

23 ***Fish Lake Valley SRMA***

24
25 The BLM-administered Fish Lake Valley SRMA is located within the CDCA and is
26 surrounded by Death Valley NP and Death Valley WA and is composed of two areas that are
27 about 6 mi (10 km) apart. The nearest boundary of the southern, smaller area of the SRMA is
28 located about 17 mi (27 km) southwest of the SEZ and is surrounded by designated wilderness
29 within Death Valley NP. This portion of the SRMA is not designated as wilderness.

30
31 The nearest boundary of the larger northern portion of the SRMA is west of the SEZ
32 about 16 mi (26 km). This portion of the SRMA contains the Sylvania Mountains and Piper
33 Mountain WAs, the White Mountains WSA, and some undesignated public lands. Although
34 almost all of the Sylvania Mountains, a portion of the Piper Mountain WAs, and some public
35 lands are within the 25-mi (40-km) visual analysis area surrounding the SEZ this portion of the
36 SRMA has no areas with views of the SEZ; thus there would be no impact from solar energy
37 development.

38
39 Within the smaller portion of the SRMA, there is very limited visibility of the SEZ from
40 less than 500 acres (2 km²) of the northeast-facing slopes of a few of the higher peaks in the
41 area, at an approximate distance of 18 to 19 mi (29 to 31 km) from the SEZ. Land surface
42 within the SEZ would not be visible from this area, but the upper portions of power towers
43 and transmission towers located in the far northern portion of the SEZ might just be visible
44 over intervening mountains. It is unlikely that the solar facilities would be seen by casual
45 viewers, and even if they were, expected visual contrast levels would be minimal. It is

1 anticipated that there would be no impact on recreational use in this portion of the SRMA
2 from development within the SEZ.
3

4 5 **11.6.3.2.2 Transmission Facilities and Other Off-Site Infrastructure** 6

7 See Section 11.6.2.2.2 for the assumptions regarding the construction of new
8 transmission facilities. Depending on their location and visibility, new transmission facilities
9 could potentially cause additional visual impacts on the specially designated areas listed above.
10 However, because of the limited amount of area with visibility of the transmission line route and
11 the distance to the route, it is not anticipated that the impacts would be significant.
12

13 There would be no impacts outside of the SEZ to provide for road access to the area.
14

15 16 **11.6.3.3 SEZ-Specific Design Features and Design Feature Effectiveness** 17

18 Implementing the programmatic design features described in Appendix A, Section A.2.2,
19 as required under BLM's Solar Energy Program, would provide adequate mitigation for some
20 potential impacts.
21

22 A proposed design feature specific to the Gold Point SEZ includes:
23

- 24 • Transmission line construction should be routed and constructed in such a
25 way as to minimize visual impacts on specially designated areas.
26

11.6.4 Rangeland Resources

11.6.4.1 Livestock Grazing

Rangeland resources managed by the BLM on BLM-administered lands include livestock grazing and habitat for wild horses and burros. These resources and possible impacts on them from solar development within the proposed Gold Point SEZ are discussed in Sections 11.6.4.1 and 11.6.4.2.

11.6.4.1.1 Affected Environment

One grazing allotment overlaps the proposed SEZ—the large Magruder Mountain allotment. The allotment contains 667,139 acres (2,700 km²) of public and private lands and has an active grazing authorization of 6,300 AUMs (BLM 2009c). A total of 4,810 acres (19 km²), or 0.7%, of the allotment is within the SEZ.

11.6.4.1.2 Impacts

Construction and Operations

Should utility-scale solar development occur in the Gold Point SEZ, grazing would be excluded from the areas developed, as provided for in the BLM grazing regulations (43 CFR Part 4100). The regulations provide for reimbursement of permittees for their portion of the value for any range improvements in the area removed from the grazing allotment. The impact of this change in the grazing permits would depend on several factors, including (1) how much of an allotment the permittee might lose to development, (2) how important the specific land lost is to the permittee's overall operation, and (3) the amount of actual forage production that would be lost by the permittee.

Since less than 1% of the Magruder Mountain allotment overlaps the SEZ, the loss of this small amount of area is anticipated to have no impact on grazing use because the loss of use from the SEZ likely could be absorbed elsewhere in the allotment.

Transmission Facilities and Other Off-Site Infrastructure

Connecting the SEZ to the regional power grid would require the construction of about 22 mi (35 km) of new transmission line and would disturb about 667 acres (2.7 km²) allocated in the Magruder Mountain allotment. This additional loss of land also would not be significant for the operation of the allotment.

1 There would be no impacts outside of the SEZ to provide for road access to the area. See
2 Section 11.6.1.2 regarding development assumptions for the SEZ.
3
4

5 **11.6.4.1.3 SEZ-Specific Design Features and Design Feature Effectiveness**

6

7 No SEZ-specific design features are required to protect livestock grazing. Implementing
8 the programmatic design features described in Appendix A, Section A.2.2, as required under
9 BLM's Solar Energy Program, would provide adequate protection for livestock grazing.
10
11

12 **11.6.4.2 Wild Horses and Burros**

13
14

15 **11.6.4.2.1 Affected Environment**

16

17 Section 4.4.2 discusses wild horses (*Equus caballus*) and burros (*E. asinus*) that occur
18 within the six-state study area. Nearly 100 wild horse and burro herd management areas (HMAs)
19 occur within Nevada (BLM 2009d). Ten HMAs in Nevada are located wholly or partially within
20 the 50-mi (80-km) SEZ region for the proposed Gold Point SEZ, while two HMAs in California
21 also occur partially or wholly within the SEZ region (BLM 2010) (Figure 11.6.4.2-1). None of
22 the HMAs occur within the SEZ. Portions of the Palmetto and Gold Mountain HMAs occur
23 within the indirect impact area of the SEZ. They are located 2.2 and 2.9 mi (3.5 and 4.7 km),
24 respectively, from the SEZ. In FY 2009, no wild horses or burros occurred in the Palmetto HMA.
25 Six wild horses and one wild burro occurred in the Gold Mountain HMA in FY 2009; the
26 appropriate management levels were no wild horses and 78 wild burros (BLM 2010a). The
27 Goldfield HMA occurs within the assumed transmission line corridor for the proposed Gold
28 Point SEZ (Figure 11.6.4.2-1). In FY 2009, the Goldfield HMA contained a population of 8 wild
29 horses and 20 wild burros and had an appropriate management level of no wild horses and 37
30 wild burros (BLM 2010a).
31

32 In addition to the HMAs managed by the BLM, the USFS has wild horse and burro
33 territories in Arizona, California, Nevada, New Mexico, and Utah and is the lead management
34 agency that administers 37 of the territories (Giffen 2009; USFS 2007). The closest territory to
35 the proposed Gold Point SEZ is the Monitor Territory, located about 51 mi (82 km) north of the
36 Gold Point SEZ (Figure 11.6.4.2-1).
37
38

39 **11.6.4.2.2 Impacts**

40

41 Because the proposed Gold Point SEZ is about 2.2 mi (3.5 km) or more from any wild
42 horse and burro HMA managed by the BLM and about 51 mi (82 km) from any wild horse and
43 burro territory administered by the USFS, solar energy development within the SEZ would not
44 directly affect wild horses and burros that are managed by these agencies. Indirect impacts on
45 wild horses and burros within the Gold Mountain HMA could result from fugitive dust generated
46 by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment.
47 Indirect impacts would be negligible with the implementation of design features.

FIGURE 11.6.4.2-1 Wild Horse and Burro Herd Management Areas and Territories within the Analysis Area for the Proposed Gold Point SEZ (Sources: BLM 2009d, 2010a; USFS 2007)

1 About 904 acres (3.7 km²) of the assumed transmission line corridor for the Gold Point
2 SEZ occurs within the 62,367-acre (252.4-km²) Goldfield HMA (Figure 11.6.4.2-1).
3 Construction of the transmission line would result in a direct impact on 43 acres (0.2 km²), or
4 about 0.07%, of the HMA. This would result in a small temporary direct impact on the wild
5 horses and burros within the HMA and would not have an overall adverse impact on the
6 management of the animals within the Goldfield HMA. Following construction, wild horses and
7 burros would be able to use the rangelands within the transmission line ROW. Indirect impacts,
8 as discussed above, could also be incurred by the wild horses and burros within the SEZ. These
9 impacts would be negligible with the implementation of programmatic design features.

10 11 12 ***11.6.4.2.3 SEZ-Specific Design Features and Design Feature Effectiveness***

13
14 No SEZ-specific design features for solar development within the proposed Gold Point
15 SEZ would be necessary to protect or minimize direct impacts on wild horses and burros.
16 Indirect impacts should be reduced to negligible levels by implementing programmatic design
17 features and engineering controls that reduce noise lighting, spills, and fugitive dust.
18

11.6.5 Recreation

11.6.5.1 Affected Environment

The site of the proposed Gold Point SEZ is an isolated area with no natural features that invite recreational use. The area is flat but gently sloping to the northeast, with much gravel pavement and uniform low-growing vegetation consisting primarily of shadscale, greasewood, and winterfat, with some Indian ricegrass. The overall appearance of the site is uniform and somewhat monotonous. There are a few scattered dirt trails that provide access into the area. The area is classified as open to vehicle use (BLM 1997). Although there are no recreation figures for the area, it is believed that the area receives no significant recreational use.

11.6.5.2 Impacts

Construction and Operations

Any recreational use would be eliminated from portions of the SEZ developed for solar energy production, and existing recreational users would be displaced. The area is not a major recreation destination, and the loss of recreational opportunities would not be significant. If open OHV routes within the SEZ were identified during project-specific analyses, these routes would be re-designated as closed (see Section 5.5.1 for more details on how routes coinciding with proposed solar facilities would be treated). The SEZ is relatively small and there are good roads around the north and east sides of the SEZ; thus solar development within the SEZ would not cause the public to be hindered from accessing other public lands in the area.

Transmission Facilities and Other Off-Site Infrastructure

The construction of about 22 mi (35 km) of new transmission line and would disturb about 667 acres (2.7 km²) northeast of the SEZ. This additional land disturbance would not be anticipated to have a significant impact on recreation use.

There would be no impacts outside of the SEZ caused by road construction to provide road access to the area.

11.6.5.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features to protect recreational use in the area are required. Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would provide adequate mitigation for recreation resources.

11.6.6 Military and Civilian Aviation

11.6.6.1 Affected Environment

The proposed Gold Point SEZ is located under numerous MTRs, one of which can be used down to 100 ft (30 m) AGL. The area is also located between two MOAs. The area is located within a zone identified in BLM land records as a DoD Consultation Area.

The nearest public airport is the Lida Junction Airport, a small BLM airport about 10 mi (16 km) from the SEZ at the junction of State Route 266 and U.S. 95. The airport has a single dirt runway and has no regularly scheduled use.

11.6.6.2 Impacts

The military has expressed serious concern over solar energy facilities being constructed within the Gold Point SEZ. It is especially concerned over the potential use of power tower facilities. Nellis Air Force Base has indicated that it has concerns for its use of the MTRs because of potential overflight restrictions above a solar energy facility caused by the height of solar facilities, possible restrictions on hydrocarbon or residue from fuel burn by aircraft, possible glare from reflective surfaces, and any potential restrictions on supersonic operations over solar facilities. The NTTR has indicated that solar technologies requiring structures higher than 50 ft (15 m) AGL may present unacceptable electromagnetic compatibility concerns for its test mission at NTTR. The NTTR maintains that a pristine testing environment is required for the unique national security missions conducted on the NTTR. In the military's opinion, the potential electromagnetic interference impacts from solar facilities on testing activities at the NTTR, coupled with potential training route obstructions created by taller structures, make it likely that solar facilities exceeding 50 ft (50 m) could significantly affect military operations.

The Air Force has stated that the NTTR complex is unique in the world in its ability to provide realistic training of air crews. In addition to the effect of individual solar energy facilities, there is a more general concern over the potential for cumulative effects from multiple solar energy projects around the NTTR to eventually have a serious adverse effect on the training environment of the NTTR.

The Lida Junction Airport is located far enough away from the proposed SEZ that there would be no effect on airport operations. Any solar or related facilities in excess of 199 ft (61 m) would require an FAA evaluation of flight hazards and could require hazard marking lights.

11.6.6.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features to protect military or civilian aviation use in the area are required. The programmatic design features described in Appendix A, Section A.2.2, would require early coordination with the DoD to identify and mitigate, if possible, potential impacts on the use of MTRs.

11.6.7 Geologic Setting and Soil Resources

11.6.7.1 Affected Environment

11.6.7.1.1 Geologic Setting

Regional Setting

The proposed Gold Point SEZ is located in the southern part of Lida Valley, a closed intermontane basin within the Basin and Range physiographic province in southern Nevada. The southern part of the valley lies between the Mount Jackson Ridge and Cuprite Hills to the north and Slate Ridge to the south. It is bounded on the west by the Palmetto Mountains and on the east by the Stonewall Mountains (Figure 11.6.7.1-1).

Basin fill consists of Quaternary and Tertiary alluvial fan and playa deposits of variable thickness and induration. Recent gravity surveys in the southern part of Lida Valley indicate that basin-fill sediments are up to 570 ft (175 m) thick near Stonewall Pass, just west of I-95, increasing northward to greater than 1,640 ft (500 m) near the alkali flat (Hasbrouck 2010a,b).

Exposed sediments within and adjacent to the proposed SEZ consist mainly of modern alluvial, eolian, and playa deposits (Figure 11.6.7.1-2). Exposures in the surrounding mountains are predominantly Jurassic- and Cretaceous-age felsic intrusive rocks (diorite and granite), especially along Slate Ridge south and southwest of the SEZ. Paleozoic and Precambrian metamorphic rocks are exposed in the Palmetto Mountains and along Slate Ridge.

Topography

The southern part of Lida Valley (south of Mount Jackson Ridge) is a northeast-trending basin, about 20-mi (32-km) long and 7-mi (11-km) wide. Elevations along the valley axis range from about 5,300 ft (1,615 m) near the southwest end and along the valley sides to about 4,700 ft (1,430 m) at the northeastern end of the valley (Figure 11.6.7.1-1). Moderately sloping alluvial fan deposits occur along the mountain fronts, especially to the northwest (Palmetto Mountains) and northeast (Stonewall Mountains). The valley is drained by the Jackson Wash, an ephemeral stream that flows from Jackson Flat (through a breach in Mount Jackson Ridge) to an alkali flat at the valley's northeastern end and then on to the south toward Sarcobatus Flat. The alkali flat (also called the Lida Valley playa) is being explored as a source of lithium placer deposits (First Liberty Power 2010).

The proposed Gold Point SEZ is located in the southern part of Lida Valley. Its terrain gently slopes to the northeast. Elevations range from about 5,040 ft (1,535 m) along the southwestern boundary to about 4,840 ft (1,475 m) at its northeastern corner (Figure 11.6.7.1-3). Jackson Wash flows to the northeast through the center of the site.

FIGURE 11.6.7.1-2 Geologic Map of the Lida Valley Region (Ludington et al. 2007; Stewart and Carlson 1978)

Cenozoic (Quaternary, Tertiary)

- Qa** Alluvial deposits; locally includes beach and sand dune deposits
- Qp** Playa, marsh and alluvial-flat deposits, locally eroded
- QToa** Older alluvial deposits
- QTb** Basalt flows
- QTs** Sedimentary rocks, mostly lake deposits
- Tt3** Welded and nonwelded silicic ash-flow tuffs
- Tr3** Rhyolitic flows and shallow intrusive rocks
- Ta3** Andesite and related rocks of intermediate composition
- Ts3** Tuffaceous sedimentary rocks, locally includes minor amounts of tuff
- Tba** Andesite and basalt flows

Mesozoic

- Mzgr** Granitic rocks (inconclusively dated)
- Ju3** Diorite (Jurassic - Cretaceous)
- Jgr** Granitic rocks, mostly quartz monzonite and granodiorite

Paleozoic

- Os** Shale, chert and minor quartzite, greenstone, and limestone
- Cl** Shale and thin-bedded or laminated limestone and chert
- Or** Phyllitic siltstone, quartzite and lesser amounts of limestone and dolomite

Precambrian

- Zw** Wyman Formation (phyllite and phyllitic siltstone and minor amounts of limestone, dolomite and sandstone)

2 **FIGURE 11.6.7.1-3 General Terrain of the Proposed Gold Point SEZ**

Geologic Hazards

The types of geologic hazards that could potentially affect solar project sites and their mitigation are discussed in Section 5.7.3. The following sections provide a preliminary assessment of these hazards at the proposed Gold Point SEZ. Solar project developers may need to conduct a geotechnical investigation to identify and assess geologic hazards locally to better identify facility design criteria and site-specific mitigation measures to minimize their risk.

Seismicity. Lida Valley is located within the Walker Lane Belt, a northwest-trending seismic region along the Nevada–California border that accommodates (right-lateral shear) strain from movement between the Pacific and North American plates. Although there are no faults within or immediately adjacent to the Gold Point SEZ, several Quaternary faults and fault systems occur along the margins of Lida Valley. These include the Gold Mountain and Slate Ridge faults to the south, Wild Rose Spring and Lida faults to the west, and Stonewall Flat and Stonewell Mountain faults to the northeast. The most recently active faults in the region are within the northwest-striking Fish Lake Valley fault zone (less than 15,000 years old), located in California, parallel to the California–Nevada state line (Figure 11.6.7.1-4).

From June 1, 2000, to May 31, 2010, 107 earthquakes were recorded within a 61-mi (100-km) radius of the proposed Gold Point SEZ (USGS 2010a). The largest earthquake during that period occurred on August 2, 2001. It was located about 26 mi (43 km) southwest of the SEZ in the Eureka Valley (California) and registered a Richter scale magnitude¹ (ML) of 4.3 (Figure 11.6.7.1-4). During this period, 45 (42%) of the recorded earthquakes within a 61-mi (100-km) radius of the SEZ had magnitudes greater than 3.0; none were greater than 4.3 (USGS 2010a).

Liquefaction. The proposed Gold Point SEZ lies within an area where the peak horizontal acceleration with a 10% probability of exceedance in 50 years is between 0.15 and 0.20 g. Shaking associated with this level of acceleration is generally perceived as moderate; however, the potential damage to structures is light (USGS 2008). Given the deep water table (from 300 to 400 ft [91 to 122 m] below the surface [USGS 2010c]) and the low intensity of ground shaking estimated for Lida Valley, the potential for liquefaction in sediments within and around the SEZ is also likely to be low.

Volcanic Hazards. Lida Valley is located about 60 mi (90 km) to the west-northwest of the southwestern Nevada volcanic field, which consists of volcanic rocks (tuffs and lavas) of the Timber Mountain-Oasis Valley caldera complex and Silent Canyon and Black Mountain calderas. The area has been studied extensively because of its proximity to the Nevada Test Site

¹ Richter scale magnitude (ML) was the original magnitude defined by Richter and Gutenberg for local earthquakes in 1935. It was based on the maximum amplitude recorded on a Wood-Anderson torsion seismograph but is currently calculated for earthquakes with magnitudes ranging from 2 to 6, using modern instruments with adjustments (USGS 2010b).

FIGURE 11.6.7.1-4 Quaternary Faults in the Lida Valley Region (USGS and NBMG 2010; USGS 2010a)

1 and Yucca Mountain repository. Two types of fields are present in the region: (1) large-volume,
2 long-lived fields with a range of basalt types associated with more silicic volcanic rocks
3 produced by melting of the lower crust, and (2) small-volume fields formed by scattered basaltic
4 scoria cones during brief cycles of activity, called rift basalts because of their association with
5 extensional structural features. The basalts of the region typically belong to the second group;
6 examples include the basalts of Silent Canyon and Sleeping Butte (Byers et al. 1989;
7 Crowe et al. 1983).

8
9 The oldest basalts in the region were erupted during the waning stages of silicic
10 volcanism in the southern Great Basin in the Late Miocene and are associated with silicic
11 volcanic centers like Dome Mountain (the first group). Rates of basaltic volcanic activity in the
12 region have been relatively constant but generally low. Basaltic eruptions closest to the proposed
13 Gold Point SEZ occurred from 1.7 million to 700,000 years ago, creating the cinder cones within
14 Crater Flat (Stuckless and O'Leary 2007). The most recent episode of basaltic eruptions occurred
15 at the Lathrop Wells Cone complex about 80,000 years ago (about 8 mi [13 km] east of the SEZ)
16 (Stuckless and O'Leary 2007). There has been no silicic volcanism in the region in the past
17 5 million years. Current silicic volcanic activity occurs entirely along the margins of the Great
18 Basin (Crowe et al. 1983).

19
20 Crowe et al. (1983) determined that the annual probability of a volcanic event for the
21 region is very low (3.3×10^{-10} to 4.7×10^{-8}), similar to the probability of 1.7×10^{-8} calculated
22 for the proposed Yucca Mountain repository (Cline et al. 2005). The volcanic risk in the region is
23 associated only with basaltic eruptions; the risk of silicic volcanism is negligible. Perry (2002)
24 cites geologic data that could indicate an increase in the recurrence rate (and thus the probability
25 of disruption). These data include hypothesized episodes of an anomalously high strain rate, the
26 hypothesized presence of a regional mantle hot spot, and new aeromagnetic data that suggest that
27 previously unrecognized volcanoes may be buried in the alluvial-filled basins in the region.

28
29
30 ***Slope Stability and Land Subsidence.*** The incidence of rock falls and slope failures can
31 be moderate to high along mountain fronts and can present a hazard to facilities on the relatively
32 flat terrain of valley floors such as Lida Valley, if they are located at the base of steep slopes.
33 The risk of rock falls and slope failures decreases toward the flat valley center.

34
35 No land subsidence monitoring has taken place in Lida Valley to date; however,
36 Katzenstein and Bell (2005) report ground subsidence of 1 to 1.5 in. (2.5 to 3.5 cm) related to
37 groundwater withdrawal in the Amargosa Valley, about 60 mi (100 km) southeast of the Gold
38 Point SEZ, which has caused compaction in the underlying aquifer. Subsidence is not generally
39 a serious hazard if it occurs as a broad depression over a large region (except in flood-prone
40 areas sensitive to changes in elevation). The major problems associated with subsidence occur
41 as a result of differential vertical subsidence, horizontal displacement, and earth fissures
42 (Burbey 2002).

43
44
45 ***Other Hazards.*** Other potential hazards at the proposed Gold Point SEZ include those
46 associated with soil compaction (restricted infiltration and increased runoff), expanding clay

1 soils (destabilization of structures), and hydro-compactable or collapsible soil (settlement).
2 Disturbance of soil crusts and desert pavement on soil surfaces may increase the likelihood of
3 soil erosion by wind.
4

5 Alluvial fan surfaces, such as those found in Lida Valley, can be the sites of damaging
6 high-velocity flash floods and debris flows during periods of intense and prolonged rainfall.
7 The nature of the flooding and sedimentation processes (e.g., stream flow versus debris flow)
8 will depend on the specific morphology of the fan (National Research Council 1996).
9 Section 11.6.9.1.1 provides further discussion of flood risks within the Gold Point SEZ.
10
11

12 **11.6.7.1.2 Soil Resources**

13

14 Soils within the Gold Point SEZ are predominantly sandy loams, gravelly sandy loams,
15 and gravelly loams of the Keefa-Itme, Stonell-Wardenet-Izo, and Papoose-Roic associations,
16 which together cover about 84% of the site (Figure 11.6.7.1-5). Soil map units within the SEZ
17 are described in Table 11.6.7.1-1. These gently to steeply sloping soils are derived from mixed
18 alluvium and the residuum and colluvium of tuffaceous sedimentary rocks. They are
19 predominantly very deep (with the exception of Roic series soils, which occur above a shallow
20 hardpan layer) and well drained. Most of the soils on the site have a low to moderate surface
21 runoff potential and moderate to moderately rapid permeability. The natural soil surface is
22 suitable for roads, with a slight to moderate erosion hazard when used as roads or trails. The
23 water erosion potential is low to moderate for all soils at the site. The susceptibility to wind
24 erosion is moderate for most soils, with as much as 86 tons (78 metric tons) of soil eroded by
25 wind per acre (0.004 km²,) each year (NRCS 2010). Biological soil crusts and desert pavement
26 have not been documented within the SEZ, but may be present.
27

28 None of the soils within the Gold Point SEZ are rated as hydric.² Flooding is not likely
29 for soils at the site, occurring with a frequency of less than once in 500 years. None of the soils
30 are classified as prime or unique farmland (NRCS 2010).
31
32

33 **11.6.7.2 Impacts**

34

35 Impacts on soil resources would occur mainly as a result of ground-disturbing activities
36 (e.g., grading, excavating, and drilling), especially during the construction phase of a solar
37 project. These include soil compaction, soil horizon mixing, soil erosion and deposition by wind,
38 soil erosion by water and surface runoff, sedimentation, and soil contamination. Such impacts are
39 common to all utility-scale solar energy facilities in varying degrees and are described in more
40 detail for the four phases of development in Section 5.7 1.
41

42 Because impacts on soil resources result from ground-disturbing activities in the project
43 area, soil impacts would be roughly proportional to the size of a given solar facility, with larger
44 areas of disturbed soil having a greater potential for impacts than smaller areas (Section 5.7.2).

² A hydric soil is a soil that formed under conditions of saturation, flooding, or ponding (NRCS 2010).

FIGURE 11.6.7.1-5 Soil Map for the Proposed Gold Point SEZ (NRCS 2008)

TABLE 11.6.7.1-1 Summary of Soil Map Units within the Proposed Gold Point SEZ

Map Unit Symbol	Map Unit Name	Water Erosion Potential ^a	Wind Erosion Potential ^b	Description	Area ^c (% of SEZ)
1000	Keefa-Itme association	Low (0.20)	Moderate (WEG 3) ^d	Consists of about 70% Keefa sandy loam and 20% Itme gravelly loamy sand. Gently sloping soils on fan skirts, inset fans, and lake plains. Parent material consists of mixed alluvium (including from granitic rocks). Very deep and well drained, with moderate surface runoff potential and moderately rapid permeability. Available water capacity is low. Moderate rutting hazard. Used mainly as rangeland; unsuitable for cultivation.	2,405 (50)
482	Stonell-Wardenot-Izo association	Low (0.05)	Moderate (WEG 5)	Consists of about 35% Stonell very gravelly sandy loam, 30% Wardenot very gravelly sandy loam, and 20% Izo very gravelly sand. Gently sloping soils on fan remnants, inset fans, and drainage ways. Parent material is mixed alluvium. Very deep and excessively drained, with low surface runoff potential (high infiltration rate) and moderately rapid permeability. Available water capacity is low to very low. Slight rutting hazard. Used mainly as rangeland and wildlife habitat; unsuitable for cultivation.	1,077 (22)
1033	Papoose-Roic association	Moderate (0.37)	Moderate (WEG 3)	Consists of about 50% Papoose sandy loam and 45% Roic very gravelly loam. Gently to steeply sloping soils on lake terraces, hills, and pediments. Parent material is mixed alluvium and residuum and colluvium from tuffaceous sedimentary rocks. Very deep (Papoose soils) and very shallow (Roic soils over shallow paralithic bedrock) and well drained, with moderate surface runoff potential and moderate permeability. Available water capacity is low to very low. Moderate rutting hazard. Used mainly as rangeland or wildlife habitat; small areas may be irrigated and used for cropland (alfalfa and small grains).	577 (12)

TABLE 11.6.7.1-1 (Cont.)

Map Unit Symbol	Map Unit Name	Water Erosion Potential ^a	Wind Erosion Potential ^b	Description	Area (% of SEZ)
940	Belted-Keefa association	Low (0.10)	Moderate (WEG 3)	Consists of about 70% Belted gravelly loamy sand and 20% Keefa sandy loam. Gently to steeply sloping soils on beach terraces and fan skirts. Parent material consists of mixed alluvium. Very deep (Keefa soils) and very shallow (Belted soils over shallow duripan) and well drained, with high surface runoff potential (very slow infiltration rate) and moderate permeability. Available water capacity is low to very low. Moderate rutting hazard. Used mainly as rangeland, forest; unsuitable for cultivation.	451 (9)
1031	Papoose sandy loam (0 to 8% slopes)	Moderate (0.37)	Moderate (WEG 3)	Gently sloping soils on lake terraces. Parent material consists of mixed alluvium from tuffs, basalt, and andesite with small amounts of limestone and quartzite. Very deep and well drained, with moderate surface runoff potential and moderately slow permeability. Available water capacity is low. Moderate rutting hazard. Used mainly as rangeland or wildlife habitat; small areas may be irrigated and used for cropland (alfalfa and small grains).	299 (6)

^a Water erosion potential rates based on soil erosion factor K (whole rock), which indicates the susceptibility of soil to sheet and rill erosion by water. Values range from 0.02 to 0.69 and are provided in parentheses under the general rating; a higher value indicates a higher susceptibility to erosion. Estimates based on the percentage of silt, sand, and organic matter and on soil structure and saturated hydraulic conductivity.

^b Wind erosion potential here is based on the wind erodibility group (WEG) designation: groups 1 and 2, high; groups 3 through 6, moderate; and groups 7 and 8 low (see footnote c for further explanation).

^c To convert acres to km², multiply by 0.004047.

^d WEG = wind erodibility group. WEGs are based on soil texture, content of organic matter, effervescence of carbonates, content of rock fragments, and mineralogy, and also take into account soil moisture, surface cover, soil surface roughness, wind velocity and direction, and the length of unsheltered distance (USDA 2004). Groups range in value from 1 (most susceptible to wind erosion) to 8 (least susceptible to wind erosion). The NRCS provides a wind erodibility index, expressed as an erosion rate in tons per acre per year, for each of the wind erodibility groups: WEG 3, 86 tons (78 metric tons) per acre (0.004 km²) per year and WEG 5, 56 tons (51 metric tons) per acre (0.004 km²) per year.

Source: NRCS (2010).

1 The magnitude of impacts would also depend on the types of components built for a given
2 facility since installation of some components would involve greater disturbance and would take
3 place over a longer timeframe.
4

5 6 **11.6.7.3 SEZ-Specific Design Features and Design Feature Effectiveness** 7

8 No SEZ-specific design features were identified for soil resources at the proposed Gold
9 Point SEZ. Implementing the programmatic design features described under both Soils and Air
10 Quality in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would
11 reduce the potential for soil impacts during all project phases.

11.6.8 Minerals (Fluids, Solids, and Geothermal Resources)

11.6.8.1 Affected Environment

As of September 21, 2010, there were no mining claims located in the proposed Gold Point SEZ. The western half of the SEZ, however, was previously blanketed by both lode and placer claims that have been closed (BLM and USFS 2010a). The public land within the SEZ was closed to locatable mineral entry in June 2009 pending the outcome of this PEIS. There are no active oil and gas leases in the area, nor has the area been previously leased (BLM and USFS 2010b). The area remains open for discretionary mineral leasing for oil and gas and other leasable minerals and for disposal of salable minerals. There is no active or historical geothermal leasing or development in or near the SEZ (BLM and USFS 2010b).

11.6.8.2 Impacts

If the area were identified as a solar energy zone, it would continue to be closed to all incompatible forms of mineral development. Since the SEZ does not contain existing mining claims, it was also assumed that there would be no future loss of locatable mineral production.

For the purpose of this analysis, it was assumed that future development of oil and gas resources, should any be found, would still be possible, since such development could occur with directional drilling from outside the SEZ. Also, since the SEZ has no history of development of geothermal resources, it is not anticipated that solar development would adversely affect the development of geothermal resources.

The production of common minerals, such as sand and gravel and mineral materials used for road construction or other purposes, might take place in areas not directly developed for solar energy production.

11.6.8.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features are required. Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would provide adequate mitigation to protect mineral resources.

11.6.9 Water Resources

11.6.9.1 Affected Environment

The proposed Gold Point SEZ is located within the Central Nevada Desert subbasin of the Great Basin hydrologic region (USGS 2010a) and the Basin and Range physiographic province characterized by intermittent mountain ranges and desert valleys (Planert and Williams 1995). The proposed SEZ is located in the southern portion of Lida Valley, which is connected to the northern portion through narrow passes along Mount Jackson and Mount Jackson Ridge. Because a shallow surface divide separates Lida Valley and Stonewall Flat basins, Lida Valley drains south and east toward the Sarcobatus Flat area (Figure 11.6.9.1-1). Surface elevations in the proposed SEZ range from 4,831 to 5,059 ft (1,472 to 1,542 m), with a general southwest to northeast drainage pattern. Elevations in the surrounding mountains range from about 5,700 ft (1,737 m) in Slate Ridge to the south and Mount Jackson Ridge to the north, to about 9,000 ft (2,743 m) in Magruder Mountain and the Palmetto Mountains to the northwest. The climate in this region of Nevada is characterized by low humidity and precipitation, with mild winters and hot summers (Planert and Williams 1995; WRCC 2010a). The average annual precipitation ranges from 3 to 6 in. (8 to 15 cm), and the average annual snowfall ranges from 6 to 18 in. (15 to 46 cm) at the Sarcobatus and Goldfield weather stations, respectively (WRCC 2010b,c). Very little phreatic vegetation is present in the Lida Valley, so evapotranspiration is estimated to be negligible (Rush 1968), while the arid climate leads to high evaporation rates, with pan evaporations rates estimated to be about 97 in./yr (246 cm/yr) (Cowherd et al. 1988; WRCC 2010d).

11.6.9.1.1 Surface Waters (Including Drainages, Floodplains, and Wetlands)

No perennial surface water features are present in the proposed Gold Point SEZ. An unnamed intermittent stream crosses the SEZ site in a northeasterly direction and converges with Jackson Wash about 1.5 mi (2.4 km) east of the site. Jackson Wash is an intermittent stream that originates in the Montezuma Range in the northern portion of Lida Valley and enters the southern Lida Valley through the pass between Mount Jackson and Mount Jackson Ridge. It drains to the east and north toward a series of dry lakes located near the boundary of Lida Valley and Stonewall Flat about 8 mi (13 km) northeast of the site. Several ephemeral washes also drain toward the northeast across the proposed SEZ and converge to a small playa area in the northeast corner of the site (Figure 11.6.9.1-1).

A few, small lacustrine wetland areas near the boundary of Lida Valley and Stonewall Flat basin cover between about 40 and 780 acres (0.2 and 3 km²) according to the NWI (USFWS 2009). These dry lake wetland areas have sparse vegetation with water levels mostly below the land surface for most of the year. Surface water drainage out of Lida Valley enters a large playa region in the Sarcobatus basin about 18 mi (29 km) southeast of the proposed SEZ. The playa regions in the Sarcobatus basin also coincide with the presence of lacustrine wetland areas that cover between 755 and 1,875 acres (3 and 8 km²). Additional information regarding wetlands within the region of the proposed SEZ is presented in Section 11.6.10.1.

2 **FIGURE 11.6.9.1-1 Surface Water Features near the Proposed Gold Point SEZ**

1 Flood hazards have not been identified in Esmeralda County but have been mapped for
2 Nye County, located 9 mi (14 km) east of the proposed Gold Point SEZ. In Nye County,
3 Jackson Wash and the playa area it drains to are identified as being within a 100-year floodplain
4 (Zone A) (FEMA 2009). It is likely that this 100-year floodplain region continues upstream
5 along the riparian areas of Jackson Wash, which could potentially include portions of the
6 proposed SEZ. Erosion and sedimentation are potentially concerns along the intermittent streams
7 and ephemeral washes in the vicinity of the proposed SEZ. Additionally, temporary flooding
8 may occur near the playa region in the northeast corner of the site during large rainfall events.
9

10 11 **11.6.9.1.2 Groundwater** 12

13 The proposed Gold Point SEZ is a part of the Lida Valley groundwater basin, which
14 covers an area of 342,400 acres (1,386 km²) (NDWR 2010a). The Lida Valley groundwater
15 basin is located on the northwestern edge of the Death Valley Regional Groundwater Flow
16 System (described in Section 11.1.9.1.2); however, it is not located over any of the regional-scale
17 carbonate-rock aquifers associated with the carbonate rock province that covers approximately
18 one-third of Nevada (Harrill and Prudic 1998, Faunt et al. 2004). The general hydrogeologic
19 structure of the Lida Valley groundwater basin is that of a basin-fill aquifer containing three
20 units: consolidated rocks, older alluvium, and younger alluvium. The consolidated rocks of the
21 surrounding mountains and bedrock (underlying the basin-fill alluvium) consist primarily of
22 volcanic rocks and intrusive structures, as well as some carbonate and sedimentary rocks
23 (Rush 1968). The older and younger alluvium units of the basin-fill are composed of sand,
24 gravel, and cobbles with interbedded silts and clays of late Tertiary and Quaternary age
25 (Belcher et al. 2001). The thickness of the basin-fill in the Lida Valley is typically greater than
26 500 ft (152 m) but not more than 2,460 ft (750 m) (Faunt et al. 2004).
27

28 Historically, there has been limited groundwater development in the Lida Valley
29 groundwater basin. In the early 1900s, groundwater from springs located in the Palmetto
30 Mountains were pumped to supply water for mining near the town of Goldfield, 20 mi (32 km)
31 north of the proposed SEZ; however, many of the springs in the surrounding mountains of the
32 Lida Valley were dry or discharged less than 10 ac-ft/yr (12,300 m³/yr) by the 1960s
33 (Rush 1968). The primary source of available groundwater in the Lida Valley is within the basin-
34 fill alluvium aquifers. Groundwater recharge in the Lida Valley groundwater basin is largely
35 driven by precipitation and subsurface inflow from the Stonewall Flat region. Depending on the
36 methods of calculation used, estimates of groundwater recharge range from 500 ac-ft/yr
37 (616,700 m³/yr) by precipitation and 200 ac-ft/yr (246,700 m³/yr) by subsurface inflow
38 (NDWR 1971), to a total recharge ranging from 50 to 420 ac-ft/yr (61,700 to 518,000 m³/yr)
39 (Flint et al. 2004). Groundwater discharge is driven primarily by subsurface outflow to the
40 Sarcobatus Flat basin and has estimated as 700 ac-ft/yr (863,400 m³/yr) (NDWR 1971).
41 Groundwater discharge by evapotranspiration is assumed to be negligible in the Lida Valley
42 groundwater basin, and groundwater pumping was less than 30 ac-ft/yr (37,000 m³/yr) in 1966
43 (Rush 1968).
44

45 Depth to groundwater is typically about 300 to 400 ft (91 to 122 m) below the ground
46 surface in the Lida Valley groundwater basin, and the general groundwater flow pattern is from

1 southwest to northeast in the vicinity of the proposed Gold Point SEZ, with an approximate
2 slope of 0.7% in groundwater surface elevations (well numbers 372138117274001 and
3 373003117110101) (USGS 2010d). Groundwater flows to the northeast past the proposed SEZ,
4 where it then converges with subsurface inflow from the Stonewall Flat basin, about 8 mi
5 (13 km) northeast (in the vicinity of the dry lakes mentioned in Section 11.6.9.1.1), and then
6 discharges to the south to the Sarcobatus Flat basin (Rush 1968; NDWR 1971; Faunt et al. 2004).
7 Groundwater in the Lida Valley groundwater basin has high TDS concentrations typically
8 greater than 500 mg/L, with sulfate concentrations greater than 250 mg/L (Rush 1968). The TDS
9 concentrations typically increase as groundwater flows out of the Lida Valley groundwater basin
10 an into the Sarcobatus Flat basin, where TDS concentrations are on the order of 1,000 mg/L
11 (well number 371647117015201) (Rush 1968; USGS 2010d).

14 ***11.6.9.1.3 Water Use and Water Rights Management***

15
16 In 2005, water withdrawals from surface waters and groundwater in Esmeralda County
17 were 46,786 million ac-ft/yr (57.7 million m³/yr), of which 9% came from surface waters
18 and 91% came from groundwater. The largest water use categories for groundwater were
19 irrigation and mining at 28,235 and 14,202 ac-ft/yr (34.8 million and 17.5 million m³/yr),
20 respectively. The remaining groundwater withdrawals were for domestic use and livestock
21 watering (Kenny et al. 2009). The majority of the groundwater use in Esmeralda County occurs
22 north and west of the proposed Gold Point SEZ in the Fish Lake Valley groundwater basin
23 (NDWR 2010b); as groundwater withdrawals in the Lida Valley groundwater basin were only
24 30 ac-ft/yr (37,000 m³/yr) in 1966 (Rush 1968).

25
26 All waters in Nevada are the property of the public and are subject to the laws described
27 in Nevada Revised Statutes, Chapters 532 through 538 (available at: <http://leg.state.nv.us/nrs>).
28 The NDWR, led by the State Engineer, is the agency responsible for managing both the surface
29 water and groundwater resources. This responsibility includes overseeing water rights
30 applications, appropriations, and interbasin transfers (NDWR 2010c). The two primary
31 principles underlying water rights in Nevada are the prior appropriations doctrine and the
32 concept of beneficial use. A water right establishes an appropriation amount and date such that
33 more senior water rights have priority over newer water rights. Additionally, water rights are
34 treated as both real and personal property, such that water rights can be transferred without
35 affecting the land ownership (NDWR 2010c). Water rights applications (new or transfer of
36 existing) are approved if the water is available to be appropriated, if existing water rights will
37 not be affected, and if the proposed use is not deemed to be harmful to the public interest. If
38 these conditions are satisfied according to the State Engineer, a proof of beneficial use of the
39 approved water must be provided within a certain time period, and following that a certificate
40 of appropriation is issued (BLM 2001).

41
42 The Lida Valley groundwater basin is not a designated groundwater; thus, there are no
43 specified beneficial uses set by the NDWR (NDWR 1974). The perennial yield of the Lida
44 Valley groundwater basin is set at 350 ac-ft/yr (431,700 m³/yr), and current water rights total
45 76 ac-ft/yr (93,700 m³/yr). This water is being used for mining, stock water, and municipal
46 supply (NDWR 2010a). Solar energy developers would have to submit applications for new

1 groundwater withdrawals or transfer of existing water rights to the NDWR according to the
2 process described previously.

3 4 5 **11.6.9.2 Impacts** 6

7 Potential impacts on water resources related to utility-scale solar energy development
8 include direct and indirect impacts on surface waters and groundwater. Direct impacts occur at
9 the place of origin and at the time of the proposed activity, while indirect impacts occur away
10 from the place of origin or later in time. Impacts on water resources considered in this analysis
11 are the result of land disturbance activities (construction, final developed site plan, as well as off-
12 site activities such as road and transmission line construction) and water use requirements for
13 solar energy technologies during the four project phases: site characterization, construction,
14 operations, and decommissioning/reclamation. Both land disturbance and consumptive water use
15 activities can affect groundwater and surface water flows, cause drawdown of groundwater
16 surface elevations, modify natural drainage pathways, obstruct natural recharge zones, and alter
17 surface water-wetland-groundwater connectivity. Water quality can also be degraded through the
18 generation of wastewater, chemical spills, increased erosion and sedimentation, and increased
19 salinity (e.g., by the excessive withdrawal from aquifers).

20 21 22 **11.6.9.2.1 Land Disturbance Impacts on Water Resources** 23

24 Impacts related to land disturbance activities are common to all utility-scale solar energy
25 facilities and are described in more detail for the four phases of development in Section 5.9.1.
26 These impacts will be minimized through the implementation of programmatic design features
27 described in Appendix A, Section A.2.2. Land disturbance activities should be minimized in the
28 vicinity of the unnamed intermittent stream and the several ephemeral washes draining across the
29 site. During large storm events, these intermittent streams have the potential to flood and cause
30 sedimentation and erosion issues. Additionally, alterations to these intermittent and ephemeral
31 stream features could have adverse impacts on sedimentation and erosion to the downstream
32 playa region in the northeast corner of the proposed SEZ, as well as off-site in Jackson Wash.

33 34 35 **11.6.9.2.2 Water Use Requirements for Solar Energy Technologies** 36

37 38 **Analysis Assumptions** 39

40 A detailed description of the water use assumptions for the four utility-scale solar energy
41 technologies (parabolic trough, power tower, dish engine, and PV systems) is presented in
42 Appendix M. Assumptions regarding water use calculations specific to the proposed Gold Point
43 SEZ include the following:

- 44
45 • On the basis of a total area of 4,810 acres (19 km²), it is assumed that one
46 solar project would be constructed during the peak construction year;
47

- Water needed for making concrete would come from an off-site source;
- The maximum land disturbance for an individual solar facility during the peak construction year is 3,000 acres (12 km²);
- Assumptions on individual facility size and land requirements (Appendix M), along with the assumed number of projects and maximum allowable land disturbance, results in the potential to disturb of up to 62% of the total SEZ area during the peak construction year; and
- Water use requirements for hybrid cooling systems are assumed to be on the same order of magnitude as those for dry-cooling systems (see Section 5.9.2.1).

Site Characterization

During site characterization, water would be used mainly for controlling fugitive dust and the workforce potable water supply. Impacts on water resources during this phase of development are expected to be negligible since activities would be limited in area, extent, and duration; water needs could be met by trucking water in from an off-site source.

Construction

During construction, water would be used mainly for controlling fugitive dust and the workforce potable water supply. Because there are no significant surface water bodies on the proposed Gold Point SEZ, the water requirements for construction activities could be met by either trucking water to the site or by using on-site groundwater resources.

Water requirements for dust suppression and potable water supply during construction, shown in Table 11.6.9.2-1, could be as high as 1,707 ac-ft (2.1 million m³) for the peak construction year. The assumptions underlying these estimates for each solar energy technology are described in Appendix M. The total water use estimates for the peak construction year are on the order of 3 to 5 times greater than the perennial yield of the Lida Valley groundwater basin. Thus, at least a portion of the water supply would have to come from an off-site source or be transferred from an adjacent basin (if unappropriated groundwater is available in adjacent basins), which would have to be negotiated with the NDWR. The effects of groundwater withdrawals on groundwater surface elevations in the Lida Valley would have to be assessed during the site characterization phase. In addition, the generation of up to 74 ac-ft (91,300 m³) of sanitary wastewater during the peak construction year would have to be treated either on-site or sent to an off-site facility.

TABLE 11.6.9.2-1 Estimated Water Requirements, by Technology, during the Peak Construction Year for the Proposed Gold Point SEZ

Activity	Parabolic Trough	Power Tower	Dish Engine	PV
Water use requirements ^a				
Fugitive dust control (ac-ft) ^{b,c}	1,108	1,662	1,662	1,662
Potable supply for workforce (ac-ft)	74	45	19	9
Total water use requirements (ac-ft)	1,182	1,707	1,681	1,671
Wastewater generated				
Sanitary wastewater (ac-ft)	74	45	19	9

^a Assumptions of water use for fugitive dust control, potable supply for workforce, and wastewater generation are presented in Appendix M.

^b Fugitive dust control estimation assumes a local pan evaporation rate of 97 in./yr (246 cm/yr) (Cowherd et al. 1988; WRCC 2010d).

^c To convert ac-ft to m³, multiply by 1,234.

Operations

During operations, water would be required for mirror/panel washing, the workforce potable water supply, and cooling (parabolic trough and power tower only) (Table 11.6.9.2-2). Water needs for cooling would be a function of the type of cooling used (dry, hybrid, wet). Further refinements to water requirements for cooling would result from the percentage of time that the option was employed (30 to 60% range assumed) and the power of the system. The differences between the water requirements reported in Table 11.6.9.2-2 for the parabolic trough and power tower technologies are attributable to the assumptions of acreage per megawatt. As a result, the water usage for the more energy-dense parabolic trough technology is estimated to be almost twice as great as that for the power tower technology.

At full build-out capacity, water needs for mirror/panel washing are estimated to range from 21 to 385 ac-ft/yr (25,900 to 474,900 m³/yr) and the workforce potable water supply from 1 to 11 ac-ft/yr (1,234 to 13,600 m³/yr). The maximum total water usage during normal operation at full build-out capacity would be greatest for those technologies using the wet-cooling option and is estimated to be as high as 11,555 ac-ft/yr (14.3 million m³/yr). Water usage for dry-cooling systems would be as high as 1,166 ac-ft/yr (1.4 million m³/yr), approximately a factor of 10 times less than the wet-cooling option. Non-cooled technologies, dish engine and PV systems, require substantially less water at full build-out capacity at 219 ac-ft/yr (270,100 million m³/yr) for dish engine and 22 ac-ft/yr (27,100 million m³/yr) for PV (Table 11.6.9.2-2). Operations would produce up to 11 ac-ft/yr (13,600 m³/yr) of sanitary wastewater. In addition, for wet-cooled technologies, 121 to 219 ac-ft/yr (149,300 to 270,100 million m³/yr) of cooling system blowdown water would need to be treated either on- or off-site. Any on-site treatment of wastewater would have to ensure that treatment ponds are effectively lined in order to prevent any groundwater contamination.

TABLE 11.6.9.2-2 Estimated Water Requirements, by Technology, during Operations at the Proposed Gold Point SEZ

Activity	Parabolic Trough	Power Tower	Dish Engine	PV
Full build-out capacity (MW) ^{a,b}	770	428	428	428
Water use requirements				
Mirror/panel washing (ac-ft/yr) ^{c,d}	385	214	214	21
Potable supply for workforce (ac-ft/yr)	11	5	5	1
Dry cooling (ac-ft/yr) ^e	154–770	86–428	NA ^f	NA
Wet cooling (ac-ft/yr) ^e	3,463–11,159	1,924–6,200	NA	NA
Total water use requirements				
Non-cooled technologies (ac-ft/yr)	NA	NA	219	22
Dry-cooled technologies (ac-ft/yr)	550–1,166	305–647	NA	NA
Wet-cooled technologies (ac-ft/yr)	3,859–11,555	2,143–6,419	NA	NA
Wastewater generated				
Blowdown (ac-ft/yr) ^g	219	121	NA	NA
Sanitary wastewater (ac-ft/yr)	11	5	5	1

^a Land area for parabolic trough was estimated at 5 acres/MW (0.02 km²/MW); land area for the power tower, dish engine, and PV technologies was estimated at 9 acres/MW (0.04 km²/MW).

^b Water needs are linearly related to power. Water usage for any other size project can be estimated by using multipliers provided in Table M.9-2 (Appendix M).

^c Value assumes a usage rate of 0.5 ac-ft/yr/MW for mirror washing for parabolic trough, power tower, and dish engine technologies and a rate of 0.05 ac-ft/yr/MW for panel washing for PV systems.

^d To convert ac-ft to m³, multiply by 1,234.

^e Dry-cooling value assumes 0.2 to 1.0 ac-ft/yr per MW and wet-cooling value assumes 4.5 to 14.5 ac-ft/yr per MW (range in these values represents 30 and 60% operating times) (DOE 2009).

^f NA = not applicable.

^g Value scaled from 250-MW Beacon Solar project with an annual discharge of 44 gpm (167 L/min) (AECOM 2009). Blowdown estimates are relevant to wet cooling only.

Groundwater is the primary water resource available for solar energy development at the proposed Gold Point SEZ, and the NDWR has set the perennial yield for the Lida Valley groundwater basin at 350 ac-ft/yr (431,700 m³/yr). Estimated water needs for technologies using wet cooling are at least a factor of 10 greater than the perennial yield (total available water) of the basin, so wet cooling is not feasible at the proposed Gold Point SEZ. Technologies using dry cooling have water use estimates on the order of the perennial yield to about 3 times the perennial yield. It is doubtful that a full build-out scenario using dry-cooling technologies could be supported with the available groundwater supplies. However, water conservation measures and operational aspects (e.g. 30% operating time) could lower the water use requirements of dry-cooling technologies. Full build-out operations of dish engine and PV technologies could be supported by groundwater resources in the Lida Valley groundwater basin and would not require the transfer of any existing groundwater rights.

1 The water quality of groundwater sources would have to be assessed during the site
2 characterization phase. Water used for the workforce potable water supply would have to meet or
3 be treated to comply with water quality standards described in the Nevada Administrative
4 Code (445A.453-445A.455).
5
6

7 **Decommissioning/Reclamation**

8

9 During decommissioning/reclamation, all surface structures associated with the solar
10 project would be dismantled, and the site would be reclaimed to its preconstruction state.
11 Activities and water needs during this phase would be similar to those during the construction
12 phase (dust suppression and potable supply for workers) and may also include water to establish
13 vegetation in some areas. However, the total volume of water needed is expected to be less than
14 during the construction phase. Because quantities of water needed during the decommissioning/
15 reclamation phase would be less than those for construction, impacts on surface and groundwater
16 resources also would be less.
17
18

19 ***11.6.9.2.3 Off-Site Impacts: Roads and Transmission Lines***

20

21 Impacts associated with the construction of roads and transmission lines primarily deal
22 with water use demands for construction, water quality concerns relating to potential chemical
23 spills, and land disturbance effects on the natural hydrology. The extent of the impacts on water
24 resources is proportional to the amount and location of land disturbance needed to connect the
25 proposed SEZ to major roads and existing transmission lines. The proposed Gold Point SEZ is
26 located adjacent to existing roads and 22 mi (35 km) from existing transmission lines, as
27 described in Section 11.6.1.2. Impacts to water resources from the construction of transmission
28 lines are expected to be negligible with the implementation of programmatic design features
29 described in Appendix A, Section A.2.2.
30
31

32 ***11.6.9.2.4 Summary of Impacts on Water Resources***

33

34 The impacts on water resources associated with developing solar energy at the proposed
35 Gold Point SEZ are related to land disturbance effects to the natural hydrology, water quality
36 concerns, and water use requirements for the various solar energy technologies. Land disturbance
37 activities can cause localized erosion and sedimentation issues, as well as alter groundwater
38 recharge and discharge processes. The unnamed intermittent stream and ephemeral washes
39 within the proposed SEZ, along with the playa area in the northeast corner, may be in a 100-year
40 floodplain as they drain toward Jackson Wash, which has been identified as being within a
41 100-year floodplain in the neighboring Nye County, located 9 mi (14 km) east of the site. The
42 100-year floodplain would be identified during the site characterization phase, and solar energy
43 development should be excluded from areas of the proposed SEZ within the 100-year floodplain.
44

45 Impacts relating to water use requirements vary depending on the type of solar
46 technology built and, for technologies using cooling systems, the type of cooling used (wet, dry,

or hybrid). Groundwater is the primary water resource available to solar energy facilities in the proposed Gold Point SEZ. Water requirements during the construction phase are greater than the perennial yield of the Lida Valley groundwater basin for all technologies. Given the limited temporal extent of construction activities, off-site water sources (including water transfers from adjacent basins) would need to be considered to meet peak year construction water use requirements. During the operations phase, the water use requirements for technologies using wet cooling are at least a factor of 10 greater than the perennial yield for the Lida Valley groundwater basin, so wet cooling would not be feasible for the full build-out scenario. Water use estimates for dry cooling are on the same order of magnitude as the perennial yield of the Lida Valley groundwater basin or greater, so water conservation measures would need to be implemented to reduce water needs. Dish engine and PV technologies have full build-out water use requirements that can be supported by unallocated water rights in the Lida Valley groundwater basin, so these technologies are the preferred solar technologies for potential development at the proposed Gold Point SEZ based on water use requirements.

11.6.9.3 SEZ-Specific Design Features and Design Feature Effectiveness

The program for solar energy development on BLM-administered lands will require the programmatic design features given in Appendix A, Section A.2.2, to be implemented, thus mitigating some impacts on water resources. Design features would focus on coordinating with federal, state, and local agencies that regulate the use of water resources to meet the requirements of permits and approvals needed to obtain water for development, and conducting hydrological studies to characterize the aquifer from which groundwater would be obtained (including drawdown effects, if a new point of diversion is created). The greatest consideration for mitigating water impacts would be in the selection of solar technologies. The mitigation of impacts would be best achieved by selecting technologies with low water demands.

Design features specific to the proposed Gold Point SEZ include the following:

- Water resource analysis indicates that wet-cooling options would not be feasible; other technologies should incorporate water conservation measures;
- Land disturbance activities should minimize impacts to the unnamed intermittent stream, the playa area in the northeast corner, and ephemeral washes on site;
- Siting of solar facilities and construction activities should avoid any areas identified as within a 100-year floodplain or jurisdictional waters;
- Groundwater supplies during the construction and operations phases would need to be secured through coordination of the NDWR in terms of obtaining groundwater rights within the Lida Valley groundwater basin, and potentially from off-site sources and adjacent groundwater basins for the construction phase;

- Stormwater management plans and BMPs should comply with standards developed by the Nevada Division of Environmental Protection (NDEP 2010);
- Groundwater monitoring and production wells should be constructed in accordance with state standards (NDWR 2006); and
- Water for potable uses would have to meet or be treated to meet water quality standards in accordance with the *Nevada Administrative Code* (445A.453–445A.455).

11.6.10 Vegetation

This section addresses vegetation that could occur or is known to occur within the potentially affected area of the proposed Gold Point SEZ. The affected area considered in this assessment includes the areas of direct and indirect effects. The area of direct effects is defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur) and includes the SEZ and a 250-ft (76-m) wide portion of an assumed transmission line corridor. The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide assumed transmission line corridor, where ground-disturbing activities would not occur but that could be indirectly affected by activities in the area of direct effects.

Indirect effects considered in the assessment include effects from surface runoff, dust, and accidental spills from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ. This area of indirect effects was identified on the basis of professional judgment and was considered sufficiently large to bound the area that would potentially be subject to indirect effects. The affected area is the area bounded by the areas of direct and indirect effects. These areas are defined and the impact assessment approach is described in Appendix M.

11.6.10.1 Affected Environment

The proposed Gold Point SEZ is located primarily within the Tonopah Basin Level IV ecoregion, which primarily supports sparse shadscale (*Atriplex confertifolia*) communities on broad valleys, hills, bajadas, and alluvial fans (Bryce et al. 2003). Additional commonly occurring shrubs in this ecoregion include bud sagebrush (*Picrothamnus desertorum*), spiny hopsage (*Grayia spinosa*), seepweed (*Suaeda* sp.), fourwing saltbush (*Atriplex canescens*), spiny menodora (*Menodora spinescens*), Nevada ephedra (*Ephedra nevadensis*), littleleaf horsebrush (*Tetradymia glabrata*), Douglas rabbitbrush (*Chrysothamnus viscidiflorus*), and winterfat (*Krascheninnikovia lanata*), which, along with shadscale, often co-dominate in highly diverse mosaics. Warm season grasses, such as Indian rice grass (*Achnatherum hymenoides*) and galleta grass (*Pleuraphis jamesii*), occur in the understory. Stands of inland saltgrass (*Distichlis spicata*) and alkali sacaton (*Sporobolus airoides*) also occur. Bailey greasewood (*Sarcobatus baileyi*) and Shockley wolfberry (*Lycium* sp.) are widespread and often co-dominate on lower alluvial slopes in this ecoregion. Black greasewood (*Sarcobatus vermiculatus*) occurs in saline bottoms. Springs and sporadic precipitation in foothills provide surface water sources.

The area surrounding the SEZ consists of a mosaic of the Tonopah Basin and the Tonopah Sagebrush Foothills Level IV ecoregion. This ecoregion supports black sagebrush (*Artemisia nova*) and Mojave species such as blackbrush (*Coleogyne ramosissima*), Joshua tree (*Yucca brevifolia*), and cholla (*Cylindropuntia* sp.) on rocky substrates. The Tonopah Basin and Tonopah Sagebrush Foothills ecoregions lie within the Central Basin and Range Level III ecoregion, described in Appendix , I, and are part of the Great Basin desertscrub biome. Annual precipitation in the vicinity of the SEZ is low, averaging about 6.1 in. (15.4 cm) at Goldfield, Nevada (see Section 11.6.13).

1 Land cover types described and mapped under the SWReGAP (USGS 2005a) were used
2 to evaluate plant communities in and near the SEZ. Each cover type encompasses a range of
3 similar plant communities. Land cover types occurring within the potentially affected area of the
4 proposed Gold Point SEZ are shown in Figure 11.6.10.1-1. Table 11.6.10.1-1 lists the surface
5 area of each cover type within the potentially affected area.
6

7 Inter-Mountain Basins Mixed Salt Desert Scrub is the predominant cover type within the
8 proposed Gold Point SEZ. Additional cover types within the SEZ are given in Table 11.6.10.1-1.
9 During an August 2009 visit to the site, shadscale, greasewood, fourwing saltbush, winterfat,
10 spiny horsebrush (*Tetradymia* sp.), and Indian ricegrass were the dominant species observed in
11 the desert scrub communities throughout most of the SEZ. Joshua tree (*Yucca brevifolia*) was
12 sparse in the northwest area of the SEZ and absent elsewhere. Joshua tree density increased south
13 and southeast of the SEZ, within the area of indirect effects. Cacti observed on the SEZ included
14 beavertail (*Opuntia basilaris*). Sensitive habitats on the SEZ include riparian, desert dry wash,
15 and playa habitats. The area has a history of livestock grazing, and the plant communities on the
16 SEZ have likely been affected by grazing.
17

18 The indirect effects area, including the area within 5 mi (8 km) around the SEZ and
19 transmission line corridor, includes 16 cover types, which are listed in Table 11.6.10.1-1. The
20 predominant cover type in the indirect effects area is Inter-Mountain Basins Mixed Salt Desert
21 Scrub.
22

23 There are no wetlands mapped by the NWI within the SEZ or indirect effects area
24 (USFWS 2009). NWI maps are produced from high-altitude imagery and are subject to
25 uncertainties inherent in image interpretation (USFWS 2009). Small areas identified as Inter-
26 Mountain Basins Playa occur in the northeastern portion of the SEZ, along with scattered areas
27 of greasewood flat. An unnamed intermittent stream crosses the SEZ from west to east and
28 supports small areas of riparian plant communities. Numerous desert dry washes occur within the
29 SEZ. The dry washes typically do not support wetland or riparian habitats, but many support
30 communities of shrubs, including rabbitbrush (*Chrysothamnus/Ericameria* sp.). The dry washes,
31 greasewood flats, and playas typically contain water for short periods during or following
32 precipitation events. The entire SEZ is within the watershed of Jackson Wash, which supports
33 riparian communities downstream of the SEZ. Springs occur in the vicinity of the SEZ, primarily
34 to the west; however, discharge from these springs is generally low (see Section 11.6.9).
35

36 The State of Nevada maintains an official list of weed species that are designated noxious
37 species. Table 11.6.10.1-2 provides a summary of the noxious weed species regulated in Nevada
38 that are known to occur in Esmeralda County (USDA 2010, Creech et al. 2010), which includes
39 the proposed Gold Point SEZ. Russian thistle (*Salsola* sp.), a non-native species observed to
40 occur within much of the SEZ in August 2009, is not included in this table.
41

42 The NDA classifies noxious weeds into one of three categories (NDA 2010):
43

- 44 • “Category A: Weeds not found or limited in distribution throughout the state;
45 actively excluded from the state and actively eradicated wherever found;
46 actively eradicated from nursery stock dealer premises; control required by the
47 state in all infestations.”

FIGURE 11.6.10.1-1 Land Cover Types within the Proposed Gold Point SEZ (Source: USGS 2004)

TABLE 11.6.10.1-1 Land Cover Types within the Potentially Affected Area of the Proposed Gold Point SEZ and Potential Impacts

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b			Overall Impact Magnitude ^f
	Within SEZ (Direct Effects) ^c	Transmission Line (Direct Effects) ^d	Corridor and Outside SEZ (Indirect Effects) ^e	
Inter-Mountain Basins Mixed Salt Desert Scrub: Generally consists of open shrublands that include at least one species of <i>Atriplex</i> , along with other shrubs. Perennial grasses dominate a sparse to moderately dense herbaceous layer.	4,641 acres ^g (0.5%, 0.6%)	397 acres (<0.1%)	60,242 acres (3.5%)	Small
Inter-Mountain Basins Greasewood Flat: Dominated or codominated by greasewood (<i>Sarcobatus vermiculatus</i>) and generally occurring in areas with saline soils, a shallow water table, and intermittent flooding, although remaining dry for most growing seasons. This community type generally occurs near drainages or around playas. These areas may include, or may be codominated by, other shrubs, and may include a graminoid herbaceous layer.	106 acres (0.6%, 1.1%)	8 acres (<0.1%)	582 acres (1.1%)	Small
Inter-Mountain Basins Playa: Playa habitats are intermittently flooded and generally barren or sparsely vegetated. Depressions may contain small patches of grass, and sparse shrubs may occur around playa margins.	29 acres (0.1%, 0.1%)	2 acres (<0.1%)	46 acres (0.1%)	Small
Inter-Mountain Basins Semi-Desert Shrub Steppe: Generally consists of perennial grasses with an open shrub and dwarf shrub layer.	23 acres (<0.1%, <0.1%)	32 acres (<0.1%)	8,122 acres (2.5%)	Small
Inter-Mountain Basins Big Sagebrush Shrubland: Dominated by basin big sagebrush (<i>Artemisia tridentata tridentata</i>), Wyoming big sagebrush (<i>Artemisia tridentata wyomingensis</i>), or both. Other shrubs may be present. Perennial herbaceous plants are present but not abundant.	2 acres (<0.1%, <0.1%)	140 acres (<0.1%)	14,299 acres (3.5%)	Small

TABLE 11.6.10.1-1 (Cont.)

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b			Overall Impact Magnitude ^f
	Within SEZ (Direct Effects) ^c	Transmission Line (Direct Effects) ^d	Corridor and Outside SEZ (Indirect Effects) ^e	
Great Basin Xeric Mixed Sagebrush Shrubland: Generally occurs on level plains, slopes, and ridges. The dominant shrub species are black sagebrush (<i>Artemisia nova</i>) or, at higher elevations, little sagebrush (<i>Artemisia arbuscula</i>), and co-dominants may be Wyoming big sagebrush (<i>Artemisia tridentata</i> ssp. <i>wyomingensis</i>) or yellow rabbitbrush (<i>Chrysothamnus viscidiflorus</i>). Other shrub species may also be present as well as sparse perennial bunchgrasses.	0 acres	76 acres (<0.1%)	12,739 acres (2.9%)	Small
Developed, Open Space – Low Intensity: Includes housing, parks, golf courses, and other areas planted in developed settings. Impervious surfaces compose up to 49 percent of the total land cover.	0 acres	4 acres (0.1%)	90 acres (1.9%)	Small
Barren Lands, Nonspecific: Includes a variety of barren areas, generally with less than 15% cover of vegetation.	0 acres	3 acres (0.1%)	57 acres (1.6%)	Small
Inter-Mountain Basins Cliff and Canyon: Includes barren and sparsely vegetated (generally <10% plant cover) steep cliff faces, narrow canyons, small rock outcrops, and scree and talus slopes. Composed of widely scattered coniferous trees and a variety of shrubs.	0 acres	2 acres (<0.1%)	357 acres (1.3%)	Small
Developed, Medium-High Intensity: Includes housing and commercial/industrial development. Impervious surfaces compose 50 to 100% of the total land cover.	0 acres	1 acre (0.2%)	9 acres (2.9%)	Small
Great Basin Pinyon-Juniper Woodland: Occurs on low-elevation slopes and ridges. Singleleaf pinyon (<i>Pinus monophylla</i>), Utah juniper (<i>Juniperus osteosperma</i>), or both are the dominant species, generally associating with curl-leaf mountain mahogany (<i>Cercocarpus ledifolius</i>). Understory species include shrubs and grasses.	0 acres	<1 acre (<0.1%)	79 acres (<0.1%)	Small

TABLE 11.6.10.1-1 (Cont.)

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b			Overall Impact Magnitude ^f
	Within SEZ (Direct Effects) ^c	Transmission Line (Direct Effects) ^d	Corridor and Outside SEZ (Indirect Effects) ^e	
Inter-Mountain Basins Big Sagebrush Steppe: Dominated by basin big sagebrush (<i>Artemisia tridentata tridentata</i>), Wyoming big sagebrush (<i>Artemisia tridentata wyomingensis</i>), big sagebrush (<i>Artemisia tridentata xericensis</i>), threetip sagebrush (<i>Artemisia tripartita tripartita</i>), or antelope bitterbrush (<i>Purshia tridentata</i>), or a combination of these species. Other shrubs may be present. Perennial grasses are often abundant. The distribution of shrubs may be patchy, with grassland predominating.	0 acres	<1 acre (<0.1%)	6 acres (1.8%)	Small
Mojave Mid-Elevation Mixed Desert Scrub: The vegetation composition is quite variable. Dominant species include shrubs, forbs, and grasses and may include <i>Yucca</i> spp.	0 acres	<1 acre (<0.1%)	1,303 acres (0.4%)	Small
Introduced Upland Vegetation – Annual and Perennial Grassland: Dominated by non-native annual and perennial grass species.	0 acres	<1 acre (<0.1%)	45 acres (0.6%)	Small
Inter-Mountain Basins Semi-Desert Grassland: Consists of perennial bunchgrasses as dominants or co-dominants. Scattered shrubs or dwarf shrubs may also be present.	0 acres	<1 acre (<0.1%)	15 acres (0.3%)	Small

TABLE 11.6.10.1-1 (Cont.)

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b			Overall Impact Magnitude ^f
	Within SEZ (Direct Effects) ^c	Transmission Line (Direct Effects) ^d	Corridor and Outside SEZ (Indirect Effects) ^e	
Sonora-Mojave Creosotebush-White Bursage Desert Scrub: Occurs in broad valleys, lower bajadas, plains, and low hills in the Mojave and Sonoran deserts. Shrubs form a sparse to moderately dense cover (2 to 50%), although the ground surface may be mostly barren. The dominant species are typically creosotebush (<i>Larrea tridentata</i>) and white bursage (<i>Ambrosia dumosa</i>). Other shrubs, dwarf-shrubs, and cacti may also be dominant or form sparse understories. Herbaceous species are typically sparse, but may be seasonally abundant.	0 acres	0 acres	80 acres (<0.1%)	Small

^a Land cover descriptions are from USGS (2005a). Full descriptions of land cover types, including plant species, can be found in Appendix I.

^b Area in acres, determined from USGS (2004).

^c Includes the area of the cover type within the SEZ, the percentage that area represents of all occurrences of that cover type within the SEZ region (i.e., a 50-mi [80-km] radius from the center of the SEZ), and the percentage that area represents of all occurrences of that cover type on BLM lands within the SEZ region. The SEZ region intersects portions of Nevada and California.

^d For transmission development, direct effects were estimated within a 22-mi (35-km) long, 250-ft (76-m) wide transmission ROW from the SEZ to the nearest existing line. Direct impacts within this area were determined from the proportion of the cover type within the 1-mi (1.6-km) wide transmission corridor. Impacts are for the area of the cover type within the assumed ROW, and the percentage that area represents of all occurrences of that cover type within the SEZ region.

^e Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide assumed transmission line corridor, where ground-disturbing activities would not occur. Indirect effects include effects from surface runoff, dust, and other factors from projects. The potential degree of indirect effects would decrease with increasing distance from the SEZ. Includes the area of the cover type within the area of indirect effects and the percentage that area represents of all occurrences of that cover type within the SEZ region. The area of indirect effects occurs only in Nevada.

^f Overall impact magnitude categories were based on professional judgment and include (1) *small*: a relatively small proportion ($\leq 1\%$) of the cover type within the SEZ region would be lost; (2) *moderate*: an intermediate proportion (>1 but $\leq 10\%$) of a cover type would be lost; (3) *large*: $>10\%$ of a cover type would be lost.

^g To convert acres to km², multiply by 0.004047.

TABLE 11.6.10.1-2 Designated Noxious Weeds of Nevada Occurring in Esmeralda County

Common Name	Scientific Name	Category
Hoary cress/Whitetop ^a	<i>Cardaria</i> spp.	C
Johnsongrass ^a	<i>Sorghum halepense</i>	C
Musk thistle ^b	<i>Carduus nutans</i>	B
Perennial pepperweed ^a	<i>Lepidium latifolium</i>	C
Poison hemlock ^a	<i>Conium maculatum</i>	C
Puncture vine	<i>Tribulus terrestris</i>	C
Russian knapweed ^a	<i>Acroptilon repens</i>	B
Saltcedar ^{a,b}	<i>Tamarix</i> spp.	C
Scotch thistle ^a	<i>Onopordium acanthium</i>	B

Source: NDA (2010).

- “Category B: Weeds established in scattered populations in some counties of the state; actively excluded where possible, actively eradicated from nursery stock dealer premises; control required by the state in areas where populations are not well established or previously unknown to occur.”
- “Category C: Weeds currently established and generally widespread in many counties of the state; actively eradicated from nursery stock dealer premises; abatement at the discretion of the state quarantine officer.”

11.6.10.2 Impacts

The construction of solar energy facilities within the proposed Gold Point SEZ would result in direct impacts on plant communities due to the removal of vegetation within the facility footprint during land-clearing and land-grading operations. Approximately 80% of the SEZ (3,848 acres [15.6 km²]) would be expected to be cleared with full development of the SEZ. The plant communities affected would depend on facility locations and could include any of the communities occurring on the SEZ. Therefore, for this analysis, all the area of each cover type within the SEZ is considered to be directly affected by removal with full development of the SEZ.

Indirect effects (e.g., caused by surface runoff or dust from the SEZ) have the potential to degrade affected plant communities and to reduce biodiversity by promoting the decline or elimination of species sensitive to disturbance. Indirect effects can also cause an increase in disturbance-tolerant species or invasive species. High impact levels could result in the elimination of a community or the replacement of one community type by another. The proper

1 implementation of programmatic design features, however, would reduce indirect effects to a
2 minor or small level of impact.

3
4 Possible impacts from solar energy facilities on vegetation within the SEZ, are described
5 in more detail in Section 5.10.1. Any such impacts would be minimized through the
6 implementation of required design features described in Appendix A, Section A.2.2, and through
7 any additional mitigation applied. Section 11.6.10.2.3, below, identifies design features of
8 particular relevance to the proposed Gold Point SEZ.

11.6.10.2.1 *Impacts on Native Species*

12
13 The impacts of construction, operation, and decommissioning were considered small if
14 the impact affected a relatively small proportion ($\leq 1\%$) of the cover type in the SEZ region
15 (within 50 mi [80 km] of the center of the SEZ); moderate if it could affect an intermediate
16 proportion (>1 but $\leq 10\%$) of a cover type; and large if it could affect greater than 10% of a
17 cover type.

18
19 Solar facility construction and operation in the proposed Gold Point SEZ would
20 primarily affect communities of the Inter-Mountain Basins Mixed Salt Desert Scrub cover
21 type. Additional cover types that would be affected within the SEZ include Inter-Mountain
22 Basins Greasewood Flat, Inter-Mountain Basins Playa, Inter-Mountain Basins Semi-Desert
23 Shrub Steppe, and Inter-Mountain Basins Big Sagebrush Shrubland. Additional cover types that
24 would be affected only by the assumed transmission line include Great Basin Xeric Mixed
25 Sagebrush Shrubland, Developed, Open Space—Low Intensity, Barren Lands, Nonspecific,
26 Inter-Mountain Basins Cliff and Canyon, Developed, Medium-High Intensity, Great Basin
27 Pinyon-Juniper Woodland, Inter-Mountain Basins Big Sagebrush Steppe, Mojave Mid-Elevation
28 Mixed Desert Scrub, Introduced Upland Vegetation—Annual and Perennial Grassland, Inter-
29 Mountain Basins Semi-Desert Grassland, and Sonora-Mojave Creosotebush-White Bursage
30 Desert Scrub. Introduced Upland Vegetation—Annual and Perennial Grassland, Developed,
31 Open Space—Low Intensity, and Developed, Medium-High Intensity cover types would likely
32 have relatively minor populations of native species. Table 11.6.10.1-1 summarizes the potential
33 impacts on land cover types resulting from solar energy facilities in the proposed Gold Point
34 SEZ. While these cover types are relatively common in the SEZ region, several cover types
35 within the transmission line corridor are relatively uncommon, representing less than 1% of the
36 land area within the SEZ region: Inter-Mountain Basins Cliff and Canyon (0.5%), Inter-
37 Mountain Basins Semi-Desert Grassland (0.09%), Barren Lands, Non-specific (0.07%), and
38 Inter-Mountain Basins Big Sagebrush Steppe (0.006%). The construction, operation, and
39 decommissioning of solar projects within the proposed Gold Point SEZ would result in small
40 impacts on all cover types in the affected area. Playa, riparian, and desert dry wash are important
41 sensitive habitats in the SEZ and corridor.

42
43 Because of the arid conditions, reestablishment of desert scrub communities in
44 temporarily disturbed areas would likely be very difficult and might require extended periods
45 of time. In addition, noxious weeds could become established in disturbed areas and colonize
46 adjacent undisturbed habitats, thus reducing restoration success and potentially resulting in

1 widespread habitat degradation. Cryptogamic soil crusts occur in many of the shrubland
2 communities in the region and likely occur on the SEZ. Damage to these crusts, by the operation
3 of heavy equipment or other vehicles, can alter important soil characteristics, such as nutrient
4 cycling and availability, and affect plant community characteristics (Lovich and
5 Bainbridge 1999).

6
7 The deposition of fugitive dust from large areas of disturbed soil onto habitats outside
8 a solar project area could result in reduced productivity or changes in plant community
9 composition. Fugitive dust deposition could affect plant communities of each of the cover
10 types occurring within the area of indirect affects identified in Table 11.6.10.1-1.

11
12 Communities associated with riparian habitats, playa habitats, greasewood flats
13 communities, desert dry wash habitats, or other periodically flooded areas within solar projects
14 or the transmission line corridor could be directly affected by ground-disturbing activities.
15 Similar habitats downgradient from ground-disturbing activities could be indirectly affected.
16 Surface drainage in the northern portion of the SEZ is directed toward playa habitats. The entire
17 SEZ is within the watershed of Jackson Wash, which supports riparian communities downstream
18 of the SEZ. Site-clearing and -grading could disrupt surface water flow patterns, resulting in
19 changes in the frequency, duration, depth, or extent of inundation or soil saturation; could
20 potentially alter plant communities within riparian or playa habitats or along Jackson Wash,
21 including occurrences outside of the SEZ; and could affect community function. Increases in
22 surface runoff from a solar energy project site or transmission line could also affect hydrologic
23 characteristics of these communities. The introduction of contaminants into these habitats could
24 result from spills of fuels or other materials used on a project site. Soil disturbance could result
25 in sedimentation in these areas, which could degrade or eliminate sensitive plant communities.
26 Alteration of surface drainage patterns or hydrology could also adversely affect downstream
27 desert dry wash communities. Vegetation within these communities could be lost by erosion or
28 desiccation.

29
30 Although the use of groundwater within the Gold Point SEZ for technologies with high
31 water requirements, such as wet-cooling systems, may be unlikely, groundwater withdrawals
32 for such systems could reduce groundwater elevations. Communities that depend on accessible
33 groundwater, such as those associated with springs in the Lida Valley groundwater basin, or in
34 other hydrologically connected basins, could become degraded or lost as a result of lowered
35 groundwater levels. The potential for impacts on springs would need to be evaluated by project-
36 specific hydrological studies.

37 38 39 **11.6.10.2.2 Impacts from Noxious Weeds and Invasive Plant Species**

40
41 On February 8, 1999, the President signed E.O. 13112, "Invasive Species," which directs
42 federal agencies to prevent the introduction of invasive species and provide for their control and
43 to minimize the economic, ecological, and human health impacts of invasive species (*Federal*
44 *Register*, Volume 64, page 61836, Feb. 8, 1999). Potential impacts of noxious weeds and
45 invasive plant species resulting from solar energy facilities are described in Section 5.10.1.
46 Despite required design features to prevent the spread of noxious weeds, project disturbance

could potentially increase the prevalence of noxious weeds and invasive species in the affected area of the proposed Gold Point SEZ, such that weeds could be transported into areas that were previously relatively weed-free, which could result in reduced restoration success and possible widespread habitat degradation. Species designated as noxious weeds in Nevada and known to occur in Esmeralda County are listed in Table 11.6.10.1-2. Less than 1 acre ($<0.004 \text{ km}^2$) of Introduced Upland Vegetation—Annual and Perennial Grassland occurs within the direct effects area of the assumed transmission line and approximately 45 acres (0.2 km^2) occurs in the indirect effects area of the SEZ.

Past or present land uses may affect the susceptibility of plant communities to the establishment of noxious weeds and invasive species. Existing roads, transmission lines, and recreational OHV use within the affected area of the Gold Point SEZ would also likely contribute to the susceptibility of plant communities to the establishment and spread of noxious weeds and invasive species. Disturbed areas may contribute to the establishment of noxious weeds and invasive species. Approximately 1 acre (0.004 km^2) of Developed, Medium-High Intensity occurs within the direct effects area of the assumed transmission line and 9 acres (0.04 km^2) in the area of indirect effects; 4 acres (0.02 km^2) of Developed, Open Space—Low Intensity occurs within the direct effects area of the assumed transmission line and 90 acres (0.4 km^2) in the area of indirect effects.

11.6.10.3 SEZ-Specific Design Features and Design Feature Effectiveness

In addition to programmatic design features, SEZ-specific design features would reduce the potential for impacts on plant communities. While specific practices are best established when project details are considered, some SEZ-specific design features can be identified at this time, as follows.

- An Integrated Vegetation Management Plan, addressing invasive species control, and an Ecological Resources Mitigation and Monitoring Plan, addressing habitat restoration, should be approved and implemented to increase the potential for successful restoration of desert scrub, greasewood flat, and other affected habitats, and to minimize the potential for the spread of invasive species. Invasive species control should focus on biological and mechanical methods where possible to reduce the use of herbicides.
- All riparian, dry wash, and playa communities within the SEZ and transmission line corridor should be avoided to the extent practicable, and any impacts minimized and mitigated. Any Joshua tree or other *Yucca* species, cacti, or succulent plant species that cannot be avoided should be salvaged. A buffer area should be maintained around dry wash, riparian, and playa habitats to reduce the potential for impacts.
- Appropriate engineering controls should be used to minimize impacts on dry wash, playa, wetland, greasewood flat, and riparian habitats, including downstream occurrences, resulting from surface water runoff, erosion,

1 sedimentation, altered hydrology, accidental spills, or fugitive dust deposition
2 to these habitats. Appropriate buffers and engineering controls would be
3 determined through agency consultation.

- 4
5 • Groundwater withdrawals should be limited to reduce the potential for indirect
6 impacts on habitats associated with springs. Potential impacts on springs
7 should be determined through hydrological studies.
8

9 If these SEZ-specific design features are implemented in addition to other programmatic
10 design features, it is anticipated that a high potential for impacts from invasive species and
11 potential impacts on dry washes, playas, riparian habitats, wetlands, and springs would be
12 reduced to a minimal potential for impact.
13

11.6.11 Wildlife and Aquatic Biota

This section addresses wildlife (amphibians, reptiles, birds, and mammals) and aquatic biota that could occur within the potentially affected area of the proposed Gold Point SEZ. Wildlife known to occur within 50 mi (80 km) of the SEZ (i.e., the SEZ region) were determined from the SWReGAP (USGS 2007). Land cover types suitable for each species were determined from the SWReGAP (USGS 2004, 2005a, 2007). The amount of aquatic habitat within the SEZ region was determined by estimating the length of linear perennial stream and canal features and the area of standing water body features (i.e., ponds, lakes, and reservoirs) within 50 mi (80 km) of the SEZ using available GIS surface water datasets.

The affected area considered in this assessment included the areas of direct and indirect effects. The area of direct effects was defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur) and included the SEZ and a 250-ft (76-m) wide portion of an assumed 22-mi (35.4-km) long transmission line corridor. The maximum developed area within the SEZ would be 3,848 acres (15.6 km²).

The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary and within a 1.0-mi (1.6-km) wide transmission line corridor where ground-disturbing activities would not occur, but that could be indirectly affected by activities in the areas of direct effects (e.g., surface runoff, dust, noise, lighting, and accidental spills). An additional area of indirect effects was considered for 17 mi (27.4 km) of the transmission line corridor that would extend beyond the 5-mi (8-km) area of indirect effects for the SEZ. The potential degree of indirect effects would decrease with increasing distance from the SEZ. The area of indirect effects was identified on the basis of professional judgment and was considered sufficiently large to bound the area that would potentially be subject to indirect effects. These areas of direct and indirect effects are defined and the impact assessment approach is described in Appendix M.

Dominant land cover habitats in the affected area are sagebrush shrubland and desert scrub (see Section 11.6.10). An unnamed wash traverses the SEZ, and converges with Jackson Wash, about 1.5 mi (2.4 km) east of the proposed Gold Point SEZ (Figure 11.6.9.1-1). Several ephemeral washes converge to a small playa area in the northeast corner of the SEZ.

11.6.11.1 Amphibians and Reptiles

11.6.11.1.1 Affected Environment

This section addresses amphibian and reptile species that are known to occur, or for which potentially suitable habitat occurs, on or within the potentially affected area of the proposed Gold Point SEZ. The list of amphibian and reptile species potentially present in the SEZ area was determined from species lists available from the Nevada Natural Heritage Program (NDCNR 2002) and range maps and habitat information available from the California Wildlife Habitat Relationships System (CDFG 2008) and the SWReGAP (USGS 2007). Land cover types

1 suitable for each species were determined from the SWReGAP (USGS 2004, 2005a, 2007). See
2 Appendix M for additional information on the approach used.

3
4 Based on species distributions within the area of the SEZ and habitat preferences of the
5 amphibian species, the Great Plains toad (*Bufo cognatus*) and red-spotted toad (*Bufo punctatus*)
6 would be expected to occur within the SEZ (USGS 2007; Stebbins 2003). Both toad species
7 would most likely occur in or near the wash and playa habitats within the SEZ.

8
9 More than 25 reptile species occur within the area that encompasses the proposed Gold
10 Point SEZ (USGS 2007; Stebbins 2003). The desert tortoise (*Gopherus agassizii*) is a federal and
11 state listed threatened species. This species is discussed in Section 11.6.12. Lizard species
12 expected to occur within the SEZ include the desert horned lizard (*Phrynosoma platyrhinos*),
13 Great Basin collared lizard (*Crotaphytus bicinctores*), long-nosed leopard lizard (*Gambelia*
14 *wislizenii*), western fence lizard (*Sceloporus occidentalis*), western whiptail (*Cnemidophorus*
15 *tigris*), and zebra-tailed lizard (*Callisaurus draconoides*). Snake species expected to occur within
16 the SEZ are the coachwhip (*Masticophis flagellum*), common kingsnake (*Lampropeltis getula*),
17 glossy snake (*Arizona elegans*), gophersnake (*Pituophis catenifer*), groundsnake (*Sonora*
18 *semiannulata*), long-nosed snake (*Rhinocheilus lecontei*), and nightsnake (*Hypsiglena torquata*).
19 The Mojave rattlesnake (*Crotalus scutulatus*) would be the most common poisonous snake
20 species expected to occur on the SEZ.

21
22 Table 11.6.11.1-1 provides habitat information for representative amphibian and reptile
23 species that could occur within the proposed Gold Point SEZ. Special status amphibian and
24 reptile species are addressed in Section 11.6.12.

25 26 27 **11.6.11.1.2 Impacts**

28
29 The types of impacts that amphibians and reptiles could incur from construction,
30 operation, and decommissioning of utility-scale solar energy facilities are discussed in
31 Section 5.10.2.1. Any such impacts would be minimized through the implementation of required
32 programmatic design features described in Appendix A, Section A.2.2, and through the
33 application of any additional mitigation measures. Section 11.6.11.1.3, below, identifies SEZ-
34 specific design features of particular relevance to the proposed Gold Point SEZ.

35
36 The assessment of impacts on amphibian and reptile species is based on available
37 information on the presence of species in the affected area as presented in Section 11.6.11.1.1,
38 following the analysis approach described in Appendix M. Additional NEPA assessments
39 and coordination with state natural resource agencies may be needed to address project-
40 specific impacts more thoroughly. These assessments and consultations could result in
41 additional required actions to avoid or mitigate impacts on amphibians and reptiles
42 (see Section 11.6.11.1.3).

43
44 In general, impacts on amphibians and reptiles would result from habitat disturbance
45 (i.e., habitat reduction, fragmentation, and alteration) and from disturbance, injury, or mortality
46 to individual amphibians and reptiles. On the basis of the magnitude of impacts on amphibians

TABLE 11.6.11.1-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Amphibian and Reptile Species That Could Occur on or in the Affected Area of the Proposed Gold Point SEZ

		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
Common Name (Scientific Name)	Habitat ^a	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Amphibians					
Great Plains toad (<i>Bufo cognatus</i>)	Prefers desert, grassland, and agricultural habitats. Breeds in shallow temporary pools, quiet areas of streams, marshes, irrigation ditches, and flooded fields. In cold winter months, it burrows underground and becomes inactive. About 1,165,800 acres ^h of potentially suitable habitat occurs within the SEZ region.	129 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) during construction and operations	10,101 acres of potentially suitable habitat (0.9% of available potentially suitable habitat)	40 acres of potentially suitable habitat lost (0.003% of available potentially suitable habitat) and 805 acres in area of indirect effects	Small overall impact. Avoid playa and wash habitats.
Red-spotted toad (<i>Bufo punctatus</i>)	Dry, rocky areas at lower elevations near desert springs and persistent pools along rocky arroyos; desert streams and oases; open grassland; scrubland oaks; and dry woodlands. About 3,104,100 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	62,556 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	397 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 7,988 acres in area of indirect effects	Small overall impact. Other than avoidance of wash and playa habitats, no species-specific mitigation of direct effects is feasible because suitable habitat is widespread in the area of direct effects.
Lizards					
Desert horned lizard (<i>Phrynosoma platyrhinos</i>)	Deserts dominated by sagebrush, creosotebush, greasewood, or cactus. Occurs on sandy flats, alluvial fans, washes, and edges of dunes. Burrows in soil during periods of inactivity. About 4,700,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,366 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	655 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,179 acres in area of indirect effects	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.1-1 (Cont.)

		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
Common Name (Scientific Name)	Habitat ^a	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Lizards (Cont.)					
Great Basin collared lizard (<i>Crotaphytus bicinctores</i>)	Usually inhabits alluvia, lava flows, mountain slopes, canyons, buttes, rock outcrops, washes, and rocky plains. Limiting factors are presence of large boulders and open/sparse vegetation. About 3,794,700 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	83,658 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	508 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 10,221 acres in area of indirect effect	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Long-nosed leopard lizard (<i>Gambelia wislizenii</i>)	Desert and semidesert areas with scattered shrubs. Prefers sandy or gravelly flats and plains. Also prefers areas with abundant rodent burrows that they occupy when inactive. About 3,740,500 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	89,458 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	613 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 12,340 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Western fence lizard (<i>Sceloporus occidentalis</i>)	Disturbed areas, roadsides, gravel beds, rock quarries, lava flows, outcrops, talus slopes, shrublands, riparian areas, and coniferous woodlands. About 4,792,900 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	96,741 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	648 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,038 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.1-1 (Cont.)

		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Lizards (Cont.)					
Western whiptail (<i>Aspidoscelis tigris</i>)	Primarily occurs in sparsely vegetated desert and shrubland habitats. During cold winter months, it often occupies underground burrows created by rodents or other lizards. About 3,818,200 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	84,083 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	514 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 10,342 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Zebra-tailed lizard (<i>Callisaurus draconoides</i>)	Open, warm-desert habitats, especially dry washes and canyons with fine gravel and sand. About 3,228,400 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	75,157 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	473 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 9,517 acres in area of indirect effects	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Snakes					
Coachwhip (<i>Masticophis flagellum</i>)	Creosotebush desert, shortgrass prairie, shrub-covered flats and hills. Sandy to rocky substrates. Avoids dense vegetation. About 2,940,100 acres of potentially suitable habitat occurs within the SEZ region.	131 acres of potentially suitable habitat lost (0.004% of available potentially suitable habitat) during construction and operations	36,272 acres of potentially suitable habitat (1.2% of available potentially suitable habitat)	259 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 5,211 acres in area of indirect effects	Small overall impact.

		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Snakes (Cont.)					
Common kingsnake (<i>Lampropeltis getula</i>)	Coniferous forests, woodlands, swampland, coastal marshes, river bottoms, farmlands, prairies, chaparral, and deserts. Uses rock outcrops and rodent burrows for cover. About 4,581,300 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	85,515 acres of potentially suitable habitat (1.8% of available potentially suitable habitat)	518 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 10,422 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible because suitable habitat is widespread in the area of direct effects.
Glossy snake (<i>Arizona elegans</i>)	Light shrubby to barren deserts, sagebrush flats, grasslands, and chaparral-covered slopes and woodlands. Prefers sandy grasslands, shrublands and woodlands. About 1,604,100 acres of potentially suitable habitat occurs within the SEZ region.	54 acres of potentially suitable habitat lost (0.003% of available potentially suitable habitat) during construction and operations	22,562 acres of potentially suitable habitat (1.4% of available potentially suitable habitat)	174 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 3,501 acres in area of indirect effects	Small overall impact.
Gophersnake (<i>Pituophis catenifer</i>)	Plains grasslands, sandhills, riparian areas, marshes, edges of ponds and lakes, rocky canyons, semidesert and mountain shrublands, montane woodlands, rural and suburban areas, and agricultural areas. Likely inhabits pocket gopher burrows in winter. About 2,739,600 acres of potentially suitable habitat occurs in the SEZ region.	31 acres of potentially suitable habitat lost (0.001% of available potentially suitable habitat) during construction and operations	28,660 acres of potentially suitable habitat (1.0% of available potentially suitable habitat)	223 acres of potentially suitable habitat lost (0.008% of available potentially suitable habitat) and 4,487 acres in area of indirect effect	Small overall impact.

TABLE 11.6.11.1-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Snakes (Cont.)					
Groundsnake (<i>Sonora semiannulata</i>)	Arid and semiarid regions with rocky to sandy soils. River bottoms, desert flats, sand hummocks, and rocky hillsides. About 2,748,300 acres of potentially suitable habitat occurs within the SEZ region.	25 acres of potentially suitable habitat lost (0.001% of available potentially suitable habitat) during construction and operations	36,642 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	249 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 5,010 acres in area of indirect effects	Small overall impact. Avoid greasewood flat habitat.
Mojave rattlesnake (<i>Crotalus scutulatus</i>)	Mostly upland desert and lower mountain slopes. Barren desert, grassland, open juniper woodland, and scrubland; especially common in areas of scattered scrubby growth such as creosote and mesquite. About 5,435,700 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	99,023 acres of potentially suitable habitat (1.8% of available potentially suitable habitat)	666 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,400 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Nightsnake (<i>Hypsiglena torquata</i>)	Arid and semiarid desert flats, plains, and woodlands; areas with rocky and sandy soils are preferred. During cold periods of the year, it seeks refuge underground, in crevices, or under rocks. About 3,460,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	69,785 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	434 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,732 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

Footnotes on next page.

TABLE 11.6.11.1-1 (Cont.)

-
- ^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.
- ^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area.
- ^c Direct effects within the SEZ would consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations. A maximum of 3,848 acres (15.6 km²) would be developed in the SEZ.
- ^d The area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide transmission line corridor (less the assumed area of direct effects) that extends beyond the 5-mi (8-km) area adjacent to the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 3,848 acres (15.6 km²) of direct effects was also added to the area of indirect effects. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ.
- ^e For transmission line development, direct effects were estimated within a 22-mi (35-km) long, 250-ft (76-m) wide ROW for an assumed new transmission line connecting to the nearest existing line. Indirect effects were estimated within a 1-mi (1.6-km) wide transmission corridor to the existing transmission line, less the assumed area of direct effects. Additional indirect effects for the transmission line considered only the 17-mi (27-km) long portion that extends outside of the 5-mi (8-km) area of indirect effects for the SEZ.
- ^f Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: ≤1% of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but ≤10% of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: >10% of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^g Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ^h To convert acres to km², multiply by 0.004047.

Sources: CDFG (2008); NatureServe (2010); NDCNR (2002); USGS (2004, 2005a, 2007).

1 and reptiles summarized in Table 11.6.11.1-1, direct impacts on amphibian and reptile species
2 would be small, as 0.1% or less of potentially suitable habitats identified for the species in the
3 SEZ region would be lost. Larger areas of potentially suitable habitats for most amphibian and
4 reptile species occur within the area of potential indirect effects (e.g., up to 2.4% of available
5 habitat for the long-nosed leopard lizard). Other impacts on amphibians and reptiles could result
6 from surface water and sediment runoff from disturbed areas, fugitive dust generated by project
7 activities, accidental spills, collection, and harassment. These indirect impacts are expected to be
8 negligible with implementation of programmatic design features.
9

10 Decommissioning after operations cease could result in short-term negative impacts on
11 individuals and habitats within and adjacent to the SEZ. The negative impacts of
12 decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term
13 benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4
14 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of
15 particular importance for amphibian and reptile species would be the restoration of original
16 ground surface contours, soils, and native plant communities associated with semiarid
17 shrublands.
18
19

20 ***11.6.11.1.3 SEZ-Specific Design Features and Design Feature Effectiveness***

21

22 The successful implementation of programmatic design features presented in Appendix
23 A, Section A.2.2, would reduce the potential for effects on amphibians and reptiles, especially
24 for those species that depend on habitat types that can be avoided (e.g., washes and playas).
25 Indirect impacts could be reduced to negligible levels by implementing programmatic design
26 features, especially those engineering controls that would reduce runoff, sedimentation, spills,
27 and fugitive dust. While SEZ-specific design features are best established when considering
28 specific project details, one design feature can be identified at this time:
29

- 30 • Development in wash, playa, and cliff and canyon habitats should be avoided.
- 31

32 If this SEZ-specific design feature is implemented in addition to the programmatic design
33 features, impacts on amphibian and reptile species could be reduced. However, as potentially
34 suitable habitats for a number of the representative amphibian and reptile species occur
35 throughout much of the SEZ, additional species-specific mitigation of direct effects for those
36 species would be difficult or infeasible.
37
38

39 **11.6.11.2 Birds**

40
41

42 ***11.6.11.2.1 Affected Environment***

43

44 This section addresses bird species that are known to occur, or for which potentially
45 suitable habitat occurs, on or within the potentially affected area of the proposed Gold Point
46 SEZ. The list of bird species potentially present in the SEZ area was determined from the

1 Nevada Natural Heritage Program (NDCNR 2002) and range maps and habitat information
2 available from the California Wildlife Habitat Relationships System (CDFG 2008) and the
3 SWReGAP (USGS 2007). Land cover types suitable for each species were determined from the
4 SWReGAP (USGS 2004, 2005a, 2007). See Appendix M for additional information on the
5 approach used.

6
7 Five bird species that could occur on or in the affected area of the SEZ are considered
8 focal species in the *Desert Bird Conservation Plan* (CalPIF 2009): ash-throated flycatcher
9 (*Myiarchus cinerascens*), burrowing owl
10 (*Athene cunicularia*), common raven (*Corvus*
11 *corax*), ladder-backed woodpecker (*Picoides*
12 *scalaris*), and Le Conte's thrasher (*Toxostoma*
13 *lecontei*). Habitats for most of these species are
14 described in Table 11.6.11.2-1. Because of its
15 special species status, the burrowing owl is
16 discussed in Section 11.6.12.

Desert Focal Bird Species

Bird species whose requirements define spatial attributes, habitat characteristics, and management regimes representative of a healthy desert system (Chase and Geupel 2005).

Waterfowl, Wading Birds, and Shorebirds

17
18
19 As discussed in Section 4.10.2.2.2, waterfowl (ducks, geese, and swans), wading birds
20 (herons and cranes), and shorebirds (avocets, gulls, plovers, rails, sandpipers, stilts, and terns) are
21 among the most abundant groups of birds in the six-state study area. However, within the
22 proposed Gold Point SEZ, waterfowl, wading birds, and shorebird species would be mostly
23 absent to uncommon. Playa and wash habitats within the SEZ may attract shorebird species, but
24 Deep Springs Lake, Cottonwood and Crooked creeks, and larger washes and dry lakes within 50
25 mi (80 km) of the SEZ would provide more viable habitat for this group of birds. The killdeer
26 (*Charadrius vociferus*) is the shorebird species most likely to occur within the SEZ.

Neotropical Migrants

27
28
29 As discussed in Section 4.10.2.2.3, neotropical migrants represent the most diverse
30 category of birds within the six-state study area. Species expected to occur within the proposed
31 Gold Point SEZ include the ash-throated flycatcher, Bewick's wren (*Thryomanes bewickii*),
32 Brewer's sparrow (*Spizella breweri*), cactus wren (*Campylorhynchus brunneicapillus*), common
33 poorwill (*Phalaenoptilus nuttallii*), common raven, greater roadrunner (*Geococcyx*
34 *californianus*), horned lark (*Eremophila alpestris*), ladder-backed woodpecker, Le Conte's
35 thrasher, lesser nighthawk (*Chordeiles acutipennis*), loggerhead shrike (*Lanius ludovicianus*),
36 northern mockingbird (*Mimus polyglottos*), rock wren (*Salpinctes obsoletus*), sage sparrow
37 (*Amphispiza belli*), Say's phoebe (*Sayornis saya*), and western kingbird (*Tyrannus verticalis*)
38 (CDFG 2008; NDCNR 2002; USGS 2007).

TABLE 11.6.11.2-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Bird Species That Could Occur on or in the Affected Area of the Proposed Gold Point SEZ

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Shorebirds					
Killdeer (<i>Charadrius vociferus</i>)	Open areas such as fields, meadows, lawns, mudflats, and shores. Nests on ground in open dry or gravelly locations. About 129,200 acres ^h of potentially suitable habitat occurs within the SEZ region.	29 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) during construction and operations	145 acres of potentially suitable habitat (0.1% of available potentially suitable habitat)	7 acres of potentially suitable habitat lost (0.005% of available potentially suitable habitat) and 141 acres in area of indirect effects	Small overall impact. Avoid playa and wash habitats. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Neotropical Migrants					
Ash-throated flycatcher (<i>Myiarchus cinerascens</i>)	Common in scrub and woodland habitats including desert riparian and desert washes. Requires hole/cavity for nesting. Uses shrubs or small trees for foraging perches. About 4,365,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	90,225 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	621 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 12,495 acres in area of indirect effects	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.6.11.2-1 (Cont.)

		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Neotropical Migrants (Cont.)					
Bewick’s wren (<i>Thryomanes bewickii</i>)	Generally associated with dense, brushy habitats. Permanent resident of lowland deserts and pinyon-juniper forests of southern Utah. Breeding occurs in brushy areas of open woodlands and other open habitats. Cavity nester with nests constructed in small enclosed areas such as tree cavities, nesting boxes, rock crevices, or the center of a brush pile. About 3,047,900 acres of potentially suitable habitat occurs within the SEZ region.	160 acres of potentially suitable habitat lost (0.005% of available potentially suitable habitat) during construction and operations	36,303 acres of potentially suitable habitat (1.2% of available potentially suitable habitat)	261 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 5,251 acres in area of indirect effects	Small overall impact. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Brewer’s sparrow (<i>Spizella breweri</i>)	Considered a shrub-steppe obligate. Occupies open desert scrub and cropland habitats. However, may also occur in high desert scrub (greasewood) habitats, particularly where adjacent to shrub-steppe habitats. Nests are usually located in patches of sagebrush that are taller and denser, with more bare ground and less herbaceous cover, than the surrounding habitat. Also breeds in large sagebrush openings in pinyon-juniper or coniferous forest habitats. About 3,801,700 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	89,479 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	613 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 12,334 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.6.11.2-1 (Cont.)

		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Neotropical Migrants (Cont.)					
Common poorwill (<i>Phalaenoptilus nuttallii</i>)	Scrubby and brushy areas, prairie, desert, rocky canyons, open woodlands, and broken forests. Mostly in arid and semi-arid habitats. Nests in open areas on a bare site. About 4,474,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	88,928 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	621 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 12,495 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Common raven (<i>Corvus corax</i>)	Occurs in most habitats. Trees and cliffs provide cover. Roosts primarily in trees. Nests on cliffs, bluffs, tall trees, or man-made structures. Forages in sparse, open terrain. About 4,755,500 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,891 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	661 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,299 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.6.11.2-1 (Cont.)

Common Name (Scientific Name)		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Neotropical Migrants (Cont.)					
Greater roadrunner (<i>Geococcyx californianus</i>)	Desert scrub, chaparral, edges of cultivated lands, and arid open areas with scattered brush. Requires thickets, large bushes, or small trees for shade, refuge, and roosting. Usually nests low in trees, shrubs, or clumps of cactus. Rarely nests on ground. About 4,772,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	89,983 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	620 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 12,474 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Horned lark (<i>Eremophila alpestris</i>)	Common to abundant resident in a variety of open habitats. Breeds in grasslands, sagebrush, semidesert shrublands, and alpine tundra. During migration and winter, inhabits the same habitats, other than tundra, and occurs in agricultural areas. Usually occurs where plant density is low and there are exposed soils. About 4,198,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	98,444 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	658 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 13,239 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.6.11.2-1 (Cont.)

Common Name (Scientific Name)		Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
			Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Neotropical Migrants (Cont.)</i>						
Ladder-backed woodpecker (<i>Picoides scalaris</i>)	Variety of habitats including deserts, arid scrub, riparian woodlands, mesquite, scrub oak, pinyon-juniper woodlands. Digs nest hole in rotted stub or dead or dying branches of various trees. Also nests in saguaro, agave, yucca, fence posts, and utility poles. Nests on ledges; branches of trees, shrubs, and cactus; and holes in trees or walls. About 3,179,500 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	62,853 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	400 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,048 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.	
Le Conte's thrasher (<i>Toxostoma lecontei</i>)	Open desert wash, alkali desert scrub, and desert succulent shrub habitats. Prefers to nest and forage in arroyos and washes lined with dense stands of creosotebush and salt bush. About 2,537,800 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	62,418 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	397 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 7,988 acres in area of indirect effects	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

		Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Neotropical Migrants (Cont.)					
Lesser nighthawk (<i>Chordeiles acutipennis</i>)	Open country, desert regions, scrub, savanna, and cultivated areas. Usually near water including open marshes, salt ponds, large rivers, rice paddies, and beaches. Roosts on low perches or the ground. Nests in the open on bare sites. About 4,288,300 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	89,458 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	613 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 12,334 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Loggerhead shrike (<i>Lanius ludovicianus</i>)	Open country with scattered trees and shrubs, savanna, desert scrub, desert riparian, Joshua tree, and occasionally open woodland habitats. Perches on poles, wires, or fence posts (suitable hunting perches are important aspect of habitat). Nests in shrubs and small trees. About 4,732,500 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,831 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	660 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,279 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.6.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Neotropical Migrants (Cont.)</i>					
Northern mockingbird (<i>Mimus polyglottos</i>)	Parkland, cultivated lands, second-growth habitats, desert scrub, and riparian areas. Forages on ground in short, grassy to nearly barren substrates. About 5,167,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	98,921 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	663 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,340 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Rock wren (<i>Salpinctes obsoletus</i>)	Arid and semiarid habitats. Breeds in areas with talus slopes, scrublands, or dry washes. Nests, constructed of plant materials, are located in rock crevices, and the nest entrance is paved with small rocks and stones. About 5,235,000 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	98,969 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	665 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,380 acres in area of indirect effects	Small overall impact. Other than avoidance of wash habitat, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

Neotropical Migrants (Cont.)					
Sage sparrow (<i>Amphispiza belli</i>)	Prefers shrubland, grassland, and desert habitats. The nest, constructed of twigs and grasses, is located either low in a shrub or on the ground. About 4,005,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	97,364 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	656 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 13,199 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Say's phoebe (<i>Sayornis saya</i>)	Arid open country, deserts, sagebrush plains, dry barren foothills, canyons, cliffs, ranches, and rural homes. Nests in cliff crevices, holes in banks, sheltered ledges, tree cavities, under bridges and roofs, and in mines. About 2,558,900 acres of potentially suitable habitat occurs within the SEZ region.	108 acres of potentially suitable habitat lost (0.004% of available potentially suitable habitat) during construction and operations	29,455 acres of potentially suitable habitat (1.2% of available potentially suitable habitat)	231 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 4,648 acres in area of indirect effects	Small overall impact. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

Neotropical Migrants (Cont.)						
Western kingbird (<i>Tyrannus verticalis</i>)	Occurs in a variety of habitats including riparian forests and woodlands, savannas, shrublands, agricultural lands, deserts, and urban areas. Nesting occurs in trees, bushes, and other raised areas, such as buildings. Migrates to Central America or the southeastern United States for the winter. About 4,046,000 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	98,064 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	653 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 13,138 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.	
Birds of Prey						
American kestrel (<i>Falco sparverius</i>)	Occurs in most open habitats, in various shrub and early successional forest habitats, forest openings, and various ecotones. Perches on trees, snags, rocks, utility poles and wires, and fence posts. Uses cavities in trees, snags, rock areas, banks, and buildings for nesting and cover. About 4,756,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,766 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	661 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,299 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Birds of Prey (Cont.)					
Golden eagle (<i>Aquila chrysaetos</i>)	Grasslands, shrublands, pinyon-juniper woodlands, and ponderosa pine forests. Occasionally in most other habitats, especially during migration and winter. Nests on cliffs and sometimes trees in rugged areas, with breeding birds ranging widely over surrounding areas. About 4,800,100 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,667 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	656 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,199 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Bald and Golden Eagle Protection Act.
Great horned owl (<i>Bubo virginianus</i>)	Needs large abandoned bird nest or large cavity for nesting. Usually lives on forest edges and hunts in open areas. In desert areas, requires wooded cliff areas for nesting. About 5,070,200 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	99,023 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	666 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,400 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Birds of Prey</i> (Cont.)					
Long-eared owl (<i>Asio otus</i>)	Nests and roosts in dense vegetation and hunts in open areas (e.g., creosotebush-bursage flats, desert scrub, grasslands, and agricultural fields). About 4,611,800 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,391 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	653 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,138 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Red-tailed hawk (<i>Buteo jamaicensis</i>)	Wide variety of habitats from deserts, mountains, and populated valleys. Open areas with scattered, elevated perch sites such as scrub desert, plains and montane grassland, agricultural fields, pastures, urban parklands, broken coniferous forests, and deciduous woodland. Nests on cliff ledges or in tall trees. About 3,192,100 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	85,251 acres of potentially suitable habitat (2.7% of available potentially suitable habitat)	576 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 11,589 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.2-1 (Cont.)

		Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Birds of Prey (Cont.)					
Turkey vulture (<i>Cathartes aura</i>)	Occurs in open stages of most habitats that provide adequate cliffs or large trees for nesting, roosting, and resting. Migrates and forages over most open habitats. Will roost communally in trees, exposed boulders, and occasionally transmission line support towers. About 3,517,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	62,853 acres of potentially suitable habitat (1.8% of available potentially suitable habitat)	400 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,048 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Upland Game Birds					
Chukar (<i>Alectoris chukar</i>)	Steep, semiarid slopes with rocky outcrops and shrubs with a grass and forb understory. Distribution often follows that of cheatgrass. Sources of water are required during hot, dry periods, with most birds found within 0.25 mi (0.4 km) of water during the brooding period. About 4,585,400 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	97,747 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	646 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 12,998 acres in area of indirect effects	Small overall impact. Other than avoidance of wash and playa habitats, no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Upland Game Birds</i>					
Gambel’s quail (<i>Callipepla gambelii</i>)	Deserts, especially in areas with brushy or thorny growth, and adjacent cultivated areas. Usually occurs near water. Nests on the ground under cover of small trees, shrubs, and grass tufts. About 2,781,700 acres of potentially suitable habitat occurs within the SEZ region.	131 acres of potentially suitable habitat lost (0.005% of available potentially suitable habitat) during construction and operations	37,496 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	259 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 5,211 acres in area of indirect effects	Small overall impact. Avoid wash and playa habitats.
Mourning dove (<i>Zenaida macroura</i>)	Habitat generalist, occurring in grasslands, shrublands, croplands, lowland and foothill riparian forests, ponderosa pine forests, deserts, and urban and suburban areas. Rarely in aspen and other forests, coniferous woodlands, and alpine tundra. Nests on ground or in trees. Winters mostly in lowland riparian forests adjacent to cropland. About 4,379,500 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	85,865 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	584 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 11,750 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.

^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area.

^c Direct effects within the SEZ would consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations. A maximum of 3,848 acres (15.6 km²) of direct effects within the SEZ was assumed.

Footnotes continued on next page.

TABLE 11.6.11.2-1 (Cont.)

-
- ^d The area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide transmission line corridor (less the assumed area of direct effects) that extends beyond the 5-mi (8-km) area adjacent to the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 3,848 acres (15.6 km²) of direct effects was also added to the area of indirect effects. Indirect effects include those from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ.
- ^e For transmission line development, direct effects were estimated within a 22-mi (35-km) long, 250-ft (76-m) wide ROW for an assumed new transmission line connecting to the nearest existing line. Indirect effects were estimated within a 1-mi (1.6-km) wide transmission corridor to the existing transmission line, less the assumed area of direct effects. Additional indirect effects for the transmission line only considered the 17-mi (27-km) long portion that extends outside of the 5 mi (8 km) area of indirect effects for the SEZ.
- ^f Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^g Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ^h To convert acres to km², multiply by 0.004047.

Birds of Prey

Section 4.10.2.2.4 provides an overview of the birds of prey (raptors, owls, and vultures) within the six-state study area. Twenty-seven bird of prey species have been reported from Iron County (Utah Ornithological Society 2007). Raptor species that could occur within the proposed Gold Point SEZ include the American kestrel (*Falco sparverius*), golden eagle (*Aquila chrysaetos*), great horned owl (*Bubo virginianus*), long-eared owl (*Asio otus*), red-tailed hawk (*Buteo jamaicensis*), and turkey vulture (*Cathartes aura*) (CDFG 2008; NDCNR 2002; USGS 2007). Several special status birds of prey species are discussed in Section 11.6.12.

Upland Game Birds

Section 4.10.2.2.5 provides an overview of the upland game birds (primarily pheasants, grouse, quail, and doves) that occur within the six-state study area. Upland game species that could occur within the proposed Gold Point SEZ include the chukar (*Alectoris chukar*), Gambel's quail (*Callipepla gambelii*), and mourning dove (*Zenaida macroura*) (CDFG 2008; NDCNR 2002; USGS 2007).

Table 11.6.11.2-1 provides habitat information for representative bird species that could occur within the proposed Gold Point SEZ. Special status bird species are discussed in Section 11.6.12.

11.6.11.2.2 Impacts

The types of impacts that birds could incur from construction, operation, and decommissioning of utility-scale solar energy facilities are discussed in Section 5.10.2.1. Any such impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2, and through the application of any additional mitigation measures. Section 11.6.11.2.3, below, identifies design features of particular relevance to the proposed Gold Point SEZ.

The assessment of impacts on bird species is based on available information on the presence of species in the affected area, as presented in Section 11.6.11.2.1 following the analysis approach described in Appendix M. Additional NEPA assessments and coordination with federal or state natural resource agencies may be needed to address project-specific impacts more thoroughly. These assessments and consultations could result in additional required actions to avoid or mitigate impacts on birds (see Section 11.6.11.2.3).

In general, impacts on birds would result from habitat disturbance (i.e., habitat reduction, fragmentation, and alteration), and from disturbance, injury, or mortality to individual birds. Table 11.6.11.2-1 summarizes the magnitude of potential impacts on representative bird species resulting from solar energy development in the proposed Gold Point SEZ. Direct impacts on all representative bird species would be small, as only 0.2% or less of potentially suitable habitats for the bird species would be lost (Table 11.6.11.2-1). Larger areas of potentially suitable habitat

1 for bird species occur within the area of potential indirect effects (e.g., up to 2.7% of potentially
2 suitable habitat for the red-tailed hawk). Other impacts on birds could result from collision with
3 vehicles and buildings, surface water and sediment runoff from disturbed areas, fugitive dust
4 generated by project activities, noise, lighting, spread of invasive species, accidental spills, and
5 harassment. Indirect impacts on areas outside the SEZ (e.g., impacts caused by dust generation,
6 erosion, and sedimentation) are expected to be negligible with implementation of programmatic
7 design features.

8
9 Decommissioning after operations cease could result in short-term negative impacts on
10 individuals and habitats within and adjacent to the SEZ. The negative impacts of
11 decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term
12 benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4
13 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of
14 particular importance for bird species would be the restoration of original ground surface
15 contours, soils, and native plant communities associated with desert scrub, playa, and wash
16 habitats.

17 18 19 ***11.6.11.2.3 SEZ-Specific Design Features and Design Feature Effectiveness*** 20

21 The successful implementation of programmatic design features presented in Appendix
22 A, Section A.2.2, would reduce the potential for effects on birds, especially for those species that
23 depend on habitat types that can be avoided (e.g., wash and playa habitats). Indirect impacts
24 could be reduced to negligible levels by implementing programmatic design features, especially
25 those engineering controls that would reduce runoff, sedimentation, spills, and fugitive dust.
26 While SEZ-specific design features important to reducing impacts on birds are best established
27 when project details are considered, some design features can be identified at this time:

- 28
29 • The requirements contained within the 2010 Memorandum of Understanding
30 between the BLM and USFWS to promote the conservation of migratory birds
31 will be followed.
32
- 33 • Take of golden eagles and other raptors should be avoided. Mitigation
34 regarding the golden eagle should be developed in consultation with the
35 USFWS and the NDOW. A permit may be required under the Bald and
36 Golden Eagle Protection Act.
37
- 38 • Wash and playa habitats should be avoided.
39

40 If these SEZ-specific design features are implemented in addition to the programmatic
41 design features, impacts on bird species could be reduced. However, as potentially suitable
42 habitats for a number of the bird species occur throughout much of the SEZ, additional species-
43 specific mitigation of direct effects for those species would be difficult or infeasible.
44
45

11.6.11.3 Mammals

11.6.11.3.1 Affected Environment

This section addresses mammal species that are known to occur, or for which potentially suitable habitat occurs, on or within the potentially affected area of the proposed Gold Point SEZ. The list of mammal species potentially present in the SEZ area was determined from the Nevada Natural Heritage Program (NDCNR 2002) and range maps and habitat information available from the California Wildlife Habitat Relationships System (CDFG 2008) and the SWReGAP (USGS 2007). Land cover types suitable for each species were determined from the SWReGAP (USGS 2004, 2005a, 2007). Appendix M contains additional information on the approach used.

More than 55 species of mammals have ranges that encompass the area of the proposed Gold Point SEZ (NDCNR 2002; USGS 2007); however, suitable habitats for a number of these species are limited or nonexistent within the SEZ (USGS 2007). Similar to the overview of mammals provided for the six-state study area (Section 4.10.2.3), the following discussion for the SEZ emphasizes big game and other mammal species that (1) have key habitats within or near the SEZ, (2) are important to humans (e.g., big game, small game, and furbearer species), and/or (3) are representative of other species that share similar habitats.

Big Game

The big game species that could occur within the area of the proposed Gold Point SEZ include cougar (*Puma concolor*), elk (*Cervus canadensis*), mule deer (*Odocoileus hemionus*), Nelson's bighorn sheep (*Ovis canadensis nelsoni*), and pronghorn (*Antilocapra americana*) (CDFG 2008; NDCNR 2002; USGS 2007). Because of its special species status, Nelson's bighorn sheep is addressed in Section 11.6.12. Based on land cover, potentially suitable habitat for the cougar and mule deer occur throughout the SEZ; whereas, limited suitable habitat for elk and pronghorn occurs within the SEZ (Table 11.6.11.3-1). Figures 11.6.11.3-1 and 11.6.11.3-2 show the location of the SEZ relative to the mapped ranges of mule deer and pronghorn, respectively.

Other Mammals

A number of furbearers and small game mammal species occur within the area of the proposed Gold Point SEZ. Species that could occur within the area of the SEZ include the American badger (*Taxidea taxus*), black-tailed jackrabbit (*Lepus californicus*), bobcat (*Lynx rufus*), coyote (*Canis latrans*), desert cottontail (*Sylvilagus audubonii*), gray fox (*Urocyon cinereoargenteus*), kit fox (*Vulpes macrotis*), and red fox (*Vulpes vulpes*) (CDFG 2008; NDCNR 2002; USGS 2007).

TABLE 11.6.11.3-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Mammal Species That Could Occur on or in the Affected Area of the Proposed Gold Point SEZ

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Big Game					
Cougar (<i>Puma concolor</i>)	Most common in rough, broken foothills and canyon country, often in association with montane forests, shrublands, and pinyon-juniper woodlands. About 5,040,400 acres ^h of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,059 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	648 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,038 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Elk (<i>Cervus canadensis</i>)	Semi-open forest, mountain meadows, foothills, plains, valleys, and alpine tundra. Uses open spaces such as alpine pastures, marshy meadows, river flats, brushy clean cuts, forest edges, and semidesert areas. About 1,242,200 acres of potentially suitable habitat occurs in the SEZ region.	2 acres of potentially suitable habitat lost (<0.0002% of available potentially suitable habitat) during construction and operations	27,044 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	216 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 4,346 acres in area of indirect effects	Small overall impact.

TABLE 11.6.11.3-1 (Cont.)

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Big Game (Cont.)					
Mule deer (<i>Odocoileus hemionus</i>)	Most habitats, including coniferous forests, desert shrub, chaparral, and grasslands with shrubs. Greatest densities in shrublands on rough, broken terrain that provides abundant browse and cover. About 4,182,100 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	98,401 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	658 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 13,239 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Pronghorn (<i>Antilocapra americana</i>)	Grasslands and semidesert shrublands on rolling topography that affords good visibility. Most abundant in shortgrass or midgrass prairies and least common in xeric habitats. About 1,582,200 acres of potentially suitable habitat occurs in the SEZ region.	131 acres of potentially suitable habitat lost (0.008% of available potentially suitable habitat) during construction and operations	35,757 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	256 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 5,151 acres in area of indirect effects	Small overall impact.

Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Small Game and Furbearers					
American badger (<i>Taxidea taxus</i>)	Open grasslands and deserts, meadows in subalpine and montane forests, alpine tundra. Digs burrows in friable soils. Most common in areas with abundant populations of ground squirrels, prairie dogs, and pocket gophers. About 4,698,400 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,882 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	658 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,239 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Black-tailed jackrabbit (<i>Lepus californicus</i>)	Open plains, fields, and deserts with scattered thickets or patches of shrubs. Also open, early stages of forests and chaparral habitats. Rests during the day in shallow depressions, and uses shrubs for cover. About 5,121,100 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,969 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	665 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,380 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Bobcat (<i>Lynx rufus</i>)	Most habitats except subalpine coniferous forest and montane meadow grasslands. Most common in rocky country from deserts through ponderosa forests. About 2,922,300 acres of potentially suitable habitat occurs in the SEZ region.	160 acres of potentially suitable habitat lost (0.005% of available potentially suitable habitat) during construction and operations	37,360 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	263 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 5,292 acres in area of indirect effects	Small overall impact.

TABLE 11.6.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Small Game and Furbearers (Cont.)					
Coyote (<i>Canis latrans</i>)	All habitats at all elevations. Least common in dense coniferous forest. Where human control efforts occur, restricted to broken, rough country with abundant shrub cover and a good supply of rabbits or rodents. About 5,406,700 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	99,023 acres of potentially suitable habitat (1.8% of available potentially suitable habitat)	666 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,400 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Desert cottontail (<i>Sylvilagus audubonii</i>)	Abundant to common in grasslands, open forests, and desert shrub habitats. Can occur in areas with minimal vegetation as long as adequate cover (e.g., rock piles, fallen logs, fence rows) is present. Thickets and patches of shrubs, vines, and brush also used as cover. About 4,302,400 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	110,264 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	94 acres of potentially suitable habitat lost (0.002% of available potentially suitable habitat) and 1,884 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Gray fox (<i>Urocyon cinereoargenteus</i>)	Deserts, open forests and brush. Prefer wooded areas, broken country, brushlands, and rocky areas. Tolerant of low levels of residential development. About 3,572,000 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	70,473 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	442 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,893 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
Small Game and Furbearers (Cont.)					
Kit fox (<i>Vulpes macrotis</i>)	Desert and semidesert areas with relatively open vegetative cover and soft soils. Seeks shelter in underground burrows. About 4,227,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	97,683 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	648 acres of potentially suitable habitat lost (<0.002% of available potentially suitable habitat) and 13,038 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Red fox (<i>Vulpes vulpes</i>)	Most common in open woodlands, pasturelands, riparian areas, and agricultural lands. About 2,610,500 acres of potentially suitable habitat occurs in the SEZ region.	54 acres of potentially suitable habitat lost (0.002% of available potentially suitable habitat) during construction and operations	35,736 acres of potentially suitable habitat (1.4% of available potentially suitable habitat)	253 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 5,090 acres in area of indirect effects	Small overall impact.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small)</i>					
<i>Mammals</i>					
Big brown bat <i>(Eptesicus fuscus)</i>	Most habitats from lowland deserts to timberline meadows. Roosts in hollow trees, rock crevices, mines, tunnels, and buildings. About 3,535,300 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	70,572 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	447 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,994 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Botta’s pocket gopher <i>(Thomomys bottae)</i>	Variety of habitats, including shortgrass plains, oak savanna, agricultural lands, and deserts. Burrows are more common in disturbed areas such as roadways and stream floodplains. About 3,382,300 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	84,339 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	579 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 11,649 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Brazilian free-tailed bat <i>(Tadarida brasiliensis)</i>	Cliffs, deserts, grasslands, old fields, savannas, shrublands, woodlands, and suburban/urban areas. Roosts in buildings, caves, and hollow trees. May roost in rock crevices, bridges, signs, or cliff swallow nests during migration. Large maternity colonies inhabit caves, buildings, culverts, and bridges. About 4,307,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	84,574 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	587 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 11,810 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small) Mammals (Cont.)</i>					
Cactus mouse <i>(Peromyscus eremicus)</i>	Variety of areas, including desert scrub, semidesert chaparral, desert wash, semidesert grassland, and cliff and canyon habitats. About 1,780,400 acres of potentially suitable habitat occurs in the SEZ region.	129 acres of potentially suitable habitat lost (0.007% of available potentially suitable habitat) during construction and operations	10,537 acres of potentially suitable habitat (0.6% of available potentially suitable habitat)	43 acres of potentially suitable habitat lost (0.002% of available potentially suitable habitat) and 865 acres in area of indirect effects	Small overall impact. Avoid wash habitat.
California myotis <i>(Myotis californicus)</i>	Desertscrub, semidesert shrublands, lowland riparian, swamps, riparian suburban areas, plains grasslands, scrub-grasslands, woodlands, and forests. Roosts in caves, mine tunnels, hollow trees, and loose rocks. About 3,780,400 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	84,339 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	579 acres of potentially suitable habitat lost (0.015% of available potentially suitable habitat) and 11,649 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Canyon mouse <i>(Peromyscus crinitus)</i>	Associated with rocky substrates in a variety of habitats including desert scrub, sagebrush shrublands, woodlands, cliffs and canyons, and volcanic rock and cinder lands. Source of free water not required. About 2,124,200 acres of potentially suitable habitat occurs in the SEZ region.	2 acres of potentially suitable habitat lost (<0.0001% of available potentially suitable habitat) during construction and operations	28,421 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	216 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 4,346 acres in area of indirect effects	Small overall impact.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small)</i>					
<i>Mammals (Cont.)</i>					
Deer mouse (<i>Peromyscus maniculatus</i>)	Tundra; alpine and subalpine grasslands; plains grasslands; open, sparsely vegetated deserts; warm temperate swamps and riparian forests; and Sonoran desert scrub habitats. About 4,976,700 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.08% of available potentially suitable habitat) during construction and operations	98,741 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	656 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,199 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Desert shrew (<i>Notiosorex crawfordi</i>)	Usually in arid areas with adequate cover such as semiarid grasslands, shortgrass plains, desert scrub, chaparral slopes, shortgrass plains, oak savannas and woodlands, and alluvial fans. About 3,479,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	71,340 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	440 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 8,853 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small)</i>					
<i>Mammals (Cont.)</i>					
Desert woodrat (<i>Neotoma lepida</i>)	Sagebrush scrub; chaparral; deserts and rocky slopes with scattered cactus, yucca, pine-juniper, or other low vegetation; creosotebush desert; Joshua tree woodlands; scrub oak woodlands, pinyon-juniper woodlands; and riparian zones. Dens built of debris on ground, among cacti or yucca, along cliffs, among rocks, or occasionally in trees. About 5,231,800 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	98,747 acres of potentially suitable habitat (1.9% of available potentially suitable habitat)	656 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 13,199 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Hoary bat (<i>Lasiurus cinereus</i>)	Chaparral, shortgrass plains, scrub-grassland, desertscrub, forests and woodlands. Usually roosts in trees, also in caves, rock crevices, and houses. About 1,799,700 acres of potentially suitable habitat occurs in the SEZ region.	158 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) during construction and operations	9,379 acres of potentially suitable habitat (0.5% of available potentially suitable habitat)	50 acres of potentially suitable habitat lost (0.003% of available potentially suitable habitat) and 1,006 acres in area of indirect effects	Small overall impact.

TABLE 11.6.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small) Mammals (Cont.)</i>					
Little pocket mouse <i>(Perognathus longimembris)</i>	Mostly sandy and gravelly soils, but also stony soils and rarely rocky sites. About 2,314,300 acres of potentially suitable habitat occurs in the SEZ region.	25 acres of potentially suitable habitat lost (0.001% of available potentially suitable habitat) during construction and operations	36,543 acres of potentially suitable habitat (1.6% of available potentially suitable habitat)	248 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 4,990 acres in area of indirect effects	Small overall impact.
Long-legged myotis <i>(Myotis volans)</i>	Prefers pine forest, desert, and riparian habitats. Old buildings, rock crevices, and hollow trees are used for daytime roosting and winter hibernation. Forages in open areas, such as forest clearings. About 3,605,000 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	70,925 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	449 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 9,034 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Merriam’s kangaroo rat <i>(Dipodomys merriami)</i>	Plains grasslands, scrub-grasslands, desertscrub, shortgrass plains, oak and juniper savannas, mesquite dunes, and creosote flats. About 4,206,900 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	98,387 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	655 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 13,179 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

Common Name (Scientific Name)	Habitat ^a	Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small) Mammals (Cont.)</i>					
Northern grasshopper mouse <i>(Onychomys leucogaster)</i>	Occurs in grasslands, sagebrush deserts, overgrazed pastures, weedy roadside ditches, sand dunes, and other habitats with sandy soil and sparse vegetation. About 2,793,700 acres of potentially suitable habitat occurs within the SEZ region.	25 acres of potentially suitable habitat lost (<0.001% of available potentially suitable habitat) during construction and operations	36,637 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	248 acres of potentially suitable habitat lost (0.009% of available potentially suitable habitat) and 4,990 acres in area of indirect effects	Small overall impact.
Silver-haired bat <i>(Lasionycteris noctivagans)</i>	Urban areas, chaparral, alpine and subalpine grasslands, forests, scrub-grassland, oak savanna and desertscrub habitats. Roosts under bark, in hollow trees, caves and mines. Forages over clearings and open water. About 4,252,200 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.09% of available potentially suitable habitat) during construction and operations	84,170 acres of potentially suitable habitat (2.0% of available potentially suitable habitat)	579 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 11,649 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Southern grasshopper mouse <i>(Onychomys torridus)</i>	Low, arid, shrub and semiscrub vegetation of deserts. About 2,882,400 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	70,577 acres of potentially suitable habitat (2.4% of available potentially suitable habitat)	430 acres of potentially suitable habitat lost (0.015% of available potentially suitable habitat) and 8,652 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.3-1 (Cont.)

		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small)</i>					
<i>Mammals (Cont.)</i>					
Western pipistrelle (<i>Parastrellus esperus</i>)	Deserts and lowlands, desert mountain ranges, desert scrub flats, and rocky canyons. Roosts mostly in rock crevices, sometimes mines and caves, and rarely in buildings. Suitable roosts occur in rocky canyons and cliffs. Most abundant bat in desert regions. About 3,726,700 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	84,495 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	587 acres of potentially suitable habitat lost (0.02% of available potentially suitable habitat) and 11,810 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
White-tailed antelope squirrel (<i>Ammospermophilus leucurus</i>)	Low deserts, semidesert and montane shrublands, plateaus, and foothills in areas with sparse vegetation and hard gravelly surfaces. Spends nights and other periods of inactivity in underground burrows. About 3,735,000 acres of potentially suitable habitat occurs within the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	84,085 acres of potentially suitable habitat (2.3% of available potentially suitable habitat)	516 acres of potentially suitable habitat lost (0.01% of available potentially suitable habitat) and 10,382 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.6.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b			Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Within Transmission Corridor (Indirect and Direct Effects) ^e	
<i>Nongame (small)</i>					
<i>Mammals (Cont.)</i>					
Yuma myotis (<i>Myotis yumanensis</i>)	Riparian areas, grasslands, semidesert shrubland, mountain brush, woodlands, and deserts. Occurs where there is open water, regardless of the habitat. Roosts in caves, mines, cliffs, crevices, buildings, and swallow nests. About 3,762,800 acres of potentially suitable habitat occurs in the SEZ region.	3,848 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	83,651 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	571 acres of potentially suitable habitat lost (0.015% of available potentially suitable habitat) and 11,489 acres in area of indirect effects	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

- ^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.
- ^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. A maximum of 3,848 acres (15.6 km²) of direct effects within the SEZ was assumed.
- ^c Direct effects within the SEZ would consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
- ^d The area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide transmission line corridor (less the assumed area of direct effects) that extends beyond the 5-mi (8-km) area adjacent to the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 3,848 acres (15.6 km²) of direct effects was also added to the area of indirect effects. Indirect effects include those from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ.
- ^e For transmission line development, direct effects were estimated within a 22-mi (35-km) long, 250-ft (76-m) wide ROW for an assumed new transmission line connecting to the nearest existing line. Indirect effects were estimated within a 1-mi (1.6-km) wide transmission corridor to the existing transmission line, less the assumed area of direct effects. Additional indirect effects for the transmission line only considered the 17-mi (27-km) long portion that extends outside of the 5 mi (8 km) area of indirect effects for the SEZ

Footnotes continued on next page.

TABLE 11.6.11.3-1 (Cont.)

-
- ^f Overall impact magnitude categories were based on professional judgment and are as follows: (1) small: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) moderate: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) large: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^g Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ^h To convert acres to km^2 , multiply by 0.004047.

FIGURE 11.6.11.3-1 Location of the Proposed Gold Point SEZ Relative to the Mapped Range of Mule Deer (Source: NDOW 2010)

FIGURE 11.6.11.3-2 Location of the Proposed Gold Point SEZ Relative to the Mapped Range of Pronghorn (Source: NDOW 2010)

1 The nongame (small) mammals include bats, rodents, and shrews. Representative
2 species for which potentially suitable habitat occurs within the proposed Gold Point SEZ include
3 Botta's pocket gopher (*Thomomys bottae*), cactus mouse (*Peromyscus eremicus*), canyon mouse
4 (*P. crinitis*), deer mouse (*P. maniculatus*), desert kangaroo rat (*Dipodomys deserti*), desert shrew
5 (*Notiosorex crawfordi*), little pocket mouse (*Perognathus longimembris*), Merriam's pocket
6 mouse (*Dipodomys merriami*), northern grasshopper mouse (*Onychomys leucogaster*), southern
7 grasshopper mouse (*O. torridus*), and white-tailed antelope squirrel (*Ammospermophilus*
8 *leucurus*) (CDFG 2008; NDCNR 2002; USGS 2007). Bat species that may occur within the area
9 of the SEZ include the big brown bat (*Eptesicus fuscus*), Brazilian free-tailed bat (*Tadarida*
10 *brasiliensis*), California myotis (*Myotis californicus*), hoary bat (*Lasiurus cinereus*), long-legged
11 myotis (*M. volans*), silver-haired bat (*Lasionycteris noctivagans*), and western pipistrelle
12 (*Parastrellus hesperus*) (CDFG 2008; NDCNR 2002; USGS 2007). However, roost sites for the
13 bat species (e.g., caves, hollow trees, rock crevices, or buildings) would be limited or absent
14 within the SEZ. Several other special status bat species that could occur within the SEZ area are
15 addressed in Section 11.6.12.

16
17 Table 11.6.11.3-1 provides habitat information for representative mammal species that
18 could occur within the proposed Gold Point SEZ. Special status mammal species are discussed in
19 Section 11.6.12.

20 21 22 **11.6.11.3.2 Impacts**

23
24 The types of impacts that mammals could incur from construction, operation, and
25 decommissioning of utility-scale solar energy facilities are discussed in Section 5.10.2.1. Any
26 such impacts would be minimized through the implementation of required programmatic design
27 features described in Appendix A, Section A.2.2, and through the application of any additional
28 mitigation measures. Section 11.6.11.3.3, below, identifies design features of particular
29 relevance to mammals for the proposed Gold Point SEZ.

30
31 The assessment of impacts on mammal species is based on available information on
32 the presence of species in the affected area as presented in Section 11.6.11.3.1, following the
33 analysis approach described in Appendix M. Additional NEPA assessments and coordination
34 with state natural resource agencies may be needed to address project-specific impacts more
35 thoroughly. These assessments and consultations could result in additional required actions to
36 avoid or mitigate impacts on mammals (see Section 11.6.11.3.3). Table 11.6.11.3-1 summarizes
37 the magnitude of potential impacts on representative mammal species resulting from solar
38 energy development (with the inclusion of programmatic design features) in the proposed Gold
39 Point SEZ.

40 41 42 **Cougar**

43
44 Up to 3,848 acres (15.6 km²) of potentially suitable cougar habitat could be lost by solar
45 energy development within the proposed Gold Point SEZ and another 648 acres (2.6 km²) by
46 transmission line construction. This represents about 0.09% of potentially suitable cougar habitat

1 within the SEZ region. More than 98,000 acres (396 km²) of potentially suitable cougar habitat
2 occurs within the area of indirect effects. Overall, impacts on cougar from solar energy
3 development in the SEZ would be small.
4

5 6 **Elk**

7
8 Only 2 acres (0.008 km²) of potentially suitable elk habitat could be lost by solar
9 energy development within the proposed Gold Point SEZ and another 216 acres (0.9 km²) by
10 transmission line construction. This represents about 0.02% of potentially suitable elk habitat
11 within the SEZ region. More than 27,000 acres (109 km²) of potentially suitable elk habitat
12 occurs within the area of indirect effects. No mapped elk range occurs near the SEZ (NDOW
13 2010). Overall, impacts on elk from solar energy development in the SEZ would be small.
14

15 16 **Mule Deer**

17
18 Based on land cover analyses, up to 3,848 acres (15.6 km²) of potentially suitable mule
19 deer habitat could be lost by solar energy development within the proposed Gold Point SEZ and
20 another 658 acres (2.7 km²) by transmission line construction. This represents about 0.1% of
21 potentially suitable mule deer habitat within the SEZ region. More than 98,000 acres (396 km²)
22 of potentially suitable mule deer habitat occurs within the area of indirect effects. Based on
23 mapped range, the closest year-round mule deer habitat is about 4.0 mi (6.4 km) from the SEZ
24 (Figure 11.6.11.3-1). About 4,560 acres (18.5 km²) of year-round mule deer habitat occurs
25 within the area of indirect effects. This is about 0.6% of the year-round mule deer habitat within
26 the SEZ region. The closest summer range, winter range, and crucial winter ranges are over 40
27 mi (64 km) from the SEZ (Figure 11.6.11.3-1). Thus, no direct or indirect effects on these mule
28 deer ranges would occur. Overall, impacts on mule deer from solar energy development in the
29 SEZ would be small.
30

31 32 **Pronghorn**

33
34 Based on land cover analyses, about 130 acres (0.5 km²) of potentially suitable
35 pronghorn habitat could be lost by solar energy development within the proposed Gold Point
36 SEZ and another 256 acres (1.0 km²) by transmission line construction. This represents
37 about 0.03% of potentially suitable pronghorn habitat within the SEZ region. Fewer than
38 35,800 acres (145 km²) of potentially suitable pronghorn habitat occurs within the area of
39 indirect effects. Based on mapped range, year-round pronghorn habitat occurs within the SEZ
40 (Figure 11.6.11.3-2). Over 4,430 acres (17.9 km²) of year-round habitat occurs within the SEZ;
41 therefore, up to 3,848 acres (15.6 km²) could be lost by solar energy development within the
42 SEZ and about 300 acres (1.2 km²) could be lost by construction of the proposed transmission
43 line. These losses would total about 0.3% of the year-round pronghorn range within the SEZ
44 region. About 45,630 acres (185 km²) of year-round pronghorn habitat occurs within the area of
45 indirect effects. This is about 3.9% of the year-round pronghorn habitat within the SEZ region.
46 Overall, impacts on pronghorn from solar energy development in the SEZ would be small.
47

Other Mammals

Direct impacts on small game, furbearers, and nongame (small) mammal species would be small, as about 0.01 to 0.1% of potential habitats identified for the representative species would be lost by solar energy development within the SEZ and associated transmission line construction (Table 11.6.11.3-1). Larger areas of potentially suitable habitat for these species occur within the area of potential indirect effects (i.e., ranging from 0.5% for the hoary bat to 2.5% for the desert cottontail and Botta's pocket gopher).

Summary of Impacts on Mammals

Overall, direct impacts on mammal species would be small for all species, as only 0.1% or less of potentially suitable habitats for the representative mammal species would be lost (Table 11.6.11.3-1). Larger areas of potentially suitable habitat for mammal species occur within the area of potential indirect effects (e.g., up to 2.5% for the desert cottontail and Botta's pocket gopher). Other impacts on mammals could result from collision with vehicles and facilities (e.g., fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment. Indirect impacts on areas outside the SEZ (e.g., impacts caused by dust generation, erosion, and sedimentation) would be negligible with implementation of programmatic design features.

Decommissioning after operations cease could result in short-term negative impacts on individuals and habitats within and adjacent to the SEZ. The negative impacts of decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of particular importance for mammal species would be the restoration of original ground surface contours, soils, and native plant communities associated with semiarid shrublands.

11.6.11.3.3 SEZ-Specific Design Features and Design Feature Effectiveness

The implementation of required programmatic design features presented in Appendix A, Section A.2.2, would reduce the potential for effects on mammals. Indirect impacts could be reduced to negligible levels by implementing programmatic design features, especially those engineering controls that would reduce runoff, sedimentation, spills, and fugitive dust. While SEZ-specific design features important for reducing impacts on mammals are best established when considering specific project details, design features that can be identified at this time are:

- The fencing around the solar energy development should not block the free movement of mammals, particularly big game species.
- Wash and playa habitats should be avoided.

1 If these SEZ-specific design features are implemented in addition to the programmatic
2 design features, impacts on mammals could be reduced. However, potentially suitable habitats
3 for a number of the mammal species occur throughout much of the SEZ; therefore, species-
4 specific mitigation of direct effects for those species would be difficult or infeasible.

5 6 7 **11.6.11.4 Aquatic Biota**

8 9 10 **11.6.11.4.1 Affected Environment**

11
12 The proposed Gold Point SEZ is in a desert valley where surface waters are typically
13 limited to ephemeral and intermittent washes that contain water only for short periods during or
14 following precipitation. No perennial streams or water bodies are present in the proposed Gold
15 Point SEZ or within the area of direct effects associated with the proposed new transmission line
16 corridor. Approximately 3 mi (5 km) of an unnamed intermittent stream runs through the center
17 of the SEZ and flows into the intermittent Jackson Wash. Several ephemeral streams also cross
18 the SEZ, flowing to the northeast and terminating in dry lakes. In addition, the presumed new
19 transmission line (250 ft [76 m] wide) would cross the intermittent Jackson Wash. The
20 intermittent and ephemeral streams within the area of direct effects flow primarily in response to
21 rainfall and typically do not support wetland or riparian habitats or flow into perennial surface
22 waters. Although not considered aquatic habitat, such nonpermanent surface waters may contain
23 invertebrates that are either aquatic opportunists (i.e., species that occupy both temporary and
24 permanent waters) or specialists adapted to living in temporary aquatic environments
25 (Graham 2001). On the basis of information from ephemeral pools in the American Southwest,
26 ostracods (seed shrimp) and small planktonic crustaceans (e.g., copepods or cladocerans) may be
27 present, and larger branchiopod crustaceans such as fairy shrimp could occur (Graham 2001).
28 Various types of insects that have aquatic larval stages, such as dragonflies and a variety of
29 midges and other fly larvae, may also occur depending on the duration of standing water, the
30 distance to permanent water features, and the abundance of other invertebrates for prey
31 (Graham 2001). The NWI mapping does not indicate any wetlands within the Gold Point SEZ
32 (USFWS 2009).

33
34 No perennial streams or water bodies are present within the area of indirect effects
35 associated with the proposed Gold Point SEZ or the presumed new transmission line corridor.
36 There are 8 mi (13 km) of the intermittent Jackson Wash and 8 mi (13 km) of an unnamed
37 intermittent stream present within the area of indirect effects associated with the SEZ. In
38 addition, the 1-mi (2-km) area of indirect effects associated with the proposed new transmission
39 line corridor crosses over Jackson Wash. Washes within the area of indirect effects are typically
40 dry and do not flow into any perennial surface waters. There are also several ephemeral streams
41 within the area of indirect effects. Although typically dry, such ephemeral and intermittent
42 habitat may contain opportunistic crustaceans and aquatic insect larvae. The National Wetlands
43 Inventory mapping does not indicate any wetlands within the area of indirect effects associated
44 with the Gold Point SEZ (USFWS 2009).

1 Outside of the indirect effects area, but within 50 mi (80 km) of the proposed Gold
2 Point SEZ, are approximately 70 mi (113 km) of perennial streams and 449 mi (723 km) of
3 intermittent streams, 44,389 acres (180 km²) of dry lakes and 1,255 acres (5 km²) of
4 intermittent lakes. The nearest permanent surface water is more than 14 mi (22 km) from the
5 SEZ. Intermittent streams are the only surface water feature in the area of direct and indirect
6 effects, and their area represents approximately 0.7 % of the total amount of intermittent stream
7 present in the 50-mi (80-km) SEZ region.
8
9

10 **11.6.11.4.2 Impacts**

11

12 Because surface water habitats are a unique feature in the arid landscape in the vicinity of
13 the proposed Gold Point SEZ, the maintenance and protection of such habitats may be important
14 to the survival of aquatic and terrestrial organisms. The types of impacts that aquatic habitats
15 and biota could incur from the development of utility-scale solar energy facilities are described
16 in detail in Section 5.10.3. Aquatic habitats present on or near the locations selected for
17 construction of solar energy facilities could be affected in a number of ways, including (1) direct
18 disturbance, (2) deposition of sediments, (3) changes in water quantity, and (4) degradation of
19 water quality.
20

21 There are no permanent water bodies, streams, or wetlands within the area of direct or
22 indirect effects associated with the proposed Gold Point SEZ or the presumed new transmission
23 line corridors, and consequently there would be no direct impacts on aquatic habitat from solar
24 energy development. There are intermittent and ephemeral streams in the area of direct and
25 indirect effects associated with the SEZ and presumed new transmission line corridor, and
26 ground disturbance associated with solar development could increase the transport of soil into
27 these streams via water- and airborne pathways. However, intermittent and ephemeral streams in
28 the area of direct and indirect effects are typically dry and are not expected to support aquatic
29 habitat or communities, nor do they flow into perennial surface waters. It is unlikely that
30 significant airborne dust associated with ground disturbance within the SEZ would reach aquatic
31 habitat, given the large distance from the SEZ to the nearest stream (14 mi [22 km]). However,
32 fugitive dust could be minimized using the appropriate dust suppression measures as needed.
33

34 In arid environments, reductions in the quantity of water in aquatic habitats are of
35 particular concern. Water quantity in aquatic habitats could also be affected if significant
36 amounts of surface water or groundwater are utilized for power plant cooling water, for washing
37 mirrors, or for other needs. The greatest need for water would occur if technologies employing
38 wet cooling, such as parabolic trough or power tower, were developed at the site; the associated
39 impacts would ultimately depend on the water source used (including groundwater from aquifers
40 at various depths). There are no surface water habitats on the proposed Gold Point SEZ that
41 could be used to supply water needs. Water demands during normal operations would most
42 likely be met by withdrawing groundwater from wells constructed on-site, and given the
43 subsurface connection between regional groundwater and basins outside the SEZ (see
44 Section 11.6.9.1.2), there is the potential that groundwater withdrawals could reduce surface
45 water levels in streams and wetlands outside of the proposed SEZ. Additional details on the

1 volume of water required and the types of organisms present in potentially affected water bodies
2 would be required in order to further evaluate the potential for impacts from water withdrawals.
3

4 As described in Section 5.10.3, water quality in aquatic habitats could be affected by the
5 introduction of contaminants such as fuels, lubricants, or pesticides/herbicides during site
6 characterization, construction, operation, or decommissioning/reclamation of a solar energy
7 facility. Construction activities occurring near intermittent streams in the Gold Point SEZ and
8 in the proposed new transmission line corridor could introduce contaminants into intermittent
9 streams. However, these features are not expected to contain aquatic habitat or biota and do
10 not connect to any perennial surface waters. The introduction of contaminants could be further
11 minimized by avoiding construction near streams.
12
13

14 ***11.6.11.4.3 SEZ-Specific Design Features and Design Feature Effectiveness*** 15

16 No SEZ-specific design features are identified at this time. If programmatic design
17 features described in Appendix A, Section A.2.2, are implemented as needed and if the
18 utilization of water from groundwater or surface water sources is adequately controlled to
19 maintain sufficient water levels in aquatic habitats, the potential impacts on aquatic biota and
20 habitats from solar energy development at the proposed Gold Point SEZ would be negligible.

11.6.12 Special Status Species (Threatened, Endangered, Sensitive, and Rare Species)

This section addresses special status species that are known to occur, or for which suitable habitat occurs, on or within the potentially affected area of the proposed Gold Point SEZ. Special status species include the following types of species³:

- Species listed as threatened or endangered under the ESA;
- Species that are proposed for listing, are under review, or are candidates for listing under the ESA;
- Species that are listed by the BLM as sensitive;
- Species that are listed by the State of Nevada⁴; and
- Species that have been ranked by the State of Nevada as S1 or S2 or species of concern by the State of Nevada or the USFWS; hereafter referred to as “rare” species.

Special status species known to occur within 50 mi (80 km) of the Gold Point SEZ center (i.e., the SEZ region) were determined from natural heritage records available through NatureServe Explorer (NatureServe 2010), information provided by the NDOW NNHP (Miskow 2009; NDCNR 2004, 2009a,b), CNDDDB (CDFG 2010), the SWReGAP (USGS 2004, 2005a, 2007), the CAREGAP (Davis et al. 1998; USGS 2010e), and the USFWS ECOS (USFWS 2010). Information reviewed consisted of county-level occurrences as determined from Nature Serve, element occurrences provided by the CDFG and NNHP, as well as modeled land cover types and predicted suitable habitats for the species within the 50 mi (80 km) region as determined from CAREGAP and SWReGAP. The 50-mi (80-km) SEZ region intersects Esmeralda and Nye Counties, Nevada, as well as Inyo and Mono Counties, California. However, the SEZ and affected area occurs only in Esmeralda County, Nevada. See Appendix M for additional information on the approach used to identify species that could be affected by development within the SEZ.

11.6.12.1 Affected Environment

The affected area considered in the assessment included the areas of direct and indirect effects. The area of direct effects was defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur). For the Gold Point SEZ, the area of direct effects included the SEZ and the areas within the transmission

³ See Section 4.6.4 for definitions of these species categories. Note that some of the categories of species included here do not fit BLM’s definition of special status species as defined in BLM Manual 6840 (BLM 2008b). These species are included here to ensure broad consideration of species that may be most vulnerable to impacts.

⁴ State-listed species for the state of Nevada are those protected under NRS 501.110 (animals) or NRS 527 (plants).

corridor where ground-disturbing activities are assumed to occur. No new access roads are expected to be needed to serve development on the SEZ because of the proximity of existing infrastructure (refer to Section 11.6.1.2 for development assumptions). The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary and the portion of the transmission corridor where ground-disturbing activities would not occur but that could be indirectly affected by activities in the area of direct effects. Indirect effects considered in the assessment included effects from surface runoff, dust, noise, lighting, and accidental spills from the SEZ and transmission construction area, but did not include ground-disturbing activities. The potential magnitude of indirect effects would decrease with increasing distance from the SEZ. This area of indirect effects was identified on the basis of professional judgment and was considered sufficiently large to bound the area that would potentially be subject to indirect effects. The affected area includes both the direct and indirect effects areas.

The primary land cover habitat type within the affected area is intermountain basin mixed desert scrub (see Section 11.6.10). Potentially unique habitats in the affected area in which special status species may reside include rocky cliffs and outcrops, desert washes, playas, and woodland habitats. There are no permanent or perennial surface water features on the SEZ or within the area of indirect effects. However, various intermittent streams (washes) and playas occur on the SEZ and throughout the area of indirect effects. In particular, Jackson Wash occurs northeast of the SEZ within the transmission corridor, and an unnamed tributary to Jackson Wash occurs on the SEZ (Figure 11.6.12.1-1).

All special status species that are known to occur within the Gold Point SEZ region (i.e., within 50 mi [80 km] of the center of the SEZ) are listed, with their status, nearest recorded occurrence, and habitats, in Appendix J. Of these species, 21 could be affected by solar energy development on the SEZ based on recorded occurrences or the presence of potentially suitable habitat in the area. These species, their status, and their habitats are presented in Table 11.6.12.1-1. For many of the species listed in the table, their predicted potential occurrence in the affected area is based only on a general correspondence between mapped SWReGAP land cover types and descriptions of species habitat preferences. This overall approach to identifying species in the affected area probably overestimates the number of species that actually occur in the affected area. For many of the species identified as having potentially suitable habitat in the affected area, the nearest known occurrence is more than 20 mi (32 m) away from the SEZ.

Based on NNHP records, there are no special status species known to occur within the affected area of the Gold Point SEZ (Table 11.6.12.1-1). There are no groundwater-dependent species in the vicinity of the SEZ based upon NNHP records, comments provided by the USFWS (Stout 2009), and the evaluation of groundwater resources in the Gold Point SEZ region (Section 11.6.9).

11.6.12.1.1 Species Listed under the Endangered Species Act That Could Occur in the Affected Area

In scoping comments on the proposed Gold Point SEZ (Stout 2009), the USFWS did not express concern for impacts of project development within the SEZ on any species listed as

FIGURE 11.6.12.1-1 Known or Potential Occurrences of Species Listed as Endangered or Threatened under the ESA, Candidates for Listing under the ESA, or Species under Review for ESA Listing in the Affected Area of the Proposed Gold Point SEZ (Sources: Miskow 2009; USGS 2007)

TABLE 11.6.12.1-1 Habitats, Potential Impacts, and Potential Mitigation for Special Status Species That Could Be Affected by Solar Energy Development on the Proposed Gold Point SEZ

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c			Overall Impact Magnitude ^g and Species-Specific Mitigation ^h
				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Plants							
Bullfrog Hills sweetpea	<i>Lathyrus hitchcockianus</i>	NV-S2	Open, dry to slightly moist gravels of rocky drainage bottoms in canyons and on upper alluvial slopes, often at bases of boulders or canyon walls and climbing up through shrubs, in areas of volcanic tuff or carbonate rocks in the mixed-shrub, sagebrush, and pinyon-juniper zones. Elevation ranges between 4,000 and 7,000 ft. ⁱ Nearest recorded occurrence is 35 mi ^j southeast of the SEZ. About 512,600 acres ^k of potentially suitable habitat occurs in the SEZ region.	3,850 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat)	30 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	90,300 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. Pre-disturbance surveys and avoidance or minimization of disturbance to occupied habitats in the area of direct effects; translocation of individuals from area of direct effects; or compensatory mitigation of direct effects on occupied habitats could reduce impacts. Note that these same potential mitigations apply to all special status plants.
Clokey paintbrush	<i>Castilleja martinii</i> var. <i>clokeyi</i>	FWS-SC	Pinyon-juniper woodland at elevations between 6,500 and 9,500 ft. Nearest recorded occurrence is 15 mi east of the SEZ. About 513,700 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	0 acres	80 acres of potentially suitable habitat (<0.1% of available potentially suitable habitat)	Small overall impact; no direct effects. No species-specific mitigation is warranted.

TABLE 11.6.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c			Overall Impact Magnitude ^g and Species-Specific Mitigation ^h
				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Plants (Cont.)							
Eastwood milkweed	<i>Asclepias eastwoodiana</i>	BLM-S; FWS-SC; NV-S2	Endemic to Nevada in Esmeralda, Lander, Lincoln, and Nye Counties in open areas on a wide variety of basic (pH usually >8) soils, including calcareous clay knolls, sand, carbonate or basaltic gravels, or shale outcrops, generally barren and lacking competition. Frequently occurs in small washes or other moisture-accumulating microsites at elevations between 4,700 and 7,100 ft. Nearest recorded occurrence is 30 mi northeast of the SEZ. About 37,900 acres of potentially suitable habitat occurs in the SEZ region.	An unquantified amount of potentially suitable desert wash habitat occurs on the SEZ. ¹	An unquantified amount of potentially suitable desert wash habitat occurs in the transmission corridor. ¹	420 acres of potentially suitable habitat (1.1% of available potentially suitable habitat)	Small to large overall impact. Avoiding or minimizing disturbance to desert wash habitats in the area of direct effects could reduce impacts. The amount of potentially suitable desert wash habitat in the area of direct effects is not quantified. See the Bullfrog Hills sweetpea for a list of other potential mitigation measures.
Holmgren lupine	<i>Lupinus holmgrenianus</i>	BLM-S; NV-S2	Inhabits dry desert slopes, washes, and valleys on volcanic substrates, in association with sagebrush and pinyon-juniper woodland. Elevation ranges between 4,600 and 8,200 ft. Nearest recorded occurrence is 9 mi west of the SEZ. About 119,700 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	10 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	27,300 acres of potentially suitable habitat (1.8% of available potentially suitable habitat)	Small overall impact. Avoiding or minimizing disturbance to sagebrush habitats in the area of direct effects could reduce impacts. See the Bullfrog Hills sweetpea for a list of other potential mitigations.

Plants (Cont.)							
Panamint Mountains bedstraw	<i>Galium hilendiae</i> ssp. <i>carneum</i>	NV-S1	Rocky or gravelly substrates of rocky slopes or open flats within Mojave desert scrub and pinyon-juniper woodlands at elevations between 4,000 and 11,200 ft. Nearest recorded occurrence is 30 mi southeast of the SEZ. About 962,400 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	0 acres	160 acres of potentially suitable habitat (<0.1% of available potentially suitable habitat)	Small overall impact; no direct effects. No species-specific mitigation is warranted.
Squalid milkvetch	<i>Astragalus serenoii</i> var. <i>sordescens</i>	NV-S2	Endemic to Nevada on dry, open, gravelly, or sandy soils along gentle slopes of alluvial fans or light-colored clay hills, within mixed-shrub, sagebrush, and lower pinyon-juniper communities at elevations between 5,000 and 6,800 ft. Nearest recorded occurrence is 35 mi north of the SEZ. About 2,815,250 acres of potentially suitable habitat occurs in the SEZ region.	3,850 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat)	30 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	90,000 acres of potentially suitable habitat (3.2% of available potentially suitable habitat)	Small overall impact. See the Bullfrog Hills sweetpea for a list of potential mitigations.

				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Plants (Cont.)							
Tonopah pincushion cactus	<i>Sclerocactus nyensis</i>	BLM-S; NV-P; NV-S1	Endemic to Esmeralda and Nye Counties, Nevada on dry rocky soils and low outcrops of rhyolite, tuff, and possibly other rock types, on gentle slopes in open areas or under shrubs in the upper salt desert and lower sagebrush zones. Elevation ranges between 5,700 and 5,800 ft. Known to occur in Esmeralda County, Nevada. About 2,370,300 acres of potentially suitable habitat occurs in the SEZ region.	3,850 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat)	30 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	88,600 acres of potentially suitable habitat (3.7% of available potentially suitable habitat)	Small overall impact. See the Bullfrog Hills sweetpea for a list of potential mitigations.
Weasel phacelia	<i>Phacelia mustelina</i>	NV-S2	Mojave desert scrub and pinyon-juniper woodlands on volcanic or gravelly substrates at elevations between 5,000 and 5,500 ft. Nearest recorded occurrence is 35 mi southeast of the SEZ. About 1,462,700 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	0 acres	1,450 acres of potentially suitable habitat (0.1% of available potentially suitable habitat)	Small overall impact; no direct effect. No species-specific mitigation is warranted.

TABLE 11.6.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c			Overall Impact Magnitude ^g and Species-Specific Mitigation ^h
				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Birds							
Ferruginous hawk	<i>Buteo regalis</i>	BLM-S; FWS-SC	Winter resident in project area in grasslands, sagebrush and saltbrush habitats, as well as the periphery of pinyon-juniper woodlands throughout the project area. Known to occur in Esmeralda County, Nevada. About 790,000 acres of potentially suitable habitat occurs in the SEZ region.	200 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	225 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	28,100 acres of potentially suitable foraging habitat (3.6% of available potentially suitable habitat)	Small overall impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.
Greater sage-grouse	<i>Centrocercus urophasianus</i>	ESA-C; BLM-S;	Year-round resident in SEZ region. Plains, foothills, and mountain valleys dominated by sagebrush. Lek sites are located in relatively open areas surrounded by sagebrush or in areas where sagebrush density is low. Nesting usually occurs on the ground where sagebrush density is higher. Some populations may travel up to 60 mi between summer and winter habitats. Known to occur in Esmeralda County, Nevada. About 312,800 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	50 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	900 acres of potentially suitable foraging habitat (0.3% of available potentially suitable habitat)	Small overall impact. Pre-disturbance surveys and avoidance or minimization of disturbance to occupied habitats and/or suitable leks and nesting sites in the area of direct effects or compensatory mitigation of direct effects on occupied habitats could reduce impacts. The potential for impact and need for mitigation should be determined in coordination with the USFWS and NDOW.

TABLE 11.6.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c			Overall Impact Magnitude ^g and Species-Specific Mitigation ^h
				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Birds (Cont.)							
Prairie falcon	<i>Falco mexicanus</i>	BLM-S	Year-round resident in the project area, primarily in open habitats in mountainous areas, steppe, grasslands, or cultivated areas. Nests in well-sheltered ledges of rocky cliffs and outcrops. Known to occur in Esmeralda County, Nevada. About 2,387,300 acres of potentially suitable habitat occurs in the SEZ region.	4,500 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	500 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	81,350 acres of potentially suitable habitat (3.4% of available potentially suitable habitat)	Small overall impact. No direct effects on nesting habitat. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.
Swainson's hawk	<i>Buteo swainsoni</i>	BLM-S; NV-P; CA-S2; NV-S2	Summer breeding resident in the SEZ region. Savanna, open pine-oak woodlands, grasslands, and cultivated lands. Nests typically in solitary trees, bushes, or small groves; sometimes nests near urban areas. Known to occur in Esmeralda County, Nevada. About 735,600 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	50 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	9,650 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	Small overall impact. No direct impact on nesting habitat. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.

TABLE 11.6.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c			Overall Impact Magnitude ^g and Species-Specific Mitigation ^h
				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Western burrowing owl	<i>Athene cunicularia hypugaea</i>	BLM-S; FWS-SC	Year-round resident in open grasslands and prairies, as well as disturbed sites such as golf courses, cemeteries, and airports throughout the SEZ region. Nests in burrows constructed by mammals (prairie dog, badger, etc.). Known to occur in Esmeralda County, Nevada. About 3,082,700 acres of potentially suitable habitat occurs in the SEZ region.	4,625 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat)	650 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	97,000 acres of potentially suitable habitat (3.1% of available potentially suitable habitat)	Small overall impact on foraging and nesting habitat. Pre-disturbance surveys; avoidance or minimization of disturbance to occupied burrows and habitats in the area of direct effects; or compensatory mitigation of direct effects on occupied habitats could reduce impacts.
Mammals							
Brazilian free-tailed bat	<i>Tadarida brasiliensis</i>	BLM-S; NV-P	Year-round resident in SEZ region. Forages in desert grassland, old fields, savanna, shrubland, and woodland habitats as well as urban areas. Roosts in old buildings, caves, mines, and hollow trees. Nearest recorded occurrence is 15 mi west of the SEZ. About 2,651,850 acres of potentially suitable habitat occurs in the SEZ region.	4,800 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	590 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	83,500 acres of potentially suitable habitat (3.1% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.

Mammals (Cont.)							
Fringed myotis	<i>Myotis thysanodes</i>	BLM-S; NV-P; FWS-SC; NV-S2	Year-round resident in SEZ region. Wide range of habitats including lowland riparian, desert shrub, pinyon-juniper, and sagebrush habitats. Roost in buildings and caves. Known to occur in Esmeralda County, Nevada. About 3,051,200 acres of potentially suitable habitat occurs in the SEZ region.	4,700 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	620 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	88,200 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.
Nelson’s bighorn sheep	<i>Ovis canadensis nelsoni</i>	BLM-S; FWS-SC	Open, steep rocky terrain in mountainous habitats of the eastern Mojave and Sonoran Deserts in California. Rarely uses desert lowlands, but may use them as corridors for travel between mountain ranges. Known to occur in Esmeralda County, Nevada. About 941,500 acres of potentially suitable habitat occurs in the SEZ region.	0 acres	150 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	24,100 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. Impacts could be reduced by conducting pre-disturbance surveys and avoiding occupied habitats and important movement corridors in the area of direct effects.

				Within SEZ (Direct Effects) ^d	Transmission Line (Direct Effects) ^e	Indirect Effects (Outside SEZ) ^f	
Mammals (Cont.)							
Pale kangaroo mouse	<i>Microdipodops pallidus</i>	NV-P; NV-S2	Known from southwestern Nevada and southeastern California. Inhabits fine sands in alkali sink and desert scrub dominated by shadscale or big sagebrush. Often burrows in areas of soft, windblown sand piled at the bases of shrubs. Known to occur in Esmeralda County, Nevada. About 1,251,250 acres of potentially suitable habitat occurs in the SEZ region.	4,700 acres of potentially suitable foraging habitat lost (0.4% of available potentially suitable habitat)	200 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	50,500 acres of potentially suitable habitat (4.0% of available potentially suitable habitat)	Small overall impact. Pre-disturbance surveys; avoidance or minimization of disturbance to occupied habitats on the SEZ; or compensatory mitigation of direct effects on occupied habitats could reduce impacts.
Pallid bat	<i>Antrozous pallidus</i>	BLM-S; NV-P; FWS-SC	Year-round resident in SEZ region. Low-elevation desert communities, including grasslands, shrublands, and woodlands. Roosts in caves, crevices, and mines. Nearest recorded occurrence is 15 mi west of the SEZ. About 2,616,400 acres of potentially suitable habitat occurs in the SEZ region.	4,550 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	575 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	83,175 acres of potentially suitable habitat (3.2% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.

Mammals (Cont.)							
Silver-haired bat	<i>Lasionycteris noctivagans</i>	BLM-S; FWS-SC	Year-round resident in SEZ region. Primarily high-elevation (1,600 to 8,500 ft) forested areas comprising aspen, cottonwood, white fir, pinyon-juniper, subalpine fir, willow, and spruce communities. Roost and nursery sites occur in tree foliage, cavities, or under loose bark. Rarely hibernates in caves. Nearest recorded occurrence is 15 mi west of the SEZ. About 2,609,400 acres of potentially suitable habitat occurs in the SEZ region.	4,600 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	580 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	83,200 acres of potentially suitable habitat (3.2% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.
Spotted bat	<i>Euderma maculatum</i>	BLM-S; NV-P; FWS-SC; NV-S2	Year-round resident in SEZ region. Year-round resident in SEZ region near forests and shrubland habitats throughout the SEZ region. Uses caves and rock crevices for day roosting and winter hibernation. Nearest recorded occurrence is 15 mi west of the SEZ. About 2,605,300 acres of potentially suitable habitat occurs in the SEZ region.	4,700 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	550 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	76,750 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.

Mammals (Cont.)							
Townsend's big-eared bat	<i>Corynorhinus townsendii</i>	BLM-S; NV-P; NV-S2	Year-round resident in SEZ region near forests and shrubland habitats below 9,000 ft elevation throughout the SEZ region. Roosts and hibernates in caves, mines, and buildings. Nearest recorded occurrence is 8 mi west of the SEZ. About 2,347,800 acres of potentially suitable habitat occurs in the SEZ region.	4,600 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	450 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	68,550 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.
Western small-footed myotis	<i>Myotis ciliolabrum</i>	BLM-S; FWS-SC	Year-round resident in SEZ region in a variety of woodlands and riparian habitats at elevations below 9,000 ft. Roosts in caves, buildings, mines, and crevices of cliff faces. Nearest recorded occurrence is 9 mi south of the SEZ. About 3,374,000 acres of potentially suitable habitat occurs in the SEZ region.	4,800 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	650 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	97,950 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact; direct impact on foraging habitat only. Avoidance of direct impacts on foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effects.

^a BLM-S = listed as a sensitive species by the BLM; ESA-C = candidate for listing under the ESA; FWS-SC = USFWS species of concern; NV-P = protected in the State of Nevada under NRS 501.110 (animals) or NRS 527 (plants); NV-S1 = ranked as S1 in the State of Nevada; NV-S2 = ranked as S2 in the State of Nevada.

^b For plant species, potentially suitable habitat was determined by using SWReGAP land cover types. For terrestrial vertebrate species, potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.

Footnotes continued on next page.

TABLE 11.6.12.1-1 (Cont.)

-
- ^c Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. Impacts of access road construction, upgrade, or operation are not assessed in this evaluation due to the proximity of existing infrastructure to the SEZ.
- ^d Direct effects within the SEZ consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
- ^e For transmission line development, direct effects were estimated within a 22-mi (8-km), 250-ft (76-m) wide ROW from the SEZ to the nearest transmission line. Direct impacts within this area were determined from the proportion of potentially suitable habitat within the 1-mi (1.6-km) wide transmission corridor.
- ^f Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and the portion of the transmission corridor where ground-disturbing activities would not occur. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from projects. The potential degree of indirect effects would decrease with increasing distance away from the SEZ.
- ^g Overall impact magnitude categories were based on professional judgment, as follows: (1) *small*: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^h Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ⁱ To convert ft to m, multiply by 0.3048.
- ^j To convert mi to km, multiply by 1.609.
- ^k To convert acres to km², multiply by 0.004047.
- ^l Although the SWReGAP did not map any wash habitat on the SEZ, there appear to be numerous desert washes that could provide habitat for this species on the SEZ, in the transmission corridor, and in the area of indirect effects, including Jackson Wash and its tributaries. The area of these washes has not been quantified.

1 threatened or endangered under the ESA. There are no NNHP records or potentially suitable
2 habitats for any ESA-listed species within the affected area. According to SWReGAP and USGS
3 habitat suitability models, potentially suitable habitat for the desert tortoise, a species listed as
4 threatened under the ESA, does not occur within the affected area of the Gold Point SEZ.
5
6

7 ***11.6.12.1.2 Species That Are Candidates for Listing under the ESA*** 8

9 In scoping comments on the proposed Gold Point SEZ, the USFWS did not identify any
10 candidate species for listing under the ESA that may be directly or indirectly affected by solar
11 energy development on the SEZ (Stout 2009). However, one candidate species, the greater sage-
12 grouse, may occur within the affected area. This species primarily inhabits sagebrush habitats in
13 plains, foothills, and mountain valley regions. This species is known to occur in Esmeralda
14 County, Nevada, and potentially suitable year-round sagebrush habitat is expected to occur
15 within the affected area (Figure 11.6.12.1-1). According to the SWReGAP habitat suitability
16 model, suitable habitat for this species is not expected to occur on the SEZ. However,
17 approximately 50 acres (0.2 km²) of potentially suitable habitat for this species is estimated to
18 occur in the assumed transmission ROW; approximately 900 acres (4 km²) of potentially suitable
19 habitat occurs in the area of indirect effects (Table 11.6.12.1-1). Additional basic information on
20 life history, habitat needs, and threats to populations of the greater sage-grouse is provided in
21 Appendix J.
22
23

24 ***11.6.12.1.3 Species That Are under Review for Listing under the ESA*** 25

26 On the basis of information provided by the NNHP and the USFWS (Stout 2009) and on
27 availability of potentially suitable habitats, there are no species under review for ESA listing that
28 may occur in the affected area of the Gold Point SEZ.
29
30

31 ***11.6.12.1.4 BLM-Designated Sensitive Species*** 32

33 There are 16 BLM-designated sensitive species that may occur in the affected area of
34 the Gold Point SEZ or that may be affected by solar energy development on the SEZ
35 (Table 11.6.12.1-1). These BLM-designated sensitive species include the following: (1) plants:
36 Eastwood milkweed, Holmgren lupine, and Tonopah pincushion cactus; (2) birds: ferruginous
37 hawk, greater sage-grouse, prairie falcon, Swainson's hawk, and western burrowing owl; and
38 (3) mammals: Brazilian free-tailed bat, fringed myotis, Nelson's bighorn sheep, pallid bat,
39 silver-haired bat, spotted bat, Townsend's big-eared bat, and western small-footed myotis.
40 Habitats in which BLM-designated sensitive species are found, the amount of potentially suitable
41 habitat in the affected area, and known locations of the species relative to the SEZ are presented
42 in Table 11.6.12.1-1. The greater sage-grouse has been discussed previously because of its
43 candidate status under the ESA (Section 11.6.12.1.2). The remaining 15 species as related to the
44 SEZ are described in the remainder of this section. Additional life history information for these
45 species is provided in Appendix J.
46
47

Eastwood Milkweed

The Eastwood milkweed is a perennial herb endemic to Nevada on public and private lands in Esmeralda, Lander, Lincoln, and Nye Counties. It occurs in open areas on a wide variety of basic (pH usually >8) soils, including calcareous clay knolls, sand, carbonate, or basaltic gravels, washes, or shale outcrops at elevations between 4,700 and 7,100 ft (1,430 and 2,150 m). According to the SWReGAP land cover model, potentially suitable rocky cliffs and wash habitats do not occur on the SEZ or in the transmission corridor; however, these suitable habitats may occur within the area of indirect effects (Table 11.6.12.1-1). Although the SWReGAP did not map any wash habitat on the SEZ or transmission corridor, there appear to be numerous washes that could provide habitat for this species in the area of direct effects, including Jackson Wash and its tributaries. The area of these washes has not been quantified.

Holmgren Lupine

The Holmgren lupine is a perennial herb known from southeastern California and southwestern Nevada. It inhabits dry desert slopes, washes, and valleys on volcanic substrates in sagebrush communities and pinyon-juniper woodlands. The species occurs at elevations between 4,600 and 8,200 ft (1,400 and 2,500 m). The nearest known occurrences are approximately 9 mi (14 km) west of the Gold Point SEZ. According to the SWReGAP land cover model, potentially suitable sagebrush and pinyon-juniper woodland habitats may occur within the transmission corridor and in the area of indirect effects. On the basis of an evaluation of SWReGAP land cover types, potentially suitable habitat for this species does not occur on the SEZ.

Tonopah Pincushion Cactus

The Tonopah pincushion cactus is endemic to Esmeralda and Nye Counties, Nevada. This species occurs on dry rocky soils and low outcrops on gentle slopes in open areas or under shrubs in the upper salt desert and lower sagebrush zones. This species is not known to occur in the affected area of the Gold Point SEZ; however, potentially suitable alkaline playa habitat may occur on the SEZ and within the area of indirect effects (Table 11.6.12.1-1).

Ferruginous Hawk

The ferruginous hawk occurs throughout the western United States. According to the SWReGAP habitat suitability model, only potentially suitable winter habitat for the ferruginous hawk is predicted to occur within the affected area of the Gold Point SEZ, although potentially suitable year-round habitat is expected to occur outside of the affected area within the SEZ region. The species inhabits open grasslands, sagebrush flats, desert scrub, and the edges of pinyon-juniper woodlands. This species occurs in Esmeralda County, Nevada, and potentially suitable foraging habitat occurs on the SEZ and in other portions of the affected area (Table 11.6.12.1-1).

1 **Prairie Falcon**

2
3 The prairie falcon occurs throughout the western United States. According to the
4 SWReGAP habitat suitability model, potentially suitable year-round habitat for the prairie
5 falcon may occur within the affected area of the Gold Point SEZ. The species occurs in open
6 habitats in mountainous areas, sagebrush-steppe, grasslands, or cultivated areas. Nests are
7 typically constructed in well-sheltered ledges of rocky cliffs and outcrops. This species occurs
8 in Esmeralda County, Nevada, and potentially suitable foraging habitat occurs on the SEZ and
9 in other portions of the affected area (Table 11.6.12.1-1). On the basis of an evaluation of
10 SWReGAP land cover types, there is no suitable nesting habitat within the area of direct effects,
11 but approximately 350 acres (1.5 km²) of cliff and rock outcrop habitat that may be potentially
12 suitable nesting habitat occurs in the area of indirect effects.
13

14
15 **Swainson's Hawk**

16
17 The Swainson's hawk occurs throughout the southwestern United States. According to
18 the SWReGAP habitat suitability model for the Swainson's hawk, only summer breeding
19 habitat occurs in the Gold Point SEZ region. This species inhabits desert, savanna, open pine-
20 oak woodland, grassland, and cultivated habitats. Nests are typically constructed in solitary
21 trees, bushes, or small groves. This species occurs in Esmeralda County, Nevada. According to
22 the SWReGAP habitat suitability model, suitable habitat for this species does not occur on the
23 SEZ; however, potentially suitable foraging habitat occurs in the transmission corridor and in
24 portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of
25 SWReGAP land cover types, there is no suitable nesting habitat within the area of direct effects,
26 but approximately 80 acres (0.3 km²) of pinyon-juniper woodland habitat that may be potentially
27 suitable nesting habitat occurs in the area of indirect effects.
28
29

30 **Western Burrowing Owl**

31
32 According to the SWReGAP habitat suitability model for the western burrowing owl,
33 the species is a summer breeding resident of open, dry grasslands and desert habitats in the
34 Gold Point SEZ region. The species occurs locally in open areas with sparse vegetation, where
35 it forages in grasslands, shrublands, open disturbed areas, and nests in burrows typically
36 constructed by mammals. The species occurs in Esmeralda County, Nevada, and potentially
37 suitable summer breeding habitat may occur in the SEZ, the transmission corridor, and portions
38 of the area of indirect effects (Table 11.6.12.1-1). The availability of nest sites (burrows) within
39 the affected area has not been determined, but shrubland habitat that may be suitable for either
40 foraging or nesting occurs throughout the affected area.
41
42

43 **Brazilian Free-Tailed Bat**

44
45 The Brazilian free-tailed bat is known from isolated locations throughout the
46 southwestern United States and is considered to be a year-round resident in the Gold Point SEZ

1 region. The species roosts in buildings, caves, mines, and hollow trees. Foraging occurs in desert
2 grasslands, old fields, savannas, shrublands, woodlands, and urban areas. This species occurs
3 approximately 15 mi (24 km) west of the SEZ. According to the SWReGAP habitat suitability
4 model, potentially suitable foraging habitat may occur on the SEZ, in the transmission corridor,
5 and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation
6 of SWReGAP land cover types, there is no potentially suitable roosting habitat (rocky cliffs and
7 outcrops) on the SEZ or in the transmission corridor, but approximately 350 acres (1.5 km²) of
8 potentially suitable roosting habitat occurs in the area of indirect effects.

11 **Fringed Myotis**

13 The fringed myotis is a year-round resident in the Gold Point SEZ region, where it occurs
14 in a variety of habitats including riparian, shrubland, sagebrush, and pinyon-juniper woodlands.
15 Roosting occurs in buildings and caves. This species occurs in Esmeralda County, Nevada.
16 According to the SWReGAP habitat suitability model, potentially suitable foraging habitat may
17 occur on the SEZ, in the transmission corridor, and in portions of the area of indirect effects
18 (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no
19 potentially suitable roosting habitat (rocky cliffs and outcrops) on the SEZ or transmission
20 corridor, but approximately 350 acres (1.5 km²) of potentially suitable roosting habitat occurs in
21 the area of indirect effects.

24 **Nelson's Bighorn Sheep**

26 The Nelson's bighorn sheep is one of several subspecies of bighorn sheep that occurs in
27 the southwestern United States. This species occurs in desert mountain ranges in Arizona,
28 California, Nevada, Oregon, and Utah. The Nelson's bighorn sheep uses primarily montane
29 shrubland, forest, and grassland habitats, and may utilize desert valleys as corridors for travel
30 between range habitats. According to information provided by the NDOW, the Nelson's bighorn
31 sheep occurs in Esmeralda County, Nevada and potentially suitable habitat may occur in the
32 Silver Peak Range west of the SEZ. According to the SWReGAP habitat suitability model,
33 potentially suitable habitat for this species does not occur on the SEZ; however, potentially
34 suitable habitat may occur in the transmission corridor and in portions of the area of indirect
35 effects. Despite the apparent lack of suitable habitat on the SEZ, this species may utilize portions
36 of the Gold Point SEZ and the transmission corridor as migratory habitat between range habitats
37 (Table 11.6.12.1-1).

40 **Pallid Bat**

42 The pallid bat is a large pale bat with large ears locally common in desert grasslands and
43 shrublands in the southwestern United States. It roosts in caves, crevices, and mines. The species
44 is a year-round resident throughout southern Nevada. The nearest recorded occurrence is
45 approximately 15 mi (24 km) west of the Gold Point SEZ. According to the SWReGAP habitat
46 suitability model, potentially suitable foraging habitat may occur on the SEZ, in the transmission

corridor, and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no potentially suitable roosting habitat (rocky cliffs and outcrops) on the SEZ or in the transmission corridor, but approximately 350 acres (1.5 km²) of potentially suitable roosting habitat occurs in the area of indirect effects.

Silver-Haired Bat

The silver-haired bat is a year-round resident in the Gold Point SEZ region, where it occurs in montane forested habitats such as aspen, pinyon-juniper, and spruce communities. Foraging may occur in desert shrubland habitats. This species roosts in tree foliage, rock outcrops, cavities, or under loose bark. The species is known to occur about 15 mi (24 km) west of the SEZ. According to the SWReGAP habitat suitability model, potentially suitable foraging habitat may occur on the SEZ, in the transmission corridor, and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no potentially suitable roosting habitat (woodlands) on the SEZ or transmission corridor, but approximately 80 acres (0.3 km²) of potentially suitable roosting habitat occurs in the area of indirect effects.

Spotted Bat

The spotted bat is a year-round resident in the Gold Point SEZ region, where it occurs in a variety of forested and shrubland habitats. It roosts in caves and rock crevices. The species is known to occur approximately 15 mi (24 km) west of the SEZ. Potentially suitable foraging habitat may occur on the SEZ, in the transmission corridor, and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land-cover types, there is no suitable roosting habitat within the SEZ or transmission corridor, but approximately 350 acres (1.5 km²) of cliff and rock outcrop habitat that may be potentially suitable roosting habitat occurs in the area of indirect effects.

Townsend's Big-Eared Bat

The Townsend's big-eared bat is widely distributed throughout the western United States. According to the SWReGAP habitat suitability model, the species forages year-round in a wide variety of desert and nondesert habitats in the Gold Point SEZ region. The species roosts in caves, mines, tunnels, buildings, and other man-made structures. Nearest recorded occurrences are approximately 8 mi (13 km) west of the Gold Point SEZ. According to the SWReGAP habitat suitability model, potentially suitable foraging habitat may occur on the SEZ, in the transmission corridor, and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no suitable roosting habitat within the SEZ or transmission corridor, but approximately 350 acres (1.5 km²) of cliff and rock outcrop habitat that may be potentially suitable roosting habitat occurs in the area of indirect effects.

Western Small-Footed Myotis

The western small-footed myotis is widely distributed throughout the western United States. According to the SWReGAP habitat suitability model, this species is a year-round resident in southern Nevada, where it occupies a wide variety of desert and nondesert habitats including cliffs and rock outcrops, grasslands, shrubland, and mixed woodlands. The species roosts in caves, mines, tunnels, beneath boulders or loose bark, buildings, and other man-made structures. Nearest recorded occurrences are approximately 9 mi (14 km) south of the Gold Point SEZ. According to the SWReGAP habitat suitability model, potentially suitable foraging habitat may occur on the SEZ, in the transmission corridor, and in portions of the area of indirect effects (Table 11.6.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no suitable roosting habitat within the SEZ or transmission corridor, but approximately 350 acres (1.5 km²) of cliff and rock outcrop habitat that may be potentially suitable roosting habitat occurs in the area of indirect effects.

11.6.12.1.5 State-Listed Species

There are 8 species listed by the State of Nevada that may occur in the Gold Point SEZ affected area or may be affected by solar energy development on the SEZ (Table 11.6.12.1-1). These state-listed species include the following: (1) plants: Tonopah pincushion cactus; (2) bird: Swainson's hawk; and (3) mammals: Brazilian free-tailed bat, fringed myotis, pale kangaroo mouse, pallid bat, spotted bat, and Townsend's big-eared bat. All of these species are protected in the State of Nevada under NRS 501.110 or NRS 527. Of these state-listed species, only the pale kangaroo mouse has not been previously discussed and is described in the remainder of this section. Additional life history information for these species is provided in Appendix J.

The pale kangaroo mouse is a rodent endemic to southwestern Nevada and southeastern California. This species inhabits fine sands in alkali sink and desert scrub habitats dominated by shadscale (*Atriplex confertifolia*) or big sagebrush (*Artemisia tridentata*). The species often burrows in areas of soft windblown sand piled at the bases of shrubs. Although the pale kangaroo mouse is not known to occur in the affected area of the Gold Point SEZ, the species is known to occur in Esmeralda County, Nevada, and potentially suitable habitat may occur on the SEZ, transmission corridor, and throughout portions of the area of indirect effects (Table 11.6.12.1-1).

11.6.12.1.6 Rare Species

There are 19 rare species (i.e., state rank of S1 or S2 in the State of Nevada or a species of concern by the State of Nevada or the USFWS) that may be affected by solar energy development on the Gold Point SEZ (Table 11.6.12.1-1). Of these species, five—all plants—have not been previously discussed: Bullfrog Hills sweetpea, Clokey paintbrush, Panamint Mountains bedstraw, squalid milkvetch, and weasel phacelia. The habitats and known occurrences of these species relative to the SEZ are shown in Table 11.6.12.1-1. Additional life history information for these species is provided in Appendix J.

11.6.12.2 Impacts

The potential for impacts on special status species from utility-scale solar energy development within the proposed Gold Point SEZ is presented in this section. The types of impacts that special status species could incur from construction and operation of utility-scale solar energy facilities are discussed in Section 5.10.4.

The assessment of impacts on special status species is based on available information on the presence of species in the affected area as presented in Section 11.6.12.1, following the analysis approach described in Appendix M. It is assumed that, prior to development, surveys would be conducted to determine the presence of special status species and their habitats in and near areas where ground-disturbing activities would occur. Additional NEPA assessments, ESA consultations, and coordination with state natural resource agencies may be needed to address project-specific impacts more thoroughly. These assessments and consultations could result in additional required actions to avoid, minimize, or mitigate impacts on special status species (see Section 11.6.12.3).

Solar energy development within the Gold Point SEZ could affect a variety of habitats (see Sections 11.6.9 and 11.6.10). Impacts on these habitats could in turn affect special status species that are dependent on those habitats. As discussed in Section 11.6.12.1, this approach to identifying the species that could occur in the affected area probably overestimates the number of species that actually occur in the affected area, and may therefore overestimate impacts on some special status species. Based on NNHP records, there are no special status species known to occur within the affected area of the Gold Point SEZ. There are no groundwater-dependent species within the affected area of the Gold Point SEZ based upon NNHP records, information provided by the USFWS (Stout 2009), and the evaluation of groundwater resources within the SEZ region (Section 11.6.9).

Impacts on special status species could occur during all phases of development (construction, operation, and decommissioning and reclamation) of a utility-scale solar energy project within the SEZ. Construction and operation activities could result in short- or long-term impacts on individuals and their habitats, especially if these activities are sited in areas where special status species are known to or could occur. As presented in Section 11.6.1.2, a 22-mi (35-km) long transmission corridor is assumed to be needed to serve solar facilities within this SEZ. No new access road development is assumed to be needed because of the proximity of State Route 774 adjacent to the eastern boundary of the SEZ.

Direct impacts would result from habitat destruction or modification. It is assumed that direct impacts would occur only within the SEZ and the transmission line ROW where ground-disturbing activities are expected to occur. Indirect impacts could result from surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, accidental spills, harassment, and lighting. No ground-disturbing activities associated with project development are anticipated to occur within the area of indirect effects. Decommissioning of facilities and reclamation of disturbed areas after operations cease could result in short-term negative impacts on individuals and habitats adjacent to project areas, but long-term benefits

1 would accrue if original land contours and native plant communities were restored in previously
2 disturbed areas.

3
4 The successful implementation of programmatic design features (discussed in Appendix A,
5 Section A.2.2) would reduce direct impacts on some special status species, especially those that
6 depend on habitat types that can be relatively easy to avoid (e.g., washes and playas). Indirect
7 impacts on special status species could be reduced to negligible levels by implementing
8 programmatic design features, especially those engineering controls that would reduce runoff,
9 sedimentation, spills, and fugitive dust.

10 11 12 ***11.6.12.2.1 Impacts on Species Listed under the ESA***

13
14 On the basis of information provided by the NNHP and the USFWS (Stout 2009) and
15 on availability of potentially suitable habitats, there are no species listed under the ESA that
16 may be affected by solar energy development on the Gold Point SEZ. According to SWReGAP
17 and USGS habitat suitability models, potentially suitable habitat for the desert tortoise, a
18 species listed as threatened under the ESA, does not occur within the affected area of the Gold
19 Point SEZ.

20 21 22 ***11.6.12.2.2 Impacts on Species That Are Candidates for Listing under the ESA***

23
24 The greater sage-grouse is the only ESA candidate species that could occur in the
25 affected area of the Gold Point SEZ, based upon information provided by the NNHP
26 (NDCNR 2004) and the SWReGAP (USGS 2007). This species is known to occur in
27 Esmeralda County, Nevada, and potentially suitable year-round sagebrush habitat is
28 expected to occur in portions of the affected area (Figure 11.6.12.1-1). According to the
29 SWReGAP habitat suitability model, suitable habitat for this species is not expected to occur
30 on the SEZ. However, approximately 50 acres (0.2 km²) of potentially suitable habitat in the
31 assumed transmission corridor may be directly affected by construction and operations
32 (Table 11.6.12.1-1). This direct effects area represents less than 0.1% of available suitable
33 habitat for the greater sage-grouse in the SEZ region. About 900 acres (4 km²) of suitable habitat
34 occurs in the area of potential indirect effects; this area represents about 0.3% of the available
35 suitable habitat in the SEZ region (Table 11.6.12.1-1).

36
37 The overall impact on the greater sage-grouse from construction, operation, and
38 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
39 small, because the amount of potentially suitable habitat for this species in the area of direct
40 effects represents less than 1% of potentially suitable habitat in the SEZ region. The
41 implementation of programmatic design features alone may not be sufficient to reduce impacts to
42 negligible levels, because it may not be possible to avoid all potentially suitable sagebrush
43 habitats in the area of direct effects.

44
45 Efforts to mitigate the impacts of solar energy development on the greater sage-grouse
46 should be developed in coordination with the USFWS and the NDOW following the *Strategic*

1 *Plan for Management of Sage Grouse* (UDWR 2002) and *Guidelines to Manage Sage Grouse*
2 *Populations and Their Habitats* (Connelly et al. 2000). Impacts could be reduced by conducting
3 pre-disturbance surveys and avoiding or minimizing disturbance to occupied habitats (especially
4 active leks and suitable nesting areas) in the areas of direct effects. If avoidance or minimization
5 is not feasible, a compensatory mitigation plan could be developed and implemented to mitigate
6 direct effects on occupied habitats. Compensation could involve the protection and enhancement
7 of existing occupied or suitable habitats to compensate for habitats lost to development. Any
8 mitigation plans should be developed in consultation with the USFWS and the NDOW.

11 ***11.6.12.2.3 Impacts on Species That Are under Review for Listing under the ESA***

13 On the basis of information provided by the NNHP and the USFWS (Stout 2009) and on
14 availability of potentially suitable habitats, there are no species under review for ESA listing that
15 may be affected by solar energy facilities on the Gold Point SEZ.

18 ***11.6.12.2.4 Impacts on BLM-Designated Sensitive Species***

20 BLM-designated sensitive species that may be affected by solar energy development
21 on the Gold Point SEZ and are not previously discussed as ESA-listed (Section 11.6.12.2.1),
22 candidates for ESA listing (Section 11.6.12.2.2), or under review for ESA listing
23 (Section 11.6.12.2.3) are discussed below.

26 ***Eastwood Milkweed***

28 According to the SWReGAP land cover model, potentially suitable habitats do not occur
29 in the SEZ or transmission corridor; however, these suitable habitats may occur within the area
30 of indirect effects (Table 11.6.12.1-1). Although SWReGAP did not map any wash habitat on the
31 SEZ, there appear to be numerous washes that could provide habitat for this species on the SEZ,
32 in the transmission corridor, and in the area of indirect effects, including Jackson Wash and its
33 tributaries. The area of these washes has not been quantified, but they could be affected by
34 construction and operations of solar energy development on the SEZ (Table 11.6.12.1-1). About
35 420 acres (1.5 km²) of potentially suitable mapped habitat occurs in the area of indirect effects;
36 this area represents about 1.1% of the potentially suitable habitat in the SEZ region
37 (Table 11.6.12.1-1).

39 Impacts of solar energy development in the Gold Point SEZ on the Eastwood milkweed
40 cannot be determined without quantification of the amount of potentially suitable wash habitat in
41 the area of direct effects, but is expected to be small given the unquantified, but apparently large
42 amount of wash habitat in the SEZ region. The implementation of programmatic design features
43 is expected to be sufficient to reduce indirect impacts to negligible levels.

45 Avoiding or minimizing disturbance to wash habitat in the area of direct effects could
46 reduce direct impacts on the Eastwood milkweed. In addition, pre-disturbance surveys and

1 avoiding or minimizing disturbance to occupied habitats in the area of direct effects could reduce
2 impacts. If avoidance or minimization is not feasible, plants could be translocated from the area
3 of direct effects to protected areas that would not be affected directly or indirectly by future
4 development. Alternatively, or in combination with translocation, a compensatory mitigation
5 plan could be developed and implemented to mitigate direct effects on occupied habitats.
6 Compensation could involve the protection and enhancement of existing occupied or suitable
7 habitats to compensate for habitats lost to development. A comprehensive mitigation strategy
8 that used one or more of these options could be designed to completely offset the impacts of
9 development.

12 **Holmgren Lupine**

14 The Holmgren lupine is not known to occur in the affected area of the Gold Point SEZ.
15 According to the SWReGAP land cover model, potentially suitable sagebrush and pinyon-
16 juniper woodland habitats do not occur on the SEZ. However, approximately 10 acres
17 ($<0.1 \text{ km}^2$) of potentially suitable habitat in the transmission corridor could be directly affected
18 by construction and operations (Table 11.6.12.1-1). This direct effects area represents less than
19 0.1% of potentially suitable habitat in the SEZ region. About 27,300 acres (110 km^2) of
20 potentially suitable habitat occurs in the area of indirect effects; this area represents about 1.8%
21 of the potentially suitable habitat in the SEZ region (Table 11.6.12.1-1).

23 The overall impact on the Holmgren lupine from construction, operation, and
24 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
25 small, because the amount of potentially suitable habitat for this species in the area of direct
26 effects represents less than 1% of potentially suitable habitat in the SEZ region. The
27 implementation of programmatic design features is expected to be sufficient to reduce indirect
28 impacts to negligible levels.

30 Avoiding or minimizing disturbance to sagebrush habitat in the transmission line corridor
31 could reduce direct impacts on the Holmgren lupine. In addition, impacts could be reduced with
32 the implementation of the mitigation options described previously for the Eastwood milkweed.
33 The need for mitigation, other than programmatic design features, should be determined by
34 conducting pre-disturbance surveys for the species and its habitat on the SEZ.

37 **Tonopah Pincushion Cactus**

39 The Tonopah pincushion cactus is not known to occur in the affected area of the Gold
40 Point SEZ; however, approximately 3,850 acres (16 km^2) of potentially suitable habitat on the
41 SEZ and 30 acres (0.1 km^2) of potentially suitable habitat in the transmission corridor could be
42 directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area
43 represents 0.2% of potentially suitable habitat in the SEZ region. About 88,600 acres (559 km^2)
44 of potentially suitable habitat occurs in the area of indirect effects; this area represents about
45 3.7% of the potentially suitable habitat in the SEZ region (Table 11.6.12.1-1).

1 The overall impact on the Tonopah pincushion cactus from construction, operation, and
2 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
3 small, because the amount of potentially suitable habitat for this species in the area of direct
4 effects represents less than 1% of potentially suitable habitat in the SEZ region. The
5 implementation of programmatic design features is expected to be sufficient to reduce indirect
6 impacts to negligible levels.

7
8 Avoidance of all potentially suitable habitats to mitigate impacts on the Tonopah
9 pincushion cactus is not feasible, because potentially suitable shrubland is widespread
10 throughout the area of direct effects. However, impacts could be reduced with the
11 implementation of programmatic design features and the mitigation options described
12 previously for the Eastwood milkweed. The need for mitigation, other than programmatic
13 design features, should be determined by conducting pre-disturbance surveys for the species
14 and its habitat on the SEZ.

15 16 17 **Ferruginous Hawk**

18
19 The ferruginous hawk is a winter resident in the Gold Point SEZ region and is known to
20 occur in Esmeralda County, Nevada. According to the SWReGAP habitat suitability model,
21 approximately 200 acres (0.8 km²) of potentially suitable habitat on the SEZ and 225 acres
22 (0.9 km²) of potentially suitable habitat in the transmission corridor could be directly affected by
23 construction and operations (Table 11.6.12.1-1). This direct effects area represents less than
24 0.1% of potentially suitable habitat in the SEZ region. About 28,100 acres (114 km²) of
25 potentially suitable habitat occurs in the area of indirect effects; this area represents about 3.6%
26 of the potentially suitable habitat in the SEZ region (Table 11.6.12.1-1).

27
28 The overall impact on the ferruginous hawk from construction, operation, and
29 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
30 small, because the amount of potentially suitable foraging habitat for this species in the area of
31 direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.
32 The implementation of programmatic design features is expected to be sufficient to reduce
33 indirect impacts on this species to negligible levels. Avoidance of direct impacts on foraging
34 habitat (shrublands) is not feasible, because suitable foraging habitat (shrublands) is widespread
35 in the area of direct effects and readily available in other portions of the affected area.

36 37 38 **Prairie Falcon**

39
40 The prairie falcon is a year-round resident in the Gold Point SEZ region, and potentially
41 suitable foraging and nesting habitat is expected to occur in the affected area. Approximately
42 4,500 acres (18 km²) of potentially suitable habitat on the SEZ and 500 acres (2 km²) of
43 potentially suitable habitat within the transmission corridor could be directly affected by
44 construction and operations (Table 11.6.12.1-1). This direct effects area represents 0.2% of
45 potentially suitable habitat in the SEZ region. About 81,350 acres (329 km²) of potentially
46 suitable habitat occurs in the area of indirect effects; this area represents about 3.4% of the

1 potentially suitable habitat in the SEZ region (Table 11.6.12.1-1). Most of this area could serve
2 as foraging habitat (open shrublands). On the basis of SWReGAP land cover data, potentially
3 suitable nesting habitat (cliffs and rock outcrops) does not occur on the SEZ. However,
4 approximately 350 acres (1.5 km²) of cliff and rock outcrop habitat that may be potentially
5 suitable nesting habitat occurs in the area of indirect effects.

6
7 The overall impact on the prairie falcon from construction, operation, and
8 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
9 small, because the amount of potentially suitable foraging habitat for this species in the area of
10 direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.
11 The implementation of programmatic design features is expected to be sufficient to reduce
12 indirect impacts on this species to negligible levels. Avoidance of direct impacts on foraging
13 habitat (shrublands) is not feasible, because suitable foraging habitat (shrublands) is widespread
14 in the area of direct effects and readily available in other portions of the affected area.

15 16 17 **Swainson's Hawk**

18
19 The Swainson's hawk is a summer breeding resident within the Gold Point SEZ region
20 and is known to occur in Esmeralda County, Nevada. According to the SWReGAP habitat
21 suitability model, suitable habitat for this species does not occur on the SEZ. However,
22 approximately 50 acres (0.2 km²) of potentially suitable habitat within the transmission corridor
23 could be directly affected by construction and operations (Table 11.6.12.1-1). This direct effects
24 area represents less than 0.1% of potentially suitable habitat in the SEZ region. About
25 15,200 acres (62 km²) of potentially suitable habitat occurs in the area of indirect effects;
26 this area represents about 1.1% of the potentially suitable habitat in the SEZ region
27 (Table 11.6.12.1-1). On the basis of SWReGAP land cover data, potentially suitable nesting
28 habitat (solitary trees) does not occur on the SEZ or within the transmission corridor. However,
29 approximately 80 acres (0.3 km²) of woodland habitat (pinyon-juniper) that may be potentially
30 suitable nesting habitat occurs in the area of indirect effects.

31
32 The overall impact on the Swainson's hawk from construction, operation, and
33 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
34 small, because the amount of potentially suitable habitat for this species in the area of direct
35 effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The
36 implementation of programmatic design features is expected to be sufficient to reduce indirect
37 impacts on this species to negligible levels. Avoidance of direct impacts on foraging habitat
38 (shrublands) is not feasible, because suitable foraging habitat (shrublands) is widespread in the
39 area of direct effects and readily available in other portions of the affected area.

40 41 42 **Western Burrowing Owl**

43
44 The western burrowing owl is a summer breeding resident within the Gold Point SEZ
45 region and is known to occur in Esmeralda County, Nevada. According to the SWReGAP habitat
46 suitability model, approximately 4,625 acres (19 km²) of potentially suitable habitat on the SEZ

1 and 650 acres (3 km²) of potentially suitable habitat in the transmission corridor could be
2 directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area
3 represents about 0.2% of potentially suitable habitat in the SEZ region. About 97,000 acres
4 (393 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents
5 about 3.1% of the potentially suitable habitat in the SEZ region (Table 11.6.12.1-1). Most of this
6 area could serve as foraging and nesting habitat (shrublands). The abundance of burrows suitable
7 for nesting on the SEZ and in the area of indirect effects has not been determined.
8

9 The overall impact on the western burrowing owl from construction, operation, and
10 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
11 small, because the amount of potentially suitable foraging and nesting habitat for this species in
12 the area of direct effects represents less than 1% of potentially suitable foraging and nesting
13 habitat in the region. The implementation of programmatic design features is expected to be
14 sufficient to reduce indirect impacts to negligible levels.
15

16 Avoidance of all potentially suitable habitats is not a feasible way to mitigate impacts on
17 the western burrowing owl, because potentially suitable shrubland habitats are widespread
18 throughout the area of direct effects and readily available in other portions of the SEZ region.
19 Impacts on the western burrowing owl could be reduced by implementing programmatic design
20 features, conducting pre-disturbance surveys, and avoiding or minimizing disturbance to
21 occupied burrows and habitat on the SEZ. If avoidance or minimization is not feasible, a
22 compensatory mitigation plan could be developed and implemented to mitigate direct effects.
23 Compensation could involve the protection and enhancement of existing occupied or suitable
24 habitats to compensate for habitats lost to development. A comprehensive mitigation strategy
25 that uses one or both of these options could be designed to completely offset the impacts of
26 development. The need for mitigation, other than programmatic design features, should be
27 determined by conducting pre-disturbance surveys for the species and its habitat within the area
28 of direct effects.
29
30

31 **Brazilian Free-Tailed Bat**

32

33 The Brazilian free-tailed bat is a year-round resident within the Gold Point SEZ region
34 and is known to occur approximately 15 mi (24 km) west of the SEZ. According to the
35 SWReGAP habitat suitability model, approximately 4,800 acres (19 km²) of potentially suitable
36 habitat on the SEZ and 590 acres (2 km²) of potentially suitable habitat in the transmission
37 corridor could be directly affected by construction and operations (Table 11.6.12.1-1). This
38 direct effects area represents 0.2% of potentially suitable habitat in the SEZ region. About
39 83,500 acres (338 km²) of potentially suitable habitat occurs in the area of indirect effects; this
40 area represents about 3.1% of the available suitable habitat in the region (Table 11.6.12.1-1).
41 Most of the potentially suitable habitat in the affected area is foraging habitat represented by
42 desert shrubland. On the basis of an evaluation of SWReGAP land cover data, potentially
43 suitable roost habitat (rocky cliffs and outcrops) does not occur on the SEZ or transmission
44 corridor, but about 350 acres (1.5 km²) of potentially suitable roost habitat may occur in the area
45 of indirect effects.
46

1 The overall impact on the Brazilian free-tailed bat from construction, operation, and
2 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
3 small, because the amount of potentially suitable foraging habitat for this species in the area of
4 direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.
5 The implementation of programmatic design features is expected to be sufficient to reduce
6 indirect impacts on this species to negligible levels. Avoidance of all potentially suitable
7 foraging habitats is not feasible, because potentially suitable habitat is widespread throughout the
8 area of direct effects and readily available in other portions of the SEZ region.
9

10 **Fringed Myotis**

11
12
13 The fringed myotis is a year-round resident within the Gold Point SEZ region and is
14 known to occur in Esmeralda County, Nevada. According to the SWReGAP habitat suitability
15 model, approximately 4,700 acres (19 km²) of potentially suitable habitat on the SEZ and
16 620 acres (2.5 km²) of potentially suitable habitat in the transmission corridor could be directly
17 affected by construction and operations (Table 11.6.12.1-1). This direct effects area represents
18 0.2% of potentially suitable habitat in the SEZ region. About 88,200 acres (357 km²) of
19 potentially suitable habitat occurs in the area of indirect effects; this area represents about 2.9%
20 of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially suitable
21 habitat in the affected area is foraging habitat represented by desert shrubland. On the basis of an
22 evaluation of SWReGAP land cover data, potentially suitable roost habitat (buildings and caves)
23 does not occur on the SEZ or in the transmission corridor, but about 350 acres (1.5 km²) of
24 potentially suitable roost habitat may occur in the area of indirect effects.
25

26 The overall impact on the fringed myotis from construction, operation, and
27 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
28 small, because the amount of potentially suitable foraging habitat for this species in the area of
29 direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.
30 The implementation of programmatic design features is expected to be sufficient to reduce
31 indirect impacts on this species to negligible levels. Avoidance of all potentially suitable
32 foraging habitats is not feasible, because potentially suitable habitat is widespread throughout the
33 area of direct effects and readily available in other portions of the SEZ region.
34
35

36 **Nelson's Bighorn Sheep**

37
38 The Nelson's bighorn sheep occurs within the affected area of the Gold Point SEZ, but
39 suitable range habitat is not expected to occur on the SEZ. According to the SWReGAP habitat
40 suitability model; however, approximately 150 acres (0.6 km²) of potentially suitable habitat
41 within the transmission corridor could be directly affected by construction and operations (Table
42 11.6.12.1-1). This direct effects area represents less than 0.1% of potentially suitable habitat in
43 the SEZ region. About 24,100 acres (98 km²) of potentially suitable habitat occurs in the area of
44 indirect effects; this area represents about 2.6% of the available suitable habitat in the region
45 (Table 11.6.12.1-1). Despite the apparent lack of suitable habitat on the SEZ, the Nelson's
46 bighorn sheep may utilize portions of the SEZ as a migratory corridor between range habitats.
47

1 The overall impact on the Nelson's bighorn sheep from construction, operation, and
2 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered
3 small, because the amount of potentially suitable habitat for this species in the area of direct
4 effects represents less than 1% of the potentially suitable habitat in the region. The
5 implementation of programmatic design features is expected to be sufficient to reduce indirect
6 impacts on this species to negligible levels.

8 Direct impacts on the Nelson's bighorn sheep could be reduced to small or negligible
9 levels by conducting pre-disturbance surveys and avoiding or minimizing disturbance to
10 occupied habitats and important movement corridors within the area of direct effects. If
11 avoidance or minimization is not feasible, a compensatory mitigation plan could be developed
12 and implemented to mitigate direct effects on occupied habitats. Compensation could involve the
13 protection and enhancement of existing occupied or suitable habitats to compensate for habitats
14 lost to development. A comprehensive mitigation strategy that uses one or both of these options
15 could be designed to completely offset the impacts of development. The need for mitigation
16 should first be determined by conducting pre-disturbance surveys for the species and its habitat
17 within the area of direct effects.

20 **Pallid Bat**

22 The pallid bat is a year-round resident within the Gold Point SEZ region and is known to
23 occur approximately 15 mi (24 km) west of the SEZ. According to the SWReGAP habitat
24 suitability model, approximately 4,550 acres (18 km²) of potentially suitable habitat on the SEZ
25 and 575 acres (2.5 km²) of potentially suitable habitat in the transmission corridor could be
26 directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area
27 represents 0.2% of potentially suitable habitat in the SEZ region. About 83,175 acres (337 km²)
28 of potentially suitable habitat occurs in the area of indirect effects; this area represents about
29 3.2% of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially
30 suitable habitat in the affected area is foraging habitat represented by desert shrubland. On the
31 basis of an evaluation of SWReGAP land cover data, potentially suitable roost habitat (caves and
32 crevices) does not occur on the SEZ or in the transmission corridor, but about 350 acres
33 (1.5 km²) of potentially suitable roost habitat may occur in the area of indirect effects.

35 The overall impact on pallid bat from construction, operation, and decommissioning of
36 utility-scale solar energy facilities within the Gold Point SEZ is considered small, because the
37 amount of potentially suitable foraging habitat for this species in the area of direct effects
38 represents less than 1% of potentially suitable foraging habitat in the SEZ region. The
39 implementation of programmatic design features is expected to be sufficient to reduce indirect
40 impacts on this species to negligible levels. Avoidance of all potentially suitable foraging
41 habitats is not feasible, because potentially suitable habitat is widespread throughout the area of
42 direct effects and readily available in other portions of the SEZ region.

45 **Silver-Haired Bat**

47 The silver-haired bat is a year-round resident within the Gold Point SEZ region and is
48 known to occur approximately 15 mi (25 km) west of the SEZ. According to the SWReGAP

habitat suitability model, approximately 4,600 acres (19 km²) of potentially suitable habitat on the SEZ and 580 acres (2.5 km²) of potentially suitable habitat in the transmission corridor could be directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area represents 0.2% of potentially suitable habitat in the SEZ region. About 83,200 acres (337 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 3.2% of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially suitable habitat in the affected area is foraging habitat represented by desert shrubland. On the basis of an evaluation of SWReGAP land cover data, potentially suitable roost habitat (woodlands) does not occur on the SEZ or in the transmission corridor, but about 80 acres (0.3 km²) of potentially suitable roost habitat may occur in the area of indirect effects.

The overall impact on the silver-haired bat from construction, operation, and decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered small, because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts on this species to negligible levels. Avoidance of all potentially suitable foraging habitats is not feasible, because potentially suitable habitat is widespread throughout the area of direct effects and readily available in other portions of the SEZ region.

Spotted Bat

The spotted bat is a year-round resident within the Gold Point SEZ region and is known to occur approximately 15 mi (24 km) west of the SEZ. According to the SWReGAP habitat suitability model, approximately 4,700 acres (19 km²) of potentially suitable habitat on the SEZ and 550 acres (2 km²) of potentially suitable habitat in the transmission corridor could be directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area represents 0.2% of potentially suitable habitat in the SEZ region. About 76,750 acres (311 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 3.2% of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially suitable habitat in the affected area is foraging habitat represented by desert shrubland. On the basis of an evaluation of SWReGAP land cover data, potentially suitable roost habitat (caves and crevices) does not occur on the SEZ or transmission corridor, but about 350 acres (1.5 km²) of potentially suitable roost habitat may occur in the area of indirect effects.

The overall impact on the spotted bat from construction, operation, and decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered small, because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts on this species to negligible levels. Avoidance of all potentially suitable foraging habitats is not feasible, because potentially suitable habitat is widespread throughout the area of direct effects and readily available in other portions of the SEZ region.

Townsend's Big-Eared Bat

The Townsend's big-eared bat is a year-round resident within the Gold Point SEZ region and is known to occur approximately 8 mi (13 km) west of the SEZ. According to the SWReGAP habitat suitability model, approximately 4,600 acres (19 km²) of potentially suitable habitat on the SEZ and 450 acres (2 km²) of potentially suitable habitat in the transmission corridor could be directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area represents 0.2% of potentially suitable habitat in the SEZ region. About 68,550 acres (277 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 2.9% of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially suitable habitat in the affected area is foraging habitat represented by desert shrubland. On the basis of an evaluation of SWReGAP land cover data, potentially suitable roost habitat (caves and rocky cliffs and outcrops) does not occur on the SEZ or in the transmission corridor, but about 350 acres (1.5 km²) of potentially suitable roost habitat may occur in the area of indirect effects.

The overall impact on the Townsend's big-eared bat from construction, operation, and decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered small, because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts on this species to negligible levels. Avoidance of all potentially suitable foraging habitats is not feasible, because potentially suitable habitat is widespread throughout the area of direct effects and readily available in other portions of the SEZ region.

Western Small-Footed Myotis

The western small-footed myotis is a year-round resident within the Gold Point SEZ region and is known to occur approximately 9 mi (14 km) south of the SEZ. According to the SWReGAP habitat suitability model, approximately 4,800 acres (19 km²) of potentially suitable habitat on the SEZ and 650 acres (2.5 km²) of potentially suitable habitat in the transmission corridor could be directly affected by construction and operations (Table 11.6.12.1-1). This direct impact area represents 0.2% of potentially suitable habitat in the SEZ region. About 97,950 acres (396 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 2.9% of the available suitable habitat in the region (Table 11.6.12.1-1). Most of the potentially suitable habitat in the affected area is foraging habitat represented by desert shrubland. On the basis of an evaluation of SWReGAP land cover data, potentially suitable roost habitat (rocky cliffs and outcrops) does not occur on the SEZ or in the transmission corridor, but about 350 acres (1.5 km²) of potentially suitable roost habitat may occur in the area of indirect effects.

The overall impact on the western small-footed myotis from construction, operation, and decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is considered small, because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.

1 The implementation of programmatic design features is expected to be sufficient to reduce
2 indirect impacts on this species to negligible levels. Avoidance of all potentially suitable
3 foraging habitats is not feasible, because potentially suitable habitat is widespread throughout
4 the area of direct effects and readily available in other portions of the SEZ region.

7 ***11.6.12.2.5 Impacts on State-Listed Species***

9 There are eight species listed by the State of Nevada that may occur in the Gold Point
10 SEZ affected area or that may be affected by solar energy development on the SEZ
11 (Table 11.6.12.1-1). Of these species, only the pale kangaroo mouse has not been previously
12 discussed. Impacts on this species are discussed below.

14 The pale kangaroo mouse is known to occur in Esmeralda County, Nevada, although it is
15 not known to occur in the affected area of the Gold Point SEZ. According to the SWReGAP
16 habitat suitability model, approximately 4,700 acres (19 km²) of potentially suitable habitat on
17 the SEZ and 200 acres (0.8 km²) of potentially suitable habitat in the transmission corridor could
18 be directly affected by construction and operations (Table 11.6.12.1-1). This direct effects area
19 represents 0.4% of potentially suitable habitat in the SEZ region. About 50,500 acres (204 km²)
20 of potentially suitable habitat occurs in the area of indirect effects; this area represents about
21 4.0% of the available suitable habitat in the region (Table 11.6.12.1-1).

23 The overall impact on the pale kangaroo mouse from construction, operation, and
24 decommissioning of utility-scale solar energy facilities within the Gold Point SEZ is
25 considered small, because the amount of potentially suitable habitat for this species in the area
26 of direct effects represents less than 1% of potentially suitable habitat in the SEZ region. The
27 implementation of programmatic design features is expected to be sufficient to reduce indirect
28 impacts on this species to negligible levels.

30 Direct impacts on the pale kangaroo mouse could be further reduced by conducting
31 pre-disturbance surveys and avoiding occupied habitats within the area of direct effects. If
32 avoidance or minimization is not feasible, a compensatory mitigation plan could be developed
33 and implemented to mitigate direct effects on occupied habitats. Compensation could involve the
34 protection and enhancement of existing occupied or suitable habitats to compensate for habitats
35 lost to development. A comprehensive mitigation strategy that uses one or both of these options
36 could be designed to completely offset the impacts of development. The need for mitigation
37 should first be determined by conducting pre-disturbance surveys for the species and its habitat
38 within the area of direct effects.

41 ***11.6.12.2.6 Impacts on Rare Species***

43 There are 19 rare species (state rank of S1 or S2 in Nevada or a species of concern by the
44 State of Nevada or the USFWS) that may be affected by solar energy development on the Gold
45 Point SEZ. Five species—all plants—have not been previously discussed: Bullfrog Hills
46 sweetpea, Clokey paintbrush, Panamint Mountains bedstraw, squalid milkvetch, and weasel

phacelia. Impacts and potentially applicable mitigation measures (if necessary) for each of these species is provided in Table 11.6.12.1-1. Additional life history information is provided in Appendix J.

11.6.12.3 SEZ-Specific Design Features and Design Feature Effectiveness

The implementation of required programmatic design features described in Appendix A, Section A.2.2, would greatly reduce or eliminate the potential for effects of utility-scale solar energy development on special status species. While some SEZ-specific design features are best established when specific project details are being considered, some design features can be identified at this time, including the following:

- Pre-disturbance surveys should be conducted within the SEZ to determine the presence and abundance of special status species, including those identified in Table 11.6.12.1-1; disturbance to occupied habitats for these species should be avoided or minimized to the extent practicable. If avoiding or minimizing impacts on occupied habitats is not possible, translocation of individuals from areas of direct effects or compensatory mitigation of direct effects on occupied habitats could reduce impacts. A comprehensive mitigation strategy for special status species that used one or more of these options to offset the impacts of development should be developed in coordination with the appropriate federal and state agencies.
- Avoiding or minimizing disturbance to desert wash and playa habitats within the area of direct effects could reduce or eliminate impacts on the Eastwood milkweed.
- Avoiding or minimizing disturbance to sagebrush habitat within the area of direct effects could reduce or eliminate impacts on the Holmgren lupine.
- Coordination with the USFWS and the NDOW should be conducted for the greater sage-grouse—a candidate species for listing under the ESA. Coordination would identify an appropriate survey protocol and mitigation requirements, which may include avoidance, minimization, translocation, or compensation.
- Harassment or disturbance of special status species and their habitats in the affected area should be avoided or minimized. This can be accomplished by identifying any additional sensitive areas and implementing necessary protection measures based upon consultation with the USFWS and the NDOW.

If these SEZ-specific design features are implemented in addition to required programmatic design features, impacts on the special status and rare species could be reduced.

11.6.13 Air Quality and Climate

11.6.13.1 Affected Environment

11.6.13.1.1 Climate

The proposed Gold Point SEZ is located in the southern portion of Esmeralda County in southwestern Nevada. Nevada lies on the eastern lee side of the Sierra Nevada Range, which markedly influences the climate of the state under the prevailing westerlies (NCDC 2010a). In addition, the mountains east and north of Nevada act as barriers to the cold arctic air masses, thus making long periods of extremely cold weather uncommon. The SEZ lies at an average elevation of about 4,960 ft (1,512 m) in the southwestern portion of the Great Basin Desert, which has a high desert climate marked by pleasant weather (mild winters and warm summers) with large daily temperature swings due to dry air, scant precipitation, low relative humidity, and abundant sunshine. Meteorological data collected at the Tonopah Airport, about 45 mi (72 km) north-northeast of the Gold Point SEZ boundary, and at Goldfield, about 20 mi (32 km) north-northeast, are summarized below.

A wind rose from the Tonopah Airport, taken at a level of 33 ft (10 m), for the 5-year period 2005 to 2009 is presented in Figure 11.6.13.1-1 (NCDC 2010b). During this period, the annual average wind speed at the airport was about 9.6 mph (4.3 m/s), with the prevailing wind direction from the north (about 19.7% of the time) and secondarily from the north-northwest (about 16.4% of the time). The northerly wind component predominates, with about 46.7% of wind directions from the northwest clockwise to the north. Winds blew more frequently from the north every month throughout the year except January and April, when wind blew more frequently from the north-northwest. Wind speeds categorized as calm (less than 1.1 mph [0.5 m/s]) occurred frequently (about 10% of the time) because of the stable conditions caused by strong radiative cooling from late night to sunrise. Average wind speeds were relatively uniform by season: they were highest in spring at 11.2 mph (5.0 m/s), lower in summer and fall at 9.2 mph (4.1 m/s), and lowest in winter at 9.0 mph (4.0 m/s).

For the period 1906 to 2009, the annual average temperature at Goldfield was 51.4°F (10.8°C) (WRCC 2010e). January was the coldest month, with an average minimum temperature of 20.3°F (−6.5°C), and July was the warmest, with an average maximum of 89.6°F (32.0°C). In the summer, daytime maximum temperatures higher than 90°F (32.2°C) are common, and minimums are in the 50s. The minimum temperatures recorded were below freezing ($\leq 32^\circ\text{F}$ [0°C]) throughout the year except July and August (with a peak of about 29 days in January and December), and subzero temperatures were recorded about 1.5 days per year during winter months. During the same period, the highest temperature, 108°F (42.2°C), was reached in July 1906 and the lowest, −23°F (−30.6°C), in January 1937. In a typical year, about 36 days had a maximum temperature of at least 90°F (32.2°C), while about 146 days had minimum temperatures at or below freezing.

FIGURE 11.6.13.1-1 Wind Rose at 33 ft (10 m) at Tonopah Airport, Nevada, 2005 to 2009
(Source: NCDC 2010b)

1 Along with prevailing westerlies, Pacific air masses lose most of their moisture on the
2 windward side of the Sierra Nevada Range parallel to Nevada's western boundary with
3 California. Thus, leeward areas such as the region around Gold Point SEZ experience a lack of
4 precipitation (NCDC 2010a). For 1906 to 2009, annual precipitation at Goldfield averaged about
5 6.06 in. (15.4 cm) (WRCC 2010e). On average, 29 days annually have measurable precipitation
6 (0.01 in. [0.025 cm] or higher). Precipitation is relatively evenly distributed by season, although
7 it is slightly higher in winter and spring than in summer and fall. Snow falls as early as October
8 and continues as late as May; most of the snow falls from December to March. The annual
9 average snowfall at Goldfield is about 17.8 in. (45.2 cm).

10
11 The proposed Gold Point SEZ is far from major water bodies (more than 240 mi
12 [386 km] to the Pacific Ocean). Severe weather events, such as severe thunderstorms
13 and tornadoes, are rare in Esmeralda County, which encompasses the Gold Point SEZ
14 (NCDC 2010c).

15
16 In Nevada, flooding could occur from melting of heavy snowpack. On occasion, heavy
17 summer thunderstorms also cause flooding of local streams, usually in sparsely populated
18 mountainous areas, but they are seldom destructive (NCDC 2010a). Since 1997, four flash floods
19 have been reported in Esmeralda County, two of which occurred about 10 mi (16 km) from the
20 SEZ and one of which caused minor property damage.

21
22 In Esmeralda County, no hail storms have been reported (NCDC 2010c). Forty-two high
23 wind events have been reported since 1999. Events with a maximum wind speed of up to
24 127 mph (57 m/s) can occur any month of the year, with peaks in March and June; they have
25 caused no deaths or injuries but some property damage (NCDC 2010c). In addition, one
26 thunderstorm wind event with a maximum wind speed of 52 mph (23 m/s) was reported in 2010,
27 which caused minor property damage.

28
29 No dust storms have been reported in Esmeralda County (NCDC 2010c). However, the
30 ground surface of the SEZ is covered primarily with sandy loams, gravelly sandy loams, and
31 gravelly loams, which have a relatively moderate dust storm potential. High winds can trigger
32 large amounts of blowing dust in areas of Esmeralda County that have dry and loose soils with
33 sparse vegetation. Dust storms can deteriorate air quality and visibility and may have adverse
34 effects on health, particularly for people with asthma or other respiratory problems.

35
36 Hurricanes and tropical storms formed off the coast of Central America and Mexico
37 weaken over the cold waters off the California coast. Accordingly, hurricanes never hit Nevada,
38 but one tropical depression has passed within 100 mi (160 km) of the proposed Gold Point SEZ
39 (CSC 2010). Historically, only one tornado was reported in 1982 in Esmeralda County
40 (NCDC 2010c). However, the tornado occurred far from the SEZ, was relatively weak (i.e., F0
41 on the Fujita tornado scale), and did not cause deaths, injuries, or property damage.

11.6.13.1.2 Existing Air Emissions

Esmeralda County has a few industrial emission sources related to minerals and mining, but their emissions are relatively small. All industrial sources are located far from the proposed Gold Point SEZ. Because of the sparse population, only a handful of major roads, such as U.S. 6, U.S. 95, and several State Routes (264, 265, 266, 773, and 774) are present in Esmeralda County. Thus, onroad mobile source emissions are not substantial. Data on annual emissions of criteria pollutants and volatile organic compounds (VOCs) in Esmeralda County are presented in Table 11.6.13.1-1 for 2002 (WRAP 2009). Emission data are classified into six source categories: point, area, onroad mobile, nonroad mobile, biogenic, and fire (wildfires, prescribed fires, agricultural fires, structural fires). In 2002, point sources were major contributors to total emissions of SO₂ (about 78%). Biogenic sources (i.e., vegetation—including trees, plants, and crops—and soils) that release naturally occurring emissions primarily contributed to NO_x and CO emissions (about 62% and 64%, respectively) and accounted for most of the VOC emissions (about 99%). Area sources were major contributors to total emissions of PM₁₀ (about 96%) and PM_{2.5} (about 91%), and secondary contributors to SO₂ emissions (about 20%). Onroad sources were secondary contributors to NO_x and CO emissions (about 30% and 35%, respectively). In Esmeralda County, nonroad sources were minor contributors to criteria pollutants and VOCs. (Fire emissions were not estimated in Esmeralda County in 2002.)

In 2005, Nevada produced about 56.3 MMt of *gross*⁵ carbon dioxide equivalent (CO₂e)⁶ emissions, which is about 0.8% of total U.S. GHG emissions in that year (NDEP 2008). Gross GHG emissions in Nevada increased by about 65% from 1990 to 2005 because of Nevada's rapid population growth, compared to 16.3% growth in U.S. GHG emissions during the same period. In 2005, electrical generation (48%) and transportation (30%) were the primary contributors to gross GHG emission sources in Nevada. Fuel use in the residential, commercial, and industrial sectors combined accounted for about 12% of total state emissions. Nevada's *net* emissions were about 51.3 MMt CO₂e, considering carbon sinks from forestry activities and agricultural soils throughout the state. The EPA (2009a) also estimated

TABLE 11.6.13.1-1 Annual Emissions of Criteria Pollutants and VOCs in Esmeralda County, Nevada, Encompassing the Proposed Gold Point SEZ, 2002^a

Pollutant ^b	Emissions (tons/yr) ^c
SO ₂	106
NO _x	1,116
CO	13,832
VOCs	59,144
PM ₁₀	937
PM _{2.5}	202

^a Includes point, area, onroad and nonroad mobile, biogenic, and fire emissions.

^b Notation: CO = carbon monoxide; NO_x = nitrogen oxides; PM_{2.5} = particulate matter with a diameter of ≤2.5 μm; PM₁₀ = particulate matter with a diameter of ≤10 μm; SO₂ = sulfur dioxide; and VOCs = volatile organic compounds.

^c To convert tons to kilograms, multiply by 907.

Source: WRAP (2009).

⁵ Excluding GHG emissions removed as a result of forestry and other land uses and excluding GHG emissions associated with exported electricity.

⁶ A measure used to compare the emissions from various GHGs on the basis of their global warming potential, defined as the cumulative radiative forcing effects of a gas over a specified time horizon resulting from the emission of a unit mass of gas relative to a reference gas, CO₂. The CO₂e for a gas is derived by multiplying the mass of the gas by the associated global warming potential.

2005 emissions in Nevada. Its estimate of CO₂ emissions from fossil fuel combustion was 49.6 MMt, which was comparable to the state's estimate. Electric power generation and transportation accounted for about 52.7% and 33.6% of the CO₂ emissions total, respectively, while the residential, commercial, and industrial sectors accounted for the remainder (about 13.7%).

11.6.13.1.3 Air Quality

The EPA set NAAQS for six criteria pollutants (EPA 2010a): SO₂, NO₂, CO, O₃, PM (PM₁₀ and PM_{2.5}), and Pb. Nevada has its own SAAQS, which are generally similar to the NAAQS but with some differences (NAC 445B.22097). In addition, Nevada has set standards for 1-hour H₂S, which are not addressed by the NAAQS. The NAAQS and Nevada SAAQS for criteria pollutants are presented in Table 11.6.13.1-2.

Esmeralda County is located administratively in the Nevada Intrastate AQCR, along with 10 other counties in Nevada. Not included are Las Vegas Intrastate AQCR, including Clark County only, which encompasses Las Vegas; and Northwest Nevada Intrastate AQCR, including five northwest counties, which encompasses Reno. Currently, the area surrounding the proposed SEZ is designated as being in unclassifiable/attainment of NAAQS for all criteria pollutants (Title 40, Part 81, Section 329 of the *Code of Federal Regulations* [40 CFR 81.329]).

Because of Esmeralda County's low population density, it has no significant emission sources of its own and only minor mobile emissions along major highways. Accordingly, ambient air quality in Esmeralda County is relatively good. No ambient air-monitoring stations are located in Esmeralda County. To characterize ambient air quality around the SEZ, one monitoring station in Clark County was chosen as being representative of a rural environment: Jean, about 156 mi (251 km) southeast of the SEZ. The Jean station is located upwind of the Las Vegas area but to some extent its air quality is influenced by transport of air pollutants from the South Coast Air Basin, which includes Los Angeles, along with prevailing westerlies and nearby highway traffic on I-15 (about 1.6 mi [2.6 km] away). Ambient concentrations of NO₂, O₃, PM₁₀, and PM_{2.5} are recorded at Jean. The East Sahara Avenue station, which is on the outskirts of Las Vegas, has only one SO₂ monitor in the area. The CO concentrations at the East Tonopah Avenue station in Las Vegas, which is the farthest downwind of Las Vegas among CO monitoring stations, were presented. No Pb measurements have been made in the State of Nevada because of low Pb concentration levels after the phase-out of leaded gasoline. The background concentrations of criteria pollutants at these stations for the period 2004 to 2008 are presented in Table 11.6.13.1-2 (EPA 2010b). Monitored concentration levels at either station were lower than their respective standards (up to 44%), except O₃, which approaches the 1-hour NAAQS/SAAQS and exceeds the 8-hour NAAQS. Except for PM₁₀ and PM_{2.5}, ambient concentrations around the SEZ are anticipated to be lower than those presented in the table, which are mostly associated with industrial activities and road traffic in and around urban areas. However, PM₁₀ and PM_{2.5} might be either higher or lower, as their concentrations in arid non-urbanized areas may be influenced by windblown dust or agricultural activities.

The PSD regulations (see 40 CFR 52.21), which are designed to limit the growth of air pollution in clean areas, apply to a major new source or modification of an existing major

	Annual	NA	50 µg/m ³	17 µg/m ³ (34%)	Jean, 2005
PM _{2.5}	24-hour	35 µg/m ³	NA	12.9 µg/m ³ (37%)	Jean, 2008
	Annual	15.0 µg/m ³	NA	4.9 µg/m ³ (33%)	Jean, 2008
Pb	Calendar quarter	1.5 µg/m ³	1.5 µg/m ³	NA	NA
	Rolling 3-month	0.15 µg/m ³ ⁱ	NA	NA	NA

^a Notation: CO = carbon monoxide; NO₂ = nitrogen dioxide; O₃ = ozone; Pb = lead; PM_{2.5} = particulate matter with a diameter of ≤2.5 µm; PM₁₀ = particulate matter with a diameter of ≤10 µm; and SO₂ = sulfur dioxide.

^b Monitored concentrations are the second-highest for all averaging times less than or equal to 24-hour averages, except fourth-highest daily maximum for 8-hour O₃ and the 98th percentile for 24-hour PM_{2.5} and arithmetic mean for annual SO₂, NO₂, PM₁₀, and PM_{2.5}.

^c Values in parentheses are background concentration levels as a percentage of NAAQS or SAAQS, respectively. Calculation of 1-hour SO₂ and NO₂ to NAAQS was not made, because no measurement data based on new NAAQS are available.

^d All air monitoring stations listed are located in Clark County.

^e Effective August 23, 2010.

^f NA = not applicable or not available.

^g Effective April 12, 2010.

^h The EPA revoked the 1-hour O₃ standard in all areas, although some areas have continuing obligations under that standard ("anti-backsliding").

ⁱ Effective January 12, 2009.

Sources: EPA (2010a,b); NAC 445B.22097.

1 source within an attainment or unclassified area (see Section 4.11.2.3). As a matter of policy,
2 EPA recommends that the permitting authority notify the Federal Land Managers when a
3 proposed PSD source would locate within 62 mi (100 km) of a sensitive Class I area. Several
4 Class I areas are located around the Gold Point SEZ, two of which are situated within 62 mi
5 (100 km): John Muir WA and Kings Canyon NP in California (40 CFR 81.405), about 58 mi
6 (93 km) west and about 61 mi (98 km) west-southwest, respectively, of the proposed Gold Point
7 SEZ. These Class I areas are not located downwind of prevailing winds at the Gold Point SEZ
8 (Figure 11.6.13.1-1). The next nearest Class I areas in California include Sequoia NP, Ansel
9 Adams WA, and Kaiser WA, which are about 71 mi (115 km) southwest, 84 mi (135 km) west-
10 northwest, and 93 mi (150 km) west of the Gold Point SEZ, respectively.

11 11.6.13.2 Impacts

15 Potential impacts on ambient air quality associated with a solar project would be of
16 most concern during the construction phase. Impacts on ambient air quality from fugitive dust
17 emissions resulting from soil disturbances are anticipated, but they would be of short duration.
18 During the operations phase, only a few sources with generally low levels of emissions would
19 exist for any of the four types of solar technologies evaluated. A solar facility would either not
20 burn fossil fuels or burn only small amounts during operation. (For facilities using HTFs, fuel
21 could be used to maintain the temperature of the HTFs for more efficient daily start-up.)
22 Conversely, use of solar facilities to generate electricity could displace air emissions that would
23 otherwise be released from fossil fuel power plants.

25 Air quality impacts shared by all solar technologies are discussed in detail in
26 Section 5.11.1, and technology-specific impacts are discussed in Section 5.11.2. Impacts specific
27 to the proposed Gold Point SEZ are presented in the following sections. Any such impacts would
28 be minimized through the implementation of required programmatic design features described in
29 Appendix A, Section A.2.2, and through the application of any additional mitigation measures.
30 Section 11.6.13.3, below, identifies SEZ-specific design features of particular relevance to the
31 Gold Point SEZ.

34 11.6.13.2.1 Construction

36 The Gold Point SEZ site has a relatively flat terrain; thus, only a minimum number of site
37 preparation activities, perhaps with no large-scale earthmoving operations, would be required.
38 However, fugitive dust emissions from soil disturbances during the entire construction phase
39 would be a major concern because of the large areas that would be disturbed in a region that
40 experiences windblown dust problems. Fugitive dusts, which are released near ground level,
41 typically have more localized impacts than similar emissions from an elevated stack with
42 additional plume rise induced by buoyancy and momentum effects.

Methods and Assumptions

Air quality modeling for PM₁₀ and PM_{2.5} emissions associated with construction activities was performed by using the EPA-recommended AERMOD model (EPA 2009b). Details for emissions estimation, the description of AERMOD, input data processing procedures, and modeling assumption are described in Appendix M, Section M.13. Estimated air concentrations were compared with the applicable NAAQS/SAAQS levels at the site boundaries and nearby communities and with PSD increment levels at nearby Class I areas.⁷ However, no receptors were modeled for PSD analysis at the nearest Class I area, John Muir WA in California, because this area is about 58 mi (93 km) from the SEZ, which is more than the maximum modeling distance of 31 mi (50 km) for the AERMOD. Rather, several regularly spaced receptors in the direction of the John Muir WA in California were selected as surrogates for the PSD analysis. For the Gold Point SEZ, the modeling was conducted based on the following assumptions and input:

- Uniformly distributed emissions of 3,000 acres (12.1 km²) in the southern portion of the SEZ, close to the nearest residences near Gold Point,
- Surface hourly meteorological data from the Tonopah Airport⁸ and upper air sounding data from the Mercury/Desert Rock Airport for the 2005 to 2009 period, and
- A regularly spaced receptor grid over a modeling domain of 62 × 62 mi (100 km × 100 km) centered on the proposed SEZ, and additional discrete receptors at the SEZ boundaries.

Results

The modeling results for concentration increments and total concentrations (modeled plus background concentrations) for both PM₁₀ and PM_{2.5} that would result from construction-related fugitive emissions are summarized in Table 11.6.13.2-1. Maximum 24-hour PM₁₀ concentration increments modeled to occur at the site boundaries would be an estimated 465 µg/m³, which far exceeds the relevant standard level of 150 µg/m³. Total 24-hour PM₁₀ concentrations of 531 µg/m³ would also exceed the standard level at the SEZ boundary. However, high PM₁₀

⁷ To provide a quantitative assessment, the modeled air impacts of construction were compared to the NAAQS/SAAQS levels and the PSD Class I increment levels. Although the Clean Air Act exempts construction activities from PSD requirements, a comparison with the Class I increment levels was used to quantify potential impacts. Only monitored data can be used to determine the attainment status. Modeled data are used to assess potential problems and as a consideration in the permitting process.

⁸ The number of missing hours at the Tonopah Airport amounts to about 17.6% of the total hours, which may not be acceptable for regulatory applications because that percentage exceeds the 10% limit defined by the EPA. However, because the wind patterns at Tonopah Airport are more representative of wind at the Gold Point SEZ than the wind patterns at other airports (which have more complete data but are located in different topographic features), the former values were used for the screening analysis.

TABLE 11.6.13.2-1 Maximum Air Quality Impacts from Emissions Associated with Construction Activities for the Proposed Gold Point SEZ

Pollutant ^a	Averaging Time	Rank ^b	Concentration (µg/m ³)				Percentage of NAAQS/SAAQS	
			Maximum Increment ^b	Background ^c	Total	NAAQS/SAAQS	Increment	Total
PM ₁₀	24 hours	H6H	465	66.0	531	150	310	354
	Annual	— ^d	68.3	17.0	85.3	50	137	171
PM _{2.5}	24 hours	H8H	27.8	12.9	40.7	35	79	116
	Annual	—	6.8	4.9	11.8	15.0	46	78

^a PM_{2.5} = particulate matter with a diameter of ≤2.5 µm; PM₁₀ = particulate matter with a diameter of ≤10 µm.

^b Concentrations for attainment demonstration are presented. H6H = highest of the sixth-highest concentrations at each receptor over the 5-year period. H8H = highest of the multiyear average of the eighth-highest concentrations at each receptor over the 5-year period. For the annual average, multiyear averages of annual means over the 5-year period are presented. Maximum concentrations are predicted to occur at the site boundaries.

^c See Table 11.6.13.1-2.

^d A dash indicates not applicable.

concentrations would be limited to the immediate areas surrounding the SEZ boundary and would decrease quickly with distance. Predicted maximum 24-hour PM₁₀ concentration increments would be about 15 µg/m³ at Gold Point (closest town, about 2 mi [3 km] south of the SEZ), about 3 µg/m³ at Lida, and about 2 µg/m³ or less at Goldfield and Silver Peak. Annual average modeled concentration increments and total concentrations (increment plus background) for PM₁₀ at the SEZ boundary would be about 68.3 µg/m³ and 85.3 µg/m³, respectively, both of which are higher than the SAAQS level of 50 µg/m³. Annual PM₁₀ increments would be much lower, about 2.5 µg/m³ at Gold Point, about 0.1 µg/m³ at Lida, and less than 0.1 µg/m³ at Goldfield and Silver Peak. Total 24-hour PM_{2.5} concentrations would be 40.7 µg/m³ at the SEZ boundary, which is higher than the NAAQS level of 35 µg/m³; modeled increments contribute about two times the amount of background concentration to this total. The total annual average PM_{2.5} concentration would be 11.8 µg/m³, which is lower than the NAAQS level of 15.0 µg/m³. At Gold Point, predicted maximum 24-hour and annual PM_{2.5} concentration increments would be about 1.0 and 0.3 µg/m³, respectively.

Predicted 24-hour and annual PM₁₀ concentration increments at the surrogate receptors for the nearest Class I Area—John Muir WA, California—would be about 4.1 µg/m³ and 0.06 µg/m³, or 51% and 1.5% of the PSD increments for the Class I area, respectively. These surrogate receptors are more than 28 mi (46 km) from the John Muir WA, and thus, predicted concentrations in John Muir WA would be lower than the above values (about 27% of the PSD increments for 24-hour PM₁₀), considering the same decay ratio with distance.

1 In conclusion, predicted 24-hour and annual PM₁₀ and 24-hour PM_{2.5} concentration
2 levels could exceed the standard levels at the SEZ boundaries and in the immediate surrounding
3 areas during the construction of solar facilities. To reduce potential impacts on ambient air
4 quality and in compliance with programmatic design features, aggressive dust control measures
5 would be used. Potential air quality impacts on nearby communities would be much lower.
6 Annual PM_{2.5} concentration levels are predicted to be lower than the standard level. Modeling
7 indicates that emissions from construction activities are not anticipated to exceed Class I PSD
8 PM₁₀ increments at the nearest federal Class I area (John Muir WA in California). Construction
9 activities are not subject to the PSD program, and the comparison provides only a screen for
10 gauging the magnitude of the impact. Accordingly, it is anticipated that impacts of construction
11 activities on ambient air quality would be moderate and temporary.

12
13 Emissions from the engine exhaust from heavy construction equipment and vehicles have
14 the potential to cause impacts on AQRVs (e.g., visibility and acid deposition) at the nearby
15 federal Class I areas. However, SO_x emissions from engine exhaust would be very low, because
16 programmatic design features would require ultra-low-sulfur fuel with a sulfur content of
17 15 ppm. NO_x emissions from engine exhaust would be primary contributors to potential impacts
18 on AQRVs. Construction-related emissions are temporary in nature and thus would cause some
19 unavoidable but short-term impacts.

20
21 Transmission lines within a designated ROW would be constructed to connect to the
22 nearest regional grid. A regional 120-kV transmission line is located about 22 mi (35 km) from
23 the proposed Gold Point SEZ; thus, construction of a transmission line over this relatively long
24 distance would likely be needed. Construction activities would result in fugitive dust emissions
25 from soil disturbance and engine exhaust emissions from heavy equipment and vehicles.
26 Construction time for the transmission line could be about 2 years. However, the site
27 of construction along the transmission line ROW would move continuously, so no particular area
28 would be exposed to air emissions for a prolonged period. Therefore, potential air quality
29 impacts on nearby residences along the transmission line ROW, if any, would be minor and
30 temporary in nature.

31 32 33 **11.6.13.2.2 Operations**

34
35 Emission sources associated with the operation of a solar facility would include auxiliary
36 boilers; vehicle (commuter, visitor, support, and delivery) traffic; maintenance (e.g., mirror
37 cleaning and repair and replacement of damaged mirrors); and drift from cooling towers for the
38 parabolic trough or power-tower technology, if wet cooling was implemented (drift constitutes
39 low-level PM emissions).

40
41 The type of emission sources caused by and offset by operation of a solar facility are
42 discussed in Section M.13.4 of Appendix M.

43
44 Estimates of potential air emissions displaced by solar project development at the
45 Gold Point SEZ are presented in Table 11.6.13.2-2. Total power generation capacity ranging
46 from 428 to 770 MW is estimated for the Gold Point SEZ for various solar technologies

TABLE 11.6.13.2-2 Annual Emissions from Combustion-Related Power Generation Avoided by Full Solar Development of the Proposed Gold Point SEZ

Area Size (acres)	Capacity (MW) ^a	Power Generation (GWh/yr) ^b	Emissions Displaced (tons/yr; 10 ³ tons/yr for CO ₂) ^c			
			SO ₂	NO _x	Hg	CO ₂
4,810	428–770	749–1,348	1,057–1,902	906–1,632	0.006–0.011	582–1,047
Percentage of total emissions from electric power systems in Nevada ^d			2.0–3.6%	2.0–3.6%	2.0–3.6%	2.0–3.6%
Percentage of total emissions from all source categories in Nevada ^e			1.6–2.9%	0.60–1.1%	— ^f	1.1–1.9%
Percentage of total emissions from electric power systems in the six-state study area ^d			0.42–0.76%	0.25–0.44%	0.21–0.37%	0.22–0.40%
Percentage of total emissions from all source categories in the six-state study area ^e			0.22–0.40%	0.03–0.06%	—	0.07–0.13%

^a It is assumed that the SEZ would eventually have development on 80% of the lands and that a range of 5 acres (0.020 km²) per MW (for parabolic trough technology) to 9 acres (0.036 km²) per MW (power tower, dish engine, and PV technologies) would be required.

^b A capacity factor of 20% was assumed.

^c Composite combustion-related emission factors for SO₂, NO_x, Hg, and CO₂ of 2.82, 2.42, 1.6 × 10⁻⁵, and 1,553 lb/MWh, respectively, were used for the State of Nevada.

^d Emission data for all air pollutants are for 2005.

^e Emission data for SO₂ and NO_x are for 2002, while those for CO₂ are for 2005.

^f A dash indicates not estimated.

Sources: EPA (2009a,c); WRAP (2009).

(see Section 11.6.2). The estimated amount of emissions avoided for the solar technologies evaluated depends only on the megawatts of conventional fossil fuel-generated power displaced, because a composite emission factor per megawatt-hour of power by conventional technologies is assumed (EPA 2009c). It is estimated that if the Gold Point SEZ eventually had development on 80% of its land, emissions avoided could range from 2.0 to 3.6% of total emissions of SO₂, NO_x, Hg, and CO₂ from electric power systems in the State of Nevada (EPA 2009c). Avoided emissions could be up to 0.76% of total emissions from electric power systems in the six-state study area. When compared to all source categories, power production from the same solar facilities could displace up to 2.9% of SO₂, 1.1% of NO_x, and 1.9% of CO₂ emissions in the State of Nevada (EPA 2009a; WRAP 2009). These emissions could be up to 0.40% of total emissions from all source categories in the six-state study area. Power generation from fossil fuel-fired power plants accounts for about 93% of the total electric power generated in Nevada (EPA 2009c). The contribution of natural gas combustion is about 47%, followed by that of coal

1 combustion at about 45%. Thus, solar facilities built in the Gold Point SEZ could displace
2 relatively more fossil fuel emissions than those built in other states that rely less on fossil fuel–
3 generated power.

4
5 As discussed in Section 5.11.1.5, the operation of associated transmission lines would
6 generate some air pollutants from activities such as periodic site inspections and maintenance.
7 However, these activities would occur infrequently, and the amount of emissions would be small.
8 In addition, transmission lines could produce minute amounts of O₃ and its precursor NO_x
9 associated with corona discharge (i.e., the breakdown of air near high-voltage conductors),
10 which is most noticeable for high-voltage lines during rain or very humid conditions. Since the
11 proposed Gold Point SEZ is located in an arid desert environment, these emissions would be
12 small, and potential impacts on ambient air quality associated with transmission lines would be
13 negligible, considering the infrequent occurrences and small amount of emissions from corona
14 discharges.

15 16 17 **11.6.13.2.3 Decommissioning/Reclamation**

18
19 As discussed in Section 5.11.1.4, decommissioning/reclamation activities are similar to
20 construction activities but occur on a more limited scale and are of shorter duration. Potential
21 impacts on ambient air quality would be correspondingly smaller than those from construction
22 activities. Decommissioning activities would last for a short period, and their potential impacts
23 would be moderate and temporary. The same mitigation measures adopted during the
24 construction phase would also be implemented during the decommissioning phase
25 (Section 5.11.6).

26 27 28 **11.6.13.3 SEZ-Specific Design Features and Design Feature Effectiveness**

29
30 No SEZ-specific design features are required. Limiting dust generation during
31 construction and operations at the proposed Gold Point SEZ (such as increased watering
32 frequency or road paving or treatment) is a required design feature under BLM's Solar Energy
33 Program. These extensive fugitive dust control measures would keep off-site PM levels as low as
34 possible during construction.

11.6.14 Visual Resources

11.6.14.1 Affected Environment

The proposed Gold Point SEZ is located in Esmeralda County in southwestern Nevada. The SEZ occupies 4,810 acres (19.47 km²) within Lida Valley. It extends about 2.5 mi (4.0 km) north-south and is about 4.0 mi (6.4 km) wide. The SEZ ranges in elevation from 4,840 ft (1,475 m) in the northeastern portion to 5,050 ft (1,539 m) in the northwestern portion.

The SEZ is within the Central Basin and Range Level III ecoregion, which consists of northerly trending fault-block ranges and intervening drier basins. Valleys, lower slopes, and alluvial fans are either shrub- and grass-covered or shrub-covered. Higher elevation mountain slopes support woodland, mountain brush, and scattered forests. The land is used primarily for grazing, with some irrigated cropland in valleys near mountain water sources. Gold Point SEZ is located within the Tonopah Basin Level IV ecoregion, which is a transition between the Great Basin and the more southerly Mojave Desert. It is typified by broad, nearly flat to rolling valleys containing lake plains, scattered hills, alluvial fans, bajadas, sand dunes, and hot springs. Ephemeral washes occur. Surface water comes from springs and sporadic foothill precipitation events, but is generally scarce (Bryce et al. 2003).

The SEZ occupies a narrow northeast-to-southwest trending valley surrounded by mountains. Although scenic quality within the SEZ itself is low, the nearby mountains add substantially to the overall visual qualities within the SEZ viewshed. Magruder Mountain (elevation 9,044 ft [2,756 m]), located west of the SEZ, is sacred to the Timbisha Shoshone. Mt. Jackson at 6,411 ft (1,954 m) is north of the SEZ. The mountain slopes and peaks surrounding the SEZ generally are visually pristine. The SEZ and surrounding mountain ranges are shown in Figure 11.6.14.1-1.

The SEZ is flat to slightly sloping, with the strong horizon line and surrounding mountain ranges being the dominant visual features. There is very little topographic relief, with playas occurring in the northeast portion of the SEZ, and washes that slope downward slightly from southwest to northeast. The surrounding mountains are generally a muted brown, with white and dark accents in some areas; more distant mountains appear blue to purple. In contrast, pink, tan, and gray gravels dominate the desert floor, which is sparsely dotted with the subtle greens, browns, and grays of vegetation. No permanent surface water is present within the SEZ.

Vegetation is generally sparse in much of the SEZ, with widely spaced shrubs growing on more or less barren gravel flats. Vegetation within the SEZ is predominantly scrubland, with shadscale, greasewood, and winterfat dominating the desert floor. Small Joshua trees add short vertical accents and color contrasts that add visual interest to portions of the SEZ. During an August 2009 site visit, the vegetation presented a range of muted greens, grays, and browns, with medium to coarse textures. Visual interest is generally low.

1

2 **FIGURE 11.6.14.1-1 Proposed Gold Point SEZ and Surrounding Lands**

1 Other than roads, transmission lines, and the very small community of Gold Point visible
2 south of the SEZ, the area is relatively free of cultural modifications that would detract from the
3 scenic qualities of the landscape. Upslope roads provide a noticeable line contrast in the
4 landscape.

5
6 The general lack of topographic relief, water, and physical variety results in low scenic
7 value within the SEZ itself; however, because of the flatness of the landscape, the lack of trees,
8 and the breadth of the open desert, the SEZ presents a vast panoramic landscape with sweeping
9 views of the surrounding mountains that add significantly to the scenic values within the SEZ
10 viewshed. In general, the mountains appear to be devoid of vegetation, and their varied and
11 irregular forms and muted brown colors provide visual contrasts to the strong horizontal line,
12 particularly when viewed from nearby locations within the SEZ. Panoramic views of the SEZ
13 are shown in Figures 11.6.14.1-2, 11.6.14.1-3, and 11.6.14.1-4.

14
15 The BLM conducted a visual resource inventory (VRI) for the SEZ and surrounding
16 lands in 2010; however, the VRI was not completed in time for the new data to be included in the
17 draft PEIS. The new VRI data will be incorporated into the analyses presented in the final PEIS.
18 The VRI evaluates BLM-administered lands on the basis of scenic quality; sensitivity level, in
19 terms of public concern for preservation of scenic values in the evaluated lands; and distance
20 from travel routes or KOPs. Based on these three factors, BLM-administered lands are placed
21 into one of four VRI Classes, which represent the relative value of the visual resources. Class I
22 and II are the most valued; Class III represents a moderate value; and Class IV represents the
23 least value. Class I is reserved for specially designated areas, such as national wildernesses and
24 other congressionally and administratively designated areas where decisions have been made to
25 preserve a natural landscape. Class II is the highest rating for lands without special designation.
26 More information about VRI methodology is presented in Section 5.12 and in *Visual Resource*
27 *Inventory*, BLM Manual Handbook 8410-1 (BLM 1986a).

28
29 The Tonopah Resource Management Plan (BLM 1997) indicates that the SEZ and
30 surrounding area is managed as VRM Class IV, which permits major modification of the existing
31 character of the landscape. More information about the BLM VRM program is presented in
32 Section 5.12 and in *Visual Resource Management*, BLM Manual Handbook 8400 (BLM 1984).

33 34 35 **11.6.14.2 Impacts**

36
37 The potential for impacts from utility-scale solar energy development on visual resources
38 within the proposed Gold Point SEZ and surrounding lands, as well as the impacts of related
39 projects (e.g., access roads and transmission lines) outside of the SEZ, is presented in this
40 section.

41
42 Site-specific impact assessment is needed to systematically and thoroughly assess visual
43 impact levels for a particular project. Without precise information about the location of a project
44 and a relatively complete and accurate description of its major components and their layout, it is
45 not possible to assess precisely the visual impacts associated with the facility. However, if the
46 general nature and location of a facility are known, a more generalized assessment of potential

13

1 visual impacts can be made by describing the range of expected visual changes and discussing
2 contrasts typically associated with these changes. In addition, a general analysis can identify
3 sensitive resources that may be at risk if a future project is sited in a particular area. Detailed
4 information about the methodology employed for the visual impact assessment used in this
5 PEIS, including assumptions and limitations, is presented in Appendix M.

6
7 *Potential Glint and Glare Impacts.* Similarly, the nature and magnitude of potential glint-
8 and glare-related visual impacts for a given solar facility is highly dependent on viewer position,
9 sun angle, the nature of the reflective surface and its orientation relative to the sun and the
10 viewer, atmospheric conditions and other variables. The determination of potential impacts from
11 glint and glare from solar facilities within a given proposed SEZ would require precise
12 knowledge of these variables, and is not possible given the scope of the PEIS. Therefore, the
13 following analysis does not describe or suggest potential contrast levels arising from glint and
14 glare for facilities that might be developed within the SEZ; however, it should be assumed that
15 glint and glare are possible visual impacts from *any* utility-scale solar facility, regardless of size,
16 landscape setting, or technology type. The occurrence of glint and glare at solar facilities could
17 potentially cause large though temporary increases in brightness and visibility of the facilities.
18 The visual contrast levels projected for sensitive visual resource areas discussed in the following
19 analysis do not account for potential glint and glare effects; however, these effects would be
20 incorporated into a future site-and project-specific assessment that would be conducted for
21 specific proposed utility-scale solar energy projects. For more information about potential
22 glint and glare impacts associated with utility-scale solar energy facilities, see Section 5.12 of
23 this PEIS.

24 25 26 **11.6.14.2.1 Impacts on the Proposed Gold Point SEZ**

27
28 Some or all of the SEZ could be developed for one or more utility-scale solar energy
29 projects, utilizing one or more of the solar energy technologies described in Appendix F.
30 Because of the industrial nature and large size of utility-scale solar energy facilities, large visual
31 impacts on the SEZ would occur as a result of their construction, operation, and
32 decommissioning. In addition, large impacts could occur at solar facilities incorporating highly
33 reflective surfaces or major light-emitting components (solar dish, parabolic trough, and power
34 tower technologies), with lesser impacts associated with reflective surfaces expected from
35 PV facilities. These impacts would be expected to involve major modification of the existing
36 character of the landscape and would likely dominate the views nearby. Additional, and
37 potentially large impacts could occur as a result of the construction, operation, and
38 decommissioning of related facilities, such as access roads and electric transmission lines. While
39 the primary visual impacts associated with solar energy development within the SEZ would
40 occur during daylight hours, lighting required for utility-scale solar energy facilities would be a
41 potential source of visual impacts at night, both within the SEZ and on surrounding lands.

42
43 Common and technology-specific visual impacts from utility-scale solar energy
44 development, as well as impacts associated with electric transmission lines, are discussed in
45 Section 5.12 of this PEIS. Impacts would last throughout construction, operation, and
46 decommissioning, and some impacts could continue after project decommissioning. Visual

1 impacts resulting from solar energy development in the SEZ would be in addition to impacts
2 from solar energy development and other development that may occur on other public or private
3 lands within the SEZ viewshed. For discussion of cumulative impacts, see Section 11.6.22.4.13
4 of this PEIS.

5
6 The changes described above would be expected to be consistent with BLM VRM
7 objectives for VRM Class IV, as seen from nearby KOPs. As noted above, the lands that include
8 the SEZ are currently managed as VRM Class IV. More information about impact determination
9 using the BLM VRM program is presented in Section 5.12 and in *Visual Resource Contrast*
10 *Rating*, BLM Manual Handbook 8431-1 (BLM 1986b).

11
12 Implementation of the programmatic design features intended to reduce visual impacts
13 (described in Appendix A, Section A.2.2) would be expected to reduce visual impacts associated
14 with utility-scale solar energy development within the SEZ; however, the degree of effectiveness
15 of these design features could be assessed only at the site- and project-specific level. Given the
16 large scale, reflective surfaces, and strong regular geometry of utility-scale solar energy facilities
17 and the lack of screening vegetation and landforms within the SEZ viewshed, siting the facilities
18 away from sensitive visual resource areas and other sensitive viewing areas would be the primary
19 means of mitigating visual impacts. The effectiveness of other visual impact mitigation measures
20 would generally be limited, but would be important to reduce visual contrasts to the greatest
21 extent possible.

22 23 24 **11.6.14.2.2 Impacts on Lands Surrounding the Proposed Gold Point SEZ**

25
26 Because of the large size of utility-scale solar energy facilities and the generally flat,
27 open nature of the proposed SEZ, lands outside the SEZ would be subjected to visual impacts
28 related to construction, operation, and decommissioning of utility-scale solar energy facilities.
29 The affected areas and extent of impacts would depend on a number of visibility factors and
30 viewer distance (for a detailed discussion of visibility and related factors, see Section 5.12).
31 A key component in determining impact levels is the intervisibility between the project and
32 potentially affected lands; if topography, vegetation, or structures screen the project from viewer
33 locations, there is no impact.

34
35 Preliminary viewshed analyses were conducted to identify which lands surrounding the
36 proposed SEZ would have views of solar facilities in at least some portion of the SEZ
37 (see Appendix M for information on the assumptions and limitations of the methods used).
38 Four viewshed analyses were conducted, assuming four different heights representative of
39 project components associated with potential solar energy technologies: PV and parabolic trough
40 arrays (24.6 ft [7.5 m]), solar dishes and power blocks for CSP technologies (38 ft [11.6 m]),
41 transmission towers and short solar power towers (150 ft [45.7 m]), and tall solar power towers
42 (650 ft [198.1 m]). Viewshed maps for the SEZ for all four solar technology heights are
43 presented in Appendix N.

44
45 Figure 11.6.14.2-1 shows the combined results of the viewshed analyses for all four solar
46 technologies. The colored segments indicate areas with clear lines of sight to one or more areas

FIGURE 11.6.14.2-1 Viewshed Analyses for the Proposed Gold Point SEZ and Surrounding Lands, Assuming Solar Technology Heights of 24.6 ft (7.5 m), 38 ft (11.6 m), 150 ft (45.7 m), and 650 ft (198.1 m) (shaded areas indicate lands from which solar development within the SEZ could be visible)

1 within the SEZ and from which solar facilities within these areas of the SEZ would be expected
2 to be visible, assuming the absence of screening vegetation or structures and adequate lighting
3 and other atmospheric conditions. The light brown areas are locations from which PV and
4 parabolic trough arrays located in the SEZ could be visible. Solar dishes and power blocks for
5 CSP technologies would be visible from the areas shaded in light brown and the additional areas
6 shaded in light purple. Transmission towers and short solar power towers would be visible from
7 the areas shaded light brown, light purple, and the additional areas shaded in dark purple. Power
8 tower facilities located in the SEZ could be visible from areas shaded light brown, light purple,
9 dark purple, and at least the upper portions of power tower receivers could be visible from the
10 additional areas shaded in medium brown.

11
12 For the following visual impact discussion, the tall solar power tower (650 ft [198.1 m])
13 and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds are shown in the figures and
14 discussed in the text. These heights represent the maximum and minimum landscape visibility
15 for solar energy technologies analyzed in this PEIS. Viewsheds for solar dish and CSP
16 technology power blocks (38 ft [11.6 m]) and for transmission towers and short solar power
17 towers (150 ft [45.7 m]) are presented in Appendix N. The visibility of these facilities would fall
18 between that for tall power towers and PV and parabolic trough arrays.

19 20 21 **Impacts on Selected Federal-, State-, and BLM-Designated Sensitive Visual** 22 **Resource Areas**

23
24 Figure 11.6.14.2-2 shows the results of a GIS analysis that overlays selected federal,
25 state, and BLM-designated sensitive visual resource areas onto the combined tall solar power
26 tower (650 ft [198.1 m]) and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds to
27 illustrate which of these sensitive visual resource areas would have views of solar facilities
28 within the SEZ and therefore potentially would be subject to visual impacts from those facilities.
29 Distance zones that correspond with BLM's VRM system-specified foreground-middleground
30 distance (5 mi [8 km]), background distance (15 mi [24 km]), and a 25-mi (40-km) distance zone
31 also are shown to indicate the effect of distance from the SEZ on impact levels, which are highly
32 dependent on distance.

33
34 The scenic resources included in the analyses were as follows:

- 35
36 • National Parks, National Monuments, National Recreation Areas, National
37 Preserves, National Wildlife Refuges, National Reserves, National
38 Conservation Areas, National Historic Sites;
- 39
40 • Congressionally authorized Wilderness Areas;
- 41
42 • Wilderness Study Areas;
- 43
44 • National Wild and Scenic Rivers;
- 45
46 • Congressionally authorized Wild and Scenic Study Rivers;

FIGURE 11.6.14.2-2 Overlay of Selected Sensitive Visual Resource Areas onto Combined 650-ft (198.1-m) and 24.6-ft (7.5-m) Viewsheds for the Proposed Gold Point SEZ

- National Scenic Trails and National Historic Trails;
- National Historic Landmarks and National Natural Landmarks;
- All-American Roads, National Scenic Byways, State Scenic Highways; and BLM- and USFS-designated scenic highways/byways;
- BLM-designated Special Recreation Management Areas; and
- ACECs designated because of outstanding scenic qualities.

Potential impacts on specific sensitive resource areas visible from and within 25 mi (40 km) of the proposed Gold Point SEZ are discussed below. The results of this analysis are also summarized in Table 11.6.14.2-1. Further discussion of impacts on these areas is presented in Sections 11.6.3 (Specially Designated Areas and Lands with Wilderness Characteristics) and Section 11.6.17 (Cultural Resources) of this PEIS.

TABLE 11.6.14.2-1 Selected Potentially Affected Sensitive Visual Resources within a 25-mi (40-km) Viewshed of the Proposed Gold Point SEZ, Assuming a Target Height of 650 ft (198.1 m)

Feature Type	Feature Name (Total Acreage) ^a	Feature Area ^b		
		Visible within 5 mi	Visible between	
			5 and 15 mi	15 and 25 mi
National Park	Death Valley (3,397,062 acres)	0 acres	67 acres (0.002%)	3,747 acres (0.1%)
National Conservation Area	California Desert (25,919,319 acres)	0 acres	67 acres (0.0003%)	4,198 acres (0.02%)
Was	Death Valley (3,074,256 acres)	0 acres	67 acres (0.002%)	3,707 acres (0.1%)
WSAs	Pigeon Spring (3,651 acres)	0 acres	0 acres	8 acres (0.2%)
	Queer Mountain (85,294 acres)	0 acres	1,276 acres (2%)	0 acres
SRMA	Fish Lake Valley (196,811 acres)	0 acres	0 acres	460 acres (0.2%)

^a To convert acres to km², multiply by 0.004047.

^b Percentage of total feature viewable.

1 The following visual impact analysis describes *visual contrast levels* rather than *visual*
2 *impact levels*. *Visual contrasts* are changes in the landscape as seen by viewers, including
3 changes in the forms, lines, colors, and textures of objects seen in the landscape. A measure of
4 *visual impact* includes potential human reactions to the visual contrasts arising from a
5 development activity, based on viewer characteristics, including attitudes and values,
6 expectations, and other characteristics that are viewer- and situation-specific. Accurate
7 assessment of visual impacts requires knowledge of the potential types and numbers of viewers
8 for a given development and their characteristics and expectations; specific locations where the
9 project might be viewed from; and other variables that were not available or not feasible to
10 incorporate in the PEIS analysis. These variables would be incorporated into a future site-and
11 project-specific assessment that would be conducted for specific proposed utility-scale solar
12 energy projects. For more discussion of visual contrasts and impacts, see Section 5.12 of the
13 PEIS.

14 15 16 ***National Park***

- 17
18 • *Death Valley*. Death Valley NP is located in California, about 13 mi (21 km)
19 southwest of the SEZ at the point of closest approach. The vast Death Valley
20 NP is a popular winter hiking area. The Death Valley NP contains paved roads
21 popular for scenic driving and biking, several miles of hiking trails, and four-
22 wheel drive roads. There are campgrounds, and backcountry camping is
23 allowed. Death Valley NP has some of the darkest night skies in the country
24 (NPS 2010), and they are considered an important part of the national park
25 visitor experience. Stargazing is popular year round, as are bird watching
26 and viewing spring wildflowers. Most of the park's services and facilities, as
27 well as most recreational use, are in the central and northeastern portions of
28 the park.
29
30

GOOGLE EARTH™ VISUALIZATIONS

The visual impact analysis discussion in this section utilizes three-dimensional Google Earth™ perspective visualizations of hypothetical solar facilities placed within the SEZ. The visualizations include simplified wireframe models of a hypothetical solar power tower facility. The models were placed at various locations within the SEZ as visual aids for assessing the approximate size and viewing angle of utility-scale solar facilities. The visualizations are intended to show the apparent size, distance, and configuration of the SEZ, as well as the apparent size of a typical utility-scale solar power tower project and its relationship to the surrounding landscape, as viewed from potentially sensitive visual resource areas within the viewshed of the SEZ.

The visualizations are not intended to be realistic simulations of the actual appearance of the landscape or of proposed utility-scale solar energy projects. The placement of models within the SEZ did not reflect any actual planned or proposed projects within the SEZ, and did not take into account engineering or other constraints that would affect the siting or choice of facilities for this particular SEZ. The number of facility models placed in the SEZ does not reflect the 80% development scenario analyzed in the PEIS, but it should be noted that the discussion of expected visual contrast levels does account for the 80% development scenario. A solar power tower was chosen for the models because the unique height characteristics of power tower facilities make their visual impact potential extend beyond other solar technology types.

Solar facilities within the SEZ could be visible from the summits and northeast-facing slopes of higher peaks of the Last Chance Range within the NP. Visibility of solar facilities within the SEZ would primarily be from the area surrounding Last Chance Mountain, at about 16 to 18 mi (23 to 26 km) from the SEZ. These areas include about 3,814 acres (15.4 km²) in the 650-ft (198.1-m) viewshed, or 0.1% of the total NP acreage, and 2,213 acres (9.0 km²) in the 24.6-ft (7.5-m) viewshed, or 0.07% of the total Death Valley NP acreage. Areas of Death Valley NP within the SEZ 25-mi (40 km) viewshed extend from 14 mi (23 km) to around 21 mi (34 km) from the southwestern boundary of the SEZ. Additional areas of the NP are within the SEZ viewshed beyond 30 mi (48 km) from the SEZ.

For about one-third of the area in the NP within the SEZ 25-mi (40-km) viewshed, visibility would be restricted to taller solar facility components, such as transmission towers and power towers. Furthermore, most of the area has scattered vegetation, and views of the SEZ could therefore be subject to screening. Three additional areas with visibility exist at distances from 14 to 21 mi (23 to 34 km) from the SEZ, but the largest of these areas is less than 200 acres (0.81 km²) in size, and in these smaller areas, visibility would be limited to the upper portions of tall power towers in the SEZ.

In the area around Last Chance Mountain, some viewpoints would have clear views of the SEZ, but the SEZ would occupy only a very small part of the horizontal field of view, and the vertical viewing angle would be very low, despite the elevated viewpoints. Figure 11.6.14.2-3 is a Google Earth visualization of the SEZ as seen from near the summit of Last Chance Mountain in Death Valley NP, about 18 mi (29 km) from the southwest corner of the SEZ. The visualization includes simplified wireframe models of a hypothetical solar power tower facility. The models were placed within the SEZ as a visual aide for assessing the approximate size and viewing angle of utility-scale solar facilities.

The receiver towers depicted in the visualization are properly scaled models of a 459-ft (140-m) power tower with an 867-acre (3.5-km²) field of 12-ft (3.7-m) heliostats, each representing about 100 MW of electric generating capacity. One group of two models was placed in the SEZ for this and other visualizations shown in this section of the PEIS. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The viewpoint in the visualization is about 3,500 ft (1,070 m) higher in elevation than the SEZ. The visualization suggests that from this elevated viewpoint, the tops of collector arrays within the SEZ would likely be visible, but the angle of view would be low because of the 18-mi (29-km) distance to the SEZ. The SEZ and solar facilities within it would occupy a very small portion of the horizontal field of view.

FIGURE 11.6.14.2-3 Google Earth Visualization of the Proposed Gold Point SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Last Chance Mountain in Death Valley NP (also California Desert Conservation Area and Death Valley WA)

1 If power towers were present within the SEZ, they would be visible as points
2 of light against a backdrop of the valley floor. At night, if more than 200 ft
3 (61 m) tall, power towers would have hazard navigation lights that could
4 potentially be visible from this location. The lights could be red flashing lights
5 or red or white strobe lights, and the light could be visible from this
6 viewpoint, and could attract visual attention, especially given the dark night
7 skies typical in the remote location of the SEZ. Depending on project location
8 within the SEZ, the types of solar facilities and their designs, and other
9 visibility factors, weak visual contrasts from solar energy development within
10 the SEZ could be expected at this location.

11
12 The summit of Last Chance Mountain is the highest-elevation viewpoint in
13 Death Valley NP within the 25-mi (40-km) viewshed of the SEZ. Other
14 viewpoints in the NP that are within the 25-mi (40 km) SEZ viewshed are at
15 about the same distance from the SEZ, but would be lower in elevation and
16 would therefore be subject to similar or slightly lower contrast levels from
17 solar development within the SEZ, particularly given that in some of the areas,
18 visibility would be limited to taller solar facilities, thereby reducing impact. In
19 general, visual contrast levels arising from solar facilities within the SEZ
20 would not be expected to exceed weak levels for viewpoints within Death
21 Valley NP.

22 23 24 ***National Conservation Area***

- 25
26 • *California Desert.* The California Desert Conservation Area (CDCA) is a
27 26-million-acre (105,000-km²) parcel of land in southern California
28 designated by Congress in 1976 through the Federal Land Policy and
29 Management Act. About 10 million acres (40,000 km²) of the CDCA is
30 administered by the BLM.

31
32 The CDCA management plan (BLM 1999) notes the “superb” variety of
33 scenic values in the CDCA and lists scenic resources as needing management
34 to preserve their value for future generations. The CDCA management plan
35 divides CDCA lands into multiple-use classes based on management
36 objectives. The class designations govern the type and degree of land use
37 actions allowed within the areas defined by class boundaries. All land use
38 actions and resource-management activities on public lands within a multiple-
39 use class delineation must meet the guidelines given for that class.

40
41 CDCA land within the viewshed of the Gold Point SEZ is within Death
42 Valley NP. Portions of the CDCA within the 650-ft (198.1-m) viewshed for
43 the Gold Point SEZ include about 4,265 acres (17.3 km²), or 0.02% of the
44 total CDCA acreage. Portions of the CDCA within the 24.6-ft (7.5-m)
45 viewshed encompass about 2,221 acres (9.0 km²), or 0.009% of the total
46 CDCA acreage. Areas of the CDCA within the SEZ 25-mi (40 km) viewshed

1 extend from 14 mi (23 km) to around 21 mi (34 km) from the southwestern
2 boundary of the SEZ. Additional areas of the CDCA are within the SEZ
3 viewshed beyond 30 mi (48 km) from the SEZ.

4
5 Death Valley NP is located entirely within the CDCA, and the portions of the
6 CDCA within the 25-mi (40-km) viewshed of the SEZ are identical to those
7 within the NP. Expected visual contrast levels for the CDCA are the same as
8 those expected for the NP, as described above.

9 10 11 ***Wilderness Area***

- 12
13 • *Death Valley.* Death Valley WA is a 3,074,256-acre (12,441-km²)
14 congressionally designated WA located 13 mi (21 km) southwest of the SEZ.
15 It is the largest area of designated National Park wilderness within the
16 contiguous United States (NPS 2010). Within 25 mi (40 km) of the SEZ, solar
17 energy facilities within the SEZ could be visible from portions of the WA
18 (about 3,774 acres [15.3 km²], or 0.1% of the total WA acreage, in the 650-ft
19 [198.1-m] viewshed, and 2,210 acres [8.9 km²], or 0.1% of the total WA
20 acreage, in the 25-ft [7.5-m] viewshed). The visible area of the Death Valley
21 NP extends from 14 mi (23 km) to beyond 25 mi (40 km) from the
22 southwestern boundary of the SEZ.

23
24 Death Valley WA is located entirely within Death Valley NP, and the portions
25 of the WA within the 25-mi (40 km) viewshed of the SEZ are identical to
26 those within the NP. Expected visual contrast levels for the WA are the same
27 as those expected for the NP, as described above.

28 29 30 ***Wilderness Study Areas***

- 31
32 • *Pigeon Spring.* Pigeon Spring Wilderness Study Area (WSA) is a 3,651-acre
33 (14.8-km²) WSA located 15 mi (24 km) west of the SEZ. Within 25 mi
34 (40 km) of the SEZ, solar energy facilities within the SEZ could be visible
35 from about 8 acres (0.03 km²), or 0.2% of the total WSA acreage, in the
36 650-ft (198.1-m) viewshed. None of the WSA is visible within the 25-ft
37 (7.5-m) viewshed. The visible area of the WSA is about 16 mi (26 km) from
38 the western boundary of the SEZ.

39
40 The receivers and upper portions of sufficiently tall power towers placed in
41 the far southern portion of the SEZ could potentially be visible from a very
42 small portion of the WSA. This portion of the WSA is wooded, and trees
43 would likely partially or completely block the view of solar facilities within
44 the SEZ. If operating power towers were visible in this portion of the SEZ,
45 they would be visible as points of light just above the intervening mountains.
46 At night, if more than 200 ft (61 m) tall, power towers would have hazard

navigation lights that could potentially be visible from this location. The lights could be red flashing lights or red or white strobe lights, and the light could potentially be visible from the WSA. Expected visual impacts on the WSA would be minimal.

- *Queer Mountain.* Queer Mountain WSA is an 85,294-acre (345.2-km²) wilderness study area located 7.0 mi (11.3 km) south of the SEZ. Within 25 mi (40 km) of the SEZ, solar energy facilities within the SEZ could be visible from local summits and north-facing slopes of Gold Mountain and some ridges west of Gold Mountain. Portions of the WSA within the SEZ 25-mi (40 km) viewshed include about 1,276 acres (5.2 km²), or 2% of the total WSA acreage, in the 650-ft (198.1-m) viewshed and 522 acres (2.1 km²), or 1% of the total WSA acreage, in the 25-ft (7.5-m) viewshed. The visible area of the WSA is about 8.7 to 12 mi (14 to 19 km) from the southern boundary of the SEZ.

From the highest peaks and ridges in those portions of the WSA that have views of the SEZ, the ridges of Slate Ridge generally screen at least some of the SEZ from view; however, from some viewpoints, most of the SEZ would be visible, and the SEZ would occupy a moderate amount of the horizontal field of view. Although the vertical angle of view is low, it is high enough that the tops of collector/reflector arrays within the SEZ would likely be visible. From these very high-elevation viewpoints, visual contrast levels from solar facilities could potentially reach moderate levels, but for lower elevation viewpoints, weak levels of visual contrast would be expected.

Figure 11.6.14.2-4 is a Google Earth visualization of the SEZ as seen from the summit of Gold Mountain in the WSA, about 10 mi (16 km) directly south of the SEZ. The viewpoint in the visualization is about 3,000 ft (900 m) higher in elevation than the SEZ. Solar facilities within the SEZ would be seen in a band just above the top of Slate Ridge.

The visualization suggests that from this elevated viewpoint, the tops of collector/reflector arrays within the SEZ would likely be visible, which would increase the apparent size of the collector/reflector arrays and would make the strong regular geometry of the arrays more apparent. The SEZ and solar facilities within it would occupy a moderate portion of the horizontal field of view. If power towers were present within the SEZ, the receivers could be visible as bright points of light against a backdrop of the valley floor. They would be likely to attract visual attention and likely could not be missed by casual viewers. At night, sufficiently tall power towers could have red or white flashing hazard lights that would be visible from Gold Mountain, and they would likely attract attention given the dark night skies typical of the area. Other lighting associated with solar facilities in the SEZ could be visible as well. Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, moderate visual

3

4

1 contrasts from solar energy development within the SEZ could be expected at this
2 location.

3
4 The summit of Gold Mountain is the highest-elevation viewpoint in the WSA within
5 the 25-mi (40-km) viewshed of the SEZ. Other viewpoints in the WSA that are within
6 the 25-mi (40 km) SEZ viewshed are at about the same distance or slightly less
7 distant from the SEZ, but would be lower in elevation. These viewpoints would
8 therefore be subject to similar or lower contrast levels from solar development within
9 the SEZ, particularly given that in some of the areas, visibility would be limited to
10 taller solar facilities, thereby reducing impact. In general, moderate levels of visual
11 contrast would be expected for some high-elevation viewpoints in the WSA, with
12 weaker contrasts expected for lower elevation viewpoints in the WSA.

13 14 15 ***Special Recreation Management Area***

- 16
17 • *Fish Lake Valley*—The Fish Lake Valley SRMA is a BLM-designated SRMA
18 located in California that contains two separate areas. The portion of the
19 SRMA that is within the viewshed of Gold Point SEZ is located 17 mi
20 (28 km) southwest of the SEZ at the point of closest approach. The total
21 acreage of the SRMA is 196,811 acres (796.5 km²).

22
23 The area of the SRMA within the 650-ft (198.1-m) viewshed of the SEZ
24 includes 460 acres (1.9 km²), or 0.2% of the total SRMA acreage. The area of
25 the SRMA within the 24.6-ft (7.5-m) viewshed of the SEZ includes 12 acres
26 (0.05 km²), or 0.006% of the total SRMA acreage. The visible area extends
27 from 16 mi (26 km) from the southwestern boundary of the SEZ to 19 mi
28 (31 km) into the SRMA.

29
30 As shown in Figure 11.6.14.2-2, visibility of solar facilities within the SEZ
31 would be limited to a very small area of the SRMA, and visibility of low
32 height facilities, such as PV panels or trough arrays, would be limited to
33 12 acres (0.05 km²) within the SRMA. Areas within the 25-mi (40-km)
34 viewshed of the SEZ include the summits and northeast-facing slopes of peaks
35 in the Last Chance Range in the SRMA. Views of the SEZ from the SRMA
36 are nearly completely screened by mountains and ridges between the SRMA
37 and the SEZ, including Slate Ridge. Because of the very limited visibility of
38 the SEZ and the long distance to the SEZ (17 mi [28 km]), under the 80%
39 development scenario analyzed in the PEIS, expected visual contrast levels
40 would be minimal for viewpoints within the SRMA.

41
42 Additional scenic resources exist at the national, state, and local levels, and impacts may
43 occur on both federal and nonfederal lands, including sensitive traditional cultural properties
44 important to Tribes. In addition to the resource types and specific resources analyzed in this
45 PEIS, future site-specific NEPA analyses would include state and local parks, recreation areas,
46 other sensitive visual resources, and communities close enough to the proposed project to be

1 affected by visual impacts. Selected other lands and resources are included in the discussion
2 below.

3
4 In addition to impacts associated with the solar energy facilities themselves, sensitive
5 visual resources could be affected by other facilities that would be built and operated in
6 conjunction with the solar facilities. With respect to visual impacts, the most important
7 associated facilities would be access roads and transmission lines, the precise location of which
8 cannot be determined until a specific solar energy project is proposed. The nearest large
9 transmission line is 22 mi (35 km) from the SEZ, and the construction of new transmission
10 facilities would be required both within and outside the SEZ. Depending on their location and
11 visibility, these new facilities could potentially cause large additional visual impacts to the
12 sensitive visual resource areas and sensitive viewing areas listed above, as well as other areas not
13 listed above.

14 15 16 **Impacts on Selected Other Lands and Resources**

17
18
19 **Magruder Mountain.** Magruder Mountain (elevation 9,044 ft [2,756 m]), located 5 to
20 10 mi (8 to 16 km) west of the SEZ, is sacred to the Timbisha Shoshone. The summit of the
21 mountain is about 4,000 ft (1,200 m) higher in elevation than the SEZ, and where vegetation and
22 intervening terrain do not provide screening, there are commanding views of the SEZ.

23
24 Figure 11.6.14.2-5 is a Google Earth visualization of the SEZ as seen from the main peak
25 of Magruder Mountain, about 8 mi (13 km) due west of the SEZ, facing east. The visualization
26 suggests that from this elevated viewpoint, solar facilities within the SEZ would be in full view.
27 The tops of solar facilities within the SEZ would be visible, which would reveal their size and
28 the strong regular geometry of the solar collector/reflector arrays. These views would tend to
29 increase visual contrasts with the natural appearing surroundings. In general, the SEZ would
30 occupy only a small portion of the horizontal field of view, but for some viewpoints on the
31 northeastern portion of Magruder Mountain, the SEZ is close enough that it would occupy a
32 moderate amount of the horizontal field of view.

33
34 The receivers of operating power towers within the SEZ would be visible and would
35 likely appear as bright point or non-point (i.e., having a visible cylindrical or rectangular surface)
36 light sources atop discernable tower structures. The lights would likely attract visual attention. At
37 night, sufficiently tall power towers could have red or white flashing hazard lights that would be
38 visible from Magruder Mountain. These lights would likely attract attention, given the dark night
39 skies typical of the area. Other lighting associated with solar facilities in the SEZ could be visible
40 as well.

41
42 Under the 80% development scenario analyzed in the PEIS, depending on the type,
43 number, sizes, and layouts of solar facilities within the SEZ, moderate visual contrasts would be
44 expected for this viewpoint. In general, higher contrast levels of contrast would be expected for
45 viewpoints on the eastern portions of the mountain, as they would be somewhat closer to the
46 SEZ, and lower contrast levels would be expected for viewpoints farther west on the mountain.

1

2
3

FIGURE 11.6.14.2-5 Google Earth Visualization of the Proposed Gold Point SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from Magruder Mountain West of the SEZ

1 Lower visual contrast levels would also be expected at lower-elevation viewpoints on the
2 mountain, both because the vertical angle of view to the SEZ would be lower (tending to reduce
3 visual contrast levels) and because in many areas the lower slopes of the mountain are vegetated,
4 and some screening of the SEZ by vegetation would be expected. Overall, under the 80%
5 development scenario analyzed in the PEIS, moderate visual contrast levels would be expected
6 for viewpoints on Magruder Mountain.
7
8

9 **U.S. Highway 95.** About 10 mi (16 km) of U.S. 95 are within the SEZ viewshed at a
10 distance of 9 to 10.5 mi (14.5 to 16.9 km). The AADT value for U.S. 95 in the vicinity of the
11 SEZ was about 1,900 in 2009 (NV DOT 2010).
12

13 Solar facilities would be viewed perpendicular to the direction of travel in both
14 directions, along the narrow axis of both the SEZ and the narrow Lida Valley. For northbound
15 travelers on U.S. 95, solar facilities within the SEZ could first come into view just north of
16 Stonewall Pass. For about 4 mi (7 km) (about 3½ minutes at highway speeds), only the upper
17 portions of sufficiently tall power towers could be seen. However, just after crossing the
18 Esmeralda-Nye county line, low-height solar facilities within the SEZ could come into view,
19 depending on their location within the SEZ. Low-height facilities would remain in view for
20 about 5 mi (8 km) (about 4 minutes at highway speeds), after which taller solar facilities might
21 be visible for about 1 more mile (1.6 km).
22

23 For those portions of U.S. 95 within the viewshed of the SEZ, the elevation of the
24 roadway is 200 to 300 ft (60 to 90 m) lower than the SEZ, hence the vertical angle of view to the
25 SEZ is extremely low. The SEZ would occupy a small portion of the horizontal field of view.
26 While the receivers of operating power towers within the SEZ could appear as bright points of
27 light at a distance of 10 mi (16 km), in general, because of the small apparent size of the SEZ and
28 the very low angle of view, under the 80% development scenario analyzed in the PEIS, visual
29 contrast levels from solar facilities within the SEZ would not be expected to exceed weak levels
30 for travelers on U.S. 95.
31

32 Southbound travelers on U.S. 95 would have a generally similar visual experience, but
33 the order would be reversed; that is, solar facilities within the SEZ would first come into view
34 about 6 mi (10 km) north of the county line, and disappear from view shortly before travelers
35 reached Stonewall Pass. Visual contrast levels would be similar to those observed by northbound
36 travelers.
37
38

39 **State Route 266.** As shown in Figure 11.6.14.2-2, within 25 mi (40 km) of the SEZ,
40 about 18 mi (29 km) of State Route 266 are within the SEZ viewshed at distances from 2 to
41 9.5 mi (3.2 to 15.3 km). The AADT value for State Route 266 in the vicinity of the SEZ was
42 about 210 vehicles in 2009 (NV DOT 2010).
43

44 From both directions, the road first directly approaches the SEZ but then parallels the
45 SEZ's northern boundary at a distance of about 2 mi (3 km). For westbound travelers on State
46 Route 266, solar facilities within the SEZ could be in view at the junction of State Route 266

1 with U.S. 95, about 10 mi (16 km) northeast of the SEZ's northeast corner. The elevation of the
2 roadway is lower than the SEZ but would gradually increase to that of the SEZ as travelers
3 approached the SEZ. Regardless of elevation, the angle of view would be very low, causing the
4 collector/reflector arrays of solar facilities within the SEZ to be viewed on edge, causing them to
5 appear as thin lines at the western horizon. The edge-on view would conceal much of the arrays'
6 strong regular geometry, reduce their apparent size, and cause them to appear to repeat the strong
7 line of the horizon, all of which would tend to reduce their visual contrast. However, taller
8 ancillary facilities, such as cooling towers, buildings, transmission components, and plumes (if
9 present), would likely be visible above the collector/reflector arrays. These elements could add
10 noticeable form, line, and color contrasts, which would increase as travelers approached the SEZ.
11 The receivers of operating power towers within the SEZ would likely appear as bright or very
12 bright light sources against the backdrop of Slate Ridge west of the SEZ. At night, sufficiently
13 tall power towers could have red or white flashing hazard lighting that would be visible for
14 many miles and would likely be visually conspicuous in the dark sky conditions of this remote
15 location. Other lighting associated with solar facilities within the SEZ could be visible and
16 would add increasing visual contrast as travelers approached the SEZ. In general, as travelers
17 approached the SEZ, expected visual contrast levels from solar facilities within the SEZ would
18 rise from weak to strong levels. The approach to the SEZ is a little more than 9 mi (15 km), and
19 would take about 8 minutes at highway speeds.

20
21 By the time westbound travelers reached that part of State Route 266 north of the SEZ,
22 visual contrast levels from solar facilities within the SEZ under the 80% development scenario
23 would likely have risen to strong levels. Figure 11.6.14.2-6 is a Google Earth perspective
24 visualization of the SEZ as seen from State Route 266 about 1.7 mi (2.8 km) north of the SEZ,
25 facing south toward two power tower models 2.8 mi (4.5 km) south of the viewpoint. The
26 visualization suggests that from this location, solar facilities would be in full view, and the SEZ
27 would occupy nearly the entire horizontal field of view. Solar facilities located within the closest
28 portions of the SEZ would strongly attract visual attention and would likely dominate the view
29 toward the south. The viewpoint from the road is about 60 ft (20 m) higher in elevation than the
30 nearest part of the SEZ, so solar collector arrays would be seen nearly edge-on and would repeat
31 the horizontal line of the plain in which the SEZ is situated. This would tend to reduce visual line
32 contrast somewhat. Ancillary facilities, such as buildings, transmission towers, cooling towers
33 and plumes (if present), would likely be visible projecting above the collector/reflector arrays.
34 Their forms, lines, colors, and reflective properties could contrast strongly with the horizontal
35 collector/reflector arrays and surrounding mostly natural-appearing landscape.

36
37 The receivers of operating power towers within the SEZ would likely appear as brilliant
38 white non-point light sources atop towers whose structural details could be visible. At night,
39 sufficiently tall power towers would have red or white flashing lights that would likely strongly
40 attract visual attention in the dark night sky typical of the area.

41
42 Under the 80% development scenario analyzed in this PEIS, solar facilities within the
43 SEZ to the south would likely dominate views on State Route 266 within a few miles of the SEZ,
44 and would be expected to cause strong levels of visual contrast. Moderate to weak levels of
45 visual contrasts would be expected for viewpoints on State Route 266 farther from the SEZ.
46

1

2

FIGURE 11.6.14.2-6 Google Earth Visualization of the Proposed Gold Point SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Model, as Seen from State Route 266 Directly North of the SEZ

3

1 Eastbound travelers on State Route 266 would experience the same visual contrast levels
2 as westbound travelers, but because the eastbound travelers would enter the viewshed after
3 leaving Lida Canyon much closer to the SEZ (about 4 mi [6 km]) than westbound travelers,
4 contrast levels from solar facilities within the SEZ would reach strong levels much faster than for
5 westbound travelers. The total time solar facilities would be in view in the general direction of
6 travel would also be shorter, as eastbound travelers would approach and pass the SEZ more
7 quickly than westbound travelers.
8
9

10 **Community of Gold Point.** As shown in Figure 11.6.14.2-1, the community of Gold
11 Point is less than 2 mi (3.2 km) directly south of the SEZ. Because of the proximity of the SEZ
12 and the slightly elevated viewpoints within Gold Point, solar facilities within the SEZ would be
13 expected to dominate views to the north from Gold Point, creating strong visual contrasts. A site
14 visit in August 2009 indicated largely open views of the proposed SEZ from Gold Point.
15 However, from some viewpoints in the community, at least partial screening of solar facilities
16 within the SEZ would occur, due to slight variations in topography or structures. A detailed
17 future site-specific NEPA analysis would be required to determine visibility precisely.
18

19 From the community of Gold Point, the SEZ would occupy nearly the entire horizontal
20 field of view looking north, because views from Gold Point toward the SEZ would be
21 perpendicular to the long axis of the SEZ and also because of the relatively short distance to the
22 SEZ. The elevation of Gold Point is about 400 ft (120 m) higher than the SEZ, so although the
23 vertical angle of view would be low, the tops of collector/reflector arrays of solar facilities within
24 the SEZ would likely be visible, tending to increase their contrasts with the surrounding natural-
25 appearing landscape. The structural details of facility components could be visible, with taller
26 solar facility components and plumes projecting above the collector/reflector arrays. Depending
27 on their location within the SEZ, operating power tower receivers in the closest portions of the
28 SEZ would likely be seen as brilliant white non-point light sources against either the backdrop of
29 the Lida Valley floor or the Mt. Jackson Ridge north of the SEZ. Also, under certain viewing
30 conditions, sunlight on dust particles in the air might result in the appearance of light streaming
31 down from the tower(s). At night, if more than 200 ft (61 m) tall, power towers would have
32 hazard navigation lights that could potentially be visible from this location. The lights could be
33 red flashing lights or red or white strobe lights, and the lights would likely be very conspicuous
34 from Gold Point, given the dark night skies found in the area. Other lighting associated with
35 solar facilities would likely be visible as well. Under the 80% development scenario analyzed in
36 this PEIS, strong levels of visual contrast would be expected to result from solar energy
37 development within the SEZ, as seen from unscreened viewpoints within the community of
38 Gold Point.
39

40 **Other Impacts.** In addition to the impacts described for the resource areas above, nearby
41 residents and visitors to the area may experience visual impacts from solar energy facilities
42 located within the SEZ (as well as any associated access roads and transmission lines) from
43 their residences, or as they travel area roads. The range of impacts experienced would be highly
44 dependent on viewer location, project types, locations, sizes, and layouts, as well as the presence
45 of screening, but under the 80% development scenario analyzed in the PEIS, from some
46 locations, strong visual contrasts from solar development within the SEZ could potentially
47 be observed.
48

11.6.14.2.3 Summary of Visual Resource Impacts for the Proposed Gold Point SEZ

Under the 80% development scenario analyzed in the PEIS, the SEZ would contain multiple solar facilities utilizing differing solar technologies, as well as a variety of roads and ancillary facilities. The array of facilities could create a visually complex landscape that would contrast strongly with the strongly horizontal landscape of the flat valley in which the SEZ is located. Large visual impacts on the SEZ and surrounding lands within the SEZ viewshed would be associated with solar energy development within the proposed Gold Point SEZ because of major modification of the character of the existing landscape. Potential exists for additional impacts from construction and operation of transmission lines and access roads within and outside the SEZ.

Under the 80% development scenario analyzed in the PEIS, utility-scale solar energy development within the proposed Gold Point SEZ is likely to result in moderate visual contrasts for some viewpoints within the Queer Mountain WSA, which is within 7 mi (11 km) of the SEZ at the point of closest approach. Moderate visual contrast levels would also be expected for viewpoints on Macgruder Mountain. Minimal to weak visual contrasts would be expected for some viewpoints within other sensitive visual resource areas within the SEZ 25-mi (40-km) viewshed.

Residents of the community of Gold Point would likely experience strong visual contrasts from solar energy development within the SEZ. About 18 mi (29 km) of State Route 266 are within the SEZ viewshed at distances of 2 to 9.5 mi (3.2 to 15.3 km) from the SEZ. Travelers on State Route 266 could be subjected to strong visual contrasts from solar energy development within the SEZ. Visitors to the area, workers, and residents of the community of Gold Point may experience visual impacts from solar energy facilities located within the SEZ (as well as any associated access roads and transmission lines) as they travel other area roads.

11.6.14.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features have been identified to protect visual resources for the proposed Gold Point SEZ. As noted in Section 5.12, the presence and operation of large-scale solar energy facilities and equipment would introduce major visual changes into non-industrialized landscapes and could create strong visual contrasts in line, form, color, and texture that could not easily be mitigated substantially. Implementation of programmatic design features intended to reduce visual impacts (described in Appendix A, Section A.2.2) would be expected to reduce visual impacts associated with utility-scale solar energy development within the SEZ; however, the degree of effectiveness of these design features could be assessed only at the site- and project-specific level. Given the large scale, reflective surfaces, strong regular geometry of utility-scale solar energy facilities, and the lack of screening vegetation and landforms within the SEZ viewshed, siting the facilities away from sensitive visual resource areas and other sensitive viewing areas is the primary means of mitigating visual impacts. The effectiveness of other visual impact mitigation measures would generally be limited.

11.6.15 Acoustic Environment

11.6.15.1 Affected Environment

The proposed Gold Point SEZ is located in the southern portion of Esmeralda County in southwestern Nevada. Neither the State of Nevada nor Esmeralda County has established quantitative noise-limit regulations applicable to solar energy development.

The proposed Gold Point SEZ is in an undeveloped area, the overall character of which is rural. U.S. 95 runs north–south as close as 9 mi (14 km) east of the SEZ. State Route 266 runs east–west less than 2 mi (3 km) north of the SEZ, while State Route 774 runs along the SEZ’s eastern boundary as close as 0.25 mi (0.4 km). Lida Road runs along the SEZ’s western boundary as close as 300 ft (91 m). Several dirt roads run through the SEZ. No railroad line exists around the SEZ. The nearest airport is Lida Junction Airport, which is located about 9 mi (14.5 km) east-northeast of the SEZ. Other nearby airport includes Goldfield Airport, about 21 mi (34 km) north-northeast of the SEZ. There are no agricultural activities in and around the SEZ, but cattle grazing seems to occur within the SEZ. No industrial activities other than small-scale mining are located around the SEZ. No significant recreational land use exists within the SEZ. No sensitive receptors (e.g., residences, hospitals, schools, or nursing homes) exist close to the proposed Gold Point SEZ. The nearest residences (squatters) lie about 2 mi (3 km) south of the SEZ near Gold Point, which is a well-preserved ghost town and point of interest for many tourists. Noise sources around the SEZ include road traffic, aircraft flyover, cattle grazing, and road traffic related to tourism around Gold Point. To date, no environmental noise survey has been conducted around the proposed Gold Point SEZ. On the basis of the population density, the day–night average noise level (L_{dn} or DNL) is estimated to be 17 dBA for Esmeralda County, well below the 33 to 47 dBA L_{dn} range level typical of a rural area (Eldred 1982; Miller 2002).⁹

11.6.15.2 Impacts

Potential noise impacts associated with solar projects in the Gold Point SEZ would occur during all phases of the projects. During the construction phase, potential noise impacts associated with operation of heavy equipment and vehicular traffic on the nearest residences (about 2 mi [3 km] to the south of the SEZ boundary) would be anticipated, albeit of short duration. During the operations phase, potential impacts on the nearest residences would be anticipated, depending on the solar technologies employed. Noise impacts shared by all solar technologies are discussed in detail in Section 5.13.1, and technology-specific impacts are presented in Section 5.13.2. Impacts specific to the proposed Gold Point SEZ are presented in this section. Any such impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2, and through the applications of any additional SEZ-specific design features (see Section 11.6.15.3 below). This

⁹ Rural and undeveloped areas have sound levels in the range of 33 to 47 dBA as L_{dn} (Eldred 1982). Typically, the nighttime level is 10 dBA lower than daytime level, and it can be interpreted as 33 to 47 dBA (mean 40 dBA) during the daytime hours and 23 to 37 dBA (mean 30 dBA) during nighttime hours.

1 section primarily addresses potential noise impacts on humans, although potential impacts on
2 wildlife at nearby sensitive areas are discussed. Additional discussion on potential noise impacts
3 on wildlife is presented in Section 5.10.2.

6 **11.6.15.2.1 Construction**

8 The proposed Gold Point SEZ has a relatively flat terrain; thus, minimal site preparation
9 activities would be required, and associated noise levels would be lower than those during
10 general construction (e.g., erecting building structures and installing equipment, piping, and
11 electrical).

13 For the parabolic trough and power tower technologies, the highest construction noise
14 levels would occur at the power block area, where key components (e.g., steam turbine/
15 generator) needed to generate electricity are located; a maximum of 95 dBA at a distance of
16 50 ft (15 m) is assumed, if impact equipment such as pile drivers or rock drills is not being used.
17 Typically, the power block area is located in the center of the solar facility, at a distance of more
18 than 0.5 mi (0.8 km) from the facility boundary. Noise levels from construction of the solar array
19 would be lower than 95 dBA. When geometric spreading and ground effects are considered, as
20 explained in Section 4.13.1, noise levels would attenuate to about 40 dBA at a distance of
21 1.2 mi (1.9 km) from the power block area. This noise level is typical of daytime mean rural
22 background levels. In addition, mid- and high-frequency noise from construction activities is
23 significantly attenuated by atmospheric absorption under the low-humidity conditions typical of
24 an arid desert environment, and by temperature lapse conditions typical of daytime hours; thus,
25 noise attenuation to a 40-dBA level would occur at distances somewhat shorter than 1.2 mi
26 (1.9 km). If a 10-hour daytime work schedule is considered, the EPA guideline level of 55 dBA
27 L_{dn} for residential areas (EPA 1974) would occur about 1,200 ft (370 m) from the power block
28 area, which would be well within the facility boundary. For construction activities occurring
29 near the residences closest to the southern SEZ boundary, estimated noise levels at the nearest
30 residences would be about 34 dBA¹⁰, which is lower than the typical daytime mean rural
31 background level of 40 dBA. In addition, an estimated 40 dBA L_{dn} ¹¹ at these residences (i.e., no
32 contribution from construction activities) is well below the EPA guidance of 55 dBA L_{dn} for
33 residential areas.

¹⁰ Due to the large difference in elevations between potential noise sources within the SEZ (about 4,960 ft [1,512 m] and receptors near Gold Point (5,400 ft [1,646 m]) located to the south, sound attenuation due to ground effects would likely be smaller as the source location moves north because the line-of-sight between them is higher above the ground. Without considering this effect, noise levels could be underestimated if the source location is located in the northern portion of the SEZ. It is possible that as a receptor moves farther north, the noise level would increase, depending on meteorological conditions. Accordingly, this elevation difference should be taken into account in refined noise calculations during the permitting process.

¹¹ For this analysis, background levels of 40 and 30 dBA for daytime and nighttime hours, respectively, are assumed, which result in a day-night average noise level (L_{dn}) of 40 dBA.

1 There are no specially designated areas within a 5-mi (8-km) range from the Gold Point
2 SEZ, which is the farthest distance that noise, except extremely loud noise, would be discernable.
3 Thus, noise impact analysis for nearby specially designated areas was not conducted.
4

5 Depending on soil conditions, pile driving might be required for installation of solar dish
6 engines. However, the pile drivers used, such as vibratory or sonic drivers, would be relatively
7 small and quiet, in contrast to the impulsive impact pile drivers frequently used at large-scale
8 construction sites. Potential impacts on the nearest residences would be anticipated to be
9 minimal, considering the distance to the nearest residences (about 2 mi [3 km] from the southern
10 SEZ boundary).
11

12 It is assumed that most construction activities would occur during the day, when noise is
13 better tolerated than at night because of the masking effects of background noise. In addition,
14 construction activities for a utility-scale facility are temporary in nature (typically a few years).
15 Construction within the proposed Gold Point SEZ would cause minimal unavoidable, but
16 localized, short-term noise impacts on neighboring communities.
17

18 Construction activities could result in various degrees of ground vibration, depending
19 on the equipment used and construction methods employed. All construction equipment causes
20 ground vibration to some degree, but activities that typically generate the most severe vibrations
21 are high-explosive detonations and impact pile driving. As is the case for noise, vibration would
22 diminish in strength with distance. For example, vibration levels at receptors beyond 140 ft
23 (43 m) from a large bulldozer (87 VdB at 25 ft [7.6 m]) would diminish below the threshold of
24 perception for humans, which is about 65 VdB (Hanson et al. 2006). During the construction
25 phase, no major construction equipment that can cause ground vibration would be used, and no
26 residences or sensitive structures are located in close proximity. Therefore, no adverse vibration
27 impacts are anticipated from construction activities, including pile driving for dish engines.
28

29 Transmission lines would be constructed within a designated ROW to connect to the
30 nearest regional power grid. A regional 120-kV transmission line is located about 22 mi (35 km)
31 from the proposed Gold Point SEZ; thus, construction of a transmission line over this relatively
32 long distance would be needed to connect to the regional grid. For construction of transmission
33 lines, noise sources and their noise levels might be similar to construction noise sources at an
34 industrial facility of a comparable size. Transmission line construction for the Gold Point SEZ
35 could be performed in about 2 years. However, the area under construction along the
36 transmission line ROW would move continuously, so no particular area would be exposed to
37 noise for a prolonged period. Therefore, potential noise impacts on nearby residences along the
38 transmission line ROW, if any, would be minor and temporary in nature.
39
40

41 **11.6.15.2.2 Operations**

42

43 Noise sources common to all or most types of solar technologies include equipment
44 motion from solar tracking, maintenance and repair activities (e.g., washing mirrors or replacing
45 broken mirrors) at the solar array area; commuter/visitor/support/delivery traffic within and
46 around the solar facility; and control/administrative buildings, warehouses, and other auxiliary

1 buildings/structures. Diesel-fired emergency power generators and firewater pump engines
2 would be additional sources of noise, but their operations would be limited to several hours per
3 month (for preventive maintenance testing).

4
5 With respect to the main solar energy technologies, noise-generating activities in the
6 PV solar array area would be minimal, related mainly to solar tracking, if used. On the other
7 hand, dish engine technology, which employs collector and converter devices in a single unit,
8 generally has the strongest noise sources.

9
10 For the parabolic trough and power tower technologies, most noise sources during
11 operations would be in the power block area, including the turbine generator (typically in an
12 enclosure), pumps, boilers, and dry- or wet-cooling systems. The power block is typically
13 located in the center of the facility. On the basis of a 250-MW parabolic trough facility with a
14 cooling tower (Beacon Solar, LLC 2008), simple noise modeling indicates that noise levels
15 around the power block would be more than 85 dBA, but about 51 dBA at the facility boundary,
16 about 0.5 mi (0.8 km) from the power block area. For a facility located near the southern SEZ
17 boundary, the predicted noise level would be about 36 dBA at the nearest residences, located
18 about 2 mi (3 km) from the SEZ boundary, which is below the typical daytime mean rural
19 background level of 40 dBA. If TES were not used (i.e., if the operation were limited to daytime,
20 12 hours only¹²), the EPA guideline level of 55 dBA (as L_{dn} for residential areas) would occur at
21 about 1,370 ft (420 m) from the power block area, and thus, would not be exceeded outside of
22 the proposed SEZ boundary. At the nearest residences, about 41 dBA L_{dn} (i.e., minimal
23 contribution from facility operation) would be estimated. This is well below the EPA guideline
24 of 55 dBA L_{dn} for residential areas. However, day–night average noise levels higher than those
25 estimated above by using simple noise modeling would be anticipated if TES were used during
26 nighttime hours, as explained below and in Section 4.13.1.

27
28 On a calm, clear night typical of the proposed Gold Point SEZ setting, the air temperature
29 would likely increase with height (temperature inversion), because of strong radiative cooling.
30 Such a temperature profile tends to focus noise downward toward the ground. There would be
31 little, if any, shadow zone¹³ within 1 or 2 mi (1.6 or 3 km) of the noise source in the presence of
32 a strong temperature inversion (Beranek 1988). In particular, such conditions add to the
33 effect of noise being more discernable during nighttime hours, when the background noise
34 levels are lowest. To estimate the day–night average noise level (L_{dn}), 6-hour nighttime
35 generation with TES is assumed after 12-hour daytime generation. For nighttime hours under
36 temperature inversion, 10 dB is added to noise levels estimated from the uniform atmosphere
37 (see Section 4.13.1). On the basis of these assumptions, the estimated nighttime noise level at the
38 nearest residences (about 2 mi [3.2 km] from the southern SEZ boundary) would be 46 dBA,
39 which is well above the typical nighttime mean rural background level of 30 dBA. The day–night
40 average noise level is estimated to be about 48 dBA L_{dn} , which is below the EPA guideline of
41 55 dBA L_{dn} for residential areas. The assumptions are conservative in terms of operating hours,
42 and no credit was given to other attenuation mechanisms, so it is likely that noise levels would be

¹² Maximum possible operating hours at the summer solstice, but limited to 7 to 8 hours at the winter solstice.

¹³ A shadow zone is defined as the region in which direct sound does not penetrate because of upward diffraction.

1 lower than 48 dBA L_{dn} at the nearest residences, even if TES were used at a solar facility.
2 Consequently, operating parabolic trough or power tower facilities using TES could result in
3 some adverse noise impacts on the nearest residences, depending on background noise levels
4 and meteorological conditions. In the permitting process, refined noise propagation modeling
5 considering topographical features might be warranted, along with measurement of background
6 noise levels.

7
8 The solar dish engine is unique among CSP technologies because it generates electricity
9 directly and does not require a power block. A single, large solar dish engine has relatively low
10 noise levels, but a solar facility might employ tens of thousands of dish engines, which would
11 cause high noise levels around such a facility. For example, the proposed 750-MW SES Solar
12 Two dish engine facility in California would employ as many as 30,000 dish engines
13 (SES Solar Two, LLC 2008). At the proposed Gold Point SEZ, on the basis of the assumption
14 of dish engine facilities of up to 428-MW total capacity (covering 80% of the total area, or
15 3,848 acres [15.6 km²]), up to 17,100 25-kW dish engines could be employed. For a large dish
16 engine facility, several hundred step-up transformers would be embedded in the dish engine solar
17 field, along with a substation; however, the noise from these sources would be masked by dish
18 engine noise.

19
20 The composite noise level of a single dish engine would be about 88 dBA at a distance of
21 3 ft (0.9 m) (SES Solar Two, LLC 2008). This noise level would be attenuated to about 40 dBA
22 (typical of the mean rural daytime environment) within 330 ft (100 m). However, the combined
23 noise level from tens of thousands of dish engines operating simultaneously would be high in the
24 immediate vicinity of the facility. For example, they would be about 48 dBA at 1.0 mi (1.6 km)
25 and 43 dBA at 2 mi (3 km) from the boundary of the square-shaped dish engine solar field; both
26 values are higher than the typical daytime mean rural background level of 40 dBA. However,
27 these levels would occur at somewhat shorter distances than the aforementioned distances,
28 considering noise attenuation by atmospheric absorption and temperature lapse during daytime
29 hours. To estimate noise levels at the nearest residences, it was assumed dish engines were
30 placed all over the Gold Point SEZ at intervals of 98 ft (30 m). Under these assumptions, the
31 estimated noise level at the nearest residences, about 2 mi (3.2 km) south of the SEZ boundary,
32 would be about 43 dBA, which is somewhat higher than the typical daytime mean rural
33 background level of 40 dBA. On the basis of 12-hr daytime operation, the estimated 43 dBA L_{dn}
34 at these residences is well below the EPA guideline of 55 dBA L_{dn} for residential areas. On the
35 basis of other noise attenuation mechanisms, noise levels at the nearest residences would be
36 lower than the values estimated above. However, noise from dish engines could cause adverse
37 impacts on the nearest residences, depending on background noise levels and meteorological
38 conditions. Thus, consideration of minimizing noise impacts is very important when siting dish
39 engine facilities. Direct mitigation of dish engine noise through noise control engineering could
40 also be considered.

41
42 During operations, no major ground-vibrating equipment would be used. In addition,
43 no sensitive structures are located close enough to the proposed Gold Point SEZ to experience
44 physical damage. Therefore, during operation of any solar facility, potential vibration impacts
45 on surrounding communities and vibration-sensitive structures would be negligible.
46

Transformer-generated humming noise and switchyard impulsive noises would be generated during the operation of solar facilities. These noise sources would be located near the power block area, typically near the center of a solar facility. Noise from these sources would generally be limited within the facility boundary and not be heard at the nearest residences, assuming a 2.5-mi (4.0-km) distance (at least 0.5 mi [0.8 km] to the facility boundary and 2 mi [3.2 km] to the nearest residences). Accordingly, potential impacts of these noise sources on the nearest residences would be minimal.

For impacts from transmission line corona discharge noise during rainfall events (discussed in Section 5.13.1.5), the noise level at 50 ft (15 m) and 300 ft (91 m) from the center of 230-kV transmission line towers would be about 39 and 31 dBA (Lee et al. 1996), respectively, typical of daytime and nighttime mean background noise levels in rural environments. Corona noise includes high-frequency components, considered to be more annoying than low-frequency environmental noise. However, corona noise would not likely cause impacts unless a residence was located nearby (e.g., within 500 ft [152 m] of a 230-kV transmission line). The proposed Gold Point SEZ is located in an arid desert environment, and incidents of corona discharge are infrequent. Therefore, potential impacts on nearby residences from corona noise along transmission lines within the SEZ would be negligible.

11.6.15.2.3 Decommissioning/Reclamation

Decommissioning/reclamation requires many of the same procedures and equipment used in traditional construction. Decommissioning/reclamation would include dismantling of solar facilities and support facilities such as buildings/structures and mechanical/electrical installations, disposal of debris, grading, and revegetation as needed. Activities for decommissioning would be similar to those for construction, but more limited. Potential noise impacts on surrounding communities would be correspondingly lower than those for construction activities. Decommissioning activities would be of short duration, and their potential impacts would be minimal and temporary in nature. The same mitigation measures adopted during the construction phase could also be implemented during the decommissioning phase.

Similarly, potential vibration impacts on surrounding communities and vibration-sensitive structures during decommissioning of any solar facility would be lower than those during construction and thus negligible.

11.6.15.3 SEZ-Specific Design Features and Design Feature Effectiveness

The implementation of required programmatic design features described in Appendix A, Section A.2.2, would greatly reduce or eliminate the potential for noise impacts from development and operation of solar energy facilities. While some SEZ-specific design features are best established when specific project details are being considered, measures that can be identified at this time include the following:

- Noise levels from cooling systems equipped with TES should be managed so that levels at the nearby residences to the south of the SEZ are kept within applicable guidelines. This could be accomplished in several ways, for example, through placing the power block approximately 1 to 2 mi (1.6 to 3 km) or more from residences, limiting operations to a few hours after sunset, and/or installing fan silencers.
- Dish engine facilities within the Gold Point SEZ should be located more than 1 to 2 mi (1.6 to 3 km) from the nearby residences. Direct noise control measures applied to individual dish engine systems could also be used to reduce noise impacts at nearby residences.

11.6.16 Paleontological Resources

11.6.16.1 Affected Environment

The surficial geology of the proposed Gold Point SEZ is composed entirely of thick alluvial deposits (more than 100 ft [30 m] thick), ranging in age from the Pliocene to Holocene. In the absence of a PFYC map for Nevada, a preliminary classification of PFYC Class 2 is assumed for the young Quaternary alluvial deposits, similar to that assumed for the Amargosa Valley SEZ (Section 11.1.16; see Section 4.14 for a discussion of the PFYC system). Class 2 indicates a low potential for the occurrence of significant fossil material.

11.6.16.2 Impacts

Few, if any, impacts on significant paleontological resources are likely to occur in the proposed Gold Point SEZ. However, a more detailed look at the geological deposits of the SEZ is needed to determine whether a paleontological survey is warranted. If the geological deposits are determined to be as described above and are classified as PFYC Class 2, further assessment of paleontological resources in the SEZ is not likely to be necessary. Important resources could exist; if identified, they would need to be managed on a case-by-case basis. Section 5.14 discusses the types of impacts that could occur on any significant paleontological resources found within the proposed Gold Point SEZ. Impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2.

Indirect impacts on paleontological resources outside of the SEZ, such as through looting or vandalism, are unknown but unlikely, because any such resources would be below the surface and not readily accessed. Programmatic design features for controlling water runoff and sedimentation would prevent erosion-related impacts on buried deposits outside of the SEZ.

Approximately 22 mi (35 km) of new transmission line is assessed in this PEIS. Construction of this line would result in approximately 667 acres (2.7 km²) of disturbance. This disturbance would occur in alluvial deposits as well as in residual materials developed in igneous and metamorphic rock (preliminarily classified as PFYC Class 1) and in residual materials developed in fine-grained sediments and in sedimentary rocks (preliminarily classified as PFYC Class 3b), depending on the exact location of the corridor. For PFYC Class 1 areas that would be crossed, there would be little or no potential for significant paleontological resources. For PFYC Class 3b areas, with an unknown potential for containing paleontological material, impacts are possible. A more detailed investigation of the residual sedimentary deposits is needed prior to project approval. A paleontological survey will likely be needed following consultation with the BLM. The appropriate course of action would be determined as established in BLM IM2008-009 (BLM 2007) and IM2009-011 (BLM 2008a). Impacts on paleontological resources related to the creation of new corridors not assessed in this PEIS would be evaluated at the project-specific level if new road or transmission construction or line upgrades are to occur.

1 **11.6.16.3 SEZ-Specific Design Features and Design Feature Effectiveness**
2

3 Impacts would be minimized through the implementation of required programmatic
4 design features as described in Appendix A, Section A.2.2.
5

6 The need for and the nature of any SEZ-specific design features would depend on the
7 results of future paleontological investigations; however, based on the current level of
8 information, a need for mitigation of areas potentially classified as PFYC Class 2 or lower is not
9 anticipated. For the transmission line corridor, mitigation may be necessary if significant
10 paleontological resources are encountered during the survey in PFYC Class 3b areas.
11

11.6.17 Cultural Resources

11.6.17.1 Affected Environment

11.6.17.1.1 Prehistory

The proposed Gold Point SEZ is located in the Lida Valley, within the basin and range province in western Nevada. The earliest known use of the area was likely during the Paleoindian Period, sometime between 12,000 and 10,000 B.P. Surface finds of Paleoindian projectile points, the hallmark of the Clovis culture, have been found in the Big Smoky Valley, 35 mi (56 km) north of the SEZ, and in the Mojave Desert, 20 mi (32 km) southeast of the SEZ, but no sites in the area with any stratigraphic context have been excavated. The Clovis culture is characterized by the aforementioned fluted projectile points and a hunting and gathering subsistence economy that followed migrating herds of Pleistocene mega fauna. The ephemeral nature of Paleoindian sites in the southeastern Great Basin has given rise to the idea that Paleoindians may have been inclined to subsist off of the lake and marsh habitats provided by the ancient Pleistocene pluvial lakes that occupied a large portion of the Great Basin. Consequently, the sites are difficult to find as they have been buried by the ebb and flow of the pluvial lakes. This slightly later cultural material associated with the pluvial lake habitations is referred to as the Western Pluvial Lakes Tradition, or Lake Mojave culture. The archaeological assemblage associated with this cultural tradition is characterized by stemmed projectile points, leaf-shaped bifaces, scrapers, crescents, and in some cases groundstone tools for milling plant material. Often projectile points and tools were made from locally procured obsidian, sources of which are not far from the proposed Gold Point SEZ—Montezuma Range, 15 mi (24 km) north of the SEZ, Cave Spring, 35 mi (56 km) northwest of the SEZ, and Silver Peak, 50 mi (80 km) northwest of the SEZ (Fowler and Madsen 1986; NROSL 2009).

The Early Archaic Period in the region began with the recession of most of the pluvial lakes in the area, about 8,000 to 6,000 B.P., and extended until about 4,000 B.P. Archaic Period groups likely congregated around marsh areas that were still extant, but also utilized the vast caves in the mountains of the Great Basin. The settlement system in some areas was likely based around a central base camp, with temporary camps located on the margins of their territory to exploit resources that were not in the immediate vicinity of the base camp. Archaic groups would sometimes perform communal hunts, especially antelope drives, in which antelope were herded into a corral and then shot, and rabbit drives, in which large nets were used. Some of the key Archaic Period sites in the Great Basin region are Gatecliff Shelter and Toquima Cave, near Austin, Nevada, about 150 mi (241 km) north of the SEZ. The archaeological assemblage from the Early Archaic Period maintains some cultural continuity with the previous period, consisting of large notched Elko and Gatecliff points, leaf-shaped bifaces, scrapers, drills, graters, and manos and metates. A site with an Elko point was identified within a 5-mi (8-km) radius of the proposed Gold Point SEZ (Fowler and Madsen 1986; Neusius and Gross 2007; McGonagle and Waski 1978).

1 The Middle Archaic Period, 4,000 to 1,500 B.P., is the time of the climatic shift known as
2 the Little Pluvial, a wetter and cooler climate that caused some of the pluvial lakes to re-fill. The
3 cultural material of this time period is similar to that of the Early Archaic, with an increased
4 concentration of millingsstones, mortars, and pestles and the appearance of normally perishable
5 items that become well preserved in the arid Great Basin climate, such as wicker baskets, split-
6 twig figurines, duck decoys, and woven sandals (Beck and Jones 2008).
7

8 In the vicinity of the proposed Gold Point SEZ, the Late Archaic Period began about
9 1,500 B.P. and extended until about 800 B.P. Major technological shifts occurred during this
10 period, evidenced by smaller projectile points that were more useful because groups began
11 using bow-and-arrow technology instead of the atlatl and dart technology. There were also
12 changes in subsistence techniques, particularly in the use of horticulture. Around A.D. 1000
13 Numic-speaking groups migrated into the region; however, the exact timing of these events is
14 unclear and is a subject for further research in the region. These Numic-speaking people were
15 the antecedents of the Northern Paiute and Western Shoshone, and the archaeological
16 assemblage associated with this time period consists of Desert Series projectile points,
17 brown-ware ceramics, unshaped manos and millingsstones, incised stones, mortars, pestles, and
18 shell beads. Contemporary Native Americans dispute the separation of periods between the
19 Late Archaic and Numic periods, because they believe that they have been in the area since
20 time immemorial, and see themselves as descendants of all prehistoric people, not just of
21 Numic derivation. The following section describes the cultural history of the time period in
22 greater detail.
23
24

25 **11.6.17.1.2 Ethnohistory**

26

27 The proposed Gold Point SEZ is located in territory most often ascribed to the Western
28 Shoshone (Thomas et al. 1986), but is close to areas used jointly by the Western Shoshone and
29 the Owens Valley branch of the Northern Paiute. Both Shoshone and Paiute speakers lived
30 around modern Lida, 6 mi (10 km) northwest of the proposed SEZ, and Paiute families lived at
31 Pigeon Spring, 14 mi (23 km) west of the SEZ. The families based around Lida joined the Fish
32 Lake Valley Northern Paiute during the pine nut harvest near Pigeon Springs (Steward 1938).
33
34

35 **Western Shoshone**

36

37 The Western Shoshone are a group of ethnically similar Central Numic speakers
38 who traditionally occupied a swath of the central Great Basin stretching from Death Valley
39 in California through central Nevada and northwestern Utah to southeastern Idaho
40 (Thomas et al. 1986), lying primarily within the basin and range province of the Great Basin.
41 The Western Shoshone lived in small groups with rather fluid membership, usually identified
42 with the land on which they were based. Their subsistence base and lifestyle varied with the
43 resources within their traditional range. Groups often established stable base camps near reliable
44 water sources where they could grow crops. From these base camps, they would move seasonally
45 in a flexible round to exploit resources in the surrounding mountains and other areas as they
46 became available. They gathered a wide variety of plant resources, which they supplemented by

1 hunting and fishing (Stoffle et al. 1990; Crum 1994; Fowler 1986; Steward 1938). Pine nuts,
2 available in the mountains, were a storable staple. Pronghorn antelope, bighorn sheep, and mule
3 deer were among the large game animals they hunted, but smaller game, including rodents, birds,
4 and, where available, fish, provided more of the protein in their diet. Groups varied in size and
5 composition with the season. The largest groups gathered for the pine nut harvest, which could
6 include a rabbit or antelope drive as well. Winter villages were usually close to stores of pine
7 nuts.

8
9 The Timbisha Shoshone are the proposed SEZ's closest Western Shoshone neighbors.
10 Recognized as a Tribe by the Federal Government in 1983, they remained landless until 2000
11 when the Timbisha Shoshone Homeland Act granted them lands within Death Valley National
12 Park and four parcels outside the park, including 3,000 acres (12 km²) outside Lida, Nevada,
13 about 6 mi (10 km) northwest of the SEZ. Additional information on the Western Shoshone may
14 be found in Section 11.1.17.1.2.

15 16 17 **Owens Valley Paiute**

18
19 The Owens Valley Paiute inhabit the valley of the Owens River that parallels the eastern
20 slope of the Sierra Nevada. They speak Mono, a Western Numic language, and are linguistically
21 closely tied to the Northern Paiute (Liljeblad and Fowler 1986). A brief description of the Owens
22 Valley Paiute is given in Section 11.1.17.1.2.

23 24 25 **11.6.17.1.3 History**

26
27 The Great Basin was one of the last areas in the continental United States to be fully
28 explored. The harsh and rugged landscape deterred most European and American explorers until
29 the late eighteenth century. Several early explorers made their way into the southern portion of
30 Nevada by the late eighteenth century, but the area around the proposed Gold Point SEZ was not
31 explored by non-native people until about 1826. Fur trapping was a popular enterprise during
32 this time, and overzealous trappers were quickly depleting their supplies of furs as they moved
33 west in search of further materials. Peter Ogden of the Hudson's Bay Company and Jedidiah
34 Smith of the Rocky Mountain Fur Company were part of two different expeditions that entered
35 Nevada in 1827 and 1826, respectively. These men were seeking new beaver fields, Ogden took
36 a more northerly route through Elko, Pershing, and Humbolt Counties, and Smith entered
37 Nevada near Mesquite and traveled across the southern tip of Nevada into California. When he
38 entered California, Smith was detained by Mexican authorities, as he had entered Mexican
39 territory, and was ordered to go back the way from which he had come. However, he decided to
40 travel farther north into California, being the first non-native person to cross the Sierra Nevada
41 Mountains and entered Nevada just south of Lake Tahoe. From there he crossed the State of
42 Nevada and passed about 50 mi (80 km) north of the proposed Gold Point SEZ. Fur trapping
43 never became a lucrative enterprise in Nevada; however, these trailblazers paved the way for
44 later explorers and mappers, like John C. Frémont. Frémont, a member of the Topographical
45 Engineers, was commissioned to map and report on the Great Basin area in 1843 and 1844. The
46 results of his work gained wide circulation and were of great importance in understanding the

1 topography of the Great Basin, both for official use and by those moving westward to seek new
2 homes and fortunes. Frémont passed about 75 mi (121 km) north of the proposed Gold Point
3 SEZ, at the northern-most point of Esmeralda County, where it meets Mineral and Nye Counties.
4 Another fur trapping party, the Walker-Bonneville party, explored the region in 1833 to 1834.
5 This group also likely explored the lands north of the proposed Gold Point SEZ, on its way to
6 exploring large portions of the Yosemite Valley in California and the Great Basin (Elliott 1973).

7
8 Nevada and the Great Basin region have provided a corridor of travel for those seeking to
9 emigrate west. Several heavily traveled trails crossed the region, although none of these trails
10 passes particularly close to the proposed Gold Point SEZ. The Old Spanish Trail was an evolving
11 trail system generally established in the early nineteenth century, but tended to follow previously
12 established paths used by earlier explorers and Native Americans. The 2,700-mi (4,345-km)
13 network of trails passes through six states, beginning in Santa Fe, New Mexico, and ending in
14 Los Angeles, California. The closest portion of the congressionally designated Old Spanish
15 National Historic Trail is about 131 mi (211 km) south of the proposed Gold Point SEZ, as it
16 passes near Las Vegas, Nevada. Mormons also frequently used the Old Spanish Trail in
17 emigrating farther west to Nevada, Arizona, and California, and often the trail is referred to as
18 the Old Spanish Trail/Mormon Road. Other notable trails that crossed Nevada were the
19 California Trail, a trail that followed portions of the Oregon Trail and then broke off from that
20 trail and continued through the northern portion of Nevada along the Humbolt River, about
21 135 mi (217 km) north of the proposed Gold Point SEZ, until it reached California. The Pony
22 Express Trail, a mail route that connected Saint Joseph, Missouri, to Sacramento, California,
23 entered Nevada, just northeast of Ely, and exited just south of Lake Tahoe, the closest portion
24 being about 145 mi (233 km) north of the SEZ (von Till Warren 1980).

25
26 With the ratification of the Treaty of Guadalupe Hidalgo in 1848, closing out the
27 Mexican-American War, the area came under American control. In 1847, the first American
28 settlers arrived in the Great Basin, among them Mormon immigrants under the leadership of
29 Brigham Young, who settled in the Valley of the Great Salt Lake in Utah. They sought to bring
30 the entire Great Basin under their control, establishing an independent State of Deseret. From
31 its center in Salt Lake City, the church sent out colonizers to establish agricultural communities
32 in surrounding valleys and missions to acquire natural resources such as minerals and timber.
33 Relying on irrigation to support their farms, the Mormons often settled in the same places as
34 the Native Americans had centuries before. The result was a scattering of planned agricultural
35 communities from northern Arizona to southern Idaho, and parts of Wyoming, Nevada, and
36 southern California. One of the first Mormon settlements in Nevada was a trading post, located
37 just north of Genoa, Nevada, about 166 mi (267 km) northwest of the SEZ. Established in 1850,
38 this trading post provided supplies for those traversing the California Trail.

39
40 Nevada's nickname is the "Silver State," for the 1859 Comstock Lode strike in Virginia
41 City, about 179 mi (288 km) northwest of the proposed Gold Point SEZ. This was the first major
42 silver discovery in the United States, and with the news of the strike, hopeful prospectors flocked
43 to the area in an effort to capitalize on the possible wealth under the surface of the earth. The
44 discovery of the Comstock Lode led to the creation of Virginia City and other nearby towns that
45 served the population influx. The population increase was so dramatic that in 1850 there were
46 fewer than a dozen non-native people in the State of Nevada; by 1860 there were 6,857; and by

1 1875 an estimated 75,000 people had migrated to the state. The Comstock Lode strike is
2 important to the history of Nevada, not only because of the population growth and significant
3 amount of money that was consequently brought to the area, but also because of several
4 technological innovations that were created and employed in the mines, namely, the use of
5 square-set timbering. This technique kept loose soil from collapsing on miners, a concept that
6 eventually was employed around the world in other mines (Paher 1970).

7
8 Mining for valuable deposits occurred in all regions of the State of Nevada, including in
9 the vicinity of the proposed Gold Point SEZ. The closest mine to the SEZ was the Gold Point
10 mine, just 2 mi (3 km) south of the SEZ. The Gold Point mine, originally called the Lime Mine,
11 was mined for its lime deposits. About 1908 the mine adopted the name Hornsilver, as that
12 became the more lucrative mineral for which to mine. More than 225 wooden buildings covered
13 the town, but by 1915 mining had slowed. The mine was purchased by another investor in 1922,
14 and in 1930 when more gold was mined than silver, the town changed its name to Gold Point. By
15 1942 mining operations ceased, and most of the town was abandoned when workers for the war
16 effort were needed. Other mines and small towns popped up in the mountains surrounding the
17 SEZ at Gold Mountain, 9 mi (14 km) south of the SEZ, Tule Canyon, 9 mi (14 km) west of the
18 SEZ, Lida, 7 mi (11 km) northwest of the SEZ, and Oriental, 10 mi (16 km) south of the SEZ.
19 Goldfield, about 20 mi (32 km) northeast of the SEZ, was one of the single most prosperous gold
20 strikes in the west. Initially discovered in 1902, the mining stampede to the Goldfield area began
21 in 1904, with the most lucrative years 1906 and 1907 producing about \$15 million in gold ore
22 (Paher 1970). The Goldfield Historic District is listed in the NRHP.

23
24 Nevada's desert-mountain landscape has made it a prime region for use by the
25 U.S. military for several decades. Beginning in October 1940, President Franklin D. Roosevelt
26 established the Las Vegas Bombing and Gunnery Range, a 3.5-million acre (14,164 km²) parcel
27 of land northwest of Las Vegas, near Indian Springs, Nevada, 107 mi (172 km) southeast of the
28 SEZ. At the start of the Cold War in 1948, the range was renamed Nellis Air Force Base. For the
29 next 41 years testing of nuclear weapons, as well as regular Air Force training missions, occurred
30 throughout the regions of the NTS. The proposed Gold Point SEZ does not fall within the
31 specific boundaries of the NTS and Range; the closest portion of the military installation is about
32 20 mi (36 km) east. However, the Air Force Base and associated ranges have affected the overall
33 history and context of the region.

34 35 36 **11.6.17.1.4 Traditional Cultural Properties—Landscape**

37
38 The Native Americans whose historical homelands lie within the Great Basin have
39 traditionally tended to take a holistic view of the world. They tend to view the sacred and profane
40 as inextricably intertwined. Landscapes as a whole are often culturally important. Adverse
41 effects on one part damage the whole (Stoffle 2001). From their perspective, landscapes include
42 places of power. Among the most important such places are sources of water; peaks, mountains,
43 and elevated features; caves; distinctive rock formations; and panels of rock art. Places of power
44 are important to the religious beliefs of the Western Shoshone and Paiute. They may be sought
45 out for individual vision quests or healing. The view from such a point of power or the ability to
46 see from one important place to another can be an important element of its integrity (Stoffle and

1 Zedeño 2001b). Landscapes as a whole are often tied together by a network of culturally
2 important trails (Stoffle and Zedeño 2001a).

3
4 The proposed Gold Point SEZ is located in the Lida Valley between Mount Jackson, the
5 Jackson Ridge, Magruder Mountain, and Slate Ridge. Traditionally, Tribal camps in the area
6 were located near springs in the foothills or mountains. Those closest to the proposed SEZ were
7 clustered around Lida, in the area now included in the Timbisha Shoshone Reservation. Other
8 single-family camps with ties to the Lida group were located near springs in Tule Canyon, 10 mi
9 (16 km) southwest of the SEZ; Gold Mountain, 10 mi (16 km) south of the SEZ; Stonewall
10 Mountain, 16 mi (26 km) northeast; Montezuma Peak, 20 mi (33 km) north; and near Goldfield,
11 25 mi (40 km) northeast. Rockshelters near the mouth of Lida Canyon may have served as a
12 meeting place for these groups and retain cultural significance. These groups hunted game and
13 gathered plant resources in the surrounding hills. Plant or small game resources on the valley
14 floor would have been exploited in season as well. The Lida group managed the vegetation on
15 Magruder Mountain by selective burning to encourage the growth of preferred plants. They
16 traveled through Lida Valley to reach seasonally available resources on Stonewall Flat and in
17 Clayton Canyon near Gold Point (Steward 1938).

18
19 Mountain prominences are often culturally important landscape features and may be
20 places of power. Magruder Mountain is reported to have cultural significance for the Timbisha.
21 Project-specific investigations would need to establish cultural importance through consultation
22 with the relevant Native American Tribe(s). Mt. Grant, where the Northern Paiute believe their
23 ancestors emerged (Fowler et al. 1970), is 110 mi (177 km) northwest and is not likely to be
24 visible from the SEZ.

25 26 27 ***11.6.17.1.5 Cultural Surveys and Known Archaeological and Historical Resources***

28
29 In the proposed Gold Point SEZ, no surveys have been conducted, and consequently no
30 cultural resources have been identified. However, within 5 mi (8 km) of the SEZ, 18 surveys
31 have been conducted, resulting in the recording of 12 cultural resources. Nine of these sites are
32 prehistoric in nature, two are rockshelters, and seven are isolated flakes or lithic scatters. The
33 other three sites located within 5 mi (8 km) of the SEZ are historic resources (de Dufour 2009).
34 One of these sites is a mill site, and another is the Gold Point mining camp and associated
35 buildings, which has been determined to be eligible for listing in the NRHP. The other historic
36 site is an historic Native American meeting place and medicine making area, referred to as
37 “medicine rock.” Historic mining debris was also documented at the site.

38
39 The proposed Gold Point SEZ has potential to yield significant cultural resources,
40 especially those related to historical mining operations that took place in the vicinity of the
41 SEZ. Prehistoric resources are not as likely to be encountered in the vicinity of the SEZ.

42
43 The BLM has also designated several locations within 50 mi (80 km) of the proposed
44 Gold Point SEZ as cultural resources that should be managed for conservation (BLM 1997);
45 these areas include significant petroglyph sites.

National Register of Historic Places

There are no historic properties listed in the NRHP in the SEZ or within 5 mi (8 km) of the SEZ. However, the Gold Point town site, 2 mi (3 km) south of the proposed Gold Point SEZ, has been determined to be eligible for listing in the NRHP. The rockshelters mentioned above, if grouped as a district with several other nearby sites, could be considered eligible for listing in the NRHP as well.

The county of Esmeralda maintains only one property in the NRHP, the Goldfield Historic District, about 21 mi (34 km) northeast of the proposed Gold Point SEZ. The only other NRHP property in the vicinity of the SEZ is the Death Valley Scotty Historic District, 25 mi (40 km) south of the SEZ in Inyo County, California.

11.6.17.2 Impacts

Direct impacts on significant cultural resources could occur in the proposed Gold Point SEZ; however, further investigation is needed, because no cultural resource surveys have been conducted within the boundaries of the SEZ. The area around the proposed Gold Point SEZ has the potential to provide significant resources related to historic mining operations. A cultural resource survey of the entire APE, including consultation with Native American Tribes, would first need to be conducted to identify archaeological sites, historic structures and features, and traditional cultural properties, and an evaluation would need to follow to determine whether any are eligible for listing in the NRHP as historic properties. Section 5.15 discusses the types of effects that could occur on any significant cultural resources found within the proposed Gold Point SEZ. Impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2. Programmatic design features assume that the necessary surveys, evaluations, and consultations will occur. No traditional properties have been identified to date within the vicinity of the SEZ.

Indirect impacts on cultural resources that result from erosion outside of the SEZ boundary (including along ROWs) are unlikely, assuming programmatic design features to reduce water runoff and sedimentation are implemented (as described in Appendix A, Section A.2.2).

The Gold Point town site is in view of the SEZ. Depending on the full range of reasons for its eligibility for listing in the NRHP, visual impacts on this property are likely as a result of solar energy development in the valley below.

The nearest transmission line is about 22 mi (35 km) northeast of the proposed Gold Point SEZ, and the construction of a new transmission line to connect to this one would result in the disturbance of 667 acres (2.7 km²). Four sites that are potentially eligible for inclusion in the NRHP and three additional sites that have not been evaluated for NRHP inclusion could potentially be affected either directly or indirectly, depending on the exact location of the line. One site is a multicomponent site consisting of multiple prehistoric lithic scatters, a circular rock alignment, petroglyphs, historic shelters/lean-tos, and associated historic debris; another site is an

1 historic and modern dump associated with the town of Goldfield that could possibly be affected
2 with construction of the transmission line. A prehistoric campsite could also be affected by this
3 transmission line. Another site is a potentially eligible multicomponent site, made up of
4 petroglyphs, a lithic scatter, and an historic coyote trap. Visual impacts on the Goldfield Historic
5 District are also possible. Indirect impacts, such as vandalism or theft, could occur if significant
6 resources are close to the transmission ROW. The nearest access road is NV 774, and it runs
7 adjacent to the SEZ, so no further construction for access is anticipated assuming this road would
8 be used. Programmatic design features assume that the necessary surveys, evaluations, and
9 consultations for the ROWs will occur, as with the project footprint within the SEZ. Impacts on
10 cultural resources related to the creation of new corridors not assessed in this PEIS would be
11 evaluated at the project-specific level if new road or transmission construction or line upgrades
12 are to occur.
13
14

15 **11.6.17.3 SEZ-Specific Design Features and Design Feature Effectiveness**

16

17 Programmatic design features to mitigate adverse effects on significant cultural
18 resources, such as avoidance of significant sites and features, are provided in Appendix A,
19 Section A.2.2.
20

21 SEZ-specific design features would be determined in consultation with the Nevada SHPO
22 and affected Tribes and would depend on the results of future investigations. SEZ-specific design
23 features could include:
24

- 25 • Implementation of design features to address visual impacts discussed in
26 Section 11.6.14 and in the programmatic design features listed in Appendix A,
27 Section A.2.2, would help to mitigate visual impacts on the Gold Point town
28 site from development in the SEZ and on the Goldfield Historic District as a
29 result of transmission line construction.
30
31

11.6.18 Native American Concerns

Native Americans share many environmental and socioeconomic concerns with other ethnic groups. This section focuses on concerns specific to Native Americans and to which Native Americans bring a distinct perspective. For a discussion of issues of possible Native American concern shared with the population as a whole, several sections in this PEIS should be consulted. General topics of concern are addressed in Section 4.16. Specifically for the proposed Gold Point SEZ, Section 11.6.17 discusses archaeological sites, historic structures, landscapes, and traditional cultural properties; Section 11.6.8 discusses mineral resources; Section 11.6.9.1.3 discusses water rights and water use; Section 11.6.10 discusses plant species; Section 11.6.11 discusses wildlife species, including wildlife migration patterns; Section 11.6.13 discusses air quality; Section 11.6.14 discusses visual resources; Sections 11.6.19 and 11.6.20 discuss socioeconomics and environmental justice, respectively; and issues of human health and safety are discussed in Section 5.21.

11.6.18.1 Affected Environment

The proposed Gold Point SEZ falls within the Tribal traditional use area generally attributed to the Western Shoshone (Liljeblad and Fowler 1986) and is within the area recognized as traditionally belonging to the Western Shoshone by the Indian Claims Commission (Clemmer and Stewart 1986). Lying near the northwestern edge of Western Shoshone territory, the SEZ was also accessible to the Owens Valley branch of the Northern Paiutes, who were neighbors of and on friendly terms with the Western Shoshone (Steward 1938). All federally recognized Tribes with Western Shoshone or Owens Valley Paiute roots have been contacted and provided an opportunity to comment or consult regarding this PEIS. They are listed in Table 11.6.18.1-1. Details of government-to-government consultation efforts are presented in Chapter 14; a list of all federally recognized Tribes contacted for this PEIS is given in Appendix K.

11.6.18.1.1 Territorial Boundaries

Western Shoshone

The Western Shoshone traditionally occupied a swath of the central Great Basin stretching from Death Valley in California through central Nevada and northwestern Utah to southeastern Idaho (Thomas et al. 1986). The proposed Gold Point SEZ lies near the northwestern periphery of the Shoshone traditional range, where Shoshone territory blends into Owens Valley Paiute territory. The closest Western Shoshone reservation is that of the Timbisha Shoshone. The Timbisha Shoshone Homeland Act of 2000 provided the Timbisha with a discontinuous reservation that includes parcels of land at Furnace Creek in Death Valley National Park; Death Valley Junction, California; Centennial, California; Scotty's Junction, Nevada; and Lida, Nevada. The parcel near Lida is only 6 mi (10 km) northwest of the proposed Gold Point SEZ.

TABLE 11.6.18.1-1 Federally Recognized Tribes with Traditional Ties to the Proposed Gold Point SEZ

Tribe	Location	State
Benton Paiute-Shoshone Tribe	Benton	California
Big Pine Paiute Tribe	Big Pine	California
Bishop Paiute Tribe	Bishop	California
Bridgeport Indian Colony	Bridgeport	California
Duck Valley Shoshone-Paiute Tribes	Owyhee	Nevada
Duckwater Shoshone Tribe	Duckwater	Nevada
Ely Shoshone Tribe	Ely	Nevada
Lone Pine Paiute-Shoshone Tribe	Lone Pine	California
Reno-Sparks Indian Colony	Reno	Nevada
Te-Moak Tribe of Western Shoshone	Elko	Nevada
Timbisha Shoshone Tribe	Death Valley	California
Yomba Shoshone Tribe	Austin	Nevada

Owens Valley Paiutes

The Owens Valley Paiutes occupy five relatively small reservations within Owens Valley in Inyo and Mono Counties, California, west of the proposed SEZ. Their traditional use area ranged from the headwaters of the Owens River near Benton, California, southward to Owens Lake. They shared the shores of Owens Lake with Western Shoshone groups. The Indian Claims Commission placed Owens Valley within the traditional territory of the Northern Paiutes, with whom the Owens Valley Tribes are linked linguistically (Liljeblad and Fowler 1986; Clemmer and Stewart 1986; Royster 2008).

11.6.18.1.2 Plant Resources

Native Americans continue to make use of a wide range of indigenous plants for food, medicine, construction materials, and other uses. Although the proposed SEZ is sparsely vegetated, some species traditionally used by Native Americans have been observed or are possible in the proposed SEZ. The vegetation present at the proposed Gold Point SEZ is described in Section 11.6.10. In general, the vegetation consists of widely spaced low shrubs. The vegetation cover types present at the SEZ are all part of the Inter-mountain Basin series. Mixed Salt Desert Scrub dominates, but there are substantial areas of Greasewood Flat, smaller amounts of Playa, and a sprinkling of Semi-desert Shrub Steppe. The proposed transmission line corridor would extend from the proposed SEZ to Goldfield, crossing the Mount Jackson Ridge and following the line of the Goldfield Hills. At these somewhat higher elevations with rolling hills, Big Sagebrush Shrubland and Xeric Mixed Sagebrush Shrubland would be encountered. Plant species in these cover types have much in common with those found in the SEZ. They would include a wider variety of sagebrush, seed-bearing grasses, and possibly juniper trees (USGS 2005b). As shown in Table 11.6.18.1-2, there are some plants found in the SEZ and along the transmission corridor that have been traditionally used by Native Americans for food

TABLE 11.6.18.1-2 Plant Species Important to Native Americans Observed or Likely To Be Present in the Proposed Gold Point SEZ

Common Name	Scientific Name	Status
Food		
Basin wildrye	<i>Leymus cineris</i>	Possible
Beavertail prickly pear	<i>Opuntia basilaris</i>	Observed
Buckwheat	<i>Eriognum</i> spp.	Observed
Dropseed	<i>Sporobolus airoides</i>	Possible
Galleta	<i>Pleuraphis jamesii</i>	Possible
Joshua tree	<i>Yucca brevifolia</i>	Observed
Nevada bluegrass	<i>Poa Secunda</i>	Possible
Sagebrush	<i>Artemisia</i> spp.	Possible
Saltbush	<i>Atriplex</i> spp.	Observed
Spikerush	<i>Eleocharis palustris</i>	Possible
Wheatgrass	<i>Elymus lanceolatus</i>	Possible
Wolfberry	<i>Lycium andersonii</i>	Possible
Medicine		
Mormon tea	<i>Ephedra nevadensis</i>	Possible
Saltbush	<i>Atriplex</i> spp.	Observed

Sources: Field visit; USGS (2005b); Steward (1938); Fowler (1986).

and medicine (Steward 1938; Fowler 1986). However, project-specific analyses will be needed to determine their presence at any proposed development site. The importance of any stand to Native Americans must be determined in consultation with the affected Tribe(s). For this proposed SEZ, the Timbisha are likely to be the most directly affected. Magruder Mountain, on the western end of the valley, has traditionally been an important place for gathering plant resources. Western Shoshone families living in the Lida area would burn the brush on its slopes to create a better environment for preferred food plants including wheatgrass (Steward 1938).

11.6.18.1.3 Other Resources

Water is an essential prerequisite for life in the arid areas of the Great Basin. As a result, it is a keystone of many desert cultures' religions. Desert cultures tend to consider all water sacred and a purifying agent. Water sources are often associated with rock art. Springs are often associated with powerful beings, and hot springs in particular figure prominently in Owens Valley Paiute creation stories. Water sources are seen as connected; damage to one source damages all (Stoffle and Zedeño 2001a). Tribes are also sensitive about the use of scarce local water supplies for the benefit of distant communities and recommend that determination of adequate water supplies be a primary consideration as to whether a site is suitable for the development of a utility-scale solar energy facility (Moose 2009).

Wildlife likely to be found in the proposed Gold Point SEZ is described in Section 11.6.11. Species traditionally hunted by local Native Americans whose range includes the SEZ are listed in Table 11.6.18.1-3. Most of these are small animals and birds common throughout much of the great basin. Traditionally important large game animals include mule deer (*Odocoileus hemionus*), bighorn sheep (*Ovis canadensis*), and pronghorn (*Antilocapra americana*) (Steward 1938). Pronghorn are possible, but not common, in Lida Valley. Bighorn sheep mostly occur farther north (BLM 1994). The proposed SEZ and transmission corridor are within the range of mule deer.

11.6.18.2 Impacts

In the past, the Western Shoshone and Owens Valley Paiutes have expressed concern over project impacts on a variety of resources. They tend to take a holistic view of their

TABLE 11.6.18.1-3 Animal Species used by Native Americans as Food Whose Range Includes the Proposed Gold Point SEZ

1 traditional homelands. For them, cultural and natural features are inextricably bound together.
2 Western distinctions between the sacred and the secular have no meaning in their traditional
3 worldview. Impacts on one part are seen as having ripple effects on the whole (Stoffle and
4 Zedeño 2001b). While no comments specific to the proposed Gold Point SEZ have been received
5 from Native American Tribes to date, the Big Pine Paiute Tribe of the Owens Valley has
6 commented on the scope of the PEIS. The Tribe recommends that the BLM preserve undisturbed
7 lands intact and that recently disturbed lands, such as abandoned farm fields, rail yards, mines,
8 and airfields, be given primary consideration for solar energy development (Moose 2009).

9
10 Potential impacts on existing water supplies are also a primary concern (Moose 2009).
11 There are springs located throughout the hills that surround Lida Valley. Excessive drawdown
12 of groundwater for the construction and operation of solar energy facilities could reduce or
13 eliminate the flow from these culturally important resources.

14
15 During energy development projects in adjacent areas, other Great Basin Tribes have
16 expressed concern over adverse effects on a wide range of resources. Among these are
17 geophysical features and physical cultural remains. Known resources of this type in the area of
18 the proposed Gold Point SEZ are discussed in Section 11.6.17.1.4. Such places are often seen as
19 important because they are thought to be places of power. They are often the location of or have
20 ready access to a variety of plant, animal, and mineral resources (Stoffle et al. 1997). Resources
21 that Native Americans have identified as important include food plants, medicinal plants, plants
22 used in basketry, and plants used in construction; game animals and birds; and sources of clay,
23 salt, and pigments (Stoffle and Dobyns 1983). Those likely to be found within the proposed
24 Gold Point SEZ are discussed in Section 11.6.18.1.

25
26 In the past, the mountains and hills surrounding the Lida Valley have been the sites of
27 Western Shoshone camps and villages (Steward 1938; Thomas et al. 1986). The valley floor
28 where the SEZ would be located appears to have been a travel corridor, not a habitation area.
29 The valley floor is sparsely vegetated; however, food plants traditionally used by the Shoshone
30 have been observed there. It is likely that the Shoshone in the surrounding hills made seasonal
31 use of the flora on the valley floor. An early ethnography reported great quantities of wolfberries
32 (*Lycium* sp.) growing near Gold Point were gathered by local Tribal groups (Steward 1938).

33
34 The construction of solar energy facilities in the proposed SEZ will result in the
35 elimination of some plants traditionally used by Native Americans. Consultation with affected
36 Tribes will be necessary to determine whether or not traditional plant resources are present in
37 significant amounts at a proposed project site. Lida Valley is also within the range of a number
38 of traditional Native American game species. Construction of solar facilities will eliminate some
39 habitat for these species. For the most part, these species are common throughout the area (see
40 Section 11.6.11). Project-specific consultation with Western Shoshone and Northern Paiute
41 Tribes will be required to determine whether the resources present at the proposed SEZ are
42 significant.

43
44 As consultation with the Tribes continues and project-specific analyses are undertaken, it
45 is possible that Native Americans will express concern over potential visual, acoustic, and other

1 effects of solar energy development within the SEZ on specific resources, including culturally
2 important landscapes.

3
4 Implementation of programmatic design features, as discussed in Appendix A, Section
5 A.2.2, should eliminate impacts on tribes' reserved water rights and the potential for
6 groundwater contamination issues.
7

8 9 **11.6.18.3 SEZ-Specific Design Features and Design Feature Effectiveness**

10
11 Programmatic design features that would address impacts of potential concern to Native
12 Americans, such as avoidance of sacred sites, water sources, and tribally important plant and
13 animal species are provided in Appendix A, Section A.2.2. Mitigation of impacts on
14 archaeological sites and traditional cultural properties is discussed in Section 11.6.17.3, in
15 addition to the programmatic design features for historic properties presented in Appendix A,
16 Section A.2.2.
17

18 The need for and nature of SEZ-specific design features addressing issues of potential
19 concern would be determined during government-to-government consultation with affected
20 Tribes listed in Table 11.6.18.1-1.
21
22

11.6.19 Socioeconomics

11.6.19.1 Affected Environment

This section describes current socioeconomic conditions and local community services within the ROI surrounding the proposed Gold Point SEZ. The ROI is a two-county area comprising Esmeralda and Nye Counties in Nevada. It encompasses the area in which workers are expected to spend most of their salaries and in which a portion of site purchases and nonpayroll expenditures from the construction, operation, and decommissioning phases of the proposed SEZ facility are expected to take place.

11.6.19.1.1 ROI Employment

In 2008, employment in the ROI stood at 16,484 (Table 11.6.19.1-1). Over the period 1999 to 2008, the annual average employment growth rate was 0.5% in Nye County and -2.7% in Esmeralda County. At 0.4%, the growth rate in the ROI as a whole was lower than the average rate for the entire state (2.7%).

In the ROI in 2006, the services sector provided the highest percentage of employment at 47.6%, followed by wholesale and retail trade at 19.3%, with a smaller employment shares held by construction (10.2%) and mining (8.3%) (Table 11.6.19.1-2).

11.6.19.1.2 ROI Unemployment

The average unemployment rate in Nye County over the period 1999 to 2008 was 6.9%, higher than the 6.1% rate for Esmeralda County (Table 11.6.19.1-3). The average rate in the

Nye County	6.9	9.7	14.3
ROI	6.9	9.6	14.2
Nevada	5.0	6.7	11.0

^a Rates for 2009 are the average for January through November.

Sources: U.S. Department of Labor (2009a–c).

ROI as a whole over this period was 6.9%, higher than the average rate for Nevada (5.0%). Unemployment rates for the first 11 months of 2009 contrast with rates for 2008 as a whole; in Nye County, the unemployment rate increased to 14.3%, and in Esmeralda County to 8.4%. The average rates for the ROI (14.2%) and for Nevada as a whole (11.0%) were also higher during this period than the corresponding average rates for 2008.

11.6.19.1.3 ROI Urban Population and Income

There are no incorporated places in the ROI and, consequently, no urban population or income.

11.6.19.1.4 ROI Population

Table 11.6.19.1-4 presents recent and projected populations in the ROI and for the state as a whole. Population in the ROI stood at 44,839 in 2008, having grown at an average annual rate of 3.7% since 2000. Growth rates for the ROI were higher than those for the entire state (3.4%) over the same period. Only one of the two counties in the ROI experienced growth in population between 2000 and 2008; population in Nye County grew at an annual rate of 3.9%, while in Esmeralda County population fell at –4.6%. The ROI population is expected to increase to 78,122 by 2021 and to 80,872 by 2023.

11.6.19.1.5 ROI Income

Total personal income in the ROI stood at \$1.4 billion in 2007 and has grown at an annual average rate of 4.7% over the period 1998 to 2007 (Table 11.6.19.1-5). Per-capita income

TABLE 11.6.19.1-4 ROI Population for the Proposed Gold Point SEZ

Nevada			
Total income (\$ billion 2008)	68.9	105.3	4.3
Per-capita income (\$)	37,188	41,022	1.0

Sources: U.S. Department of Commerce (2009); U.S. Bureau of the Census (2009d,e).

1 also rose over the same period at a rate of 1.1%, increasing from \$28,788 to \$31,983. Per-capita
2 incomes were higher in Esmeralda County (\$41,370) than in Nye County (\$31,836) in 2007.
3 Growth rates in total personal income have been higher in Nye County than in Esmeralda
4 County. Personal income growth rates in the ROI (4.7%) were higher than the rate for Nevada
5 (4.3%), while per-capita income growth rates in the two counties were slightly lower (Esmeralda
6 County) or much lower (Nye County) than in Nevada as a whole (1.0%).
7

8 Median household income in 2006 to 2008 varied from \$42,275 in Nye County
9 to \$42,749 in Esmeralda County (U.S. Bureau of the Census 2009c).
10
11

12 ***11.6.19.1.6 ROI Housing***

13

14 In 2007, more than 17,400 housing units were located in the two ROI counties, with
15 about 95% of these located in Nye County (Table 11.6.19.1-6). Owner-occupied units account
16 for about 72% of the occupied units in the two counties, with rental housing making up 28% of
17 the total. Vacancy rates in 2007 were 45.4% in Esmeralda County and 19.3% in Nye County;
18 with an overall vacancy rate of 20.6%. In 2007, 3,591 housing units in the ROI were vacant, of
19 which 1,014 are estimated to be rental units that would be available to construction workers.
20 There were 641 units in seasonal, recreational, or occasional use in the ROI at the time of the
21 2000 Census, with 9.5% of housing units in Esmeralda County and 3.5% in Nye County used for
22 seasonal or recreational purposes.
23

24 Housing stock in the ROI as a whole grew at an annual rate of 0.6% over the period
25 2000 to 2007, with 682 new units added (Table 11.6.19.1-6).
26

27 The median value of owner-occupied housing in 2006 to 2008 varied from \$75,600 in
28 Esmeralda County to \$122,100 in Nye County (U.S. Bureau of the Census 2009f).
29
30

31 ***11.6.19.1.7 ROI Local Government Organizations***

32

33 The various local, county, and Tribal government organizations in the ROI are listed in
34 Table 11.6.19.1-7. Although there are no Tribal government located in the ROI, members
35 of other Tribal groups whose Tribal governments are located in adjacent counties or states reside
36 in the ROI.
37
38

39 ***11.6.19.1.8 ROI Community and Social Services***

40

41 This section describes educational, health-care, law enforcement, and firefighting
42 resources in the ROI.
43
44

45 ***Schools***

46

47 In 2007, the two-county ROI had a total of 28 public and private elementary, middle, and
48 high schools (NCES 2009). Table 11.6.19.1-8 provides summary statistics for enrollment and

educational staffing and two indices of educational quality—student-teacher ratios and levels of service (number of teachers per 1,000 population). The student-teacher ratio in Nye County schools (16.2) is higher than that in Esmeralda County schools (9.6), while the level of service is higher in Esmeralda County (11.6) than elsewhere in the ROI, where there are fewer teachers per 1,000 population.

Health Care

The total number of physicians in Nye County is 41, while the number of physicians per 1,000 population is 0.9. No data are available for Esmeralda County (Table 11.6.19.1-9).

Public Safety

Several state, county, and local police departments provide law enforcement in the ROI (Table 11.6.19.1-10). Esmeralda County has 10 officers and would provide law enforcement

TABLE 11.6.19.1-9 Physicians in the Proposed Gold Point SEZ ROI, 2007

services to the SEZ; there are 104 officers in Nye County. Levels of service of police protection are 14.5 officers per 1,000 population in Esmeralda County and 2.4 in Nye County. Currently, there are 114 professional firefighters in the ROI (Table 11.6.19.1-10).

11.6.19.1.9 ROI Social Structure and Social Change

Community social structures and other forms of social organization within the ROI are related to various factors, including historical development, major economic activities and sources of employment, income levels, race and ethnicity, and forms of local political organization. Although an analysis of the character of community social structures is beyond the scope of the current programmatic analysis, project-level NEPA analyses would include a description of ROI social structures, contributing factors, their uniqueness, and consequently, the susceptibility of local communities to various forms of social disruption and social change.

Various energy development studies have suggested that once the annual growth in population in smaller rural communities is between 5 and 15%, alcoholism, depression, suicide, social conflict, divorce, and delinquency would increase and levels of community satisfaction would deteriorate (BLM 1980, 1983, 1996). Data on violent crime and property crime rates and on alcoholism and illicit drug use, mental health, and divorce, which might be used as indicators of social change, are presented in Tables 11.6.19.1-11 and 11.6.19.1-12, respectively.

Some variation in the level of crime exists across the ROI, with a higher rate of violent crime in Esmeralda County (4.5 crimes per 1,000 population) than in Nye County (2.8) (Table 11.6.19.1-11). Property-related crime rates are higher in Nye County (20.2) than in Esmeralda County (15.1); overall crime rates in Nye County (23.0) were higher than in Esmeralda County (19.6).

TABLE 11.6.19.1-11 County and ROI Crime Rates for the Proposed Gold Point SEZ^a

Location	Violent Crime ^b		Property Crime ^c		All Crime	
	Offenses	Rate	Offenses	Rate	Offenses	Rate
Esmeralda County	3	4.5	10	15.1	13	19.6
Nye County	124	2.8	892	20.2	1,016	23.0
ROI	127	2.8	902	20.1	1,029	22.9

^a Rates are the number of crimes per 1,000 population.

^b Violent crime includes murder and non-negligent manslaughter, forcible rape, robbery, and aggravated assault.

^c Property crime includes burglary, larceny, theft, motor vehicle theft, and arson.

Sources: U.S. Department of Justice (2009a,b).

TABLE 11.6.19.1-12 Alcoholism, Drug Use, Mental Health, and Divorce in the Proposed Gold Point SEZ ROI^a

Geographic Area	Alcoholism ^a	Illicit Drug Use ^a	Mental Health ^b	Divorce ^c
Nevada Rural (includes Esmeralda County and Nye County)	8.0	2.7	9.5	NA ^d
Nevada				6.5

^a Data for alcoholism and drug use represent percentage of the population over 12 years of age with dependence or abuse of alcohol, illicit drugs. Data are averages for 2004 to 2006.

^b Data for mental health represent percentage of the population over 18 years of age suffering from serious psychological distress. Data are averages for 2002 to 2004.

^c Divorce rates are the number of divorces per 1,000 population. Data are for 2007.

^d NA = data not available.

Sources: SAMHSA (2009); CDC (2009).

Data on other measures of social change—alcoholism, illicit drug use, and mental health—are not available at the county level and thus are presented for the SAMHSA region in which the ROI is located (Table 11.6.19.1-12).

11.6.19.1.10 ROI Recreation

Various areas in the vicinity of the proposed Gold Point Mountain SEZ are used for recreational purposes, with natural, ecological, and cultural resources in the ROI attracting visitors for a range of activities, including hunting, fishing, boating, canoeing, wildlife watching, camping, hiking, horseback riding, mountain climbing, and sightseeing. These activities are discussed in Section 11.6.5.

Because information the number of visitors using state and federal lands for recreational activities is not available from the various administering agencies, the value of recreational resources in these areas, based solely on the number of recorded visitors, is likely to be an underestimation. In addition to visitation rates, the economic valuation of certain natural resources can also be assessed in terms of the potential recreational destination for current and future users, that is, their nonmarket value (see Section 5.17.1.1.1).

Another method of assessing recreational use is to estimate the economic impact of the various recreational activities supported by natural resources on public land in the vicinity of the proposed solar development, by identifying sectors in the economy in which expenditures on recreational activities occur. Not all activities in these sectors are directly related to recreation on state and federal lands, with some activity occurring on private land (e.g., dude ranches, golf courses, bowling alleys, and movie theaters). Expenditures associated with recreational activities formed an important part of the economy of the ROI. In 2007, 1,617 people were employed in the ROI in the various sectors identified as recreation-related, constituting 9.5% of total ROI employment (Table 11.6.19.1-13). Recreation spending also produced more than \$35.4 million in

TABLE 11.6.19.1-13 Recreation Sector Activity in the Proposed Gold Point SEZ ROI, 2007

ROI	Employment	Income (\$ million)
Amusement and recreation services	105	3.8
Automotive rental	13	0.4
Eating and drinking places	814	14.7
Hotels and lodging places	565	13.9
Museums and historic sites,	0	0.0
Recreational vehicle parks and campsites	54	1.5
Scenic tours	37	1.0
Sporting goods retailers	29	0.3
Total ROI	1,617	35.4

Source: MIG, Inc. (2010).

1 income in the ROI in 2007. The primary sources of recreation-related employment were hotels
2 and lodging places and eating and drinking places.

3 4 5 **11.6.19.2 Impacts** 6

7 The following analysis begins with a description of the common impacts of solar
8 development, including common impacts on recreation, social change, and livestock grazing.
9 These impacts would occur regardless of the solar technology developed in the SEZ. The
10 impacts of projects employing various solar energy technologies are analyzed in detail in
11 subsequent sections.

12 13 14 **11.6.19.2.1 Common Impacts** 15

16 Construction and operation of a solar energy facility at the proposed SEZ would produce
17 direct and indirect economic impacts. Direct impacts would occur as a result of expenditures on
18 wages and salaries and on procurement of goods and services required for project construction
19 and operation, and the collection of state sales and income taxes. Indirect impacts would occur as
20 project wages and salaries, procurement expenditures, and tax revenues subsequently circulated
21 through the economy of the state, thereby creating additional employment, income, and tax
22 revenues. Facility construction and operation would also require in-migration of workers and
23 their families into the ROI surrounding the site, which would affect population, rental housing,
24 health service employment, and public safety employment. Socioeconomic impacts common to
25 all utility-scale solar energy facilities are discussed in detail in Section 5.17. These impacts will
26 be minimized through the implementation of programmatic design features described in
27 Appendix A, Section A.2.2.

28 29 30 **Recreation Impacts** 31

32 Estimating the impact of solar facilities on recreation is problematic, because it is not
33 clear how solar development in the SEZ would affect recreational visitation and nonmarket
34 values (i.e., the value of recreational resources for potential or future visits; see
35 Section 5.17.1.2.3). While it is clear that some land in the ROI would no longer be accessible
36 for recreation, the majority of popular recreational locations would be precluded from solar
37 development. It is also possible that solar development in the ROI would be visible from popular
38 recreation locations, and that construction workers residing temporarily in the ROI would occupy
39 accommodations otherwise used for recreational visits, thus reducing visitation and consequently
40 affecting the economy of the ROI.

41 42 43 **Social Change** 44

45 Although an extensive literature in sociology documents the most significant components
46 of social change in energy boomtowns, the nature and magnitude of the social impact of energy

1 development in small rural communities are still unclear (see Section 5.17.1.1.4). While some
2 degree of social disruption is likely to accompany large-scale in-migration during the boom
3 phase, insufficient evidence exists to predict the extent to which specific communities are likely
4 to be affected, which population groups within each community are likely to be most affected,
5 and the extent to which social disruption is likely to persist beyond the end of the boom period
6 (Smith et al. 2001). Accordingly, because of the lack of adequate social baseline data, it has been
7 suggested that social disruption is likely to occur once an arbitrary population growth rate
8 associated with solar energy projects has been reached, with an annual rate of between 5 and
9 10% growth in population assumed to result in a breakdown in social structures, with a
10 consequent increase in alcoholism, depression, suicide, social conflict, divorce, and delinquency
11 and deterioration in levels of community satisfaction (BLM 1980, 1983, 1996).

12
13 In overall terms, the in-migration of workers and their families into the ROI would
14 represent an increase of 2.3% in regional population during construction of the trough
15 technology, with smaller increases for the power tower, dish engine, and PV technologies, and
16 during the operation of each technology. While it is possible that some construction and
17 operations workers will choose to locate in communities closer to the SEZ, the lack of available
18 housing in smaller rural communities in the ROI to accommodate all in-migrating workers and
19 families and insufficient range of housing choices to suit all solar occupations, many workers are
20 likely to commute to the SEZ from larger communities elsewhere in the ROI, thereby reducing
21 the potential impact of solar development on social change. Regardless of the pace of population
22 growth associated with the commercial development of solar resources and the likely residential
23 location of in-migrating workers and families in communities some distance from the SEZ itself,
24 the number of new residents from outside the ROI is likely to lead to some demographic and
25 social change in small rural communities in the ROI. Communities hosting solar development
26 are likely to be required to adapt to a different quality of life, with a transition away from a more
27 traditional lifestyle involving ranching and taking place in small, isolated, close-knit,
28 homogenous communities with a strong orientation toward personal and family relationships,
29 toward a more urban lifestyle, with increasing cultural and ethnic diversity and increasing
30 dependence on formal social relationships within the community.

31 32 33 **Livestock Grazing Impacts**

34
35 Cattle ranching and farming supported 80 jobs and \$1.7 million in income in the ROI in
36 2007 (MIG, Inc. 2010). The construction and operation of solar facilities in the SEZ could result
37 in a decline in the amount of land available for livestock grazing. However, because the amount
38 of acreage that would be used in the proposed SEZ would be small compared to the overall size
39 of locally affected land allotments, acreage loss would not have a significant impact on overall
40 grazing operations, with livestock management changes or the provision of additional livestock
41 management facilities, meaning that no loss of AUMs is anticipated.

Transmission Line Impacts

The impacts of transmission line construction could include the addition of 79 jobs in the ROI (including direct and indirect impacts) in the peak year of construction (Table 11.6.19.2-1). Construction activities in the peak year would constitute less than 0.1% of total ROI employment. A transmission line would also produce \$3.7 million in income. Direct sales taxes would be \$0.1 million.

Given the likelihood of local worker availability in the required occupational categories, construction of a transmission line would mean that some in-migration of workers and their families from outside the ROI would be required, with 116 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) would mean that the impact of solar facility construction on the number of vacant rental housing units is not expected to be large, with 58 rental units expected to be occupied in

**TABLE 11.6.19.2-1 Proposed Gold Point SEZ ROI
Socioeconomic Impacts of Transmission Line Facilities^a**

Parameter	Construction	Operations
Employment (no.)		
Direct	46	<1
Total	79	<1
Income (\$ million 2008)		
Total	3.7	<0.1
Direct state taxes (\$ million 2008)		
Sales	0.1	<0.1
In-migrants (no.)	116	0
Vacant housing ^b (no.)	58	0
Local community service employment (no.)		
Teachers	1	0
Physicians	0	0
Public safety	1	0

^a Construction impacts assume 22 mi [35 km] of transmission line is required to connect SEZ solar facilities to the grid. Construction impacts were assessed for a single representative year, 2021.

^b Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

1 the ROI. This occupancy rate would represent less than 0.1% of the vacant rental units expected
2 to be available in the ROI.

3
4 In addition to the potential impact on housing markets, in-migration would affect
5 community service employment (education, health, and public safety). Accordingly, one new
6 teacher and one new public safety employee would be required in order to meet existing levels of
7 service in the ROI.

8
9 Total operations employment impacts on the ROI (including direct and indirect impacts)
10 of a transmission line would be less than 1 job (Table 11.6.19.2-2) and would also produce less
11 than \$0.1 million in income. Direct sales taxes would be less than \$0.1 million. Operation of a
12 transmission line would not require the in-migration of workers and their families from outside
13 the ROI; consequently, no impacts on housing markets in the ROI would be expected, and no
14 new community service employment would be required in order to meet existing levels of
15 service in the ROI.

16 17 18 **11.6.19.2.2 Technology-Specific Impacts**

19
20 The economic impacts of solar energy development in the proposed SEZ were measured
21 in terms of employment, income, state tax revenues (sales), BLM acreage rental and capacity
22 payments, population in-migration, housing, and community service employment (education,
23 health, and public safety). More information on the data and methods used in the analysis are
24 provided in Appendix M.

25
26 The assessment of the impact of the construction and operation of each solar technology
27 was based on SEZ acreage, assuming 80% of the area could be developed. To capture a range of
28 possible impacts, solar facility size was estimated on the basis of the land requirements of
29 various solar technologies, assuming that 9 acres/MW (0.04 km²/MW) would be required for
30 power tower, dish engine, and PV technologies and 5 acres/MW (0.02 km²/MW) for solar trough
31 technologies. Impacts of multiple facilities employing a given technology at each SEZ were
32 assumed to be the same as impacts for a single facility with the same total capacity. Construction
33 impacts were assessed for a representative peak year of construction, assumed to be 2021 for
34 each technology. Construction impacts assumed that a maximum of one project could be
35 constructed within a given year, with a corresponding maximum land disturbance of up to
36 3,000 acres (12 km²). For operations impacts, a representative first year of operations was
37 assumed to be 2023 for trough and power tower, 2022 for the minimum facility size for dish
38 engine and PV, and 2023 for the maximum facility size for these technologies. The years of
39 construction and operations were selected as representative of the entire 20-year study period,
40 because they are the approximate midpoint; construction and operations could begin earlier.

41 42 43 **Solar Trough**

44
45
46 **Construction.** Total construction employment impacts in the ROI (including direct
47 and indirect impacts) from the use of solar trough technologies would be up to 2,287 jobs

1 (Table 11.6.19.2-2). Construction activities would constitute 8.0% of total ROI employment.
2 A solar facility would also produce \$138.9 million in income and \$0.1 million in direct sales
3 taxes.
4

5 Based on the scale of construction activities and the likelihood of local worker
6 availability in the required occupational categories, construction of a solar facility would mean
7 that some in-migration of workers and their families from outside the ROI would be required,
8 with 1,827 persons in-migrating into the ROI. The relatively small number of in-migrants and the
9 availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the
10 impact of solar facility construction on the number of vacant rental housing units would be
11 expected to be large, with 914 rental units expected to be occupied in the ROI. This occupancy
12 rate would represent 51.6% of the vacant rental units expected to be available in the ROI.
13

14 In addition to the potential impact on housing markets, in-migration would affect
15 community service employment (education, health, and public safety). An increase in such
16 employment would be required to meet existing levels of service in the ROI. Accordingly,
17 16 new teachers, 2 physicians, and 8 public safety employees (career firefighters and uniformed
18 police officers) would be required in the ROI. These increases would represent 2.3% of total
19 ROI employment expected in these occupations.
20

21
22 **Operations.** Total operations employment impacts in the ROI (including direct and
23 indirect impacts) of a build-out using solar trough technologies would be 224 jobs
24 (Table 11.6.19.2-2). Such a solar facility would also produce \$7.6 million in income and
25 \$0.1 million in direct sales taxes. Based on fees established by the BLM in its Solar Energy
26 Interim Rental Policy (BLM 2010b), acreage rental payments would be \$0.3 million, and solar
27 generating capacity payments would total at least \$5.1 million.
28

29 Based on the likelihood of local worker availability in the required occupational
30 categories, operation of a solar facility would mean that some in-migration of workers and their
31 families from outside the ROI would be required, with 107 persons in-migrating into the ROI.
32 Although in-migration may potentially affect local housing markets, the relatively small number
33 of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile
34 home parks) mean that the impact of solar facility operation on the number of vacant owner-
35 occupied housing units would not be expected to be large, with 96 owner-occupied units
36 expected to be occupied in the ROI.
37

38 In addition to the potential impact on housing markets, in-migration would affect
39 community service (health, education, and public safety) employment. An increase in such
40 employment would be required to meet existing levels of service in the provision of these
41 services in the ROI. Accordingly, one new teacher would be required in the ROI.
42
43

TABLE 11.6.19.2-2 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Gold Point SEZ with Trough Facilities

Parameter	Maximum Annual Construction Impacts ^a	Operations Impacts ^b
Employment (no.)		
Direct	1,641	168
Total	2,287	224
Income (\$ million 2008)		
Total	138.9	7.6
Direct state taxes ^c (\$ million 2008)		
Sales	0.1	0.1
BLM payments (\$ million 2008)		
Rental	NA	0.3
Capacity ^d	NA	5.1
In-migrants (no.)	1,827	107
Vacant housing ^f (no.)	914	96
Local community service employment		
Teachers (no.)	16	1
Physicians (no.)	2	0
Public safety (no.)	8	0

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 600 MW (corresponding to 3,000 acres [12 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 770 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010c), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 **Power Tower**

2
3
4 **Construction.** Total construction employment impacts in the ROI (including direct
5 and indirect impacts) from the use of power tower technologies would be up to 911 jobs
6 (Table 11.6.19.2-3). Construction activities would constitute 3.2% of total ROI employment.
7 Such a solar facility would also produce \$55.3 million in income and less than \$0.1 million in
8 direct sales taxes.
9

10 Based on the scale of construction activities and the likelihood of local worker
11 availability in the required occupational categories, construction of a solar facility would mean
12 that some in-migration of workers and their families from outside the ROI would be required,
13 with 728 persons in-migrating into the ROI. The relatively small number of in-migrants and the
14 availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the
15 impact of solar facility construction on the number of vacant rental housing units would not be
16 expected to be large, with 364 rental units expected to be occupied in the ROI. This occupancy
17 rate would represent 20.6% of the vacant rental units expected to be available in the ROI.
18

19 In addition to the potential impact on housing markets, in-migration would affect
20 community service (education, health, and public safety) employment. An increase in such
21 employment would be required to meet existing levels of service in the ROI. Accordingly,
22 seven new teachers, one physician, and three public safety employees would be required in the
23 ROI. These increases would represent 0.9% of total ROI employment expected in these
24 occupations.
25
26

27 **Operations.** Total operations employment impacts in the ROI (including direct and
28 indirect impacts) of a build-out using power tower technologies would be 106 jobs
29 (Table 11.6.19.2-3). Such a solar facility would also produce \$3.4 million in income. Direct
30 sales taxes would be less than \$0.1 million. Based on fees established by the BLM in its Solar
31 Energy Interim Rental Policy (BLM 2010b), acreage rental payments would be \$0.3 million,
32 and solar generating capacity payments would total at least \$2.8 million.
33

34 Based on the likelihood of local worker availability in the required occupational
35 categories, operation of a solar facility means that some in-migration of workers and their
36 families from outside the ROI would be required, with 55 persons in-migrating into the ROI.
37 Although in-migration may potentially affect local housing markets, the relatively small number
38 of in-migrants and the availability of temporary accommodations (hotels, motels and mobile
39 home parks) mean that the impact of solar facility operation on the number of vacant
40 owner-occupied housing units would not be expected to be large, with 50 owner-occupied units
41 expected to be required in the ROI.
42

43 No new community service employment would be required to meet existing levels of
44 service in the ROI.
45
46

TABLE 11.6.19.2-3 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Gold Point SEZ with Power Tower Facilities

Parameter	Maximum Annual Construction Impacts ^a	Operations Impacts ^b
Employment (no.)		
Direct	654	87
Total	911	106
Income (\$ million 2008)		
Total	55.3	3.4
Direct state taxes ^c (\$ million 2008)		
Sales	<0.1	<0.1
BLM payments (\$ million 2008)		
Rental	NA	0.3
Capacity ^d	NA	2.8
In-migrants (no.)	728	55
Vacant housing ^f (no.)	364	50
Local community service employment		
Teachers (no.)	7	0
Physicians (no.)	1	0
Public safety (no.)	3	0

- ^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 333 MW (corresponding to 3,000 acres [12 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 428 MW.
- ^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.
- ^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.
- ^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010b), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

Dish Engine

Construction. Total construction employment impacts in the ROI (including direct and indirect impacts) from the use of dish engine technologies would be up to 370 jobs (Table 11.6.19.2-4). Construction activities would constitute 1.3% of total ROI employment. Such a solar facility would also produce \$22.5 million in income and less than \$0.1 million in direct sales taxes.

Based on the scale of construction activities and the likelihood of local worker availability in the required occupational categories, construction of a solar facility would mean that some in-migration of workers and their families from outside the ROI would be required, with 296 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility construction on the number of vacant rental housing units would not be expected to be large, with 148 rental units expected to be occupied in the ROI. This occupancy rate would represent 8.4% of the vacant rental units expected to be available in the ROI.

In addition to the potential impact on housing markets, in-migration would affect community service (education, health, and public safety) employment. An increase in such employment would be required to meet existing levels of service in the ROI. Accordingly, three new teachers, and one public safety employees would be required in the ROI. These increases would represent less than 0.4% of total ROI employment expected in these occupations.

Operations. Total operations employment impacts in the ROI (including direct and indirect impacts) of a build-out using dish engine technologies would be 103 jobs (Table 11.6.19.2-4). Such a solar facility would also produce \$3.4 million in income and less than \$0.1 million in direct sales taxes. Based on fees established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010b), acreage rental payments would be \$0.3 million, and solar generating capacity payments would total at least \$2.8 million.

Based on the likelihood of local worker availability in the required occupational categories, operation of a dish engine solar facility means that some in-migration of workers and their families from outside the ROI would be required, with 54 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility operation on the number of vacant owner-occupied housing units would not be expected to be large, with 48 owner-occupied units expected to be required in the ROI.

No new community service employment would be required to meet existing levels of service in the ROI.

TABLE 11.6.19.2-4 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Gold Point SEZ with Dish Engine Facilities

Parameter	Maximum Annual Construction Impacts ^a	Operations Impacts ^b
Employment (no.)		
Direct	266	84
Total	370	103
Income (\$ million 2008)		
Total	22.5	3.4
Direct state taxes ^c (\$ million 2008)		
Sales	<0.1	<0.1
BLM payments (\$ million 2008)		
Rental	NA	0.3
Capacity ^d	NA	2.8
In-migrants (no.)	296	54
Vacant housing ^f (no.)	148	48
Local community service employment		
Teachers (no.)	3	0
Physicians (no.)	0	0
Public safety (no.)	1	0

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 333 MW (corresponding to 3,000 acres [12 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 428 MW.

^c Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.

^d Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010b), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 **Photovoltaic**

2
3
4 **Construction.** Total construction employment impacts in the ROI (including direct and
5 indirect impacts) from the use of PV technologies would be up to 173 jobs (Table 11.6.19.2-5).
6 Construction activities would constitute 0.6% of total ROI employment. Such a solar
7 development would also produce \$10.5 million in income and less than \$0.1 million in direct
8 sales taxes.
9

10 Based on the scale of construction activities and the likelihood of local worker
11 availability in the required occupational categories, construction of a solar facility would mean
12 that some in-migration of workers and their families from outside the ROI would be required,
13 with 138 persons in-migrating into the ROI. Although in-migration may potentially affect local
14 housing markets, the relatively small number of in-migrants and the availability of temporary
15 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
16 construction on the number of vacant rental housing units would not be expected to be large,
17 with 69 rental units expected to be occupied in the ROI. This occupancy rate would represent
18 3.9% of the vacant rental units expected to be available in the ROI.
19

20 In addition to the potential impact on housing markets, in-migration would affect
21 community service (education, health, and public safety) employment. An increase in such
22 employment would be required to meet existing levels of service in the ROI. Accordingly,
23 one new teacher and one public safety employee would be required in the ROI. This increase
24 would represent less than 0.2% of total ROI employment expected in this occupation.
25
26

27 **Operations.** Total operations employment impacts in the ROI (including direct and
28 indirect impacts) of a build-out using PV technologies would be 10 jobs (Table 11.6.19.2-5).
29 Such a solar facility would also produce \$0.3 million in income and less than \$0.1 million in
30 direct sales taxes. Based on fees established by the BLM in its Solar Energy Interim Rental
31 Policy (BLM 2010b), acreage rental payments would be \$0.3 million, and solar generating
32 capacity payments would total \$2.2 million.
33

34 Given the likelihood of local worker availability in the required occupational categories,
35 operation of a solar facility would mean that some in-migration of workers and their families
36 from outside the ROI would be required, with five persons in-migrating into the ROI. Although
37 in-migration may potentially affect local housing markets, the relatively small number of
38 in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home
39 parks) mean that the impact of solar facility operation on the number of vacant owner-occupied
40 housing units would not be expected to be large, with five owner-occupied units expected to be
41 required in the ROI.
42

43 No new community service employment would be required to meet existing levels of
44 service in the ROI.
45
46

11.6.19.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features addressing socioeconomic impacts have been identified for the Gold Point SEZ. Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would reduce the potential for socioeconomic impacts during all project phases.

11.6.20 Environmental Justice

11.6.20.1 Affected Environment

Executive Order 12898, “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,” formally requires federal agencies to incorporate environmental justice as part of their missions (*Federal Register*, Volume 59, page 7629, 1994). Specifically, it directs them to address, as appropriate, any disproportionately high and adverse human health or environmental effects of their actions, programs, or policies on minority and low-income populations.

The analysis of the impacts of solar energy projects on environmental justice issues follows guidelines described in the CEQ’s *Environmental Justice Guidance under the National Environmental Policy Act* (CEQ 1997). The analysis method has three parts: (1) a description of the geographic distribution of low-income and minority populations in the affected area is undertaken; (2) an assessment is conducted to determine whether construction and operation would produce impacts that are high and adverse; and (3) if impacts are high and adverse, a determination as to whether these impacts disproportionately affect minority and low-income populations.

Construction and operation of solar energy projects in the proposed SEZ could affect environmental justice if any adverse health and environmental impacts resulting from any phase of development are significantly high and if these impacts disproportionately affect minority and low-income populations. If the analysis determines that health and environmental impacts are not significant, there can be no disproportionate impacts on minority and low-income populations. In the event impacts are significant, disproportionality would be determined by comparing the proximity of any high and adverse impacts with the location of low-income and minority populations.

The analysis of environmental justice issues associated with the development of solar facilities considered impacts within the SEZ and an associated 50-mi (80-km) radius around the boundary of the SEZ. A description of the geographic distribution of minority and low-income groups in the affected area was based on demographic data from the 2000 Census (U.S. Bureau of the Census 2009j,k). The following definitions were used to define minority and low-income population groups:

- **Minority.** Persons who identify themselves as belonging to any of the following racial groups: (1) Hispanic, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or Other Pacific Islander.

Beginning with the 2000 Census, where appropriate, the census form allows individuals to designate multiple population group categories to reflect their ethnic or racial origin. In addition, persons who classify themselves as being of multiple racial origin may choose up to six racial groups as the basis of

1 their racial origins. The term minority includes all persons, including those
2 classifying themselves in multiple racial categories, except those who classify
3 themselves as not of Hispanic origin and as White or “Other Race”
4 (U.S. Bureau of the Census 2009j).

5
6 The CEQ guidance proposed that minority populations should be identified
7 where either (1) the minority population of the affected area exceeds 50% or
8 (2) the minority population percentage of the affected area is meaningfully
9 greater than the minority population percentage in the general population or
10 other appropriate unit of geographic analysis.

11
12 This PEIS applies both criteria in using the Census data for census block
13 groups, wherein consideration is given to the minority population that is both
14 greater than 50% and 20 percentage points higher than in the state (the
15 reference geographic unit).

- 16
17 • **Low-Income.** Individuals who fall below the poverty line. The poverty line
18 takes into account family size and age of individuals in the family. In 1999,
19 for example, the poverty line for a family of five with three children below
20 the age of 18 was \$19,882. For any given family below the poverty line, all
21 family members are considered as being below the poverty line for the
22 purposes of analysis (U.S. Bureau of the Census 2009k).

23
24 The data in Table 11.6.20.1-1 show the minority and low-income composition of the
25 total population located in the proposed SEZ based on 2000 Census data and CEQ guidelines.
26 Individuals identifying themselves as Hispanic or Latino are included in the table as a separate
27 entry. However, because Hispanics can be of any race, this number also includes individuals
28 identifying themselves as being part of one or more of the population groups listed in the table.

29
30 Minority and low-income individuals are located in the 50-mi (80-km) area around the
31 boundary of the SEZ. Within the 50-mi (80-km) radius in Nevada, 18.7% of the population is
32 classified as minority, while 9.8% is classified as low-income. However, the number of minority
33 individuals does not exceed 50% of the total population in the area and does not exceed the state
34 average by 20 percentage points or more; thus, in aggregate, there is no minority population in
35 the SEZ area based on 2000 Census data and CEQ guidelines. The number of low-income
36 individuals does not exceed the state average by 20 percentage points or more and does not
37 exceed 50% of the total population in the area; thus, in aggregate, there are no low-income
38 populations in the Nevada portion of the SEZ area.

39
40 In the California portion of the 50-mi (80-km) radius, 14.6% of the population is
41 classified as minority, while 11.9% is classified as low-income. The number of minority
42 individuals does not exceed 50% of the total population in the area and does not exceed the state
43 average by 20 percentage points or more; thus, in aggregate, there is no minority population in
44 the California portion of the SEZ area based on 2000 Census data and CEQ guidelines. The
45 number of low-income individuals does not exceed the state average by 20 percentage points or

**TABLE 11.6.20.1-1 Minority and Low-Income Populations
within the 50-mi (80-km) Radius Surrounding the Proposed Gold
Point SEZ**

Parameter	California	Nevada
Total population	3,800	4,966
White, non-Hispanic	3,089	4,243
Hispanic or Latino	391	370
Non-Hispanic or Latino minorities	320	353
One race	247	206
Black or African American	5	56
American Indian or Alaskan Native	207	96
Asian	21	27
Native Hawaiian or Other Pacific Islander	9	10
Some other race	5	17
Two or more races	73	147
Total minority	711	723
Low-income	372	589
Percentage minority	18.7	14.6
State percentage minority	53.3	34.8
Percentage low-income	9.8	11.9
State percentage low-income	14.2	10.5

Source: U.S. Bureau of the Census (2009j,k).

more and does not exceed 50% of the total population in the area; thus, in aggregate, there are no low-income populations in the SEZ area.

11.6.20.2 Impacts

Environmental justice concerns common to all utility-scale solar energy facilities are described in detail in Section 5.18. These impacts would be minimized through the implementation of the programmatic design features described in Appendix A, Section A.2.2, which address the underlying environmental impacts contributing to the concerns. The potentially relevant environmental impacts associated with solar facilities within the proposed SEZ include noise and dust during the construction; noise and EMF effects associated with operations; visual impacts of solar generation and auxiliary facilities, including transmission lines; access to land used for economic, cultural, or religious purposes; and effects on property values as areas of concern that might potentially affect minority and low-income populations.

1 Potential impacts on low-income and minority populations could be incurred as a result
2 of the construction and operation of solar facilities involving each of the four technologies.
3 Impacts are likely to be small, however, and there are no minority or low-income populations,
4 as defined by CEQ guidelines (Section 11.6.20.1), within the 50-mi (80-km) radius around the
5 boundary of the SEZ; this means that any adverse impacts of solar projects could not
6 disproportionately affect minority or low-income populations.
7
8

9 **11.6.20.3 SEZ-Specific Design Features and Design Feature Effectiveness**

10
11 No SEZ-specific design features addressing environmental justice impacts have been
12 identified for the proposed Gold Point SEZ. Implementing the programmatic design features
13 described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would
14 reduce the potential for environmental justice impacts during all project phases.
15
16

11.6.21 Transportation

The proposed Gold Point SEZ is accessible by road. One U.S. highway serves the immediate area. The nearest railroad access is about 160 mi (257 km) away. Four small airports serve the area within a drive of about 91 mi (146 km). General transportation considerations and impacts are discussed in Sections 3.4 and 5.19, respectively.

11.6.21.1 Affected Environment

U.S. 95 extends north to south as it passes within 9 mi (14 km) east of the proposed Gold Point SEZ, as shown in Figure 11.6.21.1-1. The small town of Tonopah is about 50 mi (80 km) north of the SEZ along U.S. 95. I-80 is about 250 mi (400 km) northwest of the SEZ at its closest approach. Southeast of the SEZ, U.S. 95 passes through Beatty, about 60 mi (97 km) away, on its way to the Las Vegas metropolitan area, a distance of about 180 mi (290 km) from the SEZ. As seen in Figure 11.6.21.1-1. State Route 266 passes along the northern edge of the SEZ at a distance of about 1.6 mi (2.6 km), connects with U.S. 95 to the east, and passes into California to the west. Access to the proposed Gold Point SEZ would be from State Route 774, which parallels the eastern edge of the SEZ as it extends from State Route 266 to Gold Point south of the SEZ. Some unimproved dirt roads are also in the area. The area is classified as open to vehicle use (BLM 1997). As listed in Table 11.6.21.1-1, State Routes 266 and 774 and U.S. 95 carry average traffic volumes of about 210, 20, and 2,000 vehicles per day, respectively, in the vicinity of the proposed Gold Point SEZ (NV DOT 2010).

The UP Railroad serves the region. A spur from the main line that crosses northern Nevada ends at Thorne (UP 2009), 160 mi (257 km) northwest of the SEZ along U.S. 95, immediately north of Hawthorne. Access to the UP Railroad is also available 180 mi (290 km) away in Las Vegas.

The nearest public airport is the Lida Junction Airport, a small BLM airport about 10 mi (16 km) from the proposed Gold Point SEZ at the junction of State Route 266 with U.S. 95. The airport has a single dirt runway in good condition, as listed in Table 11.6.21.1-2. A similar BLM-managed airport is 48 mi (77 km) away in Dyer. Other small airports are located in Tonopah, Nevada, and Bishop, California. None of these four airports has scheduled commercial passenger service or regular freight service, with the exception of the Sierra Regional Airport in Bishop, California, which has regular UPS freight service (Eastern Sierra Regional Airport 2010). In 2008, 72,724 lb (32,980 kg) of freight was shipped, and 289,323 lb (131,212 kg) of freight was received (BTS 2009). The nearest major airport to the proposed Gold Point SEZ is in Las Vegas.

11.6.21.2 Impacts

As discussed in Section 5.19, the primary transportation impacts are anticipated to be from commuting construction worker traffic. Single projects could involve up to 1,000 workers each day, with an additional 2,000 vehicle trips per day (maximum). The increase in the volume

^b NA = not applicable.

1 of traffic on U.S. 95 east of the proposed Gold Point SEZ, on State Route 266 past the northern
2 border of the SEZ, and along State Route 744 along the eastern edge of the SEZ would represent
3 increases in traffic of about 100%, 1,000%, and 10,000%, respectively. Also, higher traffic
4 volumes would be experienced during shift changes. Thus, traffic on U.S. 95 could experience
5 slowdowns during these periods in the vicinity of the junction with State Route 266, and local
6 road improvements would be necessary on State Routes 266 and 774 so as not to overwhelm the
7 local access roads near any site access points.

8
9 Solar development within the SEZ would affect public access along OHV routes
10 designated open and available for public use. If there are any routes designated as open within
11 the proposed SEZ, open routes crossing areas issued ROWs for solar facilities would be
12 redesignated as closed (see Section 5.5.1 for more details on how routes coinciding with
13 proposed solar facilities would be treated).

14 15 16 **11.6.21.3 SEZ-Specific Design Features and Design Feature Effectiveness**

17
18 No SEZ-specific design features have been identified related to impacts on transportation
19 systems around the proposed Gold Point SEZ. The programmatic design features described in
20 Appendix A, Section A.2.2, including local road improvements, multiple site access locations,
21 staggered work schedules, and ride-sharing, would all provide some relief to traffic congestion
22 on local roads leading to the site. Depending on the location of solar facilities within the SEZ,
23 more specific access locations and local road improvements could be implemented.

11.6.22 Cumulative Impacts

The analysis presented in this section addresses the potential cumulative impacts in the vicinity of the proposed Gold Point SEZ in Esmeralda County, Nevada. The CEQ guidelines for implementing NEPA define cumulative impacts as environmental impacts resulting from the incremental effects of an action when added to other past, present, and reasonably foreseeable future actions (40 CFR 1508.7). The impacts of other actions are considered without regard to the agency (federal or nonfederal), organization, or person that undertakes them. The time frame of this cumulative impacts assessment could appropriately include activities that would occur up to 20 years in the future (the general time frame for PEIS analyses), but little or no information is available for projects that could occur further than 5 to 10 years in the future.

The land surrounding the proposed Gold Point SEZ is undeveloped with several ghost towns and few permanent residents living in the area. The nearest population centers are the small communities of Goldfield, population 310, located 25 mi (40 km) northeast of the SEZ; Tonopah, population 1,500, located 45 mi (72 km) northeast of the SEZ; and Beatty, population 1,600, located approximately 45 mi (72 km) southeast of the SEZ. Death Valley NP in California is 10 mi (16 km) southwest of the SEZ. The NTTR is 12 mi (19 km) east of the SEZ, and the NTS is 45 mi (72 km) east of the SEZ. The Sylvania Mountains, Piper Mountain and White Mountains WAs are located within a 50-mi (80-km) radius of the SEZ in California.

The geographic extent of the cumulative impacts analysis for potentially affected resources near the Gold Point SEZ is identified in Section 11.6.22.1. An overview of ongoing and reasonably foreseeable future actions is presented in Section 11.6.22.2. General trends in population growth, energy demand, water availability, and climate change are discussed in Section 11.6.22.3. Cumulative impacts for each resource area are discussed in Section 11.6.22.4.

11.6.22.1 Geographic Extent of the Cumulative Impacts Analysis

The geographic extent of the cumulative impacts analysis for potentially affected resources evaluated near the Gold Point SEZ is provided in Table 11.6.22.1-1. These geographic areas define the boundaries encompassing potentially affected resources. Their extent may vary based on the nature of the resource being evaluated and the distance at which an impact may occur (e.g., air quality may have a greater regional extent of impact than visual resources). The BLM, the NPS, the DOE, and the DoD administer most of the land around the SEZ. The BLM administers approximately 47.3% of the lands within a 50-mi (80-km) radius of the SEZ.

11.6.22.2 Overview of Ongoing and Reasonably Foreseeable Future Actions

The future actions described below are those that are “reasonably foreseeable”; that is, they have already occurred, are ongoing, are funded for future implementation, or are included in firm near-term plans. Types of proposals with firm near-term plans are as follows:

- Proposals for which NEPA documents are in preparation or finalized;

**TABLE 11.6.22.1-1 Geographic Extent of the Cumulative Impacts Analysis by Resource Area:
Proposed Gold Point SEZ**

Resource Area	Geographic Extent
Land Use	Southern Esmeralda County
Specially Designated Areas and Lands with Wilderness Characteristics	Within a 25-mi (40-km) radius of the Gold Point SEZ
Rangeland Resources	Southern Esmeralda County and Southwestern Nye County in Nevada and Western Inyo County in California
Grazing	Grazing allotments within 50 mi (80 km) of the Gold Point SEZ
Wild Horses and Burros	A 50-mi (80-km) radius from the center of the Gold Point SEZ
Recreation	Southern Esmeralda County and Southwestern Nye County in Nevada and Western Inyo County in California
Military and Civilian Aviation	Southern Nye County
Soil Resources	Areas within and adjacent to the Gold Point SEZ
Minerals	Southern Esmeralda County
Water Resources	
Surface Water	Jackson Wash and tributaries
Groundwater	Lida Valley groundwater basin
Air Quality and Climate	A 31-mi (50-km) radius from the center of the Gold Point SEZ
Vegetation, Wildlife and Aquatic Biota, Special Status Species	A 50-mi (80-km) radius from the center of the Gold Point SEZ, including portions of Esmeralda and Nye Counties in Nevada and Inyo County in California
Visual Resources	Viewshed within a 25-mi (40-km) radius of the Gold Point SEZ
Acoustic Environment (noise)	Areas adjacent to the Gold Point SEZ
Paleontological Resources	Areas within and adjacent to the Gold Point SEZ
Cultural Resources	Areas within and adjacent to the Gold Point SEZ for archaeological sites; viewshed within a 25-mi (40-km) radius of the Gold Point SEZ for other properties, such as traditional cultural properties
Native American Concerns	Areas within and adjacent to the Gold Point SEZ including the surrounding mountains; viewshed within a 25-mi (40-km) radius of the Gold Point SEZ
Socioeconomics	A 50-mi (80-km) radius from the center of the Gold Point SEZ
Environmental Justice	A 50-mi (80-km) radius from the center of the Gold Point SEZ
Transportation	U.S. 95, State Routes 266 and 774

- Proposals in a detailed design phase;
- Proposals listed in formal NOIs published in the *Federal Register* or state publications;
- Proposals for which enabling legislation has been passed; and
- Proposals that have been submitted to federal, state, or county regulators to begin a permitting process.

Projects in the bidding or research phase or that have been put on hold were not included in the cumulative impact analysis.

The ongoing and reasonably foreseeable future actions described below are grouped into two categories: (1) actions that relate to renewable energy production and energy distribution, including potential solar energy projects under the proposed action (Section 11.6.22.2.1) and (2) other ongoing and reasonably foreseeable actions (Section 11.6.22.2.2). Together, these actions have the potential to affect human and environmental receptors within the geographic range of potential impacts over the next 20 years.

11.6.22.2.1 Energy Production and Distribution

On February 16, 2007, Governor Gibbons signed an Executive Order to encourage the development of renewable energy resources in Nevada (Gibbons 2007a). The Executive Order requires all relevant state agencies to review their permitting processes to ensure the timely and expeditious permitting of renewable energy projects. On May 9, 2007, and June 12, 2008, the Governor signed Executive Orders creating the Nevada Renewable Energy Transmission Access Advisory Committee Phase I and Phase II, which will propose recommendations for improved access to the grid system for renewable energy industries (Gibbons 2007b, 2008). On May 28, 2009, the Nevada Legislature passed Senate Bill 358, a bill modifying the Renewable Energy Portfolio Standards. The bill requires that 25% of the electricity sold be produced by renewable energy sources by 2025.

Renewable Energy and Energy Distribution Projects

Renewable energy applications are considered in two categories, fast-track and regular-track applications. Fast-track applications, which apply principally to solar and wind energy facilities, are those applications on public lands for which the environmental review and public participation process is under way and the applications could be approved by December 2010. A fast-track project would be considered foreseeable, because the permitting and environmental review processes would be under way. Regular-track proposals are considered potential future projects, but not necessarily foreseeable projects, since not all applications would be expected to be carried to completion.

1 No fast-track or other reasonably foreseeable future renewable energy or foreseeable
2 energy distribution projects are within 50 mi (80 km) of the proposed Gold Point SEZ.
3
4

5 **Pending Renewable Energy ROW Applications on BLM-Administered Lands** 6

7 Applications for ROWs that have been submitted to the BLM include one pending solar
8 project, one pending authorization for wind site testing, two authorized projects for wind site
9 testing, and one authorized geothermal project that would be located within 50 mi (80 km) of the
10 Gold Point SEZ. Table 11.6.22.2-1 lists these applications, and Figure 11.6.22.2-1 shows their
11 locations.
12

13 There is a pending solar project that would be on private land about 49 mi (78 km) north
14 of the Gold Point SEZ, about 1 mi (1.6 km) south of the Millers SEZ. In 2010, Altella Energy
15 Corporation proposed to Esmeralda County the development of a 100-MW solar energy facility
16 on private land near U.S. 6 and U.S. 95. The site is known as the Miller's Well site. The project's
17 estimated cost is \$500 million (Esmeralda County 2010a,b).
18

19 The likelihood of any of the regular-track application projects actually being developed
20 is uncertain, but it is generally assumed to be less than that for fast-track applications. Potential
21 projects listed in Table 11.6.22.2-1 give an indication of the level of interest in development of
22 renewable energy in the region. Some number of these applications would be expected to result
23 in actual projects. Thus, the cumulative impacts of these potential projects are analyzed in their
24 potential aggregate effects.
25

26 Wind testing would involve some relatively minor activities that could have some
27 environmental effects, mainly the erection of meteorological towers and monitoring of wind
28 conditions. These towers may or may not employ guy wires and may be 200 ft (60 m) high.
29
30

31 **11.6.22.2.2 Other Actions** 32

33 Other major ongoing and foreseeable actions within 50 mi (80 km) of the proposed Gold
34 Point SEZ are listed in Table 11.6.22.2-2 and described in the following sections.
35
36

37 **Beatty Water and Sanitation District Water Treatment Plant.** The Beatty Water and
38 Sanitation District proposes to install a water treatment facility to remove arsenic from the
39 drinking water supply for Beatty. The total disturbed area would be about 8.5 acres (0.034 km²).
40 The facility will include a septic tank leach field, backwash holding tank, and an
41 evaporation/infiltration basin (BLM 2009b).
42
43

44 **Chemetall Foote Lithium Carbonate Facility Expansion.** The DOE is proposing to
45 upgrade an existing brine field production system, brine evaporation pond system, and lithium
46 carbonate plant at the Chemetall Foote facility adjacent to the unincorporated town of Silver

FIGURE 11.6.22.2-1 Locations of Renewable Energy Project ROW Applications on Public Land within a 50-mi (80-km) Radius of the Proposed Gold Point SEZ

TABLE 11.6.22.2-2 Other Major Actions near the Proposed Gold Point SEZ^a

Description	Status	Resources Affected	Primary Impact Location
Beatty Water and Sanitation District Water Treatment Plant	EA Nov. 2009	Drinking water	43 mi (69 km) southeast of the SEZ
Chemetall Foote Lithium Carbonate Facility Expansion	FEA issued Sept 2010	Terrestrial habitats, wildlife, air quality	25 mi (40 km) northwest of the SEZ
Mineral Ridge Project	Mining expected to resume 2011		28 mi (45 km) northwest of the SEZ
Caliente Rail Realignment	FEIS June 2008	Terrestrial habitats, wildlife, cultural resources	8 mi (13 km) northwest of the SEZ
120-kV Transmission Line	Operating	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes from east to west–north of the SEZ
120-kV Transmission Line	Operating	Disturbed areas, terrestrial habitats along transmission line ROW	Corridor passes from north to south–north of the SEZ
Producing Geothermal Lease (NVN 8421)	Operating	Terrestrial habitats, wildlife	45 mi (72 km) northwest of the SEZ
Producing Geothermal Lease (NVN 8428)	Operating	Terrestrial habitats, wildlife	45 mi (72 km) northwest of the SEZ
Producing Geothermal Lease (NVN 9647)	Operating	Terrestrial habitats, wildlife	45 mi (72 km) northwest of the SEZ
Producing Geothermal Lease (NVN 31991)	Operating	Terrestrial habitats, wildlife	45 mi (72 km) northwest of the SEZ
Producing Geothermal Lease (NVN 31993)	Operating	Terrestrial habitats, wildlife	45 mi (72 km) northwest of the SEZ

^a Projects ongoing or in later stages of agency environmental review and project development.

Peak, Nevada, and about 25 mi (40 km) northwest of the SEZ. The site is about 15,000 acres (61 km²), mostly occupied by large evaporation ponds. The plant and administrative offices occupy approximately 20 acres (0.08 km²). Existing lithium brine ponds would be expanded through recovering old ponds and rebuilding the dikes. Construction of new brine production wells would require soil placement for drill pads (DOE 2010).

1 **Mineral Ridge Project.** Mineral Ridge, a formerly producing gold and silver mine, has
2 both underground workings and open pits, with a 6-acre (0.024 km²) deep leach operation and a
3 high volume crusher plant. It is currently not operational but engineering work is being
4 performed for future operations. It is anticipated that active mining will commence in 2011. The
5 site is 3 mi (5 km) northwest of the unincorporated town of Silver Peak and approximately 28 mi
6 (45 km) northwest of the SEZ. (Top Stock Picks 2010).

7
8
9 **Caliente Rail Alignment.** The DOE proposes to construct and operate a railroad for the
10 shipment of spent nuclear fuel and high-level radioactive waste to the geologic repository at
11 Yucca Mountain, Nevada. The rail line would begin near Caliente, Nevada, and extend north;
12 then turn in a westerly direction, passing about 8 mi (13 km) northwest of the SEZ, to a location
13 near the northwest corner of the NTTR (labeled Nellis Air Force Range in Figure 11.6.22.2-1);
14 and then continue south–southwest to Yucca Mountain. The rail line would range in length from
15 approximately 328 mi (528 km) to 336 mi (541 km), depending upon the exact location of the
16 alignment and would be restricted to DOE shipments. Over a 50-year period, 9,500 casks
17 containing spent nuclear fuel and high-level radioactive waste, and approximately 29,000 rail
18 cars of other materials, including construction materials, would be shipped to the repository. An
19 average of 17 one-way trains per week would travel along the rail line. Construction of support
20 facilities—interchange yard, staging yard, maintenance-of-way facility, rail equipment
21 maintenance yard, cask maintenance facility, and Nevada Rail Control Center and National
22 Transportation Operation Center—would also be required. Construction would take 4 to 10 years
23 and cost \$2.57 billion. Construction activities would occur inside a 1000-ft (300-m) wide ROW
24 for a total footprint of 40,600 acres (164 km²) (DOE 2008).

25
26
27 **Existing 120-kV Transmission Line.** Sierra Pacific owns the two existing 120-kV
28 transmission lines that run north to south and east to west, north of the SEZ (RETAAC 2007).

29
30
31 **Existing Geothermal Leases.** There is a small, contiguous, cluster of five producing
32 geothermal leases located about 40 mi (64 km) northwest of the proposed SEZ, shown in Figure
33 11.6.22.2-1.

34 35 36 **Grazing**

37
38 There are no active grazing allotments in the immediate vicinity of the SEZ.

39 40 41 **Mining**

42
43 There are no foreseeable mining projects near the proposed SEZ.

11.6.22.3 General Trends

General trends of population growth, energy demand, water availability, and climate change for the proposed Gold Point SEZ are presented in this section. Table 11.6.22.3-1 lists the relevant impacting factors for the trends.

11.6.22.3.1 Population Growth

Over the period 2000 to 2008, the population grew annually by 3.9% in Nye County, but fell by 4.6% annually in sparsely populated Esmeralda County in Nevada, portions of which compose the ROI for the Gold Point SEZ. The annual growth rate for the State of Nevada as a whole was 3.4%. The population of the ROI in 2008 was 44,839 and is expected to increase to 78,122 by 2021 and to 80,872 by 2023 (Section 11.6.19.1.4).

11.6.22.3.2 Energy Demand

The growth in energy demand is related to population growth through increases in housing, commercial floorspace, transportation, manufacturing, and services. Given that population growth is expected in seven SEZ areas in Nevada between 2006 and 2016, an increase in energy demand is also expected. However, the EIA projects a decline in per-capita

TABLE 11.6.22.3-1 General Trends Relevant to the Proposed SEZs in Nevada

General Trend	Impacting Factors
Population growth	Urbanization Increased use of roads and traffic Land use modification Employment Education and training Increased resource use (e.g., water and energy) Tax revenue
Energy demand	Increased resource use Energy development (including alternative energy sources) Energy transmission and distribution
Water availability	Drought conditions and water loss Conservation practices Changes in water distribution
Climate change	Water cycle changes Increased wildland fires Habitat changes Changes in farming production and costs

energy use through 2030, mainly because of improvements in energy efficiency and the high cost of oil throughout the projection period. Primary energy consumption in the United States between 2007 and 2030 is expected to grow by about 0.5% each year, with the fastest growth projected for the commercial sector (at 1.1% each year). Transportation, residential, and industrial energy consumption are expected to grow by about 0.5, 0.4, and 0.1% each year, respectively (EIA 2009).

11.6.22.3.3 Water Availability

As described in Section 11.6.9.1.2, the proposed Gold Point SEZ is located in the Lida Valley groundwater basin. Estimated groundwater depth is 300 to 400 ft (91 to 122 m). Groundwater recharge estimates range up to 500 ac-ft/yr (616,700 m³/yr) by precipitation and 200 ac-ft/yr (246,700 m³/yr) by subsurface inflow. Groundwater discharge by outflow to the Sarcobatus Flat basin is estimated to be 700 ac-ft/yr (863,400 m³/yr), while evapotranspiration is assumed to be negligible (Section 11.6.9.1.2).

In 2005, withdrawals from surface waters and groundwater in Esmeralda County were 46,786 million ac-ft/yr (57.7 million m³/yr), of which 9% came from surface waters and 91% from groundwater. The largest water use categories for groundwater were irrigation and mining at 28,235 and 14,202 ac-ft/yr (34.8 million and 17.5 million m³/yr), respectively.

Since the Lida Valley groundwater basin is not an NDWR-designated groundwater basin, there are no specified beneficial uses set by the NDWR. The perennial yield of the Lida Valley groundwater basin is set at 350 ac-ft/yr (431,700 m³/yr), and current water rights total 76 ac-ft/yr (93,700 m³/yr) for mining, stockwater, and municipal uses (Section 11.6.9.1.3).

11.6.22.3.4 Climate Change

Governor Jim Gibbons' Nevada Climate Change Advisory committee (NCCAC) conducted a study of climate change and its effects on Nevada (NCCAC 2008). The report summarized the present scientific understanding of climate change and its potential impacts on Nevada. A report on global climate change in the United States prepared by the U.S. Global Research Program (GCRP 2009) documents current temperature and precipitation conditions and historic trends. Excerpts of the conclusions from these reports follow.

- Precipitation will decrease, and a greater percentage of that precipitation will come from rain, resulting in a greater likelihood of winter and spring flooding and decreased stream flow in the summer.
- The average temperature in the Southwest has already increased by about 1.5°F compared to a 1960 to 1979 baseline, and by the end of the century, the average annual temperature is projected to rise by 4°F to 10°F.

- A warming climate and a related reduction in spring snowpack and soil moisture have increased the length of the wildfire season and intensity of forest fires.
- Later snow and less snow coverage in ski resort areas could force ski areas to shut down before the season would otherwise end.
- Much of the Southwest has experienced drought conditions since 1999. This represents the most severe drought in the last 110 years. Projections indicate an increasing probability of drought in the region.
- As temperatures rise, landscape will be altered as species shift their ranges northward and upward to cooler climates.
- Temperature increases, when combined with urban heat island effects for major cities such as Las Vegas, present significant stress to health, electricity, and water supply.
- Increased minimum temperatures and warmer springs extend the range and lifetime of many pests that stress trees and crops, and lead to northward migration of weed species.

11.6.22.4 Cumulative Impacts on Resources

This section addresses potential cumulative impacts in the proposed Gold Point SEZ on the basis of the following assumptions: (1) because of the small size of the proposed SEZ (<10,000 acres [$<40.5 \text{ km}^2$]), only one project could be constructed at a time, and (2) maximum total disturbance over 20 years would be about 3,848 acres (15.6 km^2) (80% of the entire proposed SEZ). For analysis, it is also assumed that no more than 3,000 acres (12.1 km^2) per project would be disturbed annually and 250 acres (1.01 km^2) monthly on the basis of construction schedules planned in current applications. An additional 667 acres (2.7 km^2) would be disturbed to construct a transmission line from the SEZ to the regional grid 22 mi (35 km) away. For site access, the nearest major road is State Route 774, which lies adjacent to the SEZ. It is assumed that no new access road would be constructed to support solar development in the SEZ.

Cumulative impacts that would result from the construction, operation, and decommissioning of solar energy development projects within the proposed SEZ when added to other past, present, and reasonably foreseeable future actions described in the previous section in each resource area are discussed below. At this stage of development, because of the uncertain nature of the future projects in terms of size, number, location within the proposed SEZ, and types of technology that would be employed, the impacts are discussed qualitatively or semi-quantitatively, with ranges given as appropriate. More detailed analyses of cumulative impacts would be performed in the environmental reviews for the specific projects in relation to all other existing and proposed projects in the geographic areas.

11.6.22.4.1 Lands and Realty

The proposed Gold Point SEZ is undeveloped and rural with only a few dirt roads present. There are no existing ROWs within the SEZ, but a designated Section 368b transmission corridor passes 6.5 mi (10 km) to the northeast, while a proposed local corridor would be located just west of the Section 368b corridor. The corridors are currently not utilized. As of February 2010, there were no ROW applications for solar energy facility development within the SEZ (Section 11.6.2.1).

Development of the SEZ for utility-scale solar energy production would establish a large industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity. Solar energy facilities would be a new and highly discordant land use to the area. However, as of February 2010, there were no ROW applications for solar energy facility development within the SEZ.

As presented in Section 11.6.22.2, no foreseeable renewable energy or transmission projects were identified within a 50-mi (80-km) radius of the proposed SEZ. The only foreseeable action is a water treatment plant in Beatty, Nevada, designed to remove arsenic from drinking water. In addition, one potential solar facility with a pending application covering 12,800 acres (52 km²), one pending and two authorized wind site testing applications covering 40,068 acres (162 km²), and one authorized geothermal application covering 47,769 acres (193 km²) lie within this distance (Figure 11.6.22.2-1). Solar development within the proposed SEZ would require construction of a 22-mi (35-km) transmission line to the nearest existing line. Existing facilities within 50 mi (80 km) of the SEZ include two 120-kV transmission lines and a cluster of five producing geothermal leases about 45 mi (72 km) northwest. The seven pending renewable energy applications indicate moderate interest in renewable energy development in the region.

Given that the approved and pending renewable energy applications are widely dispersed—all are more than 15 mi (24 km) from the proposed SEZ—and although the size of the application ROWs typically far exceeds the amount of land that would be affected for other uses, total impacts on land use within the 50-mi (80-km) geographic extent of effects would be small. Development of utility-scale solar projects in the proposed Gold Point SEZ would not be expected to contribute significantly to cumulative impacts on lands and realty.

11.6.22.4.2 Specially Designated Areas and Lands with Wilderness Characteristics

There are nine specially designated areas within 25 mi (40 km) of the proposed Gold Point SEZ in Nevada and California (Section 11.6.3.1). Potential exists for cumulative visual impacts on these areas from the construction of utility-scale solar energy facilities within the SEZ and other projects outside the SEZ. The degree of cumulative impacts would depend on the number, type, and location of potential solar, wind, and geothermal projects with pending or approved applications within the geographic extent of effects that are actually built. Given the small number and wide geographic separation of such applications, potential cumulative impacts

1 on wilderness characteristics would be relatively small. No cumulative impacts would be
2 expected from currently foreseeable actions in the region, however.

3 4 5 **11.6.22.4.3 Rangeland Resources**

6
7 The one very large grazing allotment that overlaps the proposed SEZ would be reduced
8 by 0.7% of its total size (Section 11.6.4.1.2.1). Such a small reduction would not contribute to
9 cumulative impacts on grazing.

10
11 Solar energy development within the SEZ would not directly affect wild horses and
12 burros that are managed by the BLM or the USFS, while indirect impacts would be negligible
13 with implementation of programmatic design features (Section 11.6.4.2.2). Thus, the SEZ would
14 not contribute to cumulative impacts on these species.

15 16 17 **11.6.22.4.4 Recreation**

18
19 Little or no recreation occurs on the proposed Gold Point SEZ or along the route of the
20 assumed transmission line. Construction of utility-scale solar projects on the SEZ would
21 preclude recreational use of the affected lands for the duration of the projects. However, alternate
22 routes exist nearby for any road closures within the relatively small proposed SEZ. Foreseeable
23 and potential future actions would similarly affect areas of low recreational use and would have
24 minimal effects on recreation. Thus, cumulative impacts on recreation within the geographic
25 extent of effects are not expected.

26 27 28 **11.6.22.4.5 Military and Civilian Aviation**

29
30 The proposed Gold Point SEZ is located under numerous MTRs, is located between
31 two MOAs, and lies within a mandatory DoD Consultation Area. Nellis Air Force Base and
32 NTTR have expressed a variety of concerns over solar energy facilities being constructed within
33 the Gold Point SEZ (Section 11.6.6.2). Foreseeable and potential solar, wind, and geothermal
34 facilities and transmission lines could present additional concerns and result in cumulative
35 impacts on military aviation. No impacts on civilian aviation are expected from solar facilities
36 in the proposed SEZ.

37 38 39 **11.6.22.4.6 Soil Resources**

40
41 Ground-disturbing activities (e.g., grading, excavating, and drilling) during the
42 construction phase of a solar project, including the construction of the associated transmission
43 line and any new roads, would contribute to soil loss due to wind erosion and potential
44 sedimentation of nearby washes and streams. Road use during construction, operations, and
45 decommissioning of the solar facilities would further contribute to soil loss and siltation.
46 Programmatic design features would be employed to minimize wind erosion, soil loss, and

1 stream sedimentation. Proposed renewable energy projects on the region with pending
2 applications, if built, would be too far away to combine with soil impacts from the SEZ. Thus,
3 with programmatic design features in place, cumulative impacts on soil resources near the
4 proposed SEZ are not expected.

5 6 7 **11.6.22.4.7 Minerals (Fluids, Solids, and Geothermal Resources)**

8
9 As discussed in Section 11.6.8, there are currently no active oil and gas leases within the
10 proposed Gold Point SEZ, and there are no mining claims or proposals for geothermal energy
11 development pending in the SEZ. Because of the generally low level of mineral production in the
12 area and the expected low impact on mineral accessibility of other foreseeable actions within the
13 geographic extent of effects, no cumulative impacts on mineral resources are expected.

14 15 16 **11.6.22.4.8 Water Resources**

17
18 Section 11.6.9.2 describes the water requirements for various technologies if they were to
19 be employed on the proposed SEZ to develop utility-scale solar energy facilities. The amount of
20 water needed during the peak construction year for all evaluated solar technologies would be
21 1,182 to 1,707 ac-ft (1.5 million to 2.1 million m³). During operations, with full development of
22 the SEZ over 80% of its available land area, the amount of water needed for all evaluated solar
23 technologies would range from 22 to 11,555 ac-ft/yr (27 thousand to 14 million m³). The amount
24 of water needed during decommissioning would be similar to or less than the amount used
25 during construction. As discussed in Section 11.6.22.2.3, water withdrawals in 2005 in
26 Esmeralda County were 46,786 ac-ft/yr (57.7 million m³/yr), of which 9% came from surface
27 waters and 91% came from groundwater. The largest water use categories for groundwater were
28 irrigation and mining at 28,235 and 14,202 ac-ft/yr (34.8 million and 17.5 million m³/yr),
29 respectively. Therefore, cumulatively the additional water resources needed for solar facilities
30 in the SEZ during operations would constitute from a very small (0.05%) to a large (24%)
31 increment (the ratio of the annual operations water requirement to the annual amount withdrawn
32 in Esmeralda County) depending on the solar technology used (PV technology at the low end
33 and wet-cooled parabolic trough technology at the high end).

34
35 Near the SEZ, the perennial yield of the Lida Valley groundwater basin is set at 350 ac-
36 ft/yr (431,700 m³/yr), while current water rights total 76 ac-ft/yr (93,700 m³/yr). Thus, solar
37 facilities on the SEZ would have the capacity to overwhelm the specified groundwater yield in
38 the local basin using wet-cooled technologies, while dry-cooled technologies could require three-
39 times the specified yield. Full development with non-cooled dish engine technology would
40 require up to 219 ac-ft/yr (0.27 million m³/yr), or about 63%, and PV would require 22 ac-ft/yr
41 (27 thousand m³/yr), or about 6% of this level (Section 11.6.9.2.2).

42
43 While solar development of the proposed SEZ with water-intensive technologies would
44 likely be infeasible because of impacts on groundwater supplies, excessive groundwater
45 withdrawals could disrupt the existing groundwater supplies in the Lida Valley. In addition, land
46 disturbance for solar facility construction could cause localized soil erosion and sedimentation of

1 ephemeral washes, degrade associated habitats in Jackson Wash, and alter groundwater recharge
2 and discharge processes. Cumulative impacts on surface and groundwater resources are not
3 expected, however, because of the absence of foreseeable development near the SEZ. Potential
4 solar, wind, and geothermal projects are more than 15 mi (24 km) from the SEZ and would not
5 likely affect the same water resources (Section 11.6.22.2).
6

7 Small quantities of sanitary wastewater would be generated during the construction and
8 operation of the potential utility-scale solar energy facilities. The amount generated from solar
9 facilities would range from 9 to 74 ac-ft (11 to 91 thousand m³) during the peak construction
10 year and from 1 up to 11 ac-ft/yr (up to 14,000 m³/yr) during operations. Because of the small
11 quantity, the sanitary wastewater generated by the solar energy facilities would not be expected
12 to place undue strain on available sanitary wastewater treatment facilities in the general area of
13 the SEZ. For technologies that rely on conventional wet-cooling systems, there would also be
14 121 to 219 ac-ft/yr (0.15 to 0.27 million m³/yr) of blowdown water from cooling towers.
15 Blowdown water would need to be either treated on-site or sent to an off-site facility. Any on-
16 site treatment of wastewater would have to ensure that treatment ponds are effectively lined in
17 order to prevent any groundwater contamination. Thus, blowdown water would not contribute to
18 cumulative effects on treatment systems or on groundwater.
19
20

21 **11.6.22.4.9 Vegetation**

22

23 The proposed Gold Point SEZ is located within the Tonopah Basin ecoregion, which
24 supports sparse shadscale communities. Inter-Mountain Basins Mixed Salt Desert Scrub is the
25 predominant cover type within the proposed SEZ. Sensitive habitats on the SEZ include riparian,
26 desert dry wash, and playa habitats. The area surrounding the SEZ consists of a mosaic of the
27 Tonopah Basin and the Tonopah Sagebrush Foothills ecoregion. The dominant cover type in the
28 5-mi (8-km) area of indirect effects is Inter-Mountain Basins Mixed Salt Desert Scrub. There are
29 no NWI-mapped wetlands within the SEZ or in the area of indirect effects. Ephemeral washes in
30 the SEZ drain to Jackson Wash, which supports riparian communities downstream. If utility-
31 scale solar energy projects were to be constructed within the SEZ, all vegetation within the
32 footprints of the facilities would likely be removed during land-clearing and land-grading
33 operations. Full development of the SEZ over 80% of its area would result in small impacts on
34 all cover types in the affected area (Section 11.6.10.2.1). Site-clearing and -grading could disrupt
35 surface water flow patterns and potentially alter plant communities in riparian or playa habitats
36 within or outside of the SEZ, while increased runoff from facilities could affect the hydrology of
37 these areas. In addition, groundwater drawdown by solar facilities could affect wetland
38 communities associated with springs. A further concern in disturbed areas is the establishment
39 and spread of noxious weeds and invasive species.
40

41 The fugitive dust generated during the construction of the solar facilities could increase
42 the dust loading in habitats outside a solar project area, in combination with that from other dust
43 sources. The cumulative dust loading could result in reduced productivity or changes in plant
44 community composition. Similarly, surface runoff from project areas after heavy rains could
45 increase sedimentation and siltation in areas downstream. Programmatic design features would

1 be used to reduce the impacts from solar energy projects and thus reduce the overall cumulative
2 impacts on plant communities and habitats.

3
4 Solar facilities within the SEZ would not be expected to contribute to cumulative effects
5 on vegetation within the 50-mi (80-km) geographic extent of effects because of the absence of
6 foreseeable development outside the SEZ and long distances to potential renewable energy
7 projects. Of the seven renewable energy applications, only one is for a solar facility and it lies
8 almost 50 mi (80 km) from the SEZ. Wind and geothermal applications, which lie as close as
9 16 mi (26 km), would general disturb far less land than a solar facility.

10 11 12 **11.6.22.4.10 Wildlife and Aquatic Biota**

13
14 Wildlife species that could potentially be affected by the development of utility-scale
15 solar energy facilities in the proposed SEZ include amphibians, reptiles, birds, and
16 mammals. The construction of utility-scale solar energy projects in the SEZ and any associated
17 transmission lines and roads in or near the SEZ would have an impact on wildlife through habitat
18 disturbance (i.e., habitat reduction, fragmentation, and alteration), wildlife disturbance, and
19 wildlife injury or mortality. In general, species with broad distributions and a variety of habitats
20 would be less affected than species with a narrowly defined habitat within a restricted area. The
21 use of programmatic design features would reduce the severity of impacts on wildlife. These
22 design features may include pre-disturbance biological surveys to identify key habitat areas used
23 by wildlife, followed by avoidance or minimization of disturbance to those habitats.

24
25 As noted in Section 11.6.22.2, few foreseeable or potential future actions lie within 50 mi
26 (80 km) of the proposed SEZ (Section 11.6.22.2). While impacts from full build-out over 80% of
27 the proposed SEZ would result in small impacts on amphibian, reptile, bird, and mammal species
28 (Section 11.6.11), cumulative impacts from foreseeable development within the 50-mi (80-km)
29 geographic extent of effects are not expected. Many of the wildlife species within the proposed
30 SEZ that could be affected by other actions would still have extensive habitat available within
31 the region, while regional impacts from solar facilities within the proposed SEZ would be small
32 due to its modest size.

33
34 No perennial streams or water bodies are present in the proposed Gold Point SEZ or
35 within the area of direct effects, including the area associated with the proposed new
36 transmission line corridor. Ephemeral streams flow primarily after rainfall and typically do not
37 support wetland or riparian habitats or flow into perennial surface waters. No NWI-mapped
38 wetlands are present within the SEZ or within the area of indirect effects. Within the 50-mi
39 (80-km) geographic extent of effects, the nearest permanent surface water is more than 14 mi
40 (22 km) from the SEZ (Section 11.6.11.4). Soil disturbance from construction of solar facilities
41 in the SEZ could result in soil transport to surface streams via water and airborne routes, but is
42 expected to be low with mitigations in place and is not expected to affect any perennial water
43 body. However, groundwater drawdown by operating solar facilities within the SEZ might affect
44 water levels on off-site streams and wetlands. Since development of the SEZ is not expected to
45 affect aquatic habitats, it would not contribute to cumulative impacts on such habitats. Impacts

1 from other ongoing and foreseeable development within the 50-mi (80-km) geographic extent of
2 effects would be small, given the low level of identified development.
3
4

5 **11.6.22.4.11 Special Status Species (Threatened, Endangered, Sensitive, 6 and Rare Species)** 7

8 On the basis of recorded occurrences in the region or suitable habitat, as many as
9 21 special status species could occur within the proposed Gold Point SEZ. However, no special
10 status species are known to occur within the affected area of the SEZ, and no groundwater-
11 dependent species are known to occur in the vicinity of the SEZ. Special status species that could
12 occur on or in the vicinity of the SEZ include species listed as threatened or endangered in the
13 ESA, listed as protected or sensitive species by the State of Nevada, or listed as a sensitive
14 species by the BLM (Section 11.6.12.1). Potential design features to be used to reduce or
15 eliminate the potential for effects on these species from the construction and operation of utility-
16 scale solar energy projects in the SEZ and related facilities (e.g., access roads and transmission
17 line connections) outside the SEZ include avoidance of habitat and minimization of erosion,
18 sedimentation, and dust deposition. Special status species are also affected by ongoing actions
19 within the 50-mi (80-km) geographic extent of effects, including roads, transmission lines,
20 recreation, and activities at the NTTR. Future facilities would add further effects, including those
21 from one potential solar facility with a pending application covering 12,800 acres (52 km²), one
22 pending and two authorized wind site testing applications covering 40,068 acres (162 km²), and
23 one authorized geothermal applications covering 47,769 acres (193 km²) (Section 11.6.22.2).
24 Although individual facilities would cover large areas and long linear distances and because only
25 a small number of potential actions and no foreseeable actions have been identified, cumulative
26 impacts on special status species within the geographic extent of effects are expected to be small.
27 Future projects would employ mitigation measures to limit effects.
28
29

30 **11.6.22.4.12 Air Quality and Climate** 31

32 While solar energy generates minimal emissions compared with fossil fuels, the site
33 preparation and construction activities associated with solar energy facilities would be
34 responsible for some amount of air pollutants. Most of the emissions would be particulate matter
35 (fugitive dust) and emissions from vehicles and construction equipment. When these emissions
36 are combined with those from other nearby projects outside the proposed SEZ or when they are
37 added to natural dust generation from winds and windstorms, the air quality in the general
38 vicinity of the projects could be temporarily degraded. For example, the maximum 24-hour
39 PM₁₀ concentration at or near the SEZ boundaries could at times exceed the applicable standard
40 of 150 µg/m³. The dust generated by the construction activities can be controlled by
41 implementing aggressive dust control measures, such as increased watering frequency or road
42 paving or treatment.
43

44 Because operation of solar facilities within the proposed SEZ would produce no or
45 minimal contributions of combustion emissions, the only air pollutant of concern is dust
46 generated during construction of new facilities, in addition to that produced by winds. Because

1 there are relatively few other foreseeable or potential actions that could produce fugitive dust
2 emissions near the SEZ, it is unlikely that construction of two or more projects would overlap in
3 both time and affected area and produce cumulative air quality effects due to dust emissions.
4

5 Over the long term and across the region, the development of solar energy may have
6 beneficial cumulative impacts on air quality and atmospheric values by offsetting the need for
7 energy production that results in higher levels of emissions, such as coal, oil, and natural gas.
8 As discussed in Section 11.6.13.2.2, air emissions from operating solar energy facilities are
9 relatively minor, while the displacement of criteria air pollutants, VOCs, TAPs, and GHG
10 emissions currently produced from fossil fuels could be significant. For example, if the relatively
11 small Gold Point SEZ were fully developed (80% of its acreage) with solar facilities, the quantity
12 of pollutants avoided could be as large as 3.6% of all emissions from current electric power
13 systems in Nevada.
14

15 16 **11.6.22.4.13 Visual Resources** 17

18 The proposed Gold Point SEZ is located within Lida Valley in Esmeralda County in
19 southwestern Nevada. The SEZ is flat to slightly sloping, has a strong horizon line, and is
20 surrounded by mountain ranges. The area is rural with few cultural modifications visible;
21 however, roads, transmission lines, and the very small community of Gold Point are visible
22 near the SEZ (Section 11.6.14.1).
23

24 Construction of utility-scale solar facilities in the SEZ would substantially alter the
25 natural scenic quality of the area. Other potential renewable energy projects would cumulatively
26 affect the visual resources in the region. Because of the large size of utility-scale solar energy
27 facilities and the generally flat, open nature of the proposed SEZ, some lands outside the SEZ
28 would also be subjected to visual impacts related to the construction, operation, and
29 decommissioning of utility-scale solar energy facilities. Potential impacts would include night
30 sky pollution, including increased skyglow, light spillage, and glare.
31

32 Visual impacts resulting from solar energy development within the SEZ would be in
33 addition to impacts caused by other potential projects in the area. There currently is one wind
34 project with an authorized application for wind testing on public land within the 25-mi (40-km)
35 geographic extent for visual impacts (Figure 11.6.22.2-1). There are no currently foreseeable
36 projects within this distance, however (Section 11.6.22.2). While the contribution of potential
37 projects to cumulative visual impacts would depend on the location of facilities that are actually
38 built, it may be concluded that small cumulative visual impacts could result from the presence of
39 potential facilities. Because of the topography of the region such facilities, located in basin flats,
40 would be visible at great distances from surrounding mountains, which include sensitive
41 viewsheds, including in Death Valley National Park. Given the low number and wide separation
42 of current proposals, few viewing locations would be affected by two or more facilities.
43 However, facilities would be located near roads and thus would be viewable by motorists, who
44 would also be viewing transmission lines, towns, and other infrastructure, as well as the road
45 system itself.
46

1 As additional facilities are added, multiple projects might be viewed in succession, as
2 viewers move through the landscape, for example, by driving on local roads. In general,
3 however, the small number of potential new facilities would be expected to result in small
4 cumulative visual impacts within the geographic extent of effects.
5
6

7 **11.6.22.4.14 Acoustic Environment**

8

9 The areas around the proposed Gold Point SEZ are relatively quiet. The existing noise
10 sources around the SEZ include road traffic, aircraft flyover, cattle grazing, and recreational
11 activities. The construction of solar energy facilities could increase the noise levels periodically
12 for up to 3 years per facility, but there would be little or minor noise impacts during operation of
13 solar facilities, except from solar dish engine facilities and from parabolic trough or power tower
14 facilities using TES, that could affect nearby residences.
15

16 Other ongoing and reasonably foreseeable and potential future activities in the general
17 vicinity of the SEZ are described in Section 11.6.22.2. Because the residences nearest to the
18 SEZ in Gold Point are relatively far from other potential projects with respect to noise impacts,
19 cumulative noise effects during the construction or operation of solar facilities are unlikely.
20
21

22 **11.6.22.4.15 Paleontological Resources**

23

24 The proposed Gold Point SEZ has low potential for the occurrence of significant fossil
25 material over all its area, which is covered with thick alluvial deposits. The potential for the
26 occurrence of paleontological resources in some portions of the route of the assumed 22-mi
27 (35-km) long new transmission line is unknown (Section 11.6.16.1). While impacts on
28 significant paleontological resources are unlikely to occur in the SEZ, a review of the geological
29 deposits in the specific sites selected for future projects would be needed to determine whether a
30 paleontological survey was warranted. Any paleontological resources encountered would be
31 mitigated to the extent possible. No significant contributions to cumulative impacts on
32 paleontological resources are expected.
33
34

35 **11.6.22.4.16 Cultural Resources**

36

37 The area around Gold Point is rich in cultural history, with settlements dating as far back
38 as 12,000 years. The area covered by the proposed Gold Point SEZ has the potential to contain
39 significant cultural resources, especially related to the mining industry. Visual impacts are
40 possible to the NRHP-eligible Gold Point Town Site. Areas with high potential for containing
41 archaeological sites also lie along the assumed route of the transmission line. While no surveys
42 have been conducted within the SEZ boundaries, 18 surveys have been conducted within the
43 5-mi (8-km) area of indirect effects, recording 12 cultural resources (Section 11.6.17.1). It is
44 possible that the development of utility-scale solar energy projects in the SEZ and the associated
45 transmission line could contribute to cumulative impacts on cultural resources in the region.
46 While any future solar projects would disturb large areas, the specific sites selected would be

1 surveyed; historic properties encountered would be avoided or mitigated to the extent possible.
2 Through ongoing consultation with the Nevada SHPO and appropriate Native American
3 governments, it is likely that most adverse effects on significant resources in the region could
4 be mitigated to some degree. It is unlikely that any sites recorded in the SEZ or along the
5 transmission line would be of such individual significance that, if properly mitigated,
6 development would cumulatively cause an irretrievable loss of information about a significant
7 resource type, but this would depend on the results of the future surveys and evaluations. Visual
8 impacts from the transmission lines are possible on the Goldfield Historic District and,
9 depending on the actual location of the line and the importance of the visual setting for that
10 property, solar development could result in cumulative impacts on the district.
11
12

13 ***11.6.22.4.17 Native American Concerns*** 14

15 To date, no specific concerns have been raised to the BLM regarding the proposed Gold
16 Point SEZ; however the development of utility-scale solar facilities in the proposed SEZ might
17 cumulatively affect resources important to Native Americans. In comments on the scope of this
18 PEIS, the Big Pine Paiute Tribe of the Owens Valley recommended that the BLM preserve
19 undisturbed lands intact and that recently disturbed lands be given primary consideration for
20 solar energy development. Such concerns would similarly apply to other future projects outside
21 the proposed SEZ. Potential impacts on existing water supplies and springs in the Lida Valley
22 from groundwater drawdown by solar energy facilities would be of further concern to local
23 Tribes, as would impacts on important game and plant species and on visual resources
24 (Section 11.6.18.2). Continued discussions with the area Tribes through government-to-
25 government consultation are necessary to effectively consider and address the Tribes' concern
26 tied to solar energy development in the Gold Point SEZ.
27
28

29 ***11.6.22.4.18 Socioeconomics*** 30

31 Solar energy development projects in the proposed Gold Point SEZ could cumulatively
32 contribute to socioeconomic effects in the immediate vicinity of the SEZ and in the surrounding
33 ROI. The effects could be positive (e.g., creation of jobs and generation of extra income,
34 increased revenues to local governmental organizations through additional taxes paid by the
35 developers and workers) or negative (e.g., added strain on social institutions such as schools,
36 police protection, and health care facilities). Impacts from solar development would be most
37 intense during facility construction, but of greatest duration during operations. Construction
38 would temporarily increase the number of workers in the area needing housing and services in
39 combination with temporary workers involved in other new projects in the area, including other
40 renewable energy development. The number of workers involved in the construction of solar
41 projects (including the transmission lines) in the peak construction year could range from about
42 170 to 1,600 depending on the technology being employed, with solar PV facilities at the low
43 end and solar trough facilities at the high end. The total number of jobs created in the area could
44 range from approximately 220 (solar PV) to as high as 2,300 (solar trough). Cumulative
45 socioeconomic effects in the ROI from construction of solar facilities would occur to the extent
46 that multiple construction projects of any type were ongoing at the same time. It is a reasonable

1 expectation that this condition would occur within a 50-mi (80-km) radius of the SEZ
2 occasionally over the 20-year or more solar development period.
3

4 Annual impacts during the operation of solar facilities would be less, but of 20- to
5 30-year duration, and could combine with those from other new facilities in the area, including
6 several potential solar, wind, and geothermal energy projects (Section 11.6.22.2). The number of
7 workers needed at the SEZ solar facilities would range from 8 to 120 with approximately 10 to
8 170 total jobs created in the region, assuming full build-out of the SEZ (Section 11.6.19.2.2).
9 Population increases would contribute to general upward trends in the region in recent years. The
10 socioeconomic impacts overall would be positive, through the creation of additional jobs and
11 income. The negative impacts, including some short-term disruption of rural community quality
12 of life, would not likely be considered large enough to require specific mitigation measures.
13
14

15 ***11.6.22.4.19 Environmental Justice*** 16

17 Any impacts from solar development could have cumulative effects on minority and low-
18 income populations within 50 mi (80 km) of the proposed SEZ in combination with other
19 development in the area. Such impacts could be both positive, such as from increased economic
20 activity, and negative, such as from visual degradation, noise, and exposure to fugitive dust.
21 Actual impacts would depend on where low-income populations are located relative to solar and
22 other proposed facilities and on the geographic range of effects. Overall, effects from facilities
23 within the SEZ are expected to be small, while other foreseeable and potential actions could
24 contribute additional small effects on minority and low-income populations. However, most
25 other potential actions, mainly renewable energy projects, are more than 25 mi (40 km) from the
26 proposed SEZ, while no minority or low-income populations are currently present within the
27 50-mi (80-km) ROI (Section 11.6.20.1). While future minority and low-income populations, if
28 present, could experience small cumulative effects of some types, such as on visual resources or
29 from fugitive dust, from all actions within the geographic extent of effects, contributions from
30 solar development in the proposed Gold Point SEZ would be small. If needed, mitigation
31 measures can be employed to reduce the impacts on these populations in the vicinity of the SEZ.
32
33

34 ***11.6.22.4.20 Transportation*** 35

36 U.S. 95 is the nearest major road and lies about 9 mi (14 km) east of the proposed Gold
37 Point SEZ. The Las Vegas metropolitan area lies approximately 180 mi (290 km) southeast of
38 the SEZ along U.S. 95. Access to the Gold Point SEZ would be from State Route 774, which
39 parallels the eastern edge of the SEZ. This road intersects State Route 266 to the north, which,
40 in turn, intersects U.S. 95 to the east. None of the local airports has scheduled commercial
41 passenger service; the largest major airport is in Las Vegas. The closest railroad access is
42 160 mi (257 km) northwest of the SEZ, north of Hawthorne. During construction of utility-scale
43 solar energy facilities, up to 1,000 workers could be commuting to the construction site at the
44 SEZ, which could increase the AADT on these roads by 2,000 vehicle trips for each facility
45 under construction. With a single solar facility assumed to be under construction at a given
46 time, traffic on all affected roads could experience slowdowns at access points near the SEZ

1 (Section 11.6.21.2). Construction worker traffic could likewise have minor cumulative impacts
2 on traffic flow in combination with existing traffic levels and potential increases from additional
3 future facilities in the vicinity of the proposed SEZ should project schedules overlap. Local road
4 improvements may be necessary on affected roads near access to the SEZ. Any impacts during
5 construction activities would be temporary. The impacts can also be mitigated to some degree by
6 staggered work schedules and ride-sharing programs. Traffic increases during operation would
7 be relatively small because of the low number of workers needed to operate the solar facilities
8 and would have little contribution to cumulative impacts.
9
10

11.7 MILLERS

11.7.1 Background and Summary of Impacts

11.7.1.1 General Information

The proposed Millers SEZ is located in Esmeralda County in southern Nevada (Figure 11.7.1.1-1), 44 mi (71 km) east of the California border. The SEZ has a total area of 16,787 acres (68 km²). In 2008, the county population was 664, while adjacent Nye County to the west had a population of 44,175. The nearest town is Tonopah, Nevada, about 15 mi (24 km) west in Nye County, with a population of approximately 1,500. The NTTR is 30 mi (48 km) northeast of the SEZ.

The nearest major road access to the proposed SEZ is via U.S. 95/U.S. 6, which runs east–west along its southern border. The nearest railroad stop is 90 mi (145 km) away in Thorne, which is the end of a spur from the main line of the UP Railroad. Tonopah Airport, a small county airport 23 mi (37 km) to the east of the SEZ, and three public airports managed by the BLM serve the area, though none have scheduled commercial passenger service or regular freight service.

A 120-kV transmission line passes through the SEZ. It is assumed that this existing transmission line could potentially provide access from the SEZ to the transmission grid (see Section 11.7.1.1.2).

Applications for ROWs that have been submitted to the BLM include one fast-track solar application, one pending solar project, one pending wind site testing application, four authorized wind site testing projects, and two authorized geothermal projects that would be located within 50 mi (80 km) of the Millers SEZ. These applications are discussed in Section 11.7.22.2.1. There are currently no solar applications within the SEZ.

The proposed Millers SEZ is undeveloped and rural, with few permanent residents in the area. The SEZ is located in the Big Smoky Valley, lying between the Lone Mountain to the south, the Monte Cristo Range to the west, and the San Antonio Mountains to the east. Land within the SEZ is undeveloped scrubland characteristic of a high-elevation, semiarid basin.

The criteria used to identify the proposed Millers SEZ as an appropriate location for solar energy development included proximity to existing transmission or designated corridors, proximity to existing roads, and a slope of generally less than 2%. In addition, the area was identified as being relatively free of other types of conflicts, such as USFWS-designated critical habitat for threatened and endangered species, ACECs, SRMAs, and NLCS lands (see Section 2.2.2.2 for the complete list of exclusions). Although these classes of restricted lands were excluded from the proposed Millers SEZ, other restrictions might be appropriate. The analyses in the following sections address the affected environment and potential impacts

1

2 **FIGURE 11.7.1.1-1 Proposed Millers SEZ**

associated with utility-scale solar energy development in the proposed SEZ for important environmental, cultural, and socioeconomic resources.

As initially announced in the *Federal Register* on June 30, 2009, the proposed Millers SEZ encompassed 19,205 acres (78 km²). Subsequent to the study area scoping period, the boundaries of the proposed Millers SEZ were altered somewhat to facilitate the BLM's administration of the SEZ area. The revised SEZ is approximately 2,418 acres (10 km²) smaller than the original SEZ as published in June 2009.

11.7.1.2 Development Assumptions for the Impact Analysis

Maximum solar development of the Millers SEZ is assumed to be 80% of the SEZ area over a period of 20 years, a maximum of 13,430 acres (54 km²). These values are shown in Table 11.7.1.2-1, along with other development assumptions. Full development of the Millers SEZ would allow development of facilities with an estimated total of 1,492 MW of electrical power capacity if power tower, dish engine, or PV technologies were used, assuming 9 acres/MW (0.04 km²/MW) of land required and an estimated 2,686 MW of power if solar trough technologies were used, assuming 5 acres/MW (0.02 km²/MW) of land required.

Availability of transmission from SEZs to load centers will be an important consideration for future development in SEZs. The nearest existing transmission line is a 120-kV line that runs

TABLE 11.7.1.2-1 Proposed Millers SEZ—Assumed Development Acreages, Solar MW Output, Access Roads, and Transmission Line ROWs

Total Acreage and Assumed Developed Acreage (80% of Total)	Assumed Maximum SEZ Output for Various Solar Technologies	Distance to Nearest State, U.S., or Interstate Highway	Distance and Capacity of Nearest Existing Transmission Line	Assumed Area of Transmission Line and Road ROWs	Distance to Nearest Designated Corridor ^e
16,787 acres and 13,430 acres ^a	1,492 MW ^b and 2,686 MW ^c	U.S. 95/U.S. 6 adjacent	0 mi and 120 kV	0 acres; NA ^d	Adjacent

^a To convert acres to km², multiply by 0.004047.

^b Maximum power output if the SEZ were fully developed using power tower, dish engine, or PV technologies, assuming 9 acres/MW (0.04 km²/MW) of land required.

^c Maximum power output if the SEZ were fully developed using solar trough technologies, assuming 5 acres/MW (0.02 km²/MW) of land required.

^d NA = no access road construction is assumed necessary for Millers.

^e BLM-designated corridors are developed for federal land use planning purposes only and are not applicable to state-owned or privately owned land.

1 through the SEZ. It is possible that this existing line could be used to provide access from the
2 SEZ to the transmission grid, but the 120-kV capacity of that line would be inadequate for 1,492
3 to 2,686 MW of new capacity (note that a 500 kV line can accommodate approximately the load
4 of one 700-MW facility). At full build-out capacity, it is clear that substantial new transmission
5 and/or upgrades of existing transmission lines would be required to bring electricity from the
6 proposed Millers SEZ to load centers; however, at this time the location and size of such new
7 transmission facilities are unknown. Generic impacts of transmission and associated
8 infrastructure construction and of line upgrades for various resources are discussed in Chapter 5.
9 Project-specific analyses would need to identify the specific impacts of new transmission
10 construction and line upgrades for any projects proposed within the SEZ.

11
12 For the purposes of analysis in the PEIS, it was assumed that the existing 120-kV
13 transmission line which passes through the proposed SEZ and could provide initial access to the
14 transmission grid. and thus, no additional acreage for transmission line access was assessed.
15 Access to the existing transmission line was assumed, without additional information on whether
16 this line would be available for connection of future solar facilities. If a connecting transmission
17 line were constructed in the future to connect facilities within the SEZ to a different, off-site, grid
18 location from the one assumed here, site developers would need to determine the impacts from
19 construction and operation of that line. In addition, developers would need to determine the
20 impacts of line upgrades if they are needed.

21
22 Existing road access to the proposed Millers SEZ should be adequate to support
23 construction and operation of solar facilities, because U.S. 95/U.S. 6 runs from east to west along
24 the southern border of the SEZ. Thus, no additional road construction outside of the SEZ was
25 assumed to be required to support solar development.

26 27 28 **11.7.1.3 Summary of Major Impacts and SEZ-Specific Design Features**

29
30 In this section, the impacts and SEZ-specific design features assessed in Sections 11.7.2
31 through 11.7.21 for the proposed Millers SEZ are summarized in tabular form. Table 11.7.1.3-1
32 is a comprehensive list of impacts discussed in these sections; the reader may reference the
33 applicable sections for detailed support of the impact assessment. Section 11.7.22 discusses
34 potential cumulative impacts from solar energy development in the proposed SEZ.

35
36 Only those design features specific to the proposed Millers SEZ are included in
37 Sections 11.7.2 through 11.7.21 and in the summary table. The detailed programmatic design
38 features for each resource area to be required under BLM's Solar Energy Program are presented
39 in Appendix A, Section A.2.2. These programmatic design features would also be required for
40 development in this and other SEZs.

TABLE 11.7.1.3-1 Summary of Impacts of Solar Energy Development within the Proposed Millers SEZ and SEZ-Specific Design Features^a

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Lands and Realty	Full development of the SEZ could disturb up to 13,430 acres (54 km ²). Development of the SEZ for utility-scale solar energy production would establish a large industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity. Since the SEZ is rural and undeveloped, utility-scale solar energy development would be a new and dominant land use in the area.	None.
	The designated local transmission corridor located within the SEZ occupies a portion of the proposed SEZ and could limit future solar development within the corridor.	None.
Specially Designated Areas and Lands with Wilderness Characteristics	None.	None.
Rangeland Resources: Livestock Grazing	Grazing on about 4% of the Monte Cristo allotment would be closed.	Development of range improvements in the Monte Cristo allotment should be considered if site-specific analysis determines there would need to be a reduction in permitted AUMs because of lost grazing capacity.
Rangeland Resources: Wild Horses and Burros	Less than 2% of the total land areas of each of two HMAs occur within the indirect impact area of the SEZ. The Paymaster HMA contained an estimated 52 wild horses in FY 2009. The Pilot Mountain HMA contained an estimated 342 wild horses. Indirect impacts on these HMAs and the wild horses in them are expected to be negligible with implementation of design features.	None.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Recreation	A small amount of recreational use would be eliminated from portions of the SEZ that would be developed for solar energy production.	None.
	A portion of an existing route of a competitive OHV race course that passes through the area would be closed.	Alternative routes for the race course should be considered consistent with local land use plan requirements.
Military and Civilian Aviation	The military has expressed serious concern over construction of solar energy facilities within the SEZ. Nellis Air Force Base has indicated that solar technologies requiring structures higher than 50 ft (15 m) above ground level may present unacceptable electromagnetic compatibility concerns for the NTTR test mission and could interfere with flight operations on MTRs that cross the SEZ.	None
	There are no impacts to civilian aviation.	None.
Geologic Setting and Soil Resources	Impacts on soil resources would occur mainly as a result of ground-disturbing activities (e.g., grading, excavating, and drilling) during the construction phase of a solar project. These include soil compaction, soil horizon mixing, soil erosion and deposition by wind, soil erosion by water and surface runoff, sedimentation, and soil contamination. The magnitude of impacts would depend on the types and sizes of components built for a given facility. These impacts may be impacting factors for other resources (e.g., air quality, water quality, and vegetation). Portions of the dry lake may not be a suitable location for construction. A study may be required to evaluate the potential impacts of building a solar facility in close proximity to Crescent Dunes to the northwest of the site.	None.
Minerals (fluids, solids, and geothermal resources)	None.	None.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Water Resources	Ground-disturbance activities (affecting 36% of the total area in the peak construction year) could affect surface water quality due to surface runoff, sediment erosion, and contaminant spills. Construction activities may require up to 3,300 ac-ft (4.1 million m³) of water during the peak construction year. Construction activities would generate as much as 148 ac-ft (182,600 m³) of sanitary wastewater. Assuming full development of the SEZ, operations would use the following amounts of water: • For parabolic trough facilities (2,686-MW capacity), 1,918 to 4,067 ac-ft/yr (2.4 to 5.0 million m³/yr) for dry-cooled systems; water requirements for wet-cooled systems exceed the perennial yield of the basin. • For power tower facilities (1,492-MW capacity), 1,061 to 2,255 ac-ft/yr (1.3 to 2.8 million m³/yr) for dry-cooled systems; water requirements for wet-cooled systems exceed the perennial yield of the basin. • For dish engine facilities (1,492-MW capacity), 763 ac-ft/yr (941,100 m³/yr). • For PV facilities (1,492-MW capacity), 77 ac-ft/yr (95,000 m³/yr). • Assuming full development of the SEZ, operations would generate up to 38 ac-ft/yr (46,900 m³/yr) of sanitary wastewater and up to 763 ac-ft/yr (941,000 m³/yr) of blowdown water.	Water resource analysis indicates that wet-cooling options would not be feasible; other technologies should incorporate water conservation measures. Land disturbance activities should minimize impacts on the ephemeral stream channels of Ione Wash and Peavine Creek, as well as alluvial fan features along the western edge of the SEZ. Siting of solar facilities and construction activities should avoid any areas identified as within a 100-year floodplain or jurisdictional waters. Groundwater rights must be obtained through coordination with the NDWR and current water rights holders. Stormwater management plans and BMPs should comply with standards developed by the Nevada Division of Environmental Protection. Groundwater monitoring and production wells should be constructed in accordance with state standards. Water for potable uses would have to meet or be treated to meet the water quality standards of the <i>Nevada Administrative Code</i>.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Vegetation ^b	Up to 80% (13,430 acres [54.3 km²]) of the SEZ would be cleared of vegetation; re-establishment of shrub communities in temporarily disturbed areas would likely be very difficult because of the arid climate and might require extended periods of time. Noxious weeds could become established in disturbed areas and colonize adjacent undisturbed habitats, thus reducing restoration success and potentially resulting in widespread habitat degradation. The deposition of fugitive dust from large areas of disturbed soil onto habitats outside a solar project area could result in reduced productivity or changes in plant community composition. Sand transport processes could be altered, potentially affecting sand dune plant communities in Crescent Dunes, northeast of the SEZ, or dunes southwest of the SEZ. Vegetation communities associated with playa habitats, Ione Wash, dry washes, greasewood flats communities, or other intermittently flooded areas within or downgradient from solar projects or the access road could be affected by ground-disturbing activities. Candelaria blazingstar, a plant species on the Nevada Natural Heritage Program watch list may occur within the SEZ and may be directly affected by solar project development. The population occurring east of the SEZ may be indirectly affected by project activities within the SEZ.	An Integrated Vegetation Management Plan, addressing invasive species control, and an Ecological Resources Mitigation and Monitoring Plan addressing habitat restoration should be approved and implemented to increase the potential for successful restoration of affected habitats and minimize the potential for the spread of invasive species. Invasive species control should focus on biological and mechanical methods where possible to reduce the use of herbicides. Dry washes, Ione Wash, playas, and wetlands within the SEZ should be avoided to the extent practicable, and any impacts minimized and mitigated. A buffer area should be maintained around wetlands, playas, and dry washes to reduce the potential for impacts. Appropriate engineering controls should be used to minimize impacts on the playa wetland and other playas, as well as Ione Wash shrub communities, dry washes and greasewood flat habitats within the SEZ, and downstream occurrences, resulting from surface water runoff, erosion, sedimentation, altered hydrology, accidental spills, or fugitive dust deposition to these habitats. Appropriate buffers and engineering controls would be determined through agency consultation. Groundwater withdrawals should be limited to reduce the potential for indirect impacts on plant communities that access groundwater, such as those in the vicinity of playas. Potential impacts on springs should be determined through hydrological studies.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Vegetation ^b (Cont.)		A qualified botanist or plant ecologist should survey for candelaria blazing star during a period when it is flowering and easily documented prior to any construction activities within the SEZ. If individuals are located, individuals or populations should be avoided through fencing and flagging of the area, including an appropriate buffer zone.
Wildlife: Amphibians and Reptiles ^b	Direct impacts from SEZ development for all representative amphibian and reptile species would be small (i.e., loss of $\leq 1.0\%$ of potentially suitable habitats within the SEZ region). With implementation of design features, indirect impacts would be negligible.	Wash and playa habitats should be avoided.
Wildlife: Birds ^b	Direct impacts on representative bird species would be moderate for the killdeer (i.e., loss of 1.1% of potentially suitable habitats within the SEZ region) and small for all other bird species (i.e., loss 0.5% or less of potentially suitable habitats within the SEZ region). Other impacts on birds could result from collision with vehicles and infrastructure (e.g., buildings and fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment.	The requirements contained within the 2010 Memorandum of Understanding between the BLM and USFWS to promote the conservation of migratory birds will be followed. Take of golden eagles and other raptors should be avoided. Mitigation regarding the golden eagle should be developed in consultation with the USFWS and the NDOW. A permit may be required under the Bald and Golden Eagle Protection Act. Wash and playa habitats should be avoided.
Wildlife: Mammals ^b	Direct impacts on all representative mammal species would be small.	The fencing around the solar energy development

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
	Loss of potentially suitable habitats for cougar, mule deer, and pronghorn would be 0.3%, 0.3%, and 0.2%, respectively, of potentially suitable habitats within the SEZ region. Loss of potentially suitable habitats for the other representative mammal species would be 0.4% or less of potentially suitable habitats within the SEZ region. Other impacts on mammals could result from collision with vehicles and infrastructure (e.g., fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment. These impacts are expected to be negligible with the implementation of design features.	should not block the free movement of mammals, particularly big game species. Wash and playa habitats should be avoided.
Aquatic Biota ^b	No permanent streams or water bodies occur within the proposed Millers SEZ. The surface water features that do occur in the area are generally dry most of the time and do not support wetland or riparian habitats. Consequently, potential effects on aquatic habitats or biota from solar energy development within the proposed SEZ would be negligible.	None.
Special Status Species ^b	Potentially suitable habitat for 19 special status species occurs in the affected area of the Millers SEZ. For all special status species, less than 1% of the potentially suitable habitat in the region occurs in the area of direct effects.	Pre-disturbance surveys should be conducted within the area of direct effects to determine the presence and abundance of special status species. Disturbance to occupied habitats for these species should be avoided or minimized to the extent practicable. If avoiding or minimizing impacts to occupied habitats is not possible for some species, translocation of individuals from areas of direct effects; or compensatory mitigation of direct effects on occupied habitats could reduce impacts. A comprehensive mitigation strategy for special status species that used one or more of these options to
Special Status Species ^b		offset the impacts of development should be

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
(Cont.)		developed in coordination with the appropriate federal and state agencies. Coordination should be conducted with the USFWS and NDOW for the Crescent Dunes aegialian scarab beetle, Crescent Dunes serican scarab beetle, and greater sage-grouse – species that are candidates or under review for ESA listing. Coordination would identify an appropriate survey protocol, and mitigation requirements, which may include avoidance, minimization, translocation, or compensation. Harassment or disturbance of special status species and their habitats in the affected area should be avoided or minimized. This can be accomplished by identifying any additional sensitive areas and implementing necessary protection measures based upon consultation with the USFWS and NDOW.
Air Quality and Climate	<i>Construction:</i> Predicted 24-hour and annual PM₁₀ and 24-hour PM_{2.5} concentration levels could exceed the AAQS at the SEZ boundaries and in the immediate surrounding areas during the construction of solar facilities. However, concentrations would decrease quickly with distance. Modeling indicates that emissions from construction activities are not anticipated to exceed Class I PSD PM₁₀ increments at the nearest federal Class I area. In addition, construction emissions from the engine exhaust of heavy equipment and vehicles could somewhat affect AQRVs at nearby federal Class I areas.	None.
Air Quality and Climate	<i>Operations:</i> Positive impact due to avoided emission of air pollutants	

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
(Cont.)	from combustion-related power generation: 6.9 to 12% of total SO ₂ , NO _x , Hg, and CO ₂ emissions from electric power systems in the State of Nevada (up to 6,639 tons/yr SO ₂ , 5,695 tons/yr NO _x , 0.038 tons/yr Hg, and 3,655,000 tons/yr CO ₂).	
Visual Resources	The SEZ is in an area of low scenic quality, with some cultural disturbances already present. Residents, workers, and visitors to the area may experience visual impacts from solar energy facilities located within the SEZ (as well as any associated access roads and transmission lines) as they travel area roads. The residents nearest to the SEZ could be subjected to large visual impacts from solar energy development within the SEZ. Large visual impacts on the SEZ and surrounding lands within the SEZ viewshed due to major modification of the character of the existing landscape are possible. Approximately 31 mi (50 km) of U.S. 6 is within the SEZ viewshed. Weak to strong visual contrasts could be observed within the SEZ by travelers on U.S. 6.	None.
Acoustic Environment	<i>Construction.</i> For construction activities occurring near the southeastern SEZ boundary, estimated noise levels at the nearest residences (about 11 mi [18 km] east-southeast of the SEZ) would be about 15 dBA, which is well below a typical daytime mean rural background level of 40 dBA. In addition, an estimated 40-dBA L_{dn} at these residences (i.e., no contribution from construction activities) is well below the EPA guidance of 55 dBA L_{dn} for residential areas. <i>Operations.</i> Noise levels at the nearest residences from a parabolic trough or power tower facility would be about 21 dBA, which is much lower than the typical daytime mean rural background level of 40 dBA. For 12-hour daytime operation, about 40 dBA L_{dn} (i.e., no contribution from facility operation) would be estimated for the nearest residences, which is	None.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
(Cont.)	well below the EPA guideline of 55 dBA L_{dn} for residential areas. In the case of 6-hour TES, the estimated nighttime noise level at the nearest residences would be 31 dBA, which is comparable to the typical nighttime mean rural background level of 30 dBA. The day-night average noise level is estimated to be about 41 dBA L_{dn}, which is well below the EPA guideline of 55 dBA L_{dn} for residential areas. If 80% of the SEZ were developed with dish engine facilities, the estimated noise level at the nearest residences, about 11 mi (18 km) from the SEZ boundary, would be about 33 dBA, which is below the typical daytime mean rural background level of 40 dBA. Assuming 12-hour daytime operation, the estimated 40 dBA L_{dn} at these residences would be well below the EPA guideline of 55 dBA L_{dn} for residential areas.	
Paleontological Resources	The potential for impacts on significant paleontological resources in 94% of the proposed Millers SEZ is unknown, but potentially high. A more detailed investigation of the lacustrine and playa deposits is needed prior to project approval. A paleontological survey would likely be needed. Few, if any, impacts on significant paleontological resources are likely in the remaining 6% of the proposed SEZ. However, a more detailed look at the geological deposits of the SEZ is needed to determine whether a paleontological survey is warranted.	The need for and the nature of any SEZ-specific design features would depend on the results of future paleontological investigations.
Cultural Resources	Direct impacts on significant cultural resources could occur in the proposed Millers SEZ; however, further investigation is needed. At least 30 sites have been recorded within the SEZ, although none have been evaluated for inclusion in the NRHP. Dune areas have considerable potential for containing significant sites on the valley floors suitable for solar development. The area within the proposed Millers SEZ associated with Lake Tonopah also has the potential to provide significant sites related to exploitation of lacustrine resources.	Avoidance of areas with a high potential for a high density of sites, such as in the vicinity of both the former Lake Tonopah and Millers town site, is recommended.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Cultural Resources (Cont.)	A cultural resource survey of the entire area of potential effect, including consultation with affected Native American Tribes, would first need to be conducted to identify archaeological sites, historic structures and features, and traditional cultural properties, and an evaluation would need to follow to determine whether any are eligible for listing in the NRHP.	Other SEZ-specific design features would be determined through consultation with the Nevada SHPO and affected Tribes and would depend on the results of future investigations.
Native American Concerns	While no comments specific to the proposed Millers SEZ have been received from Native American Tribes to date, as consultation with the Tribes continues and project-specific analyses are undertaken, it is possible that Native Americans will express concern over potential visual, acoustic, and other effects of solar energy development within the SEZ on specific resources, including culturally important landscapes.	The need for and nature of SEZ-specific design features would be determined during government-to-government consultations with the affected Tribes.
Socioeconomics	<i>Construction:</i> 346 to 4,578 total jobs; \$21 million to \$278.3 million income in ROI. <i>Operations:</i> 36 to 785 annual total jobs; \$1.2 million to \$26.3 million annual income in the ROI.	None.
Environmental Justice	Minority and low-income <i>individuals</i> live within 50 mi (80 km) of the SEZ. However, as defined in CEQ guidelines, no minority or low-income <i>populations</i> occur within that area; thus, there would be no disproportionately high and adverse human health or environmental effects on low-income or minority populations.	None.

TABLE 11.7.1.3-1 (Cont.)

Resource Area	Environmental Impacts—Proposed Millers SEZ	SEZ-Specific Design Features
Transportation	The primary transportation impacts are anticipated to be from commuting worker traffic. Single projects could involve up to 1,000 workers each day, with an additional 2,000 vehicle trips per day (maximum) or possibly 4,000 vehicle trips per day if two larger projects were to be developed at the same time. The volume of traffic on U.S. 95 along the southern edge of the Millers SEZ would represent an increase in traffic of about 100 or 200% for one or two projects, respectively, should all traffic access the SEZ in that area.	None.

Abbreviations: AAQS = ambient air quality standards; AQRV = air quality-related value; AUM = animal unit month; BLM = Bureau of Land Management; CEQ = Council on Environmental Quality; CO₂ = carbon dioxide; DoD = U.S. Department of Defense; EPA = U.S. Environmental Protection Agency; ESA = Endangered Species Act; FY = Fiscal Year; Hg = mercury; HMA = Herd Management Area; MTR = military training route; NDOW = Nevada Department of Wildlife; NDWR = Nevada Division of Water Resources; NO_x = nitrogen oxides; NRHP = *National Register of Historic Places*; NTTR = Nevada Test and Training Range; OHV = off-highway vehicle; PEIS = programmatic environmental impact statement; PM_{2.5} = particulate matter with an aerodynamic diameter of 2.5 µm or less; PM₁₀ = particulate matter with an aerodynamic diameter of 10 µm or less; PSD = prevention of significant deterioration; PV = photovoltaic; ROI = region of influence; SEZ = solar energy zone; SHPO = State Historic Preservation Office; SO₂ = sulfur dioxide; USFS = U.S. Forest Service; USFWS = U.S. Fish and Wildlife Service.

^a The detailed programmatic design features for each resource area to be required under BLM's Solar Energy Program are presented in Appendix A, Section A.2.2. These programmatic design features would be required for development in the proposed Millers SEZ.

^b The scientific names of all plants, wildlife, aquatic biota, and special status species are provided in Sections 11.7.10 through 11.7.12.

11.7.2 Lands and Realty

11.7.2.1 Affected Environment

The proposed Millers SEZ is a large and very well-blocked area of BLM-administered public land. The overall character of the land in the SEZ area is rural and undeveloped, although there are numerous dirt roads that cross the SEZ. The old town site of Millers is located just south of the SEZ, and there is land disturbance all around the SEZ associated with road construction, power line construction, mining, and development of the town site. U.S. 6/U.S. 95 parallels the southern side of the SEZ and provides good access to the site. There is a highway rest stop just south of the southeastern corner of the SEZ.

There are several transmission lines within ROWs in and near the SEZ. Two lines traverse the area, one in a north–south direction and the other in a northwest–southeast direction. There are maintenance roads along these transmission lines. The latter line is located within one of the two locally designated corridors near the SEZ. The second corridor, which contains two existing transmission lines, parallels the southeastern boundary of the SEZ, and small portions of the ROW for one of the transmission lines lie within the SEZ. There is a designated Section 368 (of the Energy Policy Act of 2005) energy corridor about 15 mi (24 km) southwest of the SEZ. Small portions of the ROWs for U.S. 6/U.S. 95 and a fiber optic line paralleling the highway are within the SEZ as well.

As of February 2010, there were no ROW applications for solar energy facility development on the SEZ; however, the BLM is processing a solar energy application for a site about 3 mi (5 km) east of the proposed SEZ.

11.7.2.2 Impacts

11.7.2.2.1 Construction and Operations

Full development of the proposed Millers SEZ could disturb up to 13,430 acres (54 km²) (Table 11.7.1.2-1). Development of the SEZ for utility-scale solar energy production would establish a large industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity. Since the SEZ is rural and undeveloped, utility-scale solar energy development would be a new and dominant land use in the area.

Existing ROW authorizations on the SEZ are prior existing rights, and facilities within the ROWs would not be affected by solar energy development. Since the small portions of three ROWs within the southern and southeastern boundaries of the SEZ were issued in aliquot parts rather than based on a survey, it is likely that there is no physical development in them within the SEZ. There is a technical issue about whether the existing ROW holders would agree to amend their existing ROWs to allow solar development to occur within the existing ROWs or if it would be necessary to make minor adjustments to the proposed SEZ boundary to

1 avoid these ROWs. Either way, existing rights issued to the ROW holders would be protected.
2 Should the proposed SEZ be identified as an SEZ in the ROD for this PEIS, the BLM would still
3 have discretion to authorize additional ROWs in the area until solar energy development was
4 authorized, and then future ROWs would be subject to the rights issued for solar energy
5 development. Because the area currently has so few ROWs present, and there is a large amount
6 of potentially available BLM-administered land nearby, it is not anticipated that approval of solar
7 energy development would have a significant impact on public land available for future ROWs
8 in the area.
9

10 The designated local transmission corridor located within the SEZ occupies an
11 undetermined amount of the proposed SEZ and could limit future solar development within the
12 corridor. To avoid technical or operational interference between transmission and solar energy
13 facilities, solar energy facilities cannot be constructed under transmission lines or over pipelines.
14 The corridor could be relocated outside the SEZ to allow full solar development within the SEZ.
15 This is an administrative conflict that the BLM can address through its planning process; but if
16 the existing corridor alignment is retained, there would be implications for the amount of
17 potential solar energy development that could be accommodated within the SEZ.
18
19

20 ***11.7.2.2.2 Transmission Facilities and Other Off-Site Infrastructure***

21

22 An existing 120-kV transmission line runs adjacent to the SEZ; this line might be
23 available to transport the power produced in this SEZ. Establishing a connection to the existing
24 line would not involve the construction of a new transmission line outside of the SEZ. If a
25 connecting transmission line were constructed in a different location outside of the SEZ in the
26 future, site developers would need to determine the impacts from construction and operation of
27 that line. In addition, developers would need to determine the impacts of line upgrades if they
28 were needed. .
29

30 U.S. 6/U.S. 95 is adjacent to the SEZ, and it is assumed that no new roads would be
31 required to provide access to the site. Roads and transmission lines would be constructed within
32 the SEZ as part of the development of the area.
33
34

35 ***11.7.2.3 SEZ-Specific Design Features and Design Feature Effectiveness***

36

37 There are no SEZ specific design features proposed to protect lands and realty resources.
38 Implementing the programmatic design features described in Appendix A, Section A.2.2, as
39 required under BLM's Solar Energy Program, would provide adequate mitigation for some
40 identified impacts. The exceptions would be the establishment of a large industrial area that
41 would exclude many existing and potential uses of the land and would be a new and discordant
42 land use to the area.
43

11.7.3 Specially Designated Areas and Lands with Wilderness Characteristics

11.7.3.1 Affected Environment

Specially designated areas normally consist of the following:

- National Parks, National Monuments, National Recreation Areas, National Preserves, National Wildlife Refuges, National Reserves, National Conservation Areas, National Historic Sites;
- Congressionally authorized Wilderness Areas;
- Wilderness Study Areas;
- National Wild and Scenic Rivers;
- Congressionally authorized Wild and Scenic Study Rivers;
- National Scenic Trails and National Historic Trails;
- National Historic Landmarks and National Natural Landmarks;
- All-American Roads, National Scenic Byways, State Scenic Highways; and BLM- and USFS-designated scenic highways/byways;
- BLM-designated Special Recreation Management Areas;
- BLM-designated ACECs; and
- Designated state or local facilities or attractions.

In the case of the proposed Millers SEZ, none of these types of areas are present within 25 mi (40 km) of the SEZ. In addition, there are no areas within 25 mi (40 km) of the SEZ that have been identified by the BLM as possessing wilderness characteristics.

11.7.3.2 Impacts

There would be no impacts on specially designated areas in the SEZ.

11.7.3.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features would be required to protect specially designated areas.

11.7.4 Rangeland Resources

11.7.4.1 Livestock Grazing

11.7.4.1.1 Affected Environment

The proposed Millers SEZ contains a small portion of the Monte Cristo perennial grazing allotment. The total acreage of the allotment is 496,018 acres (2,007 km²). One permittee operates in the allotment.

11.7.4.1.2 Impacts

Construction and Operations

Should utility-scale solar development occur in the SEZ, grazing would be excluded from the areas developed as provided for in the BLM grazing regulations (43 CFR Part 4100). This would include reimbursement of the permittee for their portion of the value for any range improvements in the area removed from the grazing allotment. There are 16,787 acres (68 km²) of public lands in this SEZ, which is less than 4% of the Monte Cristo allotment. Because of the size of the allotment, the loss of this portion of the allotment is not anticipated to have a significant impact on the overall grazing operation because there likely are opportunities to make livestock management changes and/or to provide additional livestock management facilities to mitigate the loss of forage within the SEZ. No loss of AUMs is anticipated.

Transmission Facilities and Other Off-Site Infrastructure

Because of the availability of a major transmission line in the SEZ, and U.S. 6/U.S. 95 near the SEZ, and assuming that additional project-specific analysis would be done for construction of such infrastructure, no assessment of the impacts of such activities outside of the SEZ was conducted (see Section 11.7.1.2).

11.7.4.1.3 SEZ-Specific Design Features and Design Feature Effectiveness

Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program would provide adequate mitigation for some identified impacts. The exception may be the loss of 4% of the Monte Cristo grazing allotment.

1 A proposed design features specific to the Millers SEZ is:

- 2
- 3 • Development of range improvements in the Monte Cristo allotment should be
 - 4 considered if site-specific analysis determines there would need to be a
 - 5 reduction in permitted AUMs because of lost grazing capacity.
 - 6

7

8 **11.7.4.2 Wild Horses and Burros**

9

10

11 **11.7.4.2.1 Affected Environment**

12

13 Section 4.4.2 discusses wild horses (*Equus caballus*) and burros (*E. asinus*) that occur

14 within the six-state study area. Nearly 100 wild horse and burro herd management areas (HMAs)

15 occur within Nevada (BLM 2009d). A number of HMAs occur within the 50-mi (80-m) SEZ

16 region for the proposed Millers SEZ (Figure 11.7.4.2-1). A portion of the Paymaster and Pilot

17 Mountain HMAs occurs within the indirect impact area of the SEZ. The Paymaster HMA

18 contained an estimated population of 52 wild horses in FY 2009, although the appropriate

19 management level is only 38 wild horses. The Pilot Mountain HMA contained an estimated

20 population of 342 wild horses, which is less than the appropriate management level of 415 wild

21 horses (BLM 2010c).

22

23 In addition to the HMAs managed by the BLM, the USFS has wild horse and burro

24 territories in Arizona, California, Nevada, New Mexico, and Utah; and is the lead management

25 agency that administers 37 of the territories (Giffen 2009; USFS 2007). The closest territories

26 to the Millers SEZ are the Toiyabe and Monitor territories located about 21 and 23 mi (34 and

27 37 km), respectively, from the SEZ (Figure 11.7.4.2-1). No wild horses occupy the Toiyabe

28 Territory; wild horses occur in the Monitor Territory, but the number present is not reported

29 (USFS 2005a,b).

30

31

32 **11.7.4.2.2 Impacts**

33

34 The Paymaster HMA totals 100,591 acres (407.1 km²), of which 99,919 acres

35 (404.4 km²) are BLM acres. About 998 acres (4 km²), or 1.0%, of the HMA would be in the

36 area of indirect impact for the proposed Millers SEZ. The Pilot Mountain HMA totals

37 477,136 acres (1,930.9 km²), of which 475,499 acres (1,924.3 km²) are BLM acres. About

38 29,219 acres (118.2 km²), or 1.6%, of the HMA would be in the area of indirect impact for the

39 SEZ. Indirect impacts on wild horses could result from surface water and sediment runoff from

40 disturbed areas, fugitive dust generated by project activities, noise, and harassment. These

41 indirect impacts are expected to be negligible with the implementation of programmatic design

42 features. USFS wild horse territories are located well outside of the indirect impact area for the

43 proposed Millers SEZ; thus, no direct or indirect impacts on any wild horses in USFS wild horse

44 territories would occur from the construction or operations of solar facilities in the SEZ.

45

46

FIGURE 11.7.4.2-1 Wild Horse and Burro Herd Management Areas and Territories within the Analysis Area for the Proposed Millers SEZ (Sources: BLM 2010b; USFS 2007)

11.7.4.2.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features for solar development within the proposed Millers SEZ would be necessary to protect or minimize direct impacts on wild horses and burros. Indirect impacts should be reduced to negligible levels by implementing programmatic design features and engineering controls that reduce noise lighting, spills, and fugitive dust.

11.7.5 Recreation

11.7.5.1 Affected Environment

The site of the proposed Millers SEZ is located adjacent to U.S. 6/U.S. 95 and is about 15 mi (24 km) from Tonopah. The area is flat and generally unremarkable, with numerous roads and trails that provide access through the area. While there are no recreational use data for the area, backcountry driving, OHV use of the roads and trails, and hunting are likely to be the major recreational activities in the area. A portion of the route for the annual Las Vegas to Reno OHV race passes through the area.

11.7.5.2 Impacts

11.7.5.2.1 Construction and Operations

Recreational use would be eliminated from portions of the SEZ developed for solar energy production. Although there are no recreational use figures for the area, the nature of the area does not encourage recreational use. The area contains numerous roads and trails that are available for travel that would be closed if solar energy development would occur, and the route of the Las Vegas to Reno OHV race within the SEZ would be closed. The potential loss of recreational use that would accompany solar development of the SEZ is anticipated to be small.

Solar development within the SEZ would affect public access along OHV routes designated open and available for public use. If open OHV routes within the SEZ were identified during project-specific analyses, they would be re-designated as closed (see Section 5.5.1 for more details on how routes coinciding with proposed solar facilities would be treated).

11.7.5.2.2 Transmission Facilities and Other Off-Site Infrastructure

Because of the availability of an existing transmission line and U.S. 6/U.S. 95 near the SEZ, no additional construction of transmission or road facilities was assessed. Should additional transmission lines be required outside of the SEZ, there may be additional recreation impacts. See Section 11.7.1.2 for the development assumptions underlying this analysis.

11.7.5.3 SEZ-Specific Design Features and Design Feature Effectiveness

Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would provide some mitigation for some identified impacts. The exceptions may be recreational use of the area developed for solar energy production would be lost and would not be mitigatable.

1 Proposed design features specific to the Millers SEZ include the following:
2

- 3 • Alternative routes for the Las Vegas to Reno race should be considered
4 consistent with local land use plan requirements.
5

11.7.6 Military and Civilian Aviation

11.7.6.1 Affected Environment

Approximately the eastern two-thirds of the proposed Millers SEZ is covered by MTRs, with 50- and 100-ft (15- and 30-m) AGL operating limits. The area is located about 26 mi (42 km) northwest of the boundary of the NTTR and the Nellis Air Force Base.

The closest civilian municipal aviation facility is the Tonopah Municipal Airport, which is located about 20 mi (32 km) southeast of the SEZ. The airport does not have scheduled commercial passenger service or regular freight service.

11.7.6.2 Impacts

The military has expressed serious concern over solar energy facilities being constructed within the proposed Millers SEZ and at the solar energy site currently being evaluated just east of the SEZ. The military is especially concerned over the potential use of power tower facilities that would obstruct existing military airspace. Nellis Air Force Base has indicated that it has concerns for its use of the MTRs because of potential overflight restrictions above a solar energy facility, the height of solar facilities, possible restrictions on hydrocarbon or residue from fuel burn by aircraft, possible glare from reflective surfaces, and any potential restrictions on supersonic operations over solar facilities. The NTTR has indicated that solar technologies requiring structures higher than 50 ft (15 m) AGL may present unacceptable electromagnetic compatibility concerns for its test mission at the NTTR. The NTTR maintains that a pristine testing environment is required for the unique national security missions conducted on the NTTR. The potential electromagnetic interference impacts from solar facilities on testing activities at the NTTR, coupled with potential training route obstructions created by taller structures, make it likely that solar facilities exceeding 50 ft (15 m) could significantly affect military operations.

The Air Force states that the NTTR complex is unique in the world in its ability to provide realistic training of air crews. In addition to the effect of individual solar energy facilities, there is a more general concern over the potential for cumulative effects from multiple solar energy projects around the NTTR to eventually have a serious adverse effect on the training environment of the NTTR.

The Tonopah Airport is located far enough away from the proposed SEZ that there would be no effect on airport operations.

11.7.6.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ specific design features are required to protect either military airspace or civilian aviation operations. The programmatic design features described in Appendix A, Section A.2.2, would require early coordination with the DoD to identify and mitigate, if possible, potential impacts on the use of MTRs.

11.7.7 Geologic Setting and Soil Resources

11.7.7.1 Affected Environment

11.7.7.1.1 Geologic Setting

Regional Setting

The proposed Millers SEZ is located in the Big Smoky Valley, a north-trending basin within the Basin and Range physiographic province in south-central Nevada. In the Millers SEZ region, the valley is bounded on the northwest by the Monte Cristo Range and Royston Hills and on the east by the San Antonio Mountains. The Lone Mountain lies to the south (Figure 11.7.7.1-1). The Big Smoky Valley is one of many structural basins (graben) typical of the Basin and Range province.

Exposed sediments in the Big Smoky Valley consist mainly of modern alluvial (Qa) and playa (Qp) sediments. Alluvial sediments at the Millers SEZ cover or partially cover lacustrine deposits (Ql) associated with Lake Tonopah, an ancient lake that covered the valley during the Pleistocene (Figure 11.7.7.1-2). These fine-grained sediments—sandy silts, silts, sandy clays, and clays—are found in the valley center and are abundant within the SEZ. Sand dunes and dune complexes also occur throughout the valley; the Crescent Dunes are located about 6 mi (10 km) to the northwest of the SEZ. In the surrounding mountains, exposures are predominantly Tertiary volcanics. The oldest rocks in the region are the Late Proterozoic to Cambrian metamorphic rocks (CZq) that occur in Lone Mountain south of the SEZ. These rocks have been intruded by Mesozoic granites and granodiorites.

Semiconsolidated to unconsolidated basin-fill deposits are estimated to be about 5,000 ft (1,530 m) thick in the northern part of the Big Smoky Valley; estimates for the southern part of the valley, where the proposed Millers SEZ is located, have not been reported. Basin-fill sediments constitute the most important aquifers in the Big Smoky Valley (Handman and Kilroy 1997).

Topography

The Big Smoky Valley covers an area of about 567,700 acres (2,300 km²) (USDA 1980) and stretches 115 mi (185 km) across three counties in south-central Nevada (Figure 11.7.7.1-1). Elevations along the valley axis range from about 6,200 ft (1,890 m) at its northern end (Lander County) and along the valley sides to about 4,750 ft (1,450 m) at its southern end (Esmeralda County). Alluvial fan deposits occur along the mountain fronts on both sides of the valley; near the SEZ, they enter the valley from the west. The valley is drained by several unnamed ephemeral streams. Other topographic features include sand dunes, playas, and the many

FIGURE 11.7.7.1-1 Physiographic Features of the Big Smoky Valley Region

- Ti Rhyolitic intrusive rocks
- Tml Intrusive rocks of mafic and intermediate composition
- Tt2 Welded and nonwelded silic ash-flow tuffs
- Tr Rhyolitic flows and shallow intrusive rocks (Tr2 and Tr3)
- Ta Andesite and related rocks of intermediate composition (Ta2 and Ta3)
- Tba Andesite and basalt flows
- Ts3 Tuffaceous sedimentary rocks, locally includes minor amounts of tuff
- TJgr Granitic rocks (inconclusively dated)

Mesozoic

- Mqr Granitic rocks, mostly quartz monzonite and granodiorite
- MJs Diorite
- Jd Dunlap Formation (conglomerate, sandstone, greenstone, felsite and tuff)
- TRgr Leucogranite and rhyolite porphyry
- Ml Massive limestone
- MZgr Granitic rocks, mostly quartz monzonite and granodiorite (inconclusively dated)

Paleozoic

- PMh Chert, argillite, shale, greenstone, and minor amounts of siltstone, sandstone, conglomerate and limestone (Havallah Sequence)
- Qdv Siliceous and volcanic rocks
- Qz Phyllitic siltstone, quartzite and lesser amounts of limestone and dolomite

Precambrian

- Zw Wyman Formation (phyllite and phyllitic siltstone and minor amounts of limestone, dolomite and sandstone)

SOL 005

FIGURE 11.7.7.1-2 (Cont.)

1 unnamed washes that drain the surrounding mountains and feed the central streams in the valley
2 center.

3
4 The proposed Millers SEZ is located in the southern part of the Big Smoky Valley,
5 between the Monte Cristo Range and Royston Hills to the northwest, the Lone Mountain to the
6 south, and the San Antonio Mountains to the east. Its terrain is relatively flat, with elevations
7 ranging from about 4,850 ft (1,480 m) along the northern border to 4,780 ft (1,460 m) near the
8 southwest end (Figure 11.7.7.1-3). Several drainages enter the SEZ from the north and drain to a
9 large playa southwest of the site. A series of unnamed sand dunes occupy the northeast corner of
10 the site.

11 12 13 **Geologic Hazards**

14
15 The types of geologic hazards that could potentially affect solar project sites and their
16 mitigation are discussed in Section 5.7.3. The following sections provide a preliminary
17 assessment of these hazards at the proposed Millers SEZ. Solar project developers may need
18 to conduct a geotechnical investigation to identify and assess geologic hazards locally to better
19 identify facility design criteria and site-specific design features to minimize their risk.

20
21
22 **Seismicity.** The Big Smoky Valley is located within the Walker Lane Belt, a northwest-
23 trending seismic region along the Nevada–California border that accommodates (right-lateral
24 shear) strain from movement between the Pacific and North American plates. The proposed
25 Millers SEZ lies within a zone of north–northeast trending extensional (normal) faults that run
26 parallel to the valley axis and border the mountains to the southeast. These include the Lone
27 Mountain and Paymaster Ridge faults, which extend from the SEZ to the southwest, and the
28 Crescent Dune fault, which extends from the SEZ to the northeast (Figure 11.7.7.1-4).

29
30 The Lone Mountain fault extends from the southeast corner of the Millers SEZ near
31 the Nye-Esmeralda county border to the southwest, along the northwest front of Lone
32 Mountain and the Weepah Hills and the southeast side of the Big Smoky Valley sand dunes
33 (Figure 11.7.7.1-4). Well-defined scarps along the fault trace in these areas show down-to-the-
34 northwest displacement of as much as 16 ft (5 m). With the estimated age of offset sediments,
35 the most recent movement along the fault is estimated at less than 15,000 years ago. The slip
36 rate along this fault is estimated to be less than 0.2 mm/yr. Recurrence intervals have not been
37 estimated (Anderson and Sawyer 1999).

38
39 The north-trending Paymaster Ridge fault is located about 4 mi (6.4 km) south of the
40 Millers SEZ (Figure 11.7.7.1-4). It extends to the south, along the eastern front of Lone
41 Mountain, and continues for the length of Paymaster Ridge to the south. The fault is thought to
42 be the major block-bounding fault separating Paymaster Ridge from the basin (graben) beneath
43 Clayton Valley to the west. The fault plane likely dips gently to the west, and displacement is
44 down to the west. With the age of offset sediments (Late Pleistocene), the most recent movement
45 along the fault is estimated at less than 130,000 years ago. The slip rate along this fault is
46

FIGURE 11.7.7.1-3 General Terrain of the Proposed Millers SEZ

FIGURE 11.7.7.1-4 Quaternary Faults in the Big Smoky Valley Region (Sources: USGS and NBMG 2010)

1 estimated to be less than 0.2 mm/yr. Recurrence intervals have not been estimated (Anderson
2 and Ernest 1999).

3
4 The Crescent Dune fault is located about 4 mi (6.4 km) east of the Millers SEZ
5 (Figure 11.7.7.1-4). It comprises a series of normal faults that extend to the north, along the
6 western front of the San Antonio Mountains and across the piedmont slopes in the eastern part of
7 the Big Smoky Valley. Scarps at the northwest end of the San Antonio Mountains and piedmont
8 slope surfaces indicate displacement of as much as 13 ft (4 m). With the age of offsets of Early
9 Pleistocene sediments and Tertiary volcanic rocks, the most recent movement along these faults
10 is estimated at less than 130,000 years ago. Slip rates along these faults are estimated to be less
11 than 0.2 mm/yr. Recurrence intervals have not been estimated (Sawyer 1999).

12
13 From June 1, 2000 to May 31, 2010, 123 earthquakes were recorded within a 61-mi
14 (100-km) radius of the proposed Millers SEZ. The largest earthquake during that period occurred
15 on November 15, 2003. It was located about 19 mi (30 km) west of the SEZ in the Monte Cristo
16 Mountains (north of the Columbus Salt Marsh) and registered a Richter scale magnitude (ML¹ of
17 4.5 (Figure 11.7.7.1-4). During this period, 63 (51 %) of the recorded earthquakes within a 61-mi
18 (100-km) radius of the SEZ had magnitudes greater than 3.0; none were greater than 4.5
19 (USGS 2010c).

20
21
22 **Liquefaction.** The proposed Millers SEZ lies within an area where the peak horizontal
23 acceleration with a 10% probability of exceedance in 50 years is between 0.15 and 0.20 g.
24 Shaking associated with this level of acceleration is generally perceived as strong to very strong;
25 however, potential damage to structures is light to moderate (USGS 2008). Given the deep water
26 table (from 8 to 78 ft [2 to 24 m] below the surface [USGS 2010b]) and the low intensity of
27 ground shaking estimated for the Big Smoky Valley, the potential for liquefaction in valley
28 sediments is likely to be low.

29
30
31 **Volcanic Hazards.** The Millers SEZ is located about 80 mi (130 km) northwest of the
32 southwestern Nevada volcanic field, which consists of volcanic rocks (tuffs and lavas) of the
33 Timber Mountain-Oasis Valley caldera complex and Silent Canyon and Black Mountain
34 calderas. The area has been studied extensively because of its proximity to the NTS and Yucca
35 Mountain repository. Two types of fields are present in the region: (1) large-volume, long-lived
36 fields with a range of basalt types associated with more silicic volcanic rocks produced by
37 melting of the lower crust, and (2) small-volume fields formed by scattered basaltic scoria cones
38 during brief cycles of activity, called rift basalts because of their association with extensional
39 structural features. The basalts of the region typically belong to the second group; examples
40 include the basalts of Silent Canyon and Sleeping Butte (Byers et al. 1989; Crowe et al. 1983).

41

1 ¹ Richter scale magnitude (ML) was the original magnitude defined by Richter and Gutenberg for local
earthquakes in 1935. It was based on the maximum amplitude recorded on a Wood-Anderson torsion
seismograph but is currently calculated for earthquakes with magnitudes ranging from 2 to 6, using modern
instruments with adjustments (USGS 2010d).

1 The oldest basalts in the region were erupted during the waning stages of silicic
2 volcanism in the southern Great Basin in the Late Miocene and are associated with silicic
3 volcanic centers like Dome Mountain (the first group). Rates of basaltic volcanic activity in the
4 region have been relatively constant but generally low. Basaltic eruptions occurred 1.7 million to
5 700,000 years ago, creating the cinder cones within Crater Flat (Stuckless and O'Leary 2007).
6 The most recent episode of basaltic eruptions occurred at the Lathrop Wells Cone complex about
7 80,000 years ago (Stuckless and O'Leary 2007). There has been no silicic volcanism in the
8 region in the past 5 million years. Current silicic volcanic activity occurs entirely along the
9 margins of the Great Basin (Crowe et al. 1983).

10
11 Crowe et al. (1983) determined that the annual probability of a volcanic event for the
12 region is very low (3.3×10^{-10} to 4.7×10^{-8}); similar to the probability of 1.7×10^{-8} calculated
13 for the proposed Yucca Mountain repository (Cline et al. 2005). The volcanic risk in the region is
14 associated only with basaltic eruptions; the risk of silicic volcanism is negligible. Perry (2002)
15 cites geologic data that could indicate an increase in the recurrence rate (and thus the probability
16 of disruption). These data include hypothesized episodes of an anomalously high strain rate, the
17 hypothesized presence of a regional mantle hot spot, and new aeromagnetic data that suggest that
18 previously unrecognized volcanoes may be buried in the alluvial-filled basins in the region.

19
20 The Long Valley Caldera of eastern California, is located about 70 mi (113 km)
21 southeast. The Long Valley Caldera is part of the Mono-Inyo Craters volcanic chain, which
22 extends from Mammoth Mountain (on the caldera rim) northward about 25 mi (40 km) to
23 Mono Lake. Small to moderate eruptions have occurred at various sites along the volcanic chain
24 in the past 5,000 years, at intervals ranging from 250 to 700 years. Windblown ash from some of
25 these eruptions is known to have drifted as far east as Nebraska. Since 1980, when Long Valley
26 experienced a swarm of strong earthquakes, the central part of the caldera has been rising,
27 indicating the rise of magma below the caldera. Although the probability of an eruption within
28 the volcanic chain in any given year is small (less than 1%), serious hazards could result from
29 an eruption. Depending on the location, size, timing (season), and type of eruption, hazards
30 could include mudflows and flooding, pyroclastic flows, small to moderate volumes of tephra,
31 and falling ash (Hill et al. 1998, 2000; Miller 1989).

32
33
34 ***Slope Stability and Land Subsidence.*** The incidence of rock falls and slope failures can
35 be moderate to high along mountain fronts and can present a hazard to facilities on the relatively
36 flat terrain of valley floors like the Big Smoky Valley, if they are located at the base of steep
37 slopes. The risk of rock falls and slope failures decreases toward the flat valley center.

38
39 There has been no land subsidence monitoring within the Big Smoky Valley to date; the
40 potential for subsidence is not currently known.

41
42
43 ***Other Hazards.*** Other potential hazards at the proposed Millers SEZ include those
44 associated with soil compaction (restricted infiltration and increased runoff), expanding clay
45 soils (destabilization of structures), and hydro-compactible or collapsible soil (settlement).

1 Disturbance of soil crusts and desert pavement on soil surfaces may increase the likelihood
2 of soil erosion by wind.

3
4 Alluvial fan surfaces, such as those found in the Big Smoky Valley, can be the sites of
5 damaging high-velocity flash floods and debris flows during periods of intense and prolonged
6 rainfall. The nature of the flooding and sedimentation processes (e.g., stream flow versus debris
7 flow) will depend on specific morphology of the fan (National Research Council 1996).
8 Section 11.7.9.1.1 provides further discussion of flood risks within the Millers SEZ.

11 12 **11.7.7.1.2 Soil Resources**

13 Soils within the proposed Millers SEZ are gravelly sands, gravelly fine sandy loams, fine
14 sands, silt loams, silty clay loams (playas), and gravelly loams of the Yomba, Youngston,
15 Belcher, Kawich, Wardenot, and Izo series, which together make up about 98% of the soil
16 coverage at the site (Figure 11.1.7.1-5). Soil map units within the Millers SEZ are described in
17 Table 11.7.7.1-1. These level to sloping soils are derived from mixed alluvium, typical of soils
18 on alluvial fans, alluvial flats, and playas. They are characterized as very deep and well to
19 excessively drained (except for playa soils, which are very poorly drained). Most soils on the site
20 have low to moderate surface runoff potential and slow to rapid permeability. The natural soil
21 surface is suitable for roads (except for playa soils which have a severe rutting hazard) with a
22 slight erosion hazard when used as roads or trails. The water erosion potential is low for most
23 soils. The susceptibility to wind erosion is moderate to high, with as much as 220 tons
24 (200 metric tons) of soil eroded by wind per acre (4,000 m²) each year (NRCS 2010). Biological
25 soil crusts and desert pavement have not been documented within the SEZ, but may be present.

26
27 All of the soils within the proposed Millers SEZ are rated as partially hydric.² Flooding is
28 rare for most soils at the site except for the Youngston-Playas and Slaw-Playas associations,
29 which cover about 319 ac (1 km²) and have an occasional flooding rating (with a 5 to 50%
30 chance in any year). None of the soils is classified as prime or unique farmland (NRCS 2010).

31 32 **11.7.7.2 Impacts**

33
34 Impacts on soil resources would occur mainly as a result of ground-disturbing activities
35 (e.g., grading, excavating, and drilling), especially during the construction phase of a solar
36 project. These include soil compaction, soil horizon mixing, soil erosion and deposition by wind,
37 soil erosion by water and surface runoff, sedimentation, and soil contamination. Such impacts are
38 common to all utility-scale solar energy facilities in varying degrees and are described in more
39 detail for the four phases of development in Section 5.7 1.

40
41

² A hydric soil is a soil that formed under conditions of saturation, flooding, or ponding (NRCS 2010).

TABLE 11.7.7.1-1 Summary of Soil Map Units within the Proposed Millers SEZ

Map Unit Symbol	Map Unit Name	Water Erosion Potential ^a	Wind Erosion Potential ^b	Description	Area, in Acres ^c (% of SEZ)
162	Yomba-Playas-Youngston association, alkali	Low	Moderate (WEG 4L) ^d	Consists of about 40% Yomba gravelly sand and 25% Playas (silty clay loam). Level to moderately sloping soils on alluvial flats, playas, and drainageways. Parent material is alluvium from mixed sources. Very deep and very poorly (Playas) to somewhat excessively drained, with moderate surface runoff potential and moderately slow to slow permeability. Available water capacity is very low (Playas) to low. Severe rutting hazard. Used mainly for livestock grazing and wildlife habitat.	4,068 (24)
131	Belcher-Playas-Yomba association	Low	High (WEG 2)	Consists of 45% Belcher gravelly sand, 20% Yomba gravelly fine sandy loam, and 20% Playas (silty clay loam). Level to nearly level soils on alluvial flats and playas. Parent material is alluvium from mixed sources. Shallow to a duripan (Belcher) and very deep and very poorly (Playas) to somewhat excessively drained, with high surface runoff potential (very slow infiltration rate) and moderate to moderately rapid permeability. Available water capacity is very low to low. Moderate rutting hazard. Used mainly for wildlife grazing, wildlife habitat, and irrigated cropland (alfalfa, corn silage, and small grains).	4,030 (24)
160	Yomba-Playas-Youngston association	Low	Moderate (WEG 4L)	Consists of 40% Yomba gravelly sand, 25% Playas (silty clay loam), and 20% Youngston silt loam. Level to moderately sloping soils on alluvial flats, playas, and drainageways. Parent material is alluvium from mixed sources. Very deep and very poorly (Playas) to somewhat excessively drained, with moderate surface runoff potential and moderately slow to slow permeability. Available water capacity is very low (Playas) to high. Severe rutting hazard. Used mainly for livestock grazing and wildlife habitat.	3,654 (22)

TABLE 11.2.7.1-1 (Cont.)

Map Unit Symbol	Map Unit Name	Water Erosion Potential ^a	Wind Erosion Potential ^b	Description	Area, in Acres ^c (% of SEZ)
163	Yomba-Playas-Kawich association	Moderate	High (WEG 1)	Consists of 30% Yomba gravelly sand, 30% Playas (silty clay loam), and 30% Kawich fine sand. Level to sloping soils on sand sheets (Kawich on stabilized sand dunes), alluvial flats, and playas. Parent material is alluvium from mixed sources and eolian sand. Very deep and very poorly (Playas) to excessively drained, with low surface runoff potential (high infiltration rate) and moderate to very rapid permeability. Available water capacity is very low (Playas) to low. Moderate rutting hazard. Used mainly for livestock grazing and wildlife habitat.	2,262 (13)
161	Yomba-Wardenot-Izo association	Low	High (WEG 2)	Consists of 45% Yomba gravelly sand, 25% Wardenot gravelly fine sandy loam, and 15% Izo very gravelly sand. Level to sloping soils formed on alluvial flats and fan skirts. Parent material is alluvium from mixed sources. Very deep and somewhat excessively to excessively drained, with moderate surface runoff potential and moderate to rapid permeability. Available water capacity is very low to low. Moderate rutting hazard. Used mainly for grazing and wildlife habitat.	1,803 (11)
164	Yomba-Kawich association	Low	High (WEG 2)	Consists of 50% Yomba gravelly sand and 35% Kawich fine sand. Level to sloping soils on alluvial flats and fan skirts (Kawich on stabilized sand dunes). Parent material is alluvium from mixed sources. Very deep and somewhat excessively to excessively drained, with low surface runoff potential (high infiltration rate) and moderate to very rapid permeability. Available water capacity is very low to low. Moderate rutting hazard. Used mainly as livestock grazing and wildlife habitat.	602 (4)

TABLE 11.2.7.1-1 (Cont.)

Map Unit Symbol	Map Unit Name	Water Erosion Potential ^a	Wind Erosion Potential ^b	Description	Area, in Acres ^c (% of SEZ)
180	Youngston-Playas association	Moderate	Moderate (WEG 4L)	Consists of 60% Youngston silt loam and 25% Playas (silty clay loam). Level to nearly level soils on alluvial flats and playas. Parent material is alluvium from mixed sources. Very deep and very poorly (Playas) to well drained, with moderate surface runoff potential and moderately slow permeability. Available water capacity is very low (Playas) to high. Severe rutting hazard. Used mainly for livestock grazing, wildlife habitat, and irrigated cropland (alfalfa, corn silage, and small grains).	182 (1)
430	Slaw-Playas complex	Moderate	Moderate (WEG 4L)	Consists of 45% Slaw loam and 40% Playas (silty clay loam). Level to nearly level soils on alluvial flats and playas. Parent material is alluvium from mixed sources. Very deep and very poorly (Playas) to well drained, with high surface runoff potential (slow infiltration rate) and slow permeability. Available water capacity is very low (Playas) to high. Severe rutting hazard. Used mainly for livestock grazing and wildlife habitat.	137 (1)

^a Water erosion potential rates based on soil erosion factor K, which indicates the susceptibility of soil to sheet and rill erosion by water. Values range from 0.02 to 0.69 and are provided in parentheses under the general rating; a higher value indicates a higher susceptibility to erosion. Estimates based on the percentage of silt, sand, and organic matter and on soil structure and saturated hydraulic conductivity.

^b Wind erosion potential here is based on the wind erodibility group (WEG) designation: groups 1 and 2, high; groups 3 through 6, moderate; and groups 7 and 8 low (see footnote d for further explanation).

^c To convert from acres to km², multiply by 0.004047.

^d WEG = wind erodibility group. WEGs are based on soil texture, content of organic matter, effervescence of carbonates, content of rock fragments, and mineralogy, and also take into account soil moisture, surface cover, soil surface roughness, wind velocity and direction, and the length of unsheltered distance (USDA 2004). Groups range in value from 1 (most susceptible to wind erosion) to 8 (least susceptible to wind erosion). The NRCS provides a wind erodibility index, expressed as an erosion rate in tons per acre per year, for each of the wind erodibility groups: WEG 1, 220 tons (200 metric tons) per acre (4,000 m²) per year; WEG 2, 134 tons (122 metric tons) per acre (4,000 m²) per year; and WEG 4L, 86 tons (78 metric tons) per acre (4,000 m²) per year.

Source: NRCS (2010).

1 Because impacts on soil resources result from ground-disturbing activities in the project
2 area, soil impacts would be roughly proportional to the size of a given solar facility, with larger
3 areas of disturbed soil having a greater potential for impacts than smaller areas (Section 5.7.2).
4 The magnitude of impacts would also depend on the types of components built for a given
5 facility since some components would involve greater disturbance and would take place over a
6 longer timeframe.
7

8 It is not known whether construction within the proposed Millers SEZ would affect the
9 eolian processes that maintain the Crescent Dunes to the northwest of the site. A study may be
10 required to evaluate the impacts of constructing and operating a solar facility in close proximity
11 to the landform and to develop specific mitigation measures to avoid or minimize them.
12
13

14 **11.7.7.3 SEZ-Specific Design Features and Design Feature Effectiveness**

15

16 No SEZ-specific design features were identified for soil resources at the proposed Millers
17 SEZ. Implementing the programmatic design features described under both Soils and Air Quality
18 in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would reduce
19 the potential for soil impacts during all project phases.

11.7.8 Minerals (Fluids, Solids, and Geothermal Resources)

11.7.8.1 Affected Environment

As of July 19, 2010, there are no locatable mining claims within the SEZ (BLM and USFS 2010a), and the public land within the SEZ has been closed to locatable mineral entry since June 2009 pending the outcome of this solar energy PEIS. There are no active oil and gas leases in the area, and the area has not been leased in the past (BLM and USFS 2010b). The area remains open for discretionary mineral leasing for oil and gas and other leasable minerals, and for disposal of salable minerals. There is no active geothermal leasing or development in or near the SEZ, nor has the area been leased previously (BLM and USFS 2010b).

11.7.8.2 Impacts

If the area is identified as a solar energy development zone, it would continue to be closed to all incompatible forms of mineral development. For the purpose of this analysis, it is assumed that future development of oil and gas resources, should any be found, would continue to be possible, since such development could occur with directional drilling from outside the SEZ. Since the SEZ does not contain existing mining claims, it was also assumed that there would be no future loss of locatable mineral production. The production of common minerals, such as sand and gravel and mineral materials used for road construction or other purposes, might take place in areas not directly developed for solar energy production.

The SEZ has had no history of development of geothermal resources. For that reason, it is not anticipated that solar development would adversely affect development of geothermal resources.

11.7.8.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ specific design features are required. Implementing the programmatic design features described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would provide adequate mitigation for mineral resource impacts.

11.7.9 Water Resources

11.7.9.1 Affected Environment

The proposed Millers SEZ is located within the Central Nevada Desert subbasin of the Great Basin hydrologic region (USGS 2010a) and the Basin and Range physiographic province characterized by intermittent mountain ranges and desert valleys (Planert and Williams 1995). Big Smoky Valley is an elongated valley with a northeast–southwest orientation that covers an area of 2,926 mi² (7,578 km²), and the proposed Millers SEZ is located in the southern half of the valley known as the “Tonopah Flat.” The northern part of Big Smoky Valley is internally drained with a shallow surface divide between the northern part and the Tonopah Flat, which connects with Ione Valley to the north through a narrow mountain pass (Meinzer 1917). The Tonopah Flat region covers an area of 1,603 mi² (4,512 km²) and has a general slope from northeast to southwest. Surface elevations within the vicinity of the proposed SEZ range from 4,775 to 4,865 ft (1,455 to 1,483 m), and surface elevations in the surrounding Monte Cristo Range and San Antonio Mountains reach greater than 7,500 ft (2,286 m) (Figure 11.7.9.1-1). The climate in this region of Nevada is characterized as having low humidity and precipitation, with mild winters and hot summers (Planert and Williams 1995; WRCC 2010a). The average annual precipitation is 5 in. (13 cm), and the average annual snowfall is 13 in. (33 cm) near the town of Tonopah, located at a slightly higher elevation than the proposed SEZ at 5,395 ft (1,644 m) (WRCC 2010b). In the mountain regions, the average annual precipitation is on the order of 7 in. (18 cm), with annual snowfalls of 50 in. (127 cm) (WRCC 2010c). Pan evaporation rates are estimated to be 94 in./yr (239 cm/yr) (Cowherd et al. 1988; WRCC 2010d), and reference crop evapotranspiration has been estimated at 58 in./yr (147 cm) (Huntington and Allen 2010) in the Big Smoky Valley.

11.7.9.1.1 Surface Waters (Including Drainages, Floodplains, and Wetlands)

There are no perennial surface water features in the proposed Millers SEZ. Three intermittent streams form braided stream channels and flow from north to south into the proposed Millers SEZ. The Ione Wash drains the Ione Valley to the north of Big Smoky Valley, and Peavine Creek and an unnamed wash flow out of the Toiyabe Range near the boundary of the northern part of Big Smoky Valley and Tonopah Flat (Figure 11.7.9.1-1). The Ione Wash contributes approximately 300 ac-ft/yr (370,000 m³/yr), and together Peavine Creek and the unnamed wash contribute approximately 2,800 ac-ft/yr (3.5 million m³/yr) of surface runoff to the Tonopah Flat (Rush and Schroer 1971). In the vicinity of the proposed SEZ is Slime Wash, an intermittent stream that flows from east to west out of the town of Tonopah and ends approximately 3 mi (5 km) east of the proposed SEZ. An elongated dry lake is located between 5 and 15 mi (8 and 24 km) southwest of the proposed SEZ and covers an area of 8,960 acres along the axis of the valley.

Approximately 2,200 acres (9 km²) of the northwestern portion of the proposed Millers SEZ is located at the base of an alluvial fan coming out of the pass between the Monte Cristo Range and Royston Hills with several ephemeral washes present along the fan

FIGURE 11.7.9.1-1 Surface Water Features near the Proposed Millers SEZ

(Figure 11.7.9.1-1). Smaller alluvial fans southwest of the proposed SEZ are generated by several ephemeral washes originating in the Monte Cristo Range. Peak discharges in these mountain washes can range from 2 to 460 ft³/s (0.06 to 13 m³/s) (USGS 2010b; stream gauge 10249680).

Several lacustrine wetlands in the Tonopah Flat area range in size from 43 to 2,770 acres (0.2 to 11 km²), according to the NWI (USFWS 2009). Wetlands near the proposed Millers SEZ are typically small, less than 200 acres (0.8 km²), and have sparse vegetation with water levels below the land surface for most of the year. Two larger wetland areas are located within the large dry lake bed southeast of the SEZ, and the Columbus Salt Marsh is located in the adjacent valley west of Big Smoky Valley. These playa features can contain a high amount of dissolved salts in certain areas (Meinzer 1917). Further information on wetlands within the region of the proposed SEZ is presented in Section 11.7.10.1.

Flood hazards have not been identified in Esmeralda County but have been mapped for Nye County just 1 mi (1.6 km) north and east of the proposed Millers SEZ (FEMA 2009). In Nye County, the braided stream channels of the intermittent Ione Wash, Peavine Creek, and the unnamed wash are all identified as being within a 100-year floodplain. It is very likely that these 100-year floodplains extend into Esmeralda County, and preliminary estimates using aerial photography suggest that approximately 2,000 acres (8 km²) of the proposed Millers SEZ would potentially be classified as within a 100-year floodplain. Additionally, erosion and sedimentation along the alluvial fan in the northwestern corner of the proposed SEZ, as well as temporary flooding in low-lying areas, may occur during large rainfall events.

11.7.9.1.2 Groundwater

The proposed Millers SEZ is located within the Big Smoky Valley-Tonopah Flat groundwater basin (simply referred to as Tonopah Flat groundwater basin), which covers an area of 1,025,900 acres (4,152 km²) (NDWR 2010a). The mountains surrounding the Tonopah Flat area are principally composed of volcanic and sedimentary rocks. Groundwater in the Tonopah Flat groundwater basin is primarily within the basin-fill aquifer, which comprises lenses of gravels, sands, and clays of Quaternary and late Tertiary age sediments (Rush and Schroer 1971; Whitebread and John 1992). The basin-fill deposits are typically 1,500 to 2,500 ft (457 to 762 m) in thickness near the proposed SEZ and reach a maximum thickness of 5,000 ft (1,524 m) toward the southern portion of the valley; transmissivity values range from 3,300 to 6,600 ft²/day (307 to 613 m²/day) (Rush and Schroer 1971).

The bedrock that contains the basin-fill deposits in the Big Smoky Valley is highly impervious, thus groundwater recharge is principally derived from precipitation and snow runoff to the valley (Meinzer 1917). Groundwater recharge from precipitation and snowfall, both on the valley surface and as runoff from the surrounding mountains, has been estimated to be 12,000 ac-ft/yr (14.8 million m³/yr) in the Tonopah Flat basin (Rush and Schroer 1971); however, more recent estimates of recharge range from 2,807 to 4,060 ac-ft/yr (3.5 million to 5.0 million m³/yr) (Flint et al. 2004). Subsurface inflow from the northern part of the Big Smoky Valley was estimated to be 2,000 ac-ft/yr (2.5 million m³/yr) (Rush and Schroer 1971), and

1 subsurface inflow from Ralston Valley to the east was estimated to be less than 500 ac-ft/yr
2 (616,700 m³/yr) (NDWR 1971). Groundwater discharge processes in the Big Smoky Valley
3 include evapotranspiration, discharge to springs, groundwater withdrawals, and subsurface
4 outflow. Evapotranspiration by phreatic vegetation was estimated at 6,000 ac-ft/yr
5 (7.4 million m³/yr); discharge to springs was estimated at 230 ac-ft/yr (283,700 m³/yr); and
6 groundwater extractions totaled 260 ac-ft/yr (320,700 m³/yr) in 1968 (Rush and Schroer 1971).
7 Subsurface outflow is primarily to the Clayton Valley directly south of the Tonopah Flat basin,
8 with an estimated annual discharge of 8,000 ac-ft/yr (9.9 million m³/yr) (NDWR 1971).
9

10 The general groundwater flow pattern in the Tonopah Flat basin is from northeast to
11 southwest along the axis of the valley. Depth to groundwater ranges from 8 to 78 ft (2 to 24 m)
12 below the land surface within a 5-mi (8-km) radius of the proposed SEZ (USGS 2010b; well
13 numbers 380645117315801, 38083011727200, 381345117230501). In general, depth to
14 groundwater is greater in the northern portion of the Tonopah Flat basin and is near surface
15 levels in the vicinity of the dry lake playas in the southern portion of the basin (Meinzer 1917;
16 Rush and Schroer 1971). Groundwater surface elevations range from 4,695 to 5,233 ft (1,431 to
17 1,595 m) along the axis of the valley, resulting in an approximate slope of 0.3% in groundwater
18 surface elevations (USGS 2010b; well numbers 375821117440201, 381906117232001).
19 Groundwater quality generally meets drinking water standards, except for the dry lake playa
20 regions in the southern portion of the Tonopah Flat basin, where there are elevated sulfate,
21 chloride, and dissolved solids concentrations (Rush and Schroer 1971).
22
23

24 ***11.7.9.1.3 Water Use and Water Rights Management***

25

26 In 2005, water withdrawals from surface waters and groundwater in Esmeralda County
27 were 46,786 ac-ft/yr (57.7 million m³/yr), of which 9% came from surface waters and 91% came
28 from groundwater. The largest water use categories for groundwater were irrigation and mining
29 at 28,235 and 14,202 ac-ft/yr (34.8 million and 17.5 million m³/yr), respectively. The remaining
30 groundwater withdrawals were used for domestic and livestock (Kenny et al. 2009). In the
31 Tonopah Flat basin, groundwater extractions totaled 260 ac-ft/yr (320,700 m³/yr) in 1968 and
32 were used primarily for irrigation purposes (Rush and Schroer 1971).
33

34 All waters in Nevada are the property of the public in the state of Nevada and subject
35 to the laws described in Nevada Revised Statutes, Chapters 532 through 538 (available at
36 <http://leg.state.nv.us/nrs>). The NDWR, led by the Office of the State Engineer, is the agency
37 responsible for managing both the surface water and groundwater resources, and this
38 responsibility includes overseeing water right applications, appropriations, and interbasin
39 transfers (NDWR 2010b). The two principal ideas behind water rights in Nevada are the prior
40 appropriations doctrine and the concept of beneficial use. A water right establishes an
41 appropriation amount and date such that more senior water rights have priority over newer water
42 rights. Additionally, water rights are treated as both real and personal property, such that water
43 rights can be transferred without affecting the land ownership (NDWR 2010b). Water rights
44 applications (new or transfer of existing) are approved if the water is available to be
45 appropriated, if existing water rights will not be affected, and if the proposed use is not deemed
46 to be harmful to the public interest. If these conditions are satisfied according to the Nevada

1 State Engineer, a proof of beneficial use of the approved water must be provided within a certain
2 time period, and following that a certificate of appropriation is issued (BLM 2001).

3
4 Both the northern part and the Tonopah Flat basins within the Big Smoky Valley are
5 designated groundwater basins according to Orders 725 and 827 (NDWR 1979, 1983a).
6 Additionally, approximately 1,300 acres (5.3 km²) of the proposed SEZ in T.3N-R.40E falls
7 under Order 828 (NDWR 1983b), which designates municipal and domestic water uses as the
8 preferred beneficial use. The perennial yield of the Tonopah Flat groundwater basin is set at
9 6,000 ac-ft/yr (7.4 million m³/yr), and water rights in the basin are over-appropriated with a total
10 of 19,588 ac-ft/yr (24.2 million m³/yr) being allotted for irrigation, mining; municipal, and
11 stockwater uses (95% of allotments used for irrigation and mining, NDWR 2010a). As
12 mentioned previously, groundwater extractions totaled 260 ac-ft/yr (320,700 m³/yr) in 1968
13 (Rush and Schroer 1971) in the Tonopah Flat basin. However, a current groundwater extraction
14 inventory is not available (NDWR 2010a), so it is not known how much of the allotted
15 groundwater rights are in use. Solar energy developers would have to purchase and transfer
16 existing water rights through coordination of the NDWR and current water rights holders.
17
18

19 **11.7.9.2 Impacts**

20
21 Potential impacts on water resources related to utility-scale solar energy development
22 include direct and indirect impacts on surface waters and groundwater. Direct impacts occur at
23 the place of origin and at the time of the proposed activity, while indirect impacts occur away
24 from the place of origin or later in time. Impacts on water resources considered in this analysis
25 are the result of land disturbance activities (construction, final developed site plan, as well as
26 off-site activities such as road and transmission line construction) and water use requirements for
27 solar energy technologies that take place during the four project phases: site characterization,
28 construction, operations, and decommissioning/reclamation. Both land disturbance and
29 consumptive water use activities can affect groundwater and surface water flows, cause
30 drawdown of groundwater surface elevations, modify natural drainage pathways, obstruct natural
31 recharge zones, and alter surface water–wetland–groundwater connectivity. Water quality can
32 also be degraded through the generation of wastewater, chemical spills, increased erosion and
33 sedimentation, and increased salinity (e.g., by excessive withdrawal from aquifers).
34
35

36 **11.7.9.2.1 Land Disturbance Impacts on Water Resources**

37
38 Impacts related to land disturbance activities are common to all utility-scale solar energy
39 facilities, which are described in more detail for the four phases of development in Section 5.9.1;
40 these impacts will be minimized through the implementation of programmatic design features
41 described in Appendix A, Section A.2.2. Land disturbance activities should be minimized in the
42 vicinity of the ephemeral stream channels of Ione Wash located through the middle of the
43 proposed SEZ, as well as in the vicinity of Peavine Creek just east of the proposed SEZ. During
44 large storm events, these intermittent streams have the potential to flood and cause sedimentation
45 and erosion issues (it is suspected that these intermittent streams are within the 100-year
46 floodplain, which will have to be determined during the site characterization phase).

1 Approximately 2,200 acres (9 km²) of the northwestern corner of the proposed SEZ is located on
2 the base of an alluvial fan containing several ephemeral washes. Disturbances to these ephemeral
3 washes could cause erosion impacts and disrupt groundwater recharge. Additionally, site design
4 and land disturbance activities could potentially alter surface water drainage and sedimentation
5 off the proposed SEZ to the southwest of the Tonopah Flat basin, which would potentially impair
6 the dry lake playa regions at the southern edge of Big Smoky Valley.

9 **11.7.9.2.2 Water Use Requirements for Solar Energy Technologies**

12 **Analysis Assumptions**

14 A detailed description of the water use assumptions for the four utility-scale solar energy
15 technologies (parabolic trough, power tower, dish engine, and PV systems) is presented in
16 Appendix M. Assumptions regarding water use calculations specific to the proposed Millers SEZ
17 are as follows:

- 19 • On the basis of a total area of 16,787 acres (68 km²), it is assumed that two
20 solar projects would be constructed during the peak construction year;
- 22 • Water needed for making concrete would come from an off-site source;
- 24 • The maximum land disturbance for an individual solar facility during the peak
25 construction year is 3,000 acres (12 km²);
- 27 • Assumptions on individual facility size and land requirements (Appendix M),
28 along with the assumed number of projects and maximum allowable land
29 disturbance, result in the potential to disturb up to 36% of the SEZ total area
30 during the peak construction year; and
- 32 • Water use requirements for hybrid cooling systems are assumed to be
33 on the same order of magnitude as those for dry-cooling systems
34 (see Section 5.9.2.1).

37 **Site Characterization**

39 During site characterization, water would be used mainly for fugitive dust suppression
40 and the workforce potable water supply. Impacts on water resources during this phase of
41 development are expected to be negligible, since activities would be limited in area, extent,
42 and duration; water needs could be met by trucking water in from an off-site source.

Construction

During construction, water would be used mainly for controlling fugitive dust and the workforce potable water supply. Because there are no significant surface water bodies on the proposed Millers SEZ, the water requirements for construction activities could be met by either trucking water to the sites or by using on-site groundwater resources.

Water requirements for dust suppression and potable water supply during construction, shown in Table 11.7.9.2-1, could be as high as 3,300 ac-ft (4.1 million m³). The assumptions underlying these estimates for each solar energy technology are described in Appendix M. Groundwater wells would have to yield an estimated 1,418 to 2,045 gpm (5,368 to 7,741 L/min) to meet the estimated construction water requirements. These yields are on the same order of magnitude as large municipal and agricultural production wells (Harter 2003), so multiple wells may be needed in order to meet the water requirements. In addition, the up to 148 ac-ft (186,600 m³) of sanitary wastewater that would be generated would need to be treated either on-site or sent to an off-site facility.

The total water use requirements for the peak construction year, listed in Table 11.7.9.2-1, are approximately one-third to one-half of the perennial yield for the Tonopah Flat groundwater basin. The potential impacts associated with groundwater withdrawals of this magnitude would have to be assessed during the site characterization phase. Significant declines in groundwater surface elevations as the result of groundwater extractions could potentially affect phreatic vegetation within the Big Smoky Valley and impair other groundwater users in the region.

TABLE 11.7.9.2-1 Estimated Water Requirements during the Peak Construction Year for the Proposed Millers SEZ

Activity	Parabolic Trough	Power Tower	Dish Engine	Photovoltaic
Water use requirements ^a				
Fugitive dust control (ac-ft) ^{b,c}	2,140	3,210	3,210	3,210
Potable supply for workforce (ac-ft)	148	90	37	19
Total water use requirements (ac-ft)	2,288	3,300	3,247	3,229
Wastewater generated				
Sanitary wastewater (ac-ft)	148	90	37	19

^a Assumptions of water use for fugitive dust control, potable supply for workforce, and wastewater generation are presented in Table M.9-1 (Appendix M).

^b Fugitive dust control estimation assumes a local pan evaporation rate of 94 in./yr (239 cm/yr) (Cowherd et al. 1988; WRCC 2010d).

^c To convert ac-ft to m³, multiply by 1,234.

Operations

During operations, water would be required for mirror/panel washing, the workforce potable water supply, and cooling (parabolic trough and power tower only) (Table 11.7.9.2-2). Water needs for cooling are a function of the type of cooling used (dry, hybrid, wet). Further refinements to water requirements for cooling would result from the percentage of time that the option was employed (30 to 60% range assumed) and the power of the system. The differences between the water requirements reported in Table 11.7.9.2-2 for the parabolic trough and power tower technologies are attributable to the assumptions of acreage per megawatt. As a result, the water usage for the more energy-dense parabolic trough technology is estimated to be almost twice as large as that for the power tower technology.

At full build-out capacity, water needs for mirror/panel washing are estimated to range from 75 to 1,343 ac-ft/yr (92,500 to 1.7 million m³/yr), and the workforce potable water supply, from 2 to 38 ac-ft/yr (2,500 to 46,900 m³/yr). The maximum total water usage during normal operation at full build-out capacity would be greatest for those technologies using the wet-cooling option and is estimated to be as high as 40,327 ac-ft/yr (49.7 million m³/yr). Water usage for dry-cooling systems would be as high as 4,067 ac-ft/yr (5.0 million m³/yr), approximately a factor of 10 times less than the wet-cooling option. Non-cooled technologies, dish engine and PV systems, require substantially less water at full build-out capacity at 763 ac-ft/yr (941,100 m³/yr) for dish engine and 77 ac-ft/yr (95,000 m³/yr) for PV (Table 11.7.9.2-2). Operations would produce up to 38 ac-ft/yr (46,900 m³/yr) of sanitary wastewater; in addition, for wet-cooled technologies, 424 to 763 ac-ft/yr (523,000 to 941,100 m³/yr) of cooling system blowdown water would need to be treated either on- or off-site. Any on-site treatment of wastewater would have to ensure that treatment ponds are effectively lined in order to prevent any groundwater contamination.

Groundwater is the primary water resource available for solar energy development at the proposed Millers SEZ. The NDWR has set the perennial yield for the Tonopah Flat groundwater basin at 6,000 ac-ft/yr (7.4 million m³/yr), which is less than half of the amount of water needed to support wet-cooled parabolic trough operations under the full build-out scenario. Water use requirements for wet-cooled power tower operations are also greater than the perennial yield, so wet cooling is not feasible for the proposed Millers SEZ. Water use requirements for dry-cooled parabolic trough and power tower technologies, as well as dish engine and PV, could be supported by groundwater resources in the Tonopah Flats groundwater basin, assuming that groundwater rights could be transferred.

Decommissioning/Reclamation

During decommissioning/reclamation, all surface structures associated with the solar project would be dismantled, and the site reclaimed to its preconstruction state. Activities and water needs during this phase would be similar to those during the construction phase (dust suppression and potable supply for workers) and might also include water to establish vegetation in some areas. However, the total volume of water needed is expected to be less. Because

TABLE 11.7.9.2-2 Estimated Water Requirements during Operations at the Proposed Millers SEZ

Activity	Parabolic Trough	Power Tower	Dish Engine	PV
Full build-out capacity (MW) ^{a,b}	2,686	1,492	1,492	1,492
Water use requirements				
Mirror/panel washing (ac-ft/yr) ^{c,d}	1,343	746	746	75
Potable supply for workforce (ac-ft/yr)	38	17	17	2
Dry cooling (ac-ft/yr) ^e	537–2,686	298–1,492	NA ^f	NA
Wet cooling (ac-ft/yr) ^e	12,087–38,946	6,715–21,637	NA	NA
Total water use requirements				
Non-cooled technologies (ac-ft/yr)	NA	NA	763	77
Dry-cooled technologies (ac-ft/yr)	1,918–4,067	1,061–2,255	NA	NA
Wet-cooled technologies (ac-ft/yr)	13,468–40,327	7,478–22,400	NA	NA
Wastewater Generated				
Blowdown (ac-ft/yr) ^g	763	424	NA	NA
Sanitary wastewater (ac-ft/yr)	38	17	17	2

^a Land area for parabolic trough was estimated at 5 acres/MW (0.02 km²/MW); land area for the power tower, dish engine, and PV technologies was estimated at 9 acres/MW (0.04 km²/MW).

^b Water needs are linearly related to power. Water usage for any other size project can be estimated by using multipliers provided in Table M.9-2 (Appendix M).

^c Value assumes a usage rate of 0.5 ac-ft/yr/MW for mirror washing for parabolic trough, power tower, and dish engine technologies and a rate of 0.05 ac-ft/yr/MW for panel washing for PV systems.

^d To convert ac-ft to m³, multiply by 1,234.

^e Dry-cooling value assumes 0.2 to 1.0 ac-ft/yr/MW, and wet-cooling value assumes 4.5 to 14.5 ac-ft/yr/MW (range in these values represents 30 and 60% operating times) (DOE 2009).

^f NA = not applicable.

^g Value scaled from 250-MW Beacon Solar project with an annual discharge of 44 gpm (167 L/min) (AECOM 2009). Blowdown estimates are relevant to wet cooling only.

quantities of water needed during the decommissioning/reclamation phase would be less than those for construction, impacts on surface and groundwater resources also would be less.

11.7.9.2.3 Off-Site Impacts: Roads and Transmission Lines

Impacts associated with the construction of roads and transmission lines primarily deal with water use demands for construction, water quality concerns relating to potential chemical spills, and land disturbance effects on the natural hydrology. The extent of the impacts on water resources is proportional to the amount and location of land disturbance needed to connect the

1 proposed SEZ to major roads and existing transmission lines. The proposed Millers SEZ is
2 located adjacent to existing roads and transmission lines, as described in Section 11.7.1.2, so it is
3 assumed that impacts would be negligible.

6 **11.7.9.2.4 Summary of Impacts on Water Resources**

8 The impacts on water resources associated with developing solar energy at the proposed
9 Millers SEZ are related to land disturbance effects on the natural hydrology, water quality
10 concerns, and water use requirements for the various solar energy technologies. Land disturbance
11 activities can cause localized erosion and sedimentation issues, as well as alter groundwater
12 recharge and discharge processes. The ephemeral stream channels of Ione Wash, Peavine Creek,
13 and an unnamed wash are likely located within a 100-year floodplain, according to FEMA maps,
14 in the adjacent Nye County (FEMA 2009). The 100-year floodplain would be identified during
15 the site characterization phase, and areas of the proposed SEZ within the 100-year floodplain
16 should be avoided. Additionally, alteration of the surface water drainage pattern off the proposed
17 SEZ toward the southwest could impair the dry lake playa areas through sedimentation and
18 erosion, as well as divert water from these natural drainage lows of the Big Smoky Valley.

20 Impacts relating to water use requirements vary depending on the type of solar
21 technology built and, for technologies using cooling systems, the type of cooling (wet, dry, or
22 hybrid) used. Groundwater is the primary water resource available to solar energy facilities in the
23 proposed Millers SEZ. The water use requirements for technologies using wet cooling are greater
24 than the perennial yield for the Tonopah Flats groundwater basin, so wet cooling would not be
25 feasible for the full build-out scenario. For evaluating wet-cooling technologies for the proposed
26 Millers SEZ, an analysis of the maximum power production was done assuming that the water
27 use was limited to the perennial yield of the basin, 6,000 ac-ft/yr (7.4 million m³/yr). This
28 analysis suggests that between 15 and 27% of the full build-out power production potential is
29 possible for wet-cooled parabolic trough and power tower technologies (assuming a
30 60% operating time) if the water supply is limited to the perennial yield of the basin.

32 Dry-cooling, dish engine, and PV technologies all have full build-out water use
33 requirements that are lower than the perennial yield of the basin, suggesting that groundwater
34 resources in the Tonopah Flats basin could support their development. However, facilities using
35 these technologies should also implement water conservation practices to limit water needs.
36 Water conservation plans will help solar energy developers in purchasing and transferring
37 needed water rights within the overappropriated Tonopah Flats basin.

40 **11.7.9.3 SEZ-Specific Design Features and Design Feature Effectiveness**

42 The program for solar energy development on BLM-administered lands would require
43 the programmatic design features presented in Appendix A, Section A.2.2, to be implemented,
44 thus mitigating some impacts on water resources. Programmatic design features would focus on
45 coordination with federal, state, and local agencies that regulate the use of water resources to
46 meet the requirements of permits and approvals needed to obtain water for development, and on

1 the performance of hydrological studies to characterize the aquifer from which groundwater
2 would be obtained (including drawdown effects, if a new point of diversion is created). The
3 greatest consideration for mitigating water impacts would be in the selection of solar
4 technologies. The mitigation of impacts would be best achieved by selecting technologies with
5 low water demands.

6
7 Design features specific to the proposed Millers SEZ include the following:

- 8
9 • Water resource analysis indicates that wet-cooling options would not be
10 feasible; other technologies should incorporate water conservation measures;
11
- 12 • Land disturbance activities should minimize impacts on the ephemeral stream
13 channels of Ione Wash and Peavine Creek, as well as alluvial fan features
14 along the western edge of the SEZ;
15
- 16 • Siting of solar facilities and construction activities should avoid any areas
17 identified as within a 100-year floodplain or jurisdictional waters
18
- 19 • Groundwater rights must be obtained through coordination with the NDWR
20 and current water rights holders;
21
- 22 • Stormwater management plans and BMPs should comply with standards
23 developed by the Nevada Division of Environmental Protection
24 (NDEP 2010);
25
- 26 • Groundwater monitoring and production wells should be constructed in
27 accordance with state standards (NDWR 2006); and
28
- 29 • Water for potable uses would have to meet or be treated to meet the water
30 quality standards of the *Nevada Administrative Code* (445A.453-445A.455).

11.7.10 Vegetation

This section addresses vegetation that could occur or is known to occur within the potentially affected area of the proposed Millers SEZ. The affected area considered in this assessment included the areas of direct and indirect effects. The area of direct effects is defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur) and included only the SEZ. No new access roads or transmission projects are expected to be needed to serve development on the SEZ because of the proximity of existing infrastructure (refer to Section 11.7.1.2 for development assumptions). The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary, where ground-disturbing activities would not occur but that could be indirectly affected by activities in the area of direct effects.

Indirect effects considered in the assessment included effects from surface runoff, dust, and accidental spills from the SEZ, but did not include ground-disturbing activities, because these would not take place outside of the SEZ. The potential degree of indirect effects would decrease with increasing distance from the SEZ. This area of indirect effects was identified on the basis of professional judgment and was considered sufficiently large to bound the area that would potentially be subject to indirect effects. The affected area is the area bounded by the areas of direct and indirect effects. These areas are defined and the impact assessment approach is described in Appendix M.

11.7.10.1 Affected Environment

The proposed Millers SEZ is located primarily within the Tonopah Basin Level IV ecoregion, which primarily supports sparse shadscale (*Atriplex confertifolia*) communities on broad valleys, hills, bajadas, and alluvial fans (Bryce et al. 2003). Additional commonly occurring shrubs in this ecoregion include bud sagebrush (*Picrothamnus desertorum*), spiny hopsage (*Grayia spinosa*), seepweed (*Suaeda* sp.), fourwing saltbush (*Atriplex canescens*), spiny menodora (*Menodora spinescens*), Nevada ephedra (*Ephedra nevadensis*), littleleaf horsebrush (*Tetradymia glabrata*), Douglas rabbitbrush (*Chrysothamnus viscidiflorus*), and winterfat (*Krascheninnikovia lanata*), which, along with shadscale, often codominate in highly diverse mosaics. Warm season grasses, such as Indian rice grass (*Achnatherum hymenoides*) and galleta grass (*Pleuraphis jamesii*), occur in the understory. Stands of inland saltgrass (*Distichlis spicata*) and alkali sacaton (*Sporobolus airoides*) also occur. Bailey greasewood (*Sarcobatus baileyi*) and Shockley wolfberry (*Lycium* sp.) are widespread and often codominate on lower alluvial slopes in this ecoregion. Black greasewood occurs in saline bottoms. Springs and sporadic precipitation in foothills provide surface water sources. The southwestern portion of the Millers SEZ is located within the Lahontan and Tonopah Playas. This Level IV ecoregion is nearly level and contains mud flats, alkali flats, intermittent saline lakes, and low sand dunes. Marshes, remnant lakes, and playas occur within this ecoregion. Rivers terminate in the playas, which during winter fill with seasonal runoff from nearby mountains. Only scattered, highly salt-tolerant plants, such as alkali sacaton, inland saltgrass, and seepweed, occur in this mostly barren ecoregion. Bordering the playas, black greasewood (*Sarcobatus vermiculatus*) or fourwing saltbush may form a transition to the salt shrub community. Playas may be sources of

1 wind-generated salt dust. Annual precipitation in the vicinity of the SEZ is very low, averaging
2 5.1 in. (12.9 cm) at Tonopah airport (see Section 11.7.13).

3
4 The Tonopah Basin and Lahontan and Tonopah Playas lie within the Central Basin and
5 Range Level III ecoregion, described in Appendix I, and are part of the Great Basin desertscrub
6 biome.

7
8 The area surrounding the SEZ consists of a mosaic of the Tonopah Basin, Lahontan and
9 Tonopah Playas, and the Tonopah Sagebrush Foothills Level IV ecoregions. This area supports
10 black sagebrush (*Artemisia nova*) and Mojave species, such as blackbrush (*Coleogyne*
11 *ramosissima*), Joshua tree (*Yucca brevifolia*), and cholla (*Cylindropuntia* sp.), on rocky
12 substrates.

13
14 Land cover types described and mapped under SWReGAP (USGS 2005a) were used to
15 evaluate plant communities in and near the SEZ. Each cover type encompasses a range of
16 similar plant communities. Land cover types occurring within the potentially affected area of
17 the proposed Millers SEZ are shown in Figure 11.7.10.1-1. Table 11.7.10.1-1 provides the
18 surface area of each cover type within the potentially affected area.

19
20 Lands within the proposed Millers SEZ are classified primarily as Inter-Mountain Basins
21 Mixed Salt Desert Scrub. Additional cover types within the SEZ are given in Table 11.7.10.1-1.
22 Dominant species in the sparse low salt scrub communities observed in most portions of the
23 SEZ in August 2009 include shadscale, Nevada ephedra, Bailey's greasewood, and spiny
24 hopsage, with rabbitbrush (*Chrysothamnus/Ericameria* sp.) in disturbed areas. The SEZ includes
25 many low playa areas, predominantly in the southern portion, containing widely scattered low
26 hummocks of black greasewood, occasionally with Indian ricegrass. The playas are bordered
27 by a predominantly black greasewood community. Much of the SEZ consists of north to south
28 trending broad, barren, gravel-covered washes, with small scattered playa areas, with shadscale
29 and fourwing saltbush along the margins or in isolated stands. Sensitive habitats on the SEZ
30 include desert dry washes, playas, and wetlands. A population of candelaria blazingstar
31 (*Mentzelia candelariae*) occurs approximately 3 mi (4.8 km) east of the SEZ. This species is on
32 the NNHP watch list and may potentially occur on the SEZ.

33
34 The area of indirect effects, including the area surrounding the SEZ within 5 mi (8 km),
35 contains 15 cover types, which are listed in Table 11.7.10.1-1. The predominant cover type is
36 Inter-Mountain Basins Mixed Salt Desert Scrub. Crescent Dunes, mapped as Inter-Mountain
37 Basins Active and Stabilized Dune, are located about 5 mi (8 km) northeast of the SEZ. Sand
38 dunes are also located about 5 mi (8 km) southwest of the SEZ.

39
40 One wetland mapped by the NWI is located within the southeastern portion of the SEZ
41 (USFWS 2009) (Figure 11.7.10.1-2). This sparsely vegetated lacustrine wetland is mapped
42 primarily as Inter-Mountain Basins Playa, with small areas of Inter-Mountain Basins
43 Greasewood Flat and Inter-Mountain Basins Mixed Salt Desert Scrub. Approximately 84 acres
44 (0.3 km²) of this 192.9-acre (0.8-km²) wetland is located within the SEZ. The remaining portion
45 is located entirely within the area of indirect effects. Smaller playa areas not mapped by the NWI

FIGURE 11.7.10.1-1 Land Cover Types within the Proposed Millers SEZ (Source: USGS 2004)

TABLE 11.7.10.1-1 Land Cover Types within the Potentially Affected Area of the Proposed Millers SEZ and Potential Impacts

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b		
	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Overall Impact Magnitude ^e
Inter-Mountain Basins Mixed Salt Desert Scrub: Generally consists of open shrublands that include at least one species of <i>Atriplex</i> , along with other shrubs. Perennial grasses dominate a sparse to moderately dense herbaceous layer.	12,211 acres ^f (0.5%, 0.5%)	93,460 acres (3.6%)	Small
Inter-Mountain Basins Greasewood Flat: Dominated or codominated by greasewood (<i>Sarcobatus vermiculatus</i>) and generally occurring in areas with saline soils, a shallow water table, and intermittent flooding, although remaining dry for most growing seasons. This community type generally occurs near drainages or around playas. These areas may include, or may be codominated by, other shrubs, and may include a graminoid herbaceous layer.	3,149 acres (3.4%, 3.7%)	19,074 acres (20.4%)	Moderate
Inter-Mountain Basins Playa: Playa habitats are intermittently flooded and generally barren or sparsely vegetated. Depressions may contain small patches of grass, and sparse shrubs may occur around playa margins.	1,290 acres (1.4%, 1.7%)	5,307 acres (5.6%)	Moderate
Inter-Mountain Basins Semi-Desert Shrub Steppe: Generally consists of perennial grasses with an open shrub and dwarf shrub layer.	137 acres (0.1%, 0.1%)	2,240 acres (0.3%)	Small
Mojave Mid-Elevation Mixed Desert Scrub: The vegetation composition is quite variable. Dominant species include shrubs forbs and grasses and may include <i>Yucca</i> spp.	4 acres (0.2%, 0.5%)	37 acres (2.3%)	Small
Great Basin Xeric Mixed Sagebrush Shrubland: Generally occurs on level plains, slopes, and ridges. The dominant shrub species are black sagebrush (<i>Artemisia nova</i>) or, at higher elevations, little sagebrush (<i>Artemisia arbuscula</i>), and codominants may be Wyoming big sagebrush (<i>Artemisia tridentata</i> ssp. <i>wyomingensis</i>) or yellow rabbitbrush (<i>Chrysothamnus viscidiflorus</i>). Other shrub species, as well as sparse perennial bunchgrasses, may also be present.	0 acres	3,788 acres (0.6%)	Small

TABLE 11.7.10.1-1 (Cont.)

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b		
	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Overall Impact Magnitude ^e
Inter-Mountain Basins Cliff and Canyon: Includes barren and sparsely vegetated (generally <10% plant cover) steep cliff faces, narrow canyons, small rock outcrops, and scree and talus slopes. Composed of widely scattered coniferous trees and a variety of shrubs.	0 acres	720 acres (1.8%)	Small
Undifferentiated Barren Land: Includes a variety of barren areas, generally with less than 15% cover of vegetation.	0 acres	683 acres (13.5%)	Small
Inter-Mountain Basins Big Sagebrush Shrubland: Dominated by basin big sagebrush (<i>Artemisia tridentata tridentata</i>), Wyoming big sagebrush (<i>Artemisia tridentata wyomingensis</i>), or both. Other shrubs may be present. Perennial herbaceous plants are present but not abundant.	0 acres	541 acres (0.1%)	Small
Inter-Mountain Basins Active and Stabilized Dune: Includes Dune and sandsheet areas that are unvegetated or sparsely vegetated, with up to 30% plant cover, but generally less than 10%. Plant communities consist of patchy or open grassland, shrubland, or shrub steppe, with species often adapted to the shifting sandy substrate.	0 acres	149 acres (6.5%)	Small
Great Basin Pinyon-Juniper Woodland: Occurs on low-elevation slopes and ridges. Singleleaf pinyon (<i>Pinus monophylla</i>), Utah juniper (<i>Juniperus osteosperma</i>), or both are the dominant species, generally associating with curl-leaf mountain mahogany (<i>Cercocarpus ledifolius</i>). Understory species include shrubs and grasses.	0 acres	54 acres (<0.1%)	Small
Introduced Upland Vegetation–Annual Grassland: Dominated by non-native annual grass species.	0 acres	33 acres (1.4%)	Small
Inter-Mountain Basins Semi-Desert Grassland: Consists of perennial bunchgrasses as dominants or codominants. Scattered shrubs or dwarf shrubs may also be present.	0 acres	5 acres (0.1%)	Small

TABLE 11.7.10.1-1 (Cont.)

Land Cover Type ^a	Area of Cover Type Affected (acres) ^b		
	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	Overall Impact Magnitude ^e
Inter-Mountain Basins Big Sagebrush Steppe: Dominated by basin big sagebrush (<i>Artemisia tridentata tridentata</i>), Wyoming big sagebrush (<i>Artemisia tridentata wyomingensis</i>), or both. Other shrubs may be present. Perennial grasses are often abundant.	0 acres	4 acres (0.2%)	Small
North American Arid West Emergent Marsh: Occurs in natural depressions, such as ponds, or bordering lakes, or slow-moving streams or rivers. Alkalinity is highly variable. The plant community is characterized by herbaceous emergent, submergent, and floating leaved species.	0 acres	2 acres (1.1%)	Small

^a Land cover descriptions are from USGS (2005a). Full descriptions of land cover types, including plant species, can be found in Appendix I.

^b Area in acres, determined from USGS (2004).

^c Includes the area of the cover type within the SEZ, the percentage that area represents of all occurrences of that cover type within the SEZ region (i.e., a 50-mi [80-km] radius from the center of the SEZ), and the percentage that area represents of all occurrences of that cover type on BLM lands within the SEZ region.

^d Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary where ground-disturbing activities would not occur. Indirect effects include effects from surface runoff, dust, and other factors from projects. The potential degree of indirect effects would decrease with increasing distance from the SEZ. Includes the area of the cover type within the indirect effects area and the percentage that area represents of all occurrences of that cover type within the SEZ region.

^e Overall impact magnitude categories were based on professional judgment and were (1) *small*: a relatively small proportion ($\leq 1\%$) of the cover type within the SEZ region would be lost; (2) *moderate*: an intermediate proportion (>1 but $\leq 10\%$) of a cover type would be lost; (3) *large*: $>10\%$ of a cover type would be lost.

^f To convert acres to km², multiply by 0.004047.

FIGURE 11.7.10.1-2 Wetlands within the Proposed Millers SEZ (Source: USFWS 2009)

1 occur within the SEZ. Numerous dry washes occur within the SEZ, generally flowing to the
2 south and terminating in the playa areas. These washes do not support wetland or riparian
3 habitats. Ione Wash, an intermittent stream, flows south into the SEZ. Two additional
4 intermittent streams, Peavine Creek and an unnamed wash, are located immediately east of the
5 SEZ. These streams generally carry surface flows during spring months. The dry washes and
6 playas typically contain water for short periods during or following precipitation events.

8 Four additional wetlands occur within the area of indirect effects. All of these are
9 sparsely vegetated lacustrine wetlands, which are mapped primarily as Inter-Mountain Basins
10 Playa, with small areas of Inter-Mountain Basins Greasewood Flat and Inter-Mountain Basins
11 Mixed Salt Desert Scrub. Large areas of these playa habitats are located southwest of the SEZ.
12 Groundwater is relatively shallow in the vicinity of the playas in the southern portion of the
13 Tonopah Flat basin, which includes the Millers SEZ (see Section 11.7.9), and supports plant
14 communities when surface water is absent. Several springs also occur in the vicinity of the SEZ.

16 The State of Nevada maintains an official list of weed species designated as noxious
17 species (NDA 2010). Table 11.7.10.1-2 provides a summary of the noxious weed species
18 regulated in Nevada that are known to occur in Esmeralda County (USDA 2010), which includes
19 the proposed Millers SEZ. According to Creech et al. (2010), none of the weed species from the
20 Nevada state list occurs in the county. No species included in Table 11.7.10.1-2 were observed
21 on the SEZ in August 2009.

23 The NDA classifies noxious weeds into one of three categories (NDA 2010):

- 25 • “Category A: Weeds not found or limited in distribution throughout the state;
26 actively excluded from the state and actively eradicated wherever found;
27 actively eradicated from nursery stock dealer premises; control required by the
28 state in all infestations.”

**TABLE 11.7.10.1-2 Designated Noxious
Weeds of Nevada Occurring in Esmeralda
County**

Common Name	Scientific Name	Category
Musk thistle	<i>Carduus nutans</i>	B
Puncture vine	<i>Tribulus terrestris</i>	C
Saltcedar	<i>Tamarix</i> spp.	C

Sources: NDA (2010); USDA (2010).

- “Category B: Weeds established in scattered populations in some counties of the state; actively excluded where possible, actively eradicated from nursery stock dealer premises; control required by the state in areas where populations are not well established or previously unknown to occur.”
- “Category C: Weeds currently established and generally widespread in many counties of the state; actively eradicated from nursery stock dealer premises; abatement at the discretion of the state quarantine officer.”

11.7.10.2 Impacts

The construction of solar energy facilities within the proposed Millers SEZ would result in direct impacts on plant communities due to the removal of vegetation within the facility footprint during land-clearing and land-grading operations. Approximately 80% of the SEZ (13,430 acres [54.3 km²]) would be expected to be cleared with full development of the SEZ. The plant communities affected would depend on facility locations and could include any of the communities occurring on the SEZ. Therefore, for this analysis, all the area of each cover type within the SEZ is considered to be directly affected by removal with full development of the SEZ.

Indirect effects (caused, e.g., by surface runoff or dust from the SEZ) have the potential to degrade affected plant communities and may reduce biodiversity by promoting the decline or elimination of species sensitive to disturbance. Indirect effects can also cause an increase in disturbance-tolerant species or invasive species. High impact levels could result in the elimination of a community or the replacement of one community type by another. The proper implementation of programmatic design features, however, would reduce indirect effects to a minor or small level of impact.

Possible impacts from solar energy facilities on vegetation within the SEZ are described in more detail in Section 5.10.1. Any such impacts would be minimized through the implementation of required design features described in Appendix A, Section A.2.2, and from any additional mitigation applied. Section 11.7.10.2.3, below, identifies design features of particular relevance to the proposed Millers SEZ.

11.7.10.2.1 Impacts on Native Species

The impacts of construction, operation, and decommissioning were considered small if the impact affected a relatively small proportion (<1%) of the cover type in the SEZ region (within 50 mi [80 km] of the center of the SEZ); moderate (>1 but <10%) if the impact could affect an intermediate proportion of cover type; and large if the impact could affect more than 10% of a cover type.

Solar facility construction and operation in the proposed Millers SEZ would primarily affect communities of the Inter-Mountain Basins Mixed Salt Desert Scrub cover type. Additional

cover types that would be affected within the SEZ include Inter-Mountain Basins Greasewood Flat, Inter-Mountain Basins Playa, Inter-Mountain Basins Semi-Desert Shrub Steppe, and Mojave Mid-Elevation Mixed Desert Scrub. Table 11.7.10.1-1 summarizes the potential impacts on land cover types resulting from solar energy facilities in the proposed Millers SEZ. Most of these cover types are relatively common in the SEZ region; however, Mojave Mid-Elevation Mixed Desert Scrub is relatively uncommon, representing 0.03% of the land area within the SEZ region. Desert dry washes, playas, and wetlands are important sensitive habitats on the SEZ.

The construction, operation, and decommissioning of solar projects within the proposed Millers Valley SEZ would result in moderate impacts on the Inter-Mountain Basins Greasewood Flat and Inter-Mountain Basins Playa cover types. Solar project development within the SEZ would result in small impacts on the remaining cover types in the affected area.

Because of the arid conditions, re-establishment of shrub or shrub steppe communities in temporarily disturbed areas would likely be very difficult and might require extended periods of time. In addition, noxious weeds could become established in disturbed areas and colonize adjacent undisturbed habitats, thus reducing restoration success and potentially resulting in widespread habitat degradation. Cryptogamic soil crusts occur in many of the shrubland communities in the region. Damage to these crusts, by the operation of heavy equipment or other vehicles, can alter important soil characteristics, such as nutrient cycling and availability and affect plant community characteristics (Lovich and Bainbridge 1999).

The deposition of fugitive dust from large areas of disturbed soil onto habitats outside a solar project area could result in reduced productivity or changes in plant community composition. Fugitive dust deposition could affect plant communities of each of the cover types occurring within the area of indirect effects identified in Table 11.7.10.1-1. Solar project development within the SEZ could alter sand transport processes, potentially affecting sand dune plant communities in Crescent Dunes, northeast of the SEZ, or dunes southwest of the SEZ.

Communities associated with playa habitats, Ione Wash, greasewood flats communities, or other intermittently flooded areas within and downgradient from solar projects could be affected by ground-disturbing activities. Extensive playa habitats southwest of the SEZ could be affected. Site-clearing and grading could disrupt surface water flow patterns, resulting in changes in the frequency, duration, depth, or extent of inundation or soil saturation and could potentially alter playa or greasewood flats plant communities and affect community function. Increases in surface runoff from a solar energy project site could also affect hydrologic characteristics of these communities. The introduction of contaminants into these habitats could result from spills of fuels or other materials used on a project site. Soil disturbance could result in sedimentation in these areas, which could degrade or eliminate sensitive plant communities. Grading could also affect dry wash habitats within the SEZ. Alteration of surface drainage patterns or hydrology could adversely affect downstream dry wash communities. Vegetation within these communities could be lost by erosion or desiccation. Disturbance of the dry washes within the SEZ could affect groundwater recharge.

Potential impacts on wetlands as a result of solar energy development are described in Section 5.6.1. Approximately 84 acres (0.3 km²) of wetland habitat have been identified within the Millers SEZ, associated with playa habitat, and could be affected by project development. Direct impacts on the wetland would occur if fill material is placed within the playa for solar facility construction. Indirect impacts, as described above, could occur if project construction occurs near or upgradient from the playa.

Although the use of groundwater within the Millers SEZ for technologies with high water requirements, such as wet-cooling systems, may be unlikely, groundwater withdrawals for such systems could reduce groundwater elevations in the Tonopah Flat groundwater basin, or other hydrologically-connected basins. Plant communities that access groundwater, such as those in the vicinity of playas, or habitats associated with springs, could become degraded or lost as a result of lowered groundwater levels. The potential for impacts on springs would need to be evaluated by project-specific hydrological studies.

Candelaria blazingstar, a plant species on the NNHP watch list, may occur within the SEZ and may be directly affected by solar project development. The population occurring east of the SEZ may be indirectly affected by project activities within the SEZ.

11.7.10.2.2 Impacts from Noxious Weeds and Invasive Plant Species

Executive Order (E.O.) 13112, “Invasive Species,” directs federal agencies to prevent the introduction of invasive species and provide for their control and to minimize the economic, ecological, and human health impacts of invasive species (*Federal Register*, Volume 64, page 61836, Feb. 8, 1999). Potential effects of noxious weeds and invasive plant species that could result from solar energy facilities are described in Section 5.10.1. Noxious weeds and invasive species could inadvertently be brought to a project site by equipment previously used in infested areas, or they may be present on or near a project site. Despite required programmatic design features to prevent the spread of noxious weeds, project disturbance could potentially increase the prevalence of noxious weeds and invasive species in the affected area of the proposed Millers SEZ, and increase the probability that weeds could be transported into areas that previously were relatively weed-free. This could result in reduced restoration success and possible widespread habitat degradation.

Invasive species potentially occur on the SEZ. Species designated as noxious weeds in Nevada, and known to occur in Esmeralda County, are given in Table 11.7.10.1-2. No cover types of introduced species occur within the SEZ. Within the area of indirect effects, 33 acres (0.13 km²) of Introduced Upland Vegetation—Annual Grassland are mapped. Disturbance associated with solar project development may promote the establishment and spread of invasive species associated with this cover type. Past or present land uses, such as OHV activity, may affect the susceptibility of plant communities to the establishment of noxious weeds and invasive species. Disturbance associated with existing roads and transmission lines within the SEZ area of potential impacts also likely contributes to the susceptibility of plant communities to the establishment and spread of noxious weeds and invasive species.

11.7.10.3 SEZ-Specific Design Features and Design Feature Effectiveness

In addition to the programmatic design features, SEZ-specific design features would reduce the potential for impacts on plant communities. While the specific practices are best established when project details are being considered, the following SEZ-specific design features can be identified at this time:

- An Integrated Vegetation Management Plan, addressing invasive species control, and an Ecological Resources Mitigation and Monitoring Plan addressing habitat restoration should be approved and implemented to increase the potential for successful restoration of affected habitats and minimize the potential for the spread of invasive species. Invasive species control should focus on biological and mechanical methods where possible to reduce the use of herbicides.
- Dry washes, Ione Wash, playas, and wetlands within the SEZ should be avoided to the extent practicable, and any impacts minimized and mitigated. A buffer area should be maintained around wetlands, playas, and dry washes to reduce the potential for impacts.
- Appropriate engineering controls should be used to minimize impacts on the playa wetland and other playas, as well as Ione Wash shrub communities, dry washes, and greasewood flat habitats within the SEZ, and downstream occurrences, resulting from surface water runoff, erosion, sedimentation, altered hydrology, accidental spills, or fugitive dust deposition to these habitats. Appropriate buffers and engineering controls would be determined through agency consultation.
- Groundwater withdrawals should be limited to reduce the potential for indirect impacts on plant communities that access groundwater, such as those in the vicinity of playas. Potential impacts on springs associated with the Tonopah Flat basin or other hydrologically connected basins should be determined through hydrological studies.
- A qualified botanist or plant ecologist should survey for candelaria blazing star during a period when it is flowering and easily documented prior to any construction activities within the SEZ. If individuals are located, individuals or populations should be avoided through fencing and flagging of the area, including an appropriate buffer zone.

If these SEZ-specific design features are implemented in addition to other programmatic design features, it is anticipated that a high potential for impacts from invasive species and impacts on dry washes, playas, wetlands, and springs would be reduced to a minimal potential for impact.

11.7.11 Wildlife and Aquatic Biota

This section addresses wildlife (amphibians, reptiles, birds, and mammals) and aquatic biota that could occur within the potentially affected area of the proposed Millers SEZ. Wildlife known to occur within 50 mi (80 km) of the SEZ (i.e., the SEZ region) were determined from SWReGAP (USGS 2007). Land cover types suitable for each species were determined from SWReGAP (USGS 2004, 2005a, 2007). The amount of aquatic habitat within the SEZ region was determined by estimating the length of linear perennial stream and canal features and the area of standing water body features (i.e., ponds, lakes, and reservoirs) within 50 mi (80 km) of the SEZ by using available GIS surface water datasets.

The affected area considered in this assessment included the areas of direct and indirect effects. The area of direct effects was defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur) within the SEZ. The maximum developed area within the SEZ would be 13,430 acres (54.3 km²). No areas of direct effects would occur for either a new transmission line or a new access road, because existing transmission line and road corridors are adjacent to or pass through the SEZ.

The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary where ground-disturbing activities would not occur, but that could be indirectly affected by activities in the area of direct effects (e.g., surface runoff, dust, noise, lighting, and accidental spills in the SEZ). Potentially suitable habitat within the SEZ greater than the maximum of 13,430 acres (54.3 km²) of direct effects was also included as part of the area of indirect effects. The potential degree of indirect effects would decrease with increasing distance from the SEZ. The area of indirect effects was identified on the basis of professional judgment and was considered sufficiently large to bound the area that would potentially be subject to indirect effects. These areas of direct and indirect effects are defined and the impact assessment approach is described in Appendix M.

The primary land cover habitat type within the affected area is Inter-Mountain Basins mixed salt desert scrub (see Section 11.7.10). Potentially unique habitats in the affected area include wash and playa habitats. Aquatic habitats that occur in the SEZ and the area of indirect effects include Ione Wash, Peavine Wash, and several small unnamed dry lakes (see Figure 11.7.9.1-1).

11.7.11.1 Amphibians and Reptiles

11.7.11.1.1 Affected Environment

This section addresses amphibian and reptile species that are known to occur, or for which potentially suitable habitat occurs, on or within the potentially affected area of the proposed Millers SEZ. The list of amphibian and reptile species potentially present in the SEZ area was determined from species lists available from the Nevada Natural Heritage Program (NDCNR 2002) and range maps and habitat information available from SWReGAP

(USGS 2007). Land cover types suitable for each species were determined from SWReGAP (USGS 2004, 2005a, 2007). Appendix M provides additional information on the approach used.

Based on species distributions within the area of the SEZ and habitat preferences of the amphibian species, the Great Basin spadefoot (*Spea intermontana*) and red-spotted toad (*Bufo punctatus*) would be expected to occur within the SEZ (USGS 2007; Stebbins 2003). They would most likely occur in or near the wash and playa habitats within the SEZ.

More than 25 reptile species occur within the area that encompasses the proposed Millers SEZ (USGS 2007; Stebbins 2003). The desert tortoise (*Gopherus agassizii*) is a federal and state-listed threatened species. This species is discussed in Section 11.7.12. Lizard species expected to occur within the SEZ include the desert horned lizard (*Phrynosoma platyrhinos*), Great Basin collared lizard (*Crotaphytus bicinctores*), long-nosed leopard lizard (*Gambelia wislizenii*), western fence lizard (*Sceloporus occidentalis*), western whiptail (*Cnemidophorus tigris*), and zebra-tailed lizard (*Callisaurus draconoides*). Snake species expected to occur within the SEZ are the coachwhip (*Masticophis flagellum*), glossy snake (*Arizona elegans*), gophersnake (*Pituophis catenifer*), groundsnake (*Sonora semiannulata*), and nightsnake (*Hypsiglena torquata*).

Table 11.7.11.1-1 provides habitat information for representative amphibian and reptile species that could occur within the proposed Millers SEZ. Special status amphibian and reptile species are addressed in Section 11.7.12.

11.7.11.1.2 Impacts

The types of impacts that amphibians and reptiles could incur from construction, operation, and decommissioning of utility-scale solar energy facilities are discussed in Section 5.10.2.1. Any such impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2, and through any additional mitigation measures applied. Section 11.7.11.1.3 identifies SEZ-specific design features of particular relevance to the proposed Millers SEZ.

The assessment of impacts on amphibian and reptile species is based on available information on the presence of species in the affected area, as presented in Section 11.7.11.1.1, following the analysis approach described in Appendix M. Additional NEPA assessments and coordination with state natural resource agencies may be needed to address project-specific impacts more thoroughly. These assessments and consultations could result in additional required actions to avoid or mitigate impacts on amphibians and reptiles (see Section 11.7.11.1.3).

In general, impacts on amphibians and reptiles would result from habitat disturbance (i.e., habitat reduction, fragmentation, and alteration) and from disturbance, injury, or mortality to individual amphibians and reptiles. On the basis of the magnitude of the impacts on amphibians and reptiles summarized in Table 11.7.11.1-1, direct impacts on representative

TABLE 11.7.11.1-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Amphibian and Reptile Species That Could Occur on or in the Affected Area of the Proposed Millers SEZ

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Amphibians				
Great Basin spadefoot (<i>Spea intermontana</i>)	Sagebrush flats, semidesert shrublands, pinyon-juniper woodlands, and spruce-fir forests. Breeds in temporary and permanent waters including rain pools, pools in intermittent streams, and flooded areas along streams. About 4,548,700 acres ^g of potentially suitable habitat occurs within the SEZ region.	12,211 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	97,831 acres of potentially suitable habitat (2.2% of available suitable habitat)	Small overall impact. Wash and playa habitats should be avoided.
Red-spotted toad (<i>Bufo punctatus</i>)	Dry, rocky areas at lower elevations near desert springs and persistent pools along rocky arroyos; desert streams and oases; open grassland; scrubland oaks; and dry woodlands. About 3,274,500 acres of potentially suitable habitat occurs within the SEZ region.	12,215 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	93,581 acres of potentially suitable habitat (2.9% of available suitable habitat)	Small overall impact. Wash and playa habitats, should be avoided.
Lizards				
Desert horned lizard (<i>Phrynosoma platyrhinos</i>)	Deserts dominated by sagebrush, creosotebush, greasewood, or cactus. Occurs on sandy flats, alluvial fans, washes, and edge of dunes. Burrows in soil during periods of inactivity. About 4,114,900 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	127,467 acres of potentially suitable habitat (3.1% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Great Basin collared lizard (<i>Crotaphytus bicinctores</i>)	Usually inhabits alluvia, lava flows, mountain slopes, canyons, buttes, rock outcrops, washes, and rocky plains. Limiting factors are presence of large boulders and open/sparse vegetation. About 3,498,200 acres of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	100,237 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.1-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Lizards (Cont.)				
Long-nosed leopard lizard (<i>Gambelia wislizenii</i>)	Desert and semidesert areas with scattered shrubs. Prefers sandy or gravelly flats and plains. Also prefers areas with abundant rodent burrows, which they occupy when inactive. About 3,757,800 acres of potentially suitable habitat occurs in the SEZ region.	12,215 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	97,818 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Western fence lizard (<i>Sceloporus occidentalis</i>)	Disturbed areas, roadsides, gravel beds, rock quarries, lava flows, outcrops, talus slopes, shrublands, riparian areas, and coniferous woodlands. About 4,764,000 acres of potentially suitable habitat occurs within the SEZ region.	12,348 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,795 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Western whiptail (<i>Cnemidophorus tigris</i>)	Arid and semiarid habitats with sparse plant cover. About 4,216,400 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	120,400 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Zebra-tailed lizard (<i>Callisaurus draconoides</i>)	Open, warm-desert habitats, especially dry washes and canyons with fine gravel and sand. About 3,288,900 acres of potentially suitable habitat occurs in the SEZ region.	12,215 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	97,426 acres of potentially suitable habitat (3.0% of available potentially suitable habitat)	Small overall impact. Avoid wash habitat, otherwise no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.1-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Snakes				
Coachwhip (<i>Masticophis flagellum</i>)	Creosotebush desert, shortgrass prairie, shrub-covered flats and hills. Sandy to rocky substrates. Avoids dense vegetation. About 2,237,800 acres of potentially suitable habitat occurs within the SEZ region.	3,286 acres of potentially suitable habitat lost (0.1% of available potentially suitable habitat) during construction and operations	26,254 acres of potentially suitable habitat (1.2% of available potentially suitable habitat)	Small overall impact.
Glossy snake (<i>Arizona elegans</i>)	Light shrubby to barren deserts, sagebrush flats, grasslands, and chaparral-covered slopes and woodlands. Prefers sandy grasslands, shrublands and woodlands. About 846,400 acres of potentially suitable habitat occurs within the SEZ region.	1,427 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	7,936 acres of potentially suitable habitat (0.9% of available potentially suitable habitat)	Small overall impact.
Gophersnake (<i>Pituophis catenifer</i>)	Plains grasslands, sandhills, riparian areas, marshes, edges of ponds and lakes, rocky canyons, semidesert and mountain shrublands, montane woodlands, rural and suburban areas, and agricultural areas. Likely inhabits pocket gopher burrows in winter. About 1,974,800 acres of potentially suitable habitat occurs in the SEZ region.	1,294 acres of potentially suitable habitat lost (0.07% of available potentially suitable habitat) during construction and operations	9,575 acres of potentially suitable habitat (0.5% of available potentially suitable habitat)	Small overall impact. Wash and playa habitats should be avoided.
Groundsnake (<i>Sonora semiannulata</i>)	Arid and semiarid regions with rocky to sandy soils. River bottoms, desert flats, sand hummocks, and rocky hillsides. About 1,996,600 acres of potentially suitable habitat occurs within the SEZ region.	141 acres of potentially suitable habitat lost (<0.01% of available potentially suitable habitat) during construction and operations	6,669 acres of potentially suitable habitat (0.3% of available potentially suitable habitat)	Small overall impact.
Nightsnake (<i>Hypsiglena torquata</i>)	Arid and semiarid desert flats, plains, and woodlands; areas with rocky and sandy soils are preferred. During cold periods of the year, seeks refuge underground, in crevices, or under rocks. About 3,569,900 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	101,974 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

Footnotes continued on next page.

TABLE 11.7.11.1-1 (Cont.)

-
- ^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.
 - ^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. A maximum of 13,430 acres of direct effects within the SEZ was assumed.
 - ^c Direct effects within the SEZ consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
 - ^d Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 13,430 acres of direct effects was also added to the area of indirect effects. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ.
 - ^e Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
 - ^f Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
 - ^g To convert acres to km^2 , multiply by 0.004047.

Sources: CDFG (2008); NatureServe (2010); NDCNR (2002); USGS (2004, 2005a, 2007).

1 amphibian and reptile species would be small, because 0.4% or less of potentially suitable
2 habitats identified for the species in the SEZ region would be lost. Larger areas of potentially
3 suitable habitats for the amphibian and reptile species occur within the area of potential indirect
4 effects. Other impacts on amphibians and reptiles could result from surface water and sediment
5 runoff from disturbed areas, fugitive dust generated by project activities, accidental spills,
6 collection, and harassment. These indirect impacts are expected to be negligible with
7 implementation of programmatic design features.

8
9 Decommissioning after operations cease could result in short-term negative impacts on
10 individuals and habitats within and adjacent to the SEZ. The negative impacts of
11 decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term
12 benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4
13 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of
14 particular importance for amphibian and reptile species would be the restoration of original
15 ground surface contours, soils, and native plant communities associated with semiarid
16 shrublands.

17 18 19 ***11.7.11.1.3 SEZ-Specific Design Features and Design Feature Effectiveness*** 20

21 The successful implementation of required programmatic design features presented in
22 Appendix A, Section A.2.2, would reduce the potential for effects on amphibians and reptiles,
23 especially for those species that utilize habitat types that can be avoided (e.g., washes and
24 playas). Indirect impacts could be reduced to negligible levels by implementing programmatic
25 design features, especially those engineering controls that would reduce runoff, sedimentation,
26 spills, and fugitive dust. While SEZ-specific design features are best established when
27 considering specific project details, one design feature can be identified at this time:

- 28
29 • Wash and playa habitats should be avoided.

30
31 If this SEZ-specific design feature is implemented in addition to the programmatic design
32 features, impacts on amphibian and reptile species could be reduced. However, because
33 potentially suitable habitats for a number of the representative amphibian and reptile species
34 occur throughout much of the SEZ, additional species-specific mitigation of direct effects for
35 those species would be difficult or infeasible.

36 37 38 ***11.7.11.2 Birds*** 39

40 41 ***11.7.11.2.1 Affected Environment*** 42

43 This section addresses bird species that are known to occur, or for which potentially
44 suitable habitat occurs, on or within the potentially affected area of the proposed Millers SEZ.
45 The list of bird species potentially present in the SEZ area was determined from the Nevada
46 Natural Heritage Program (NDCNR 2002) and range maps and habitat information available

1 from SWReGAP (USGS 2007). Land cover types suitable for each species were determined
2 from SWReGAP (USGS 2004, 2005a, 2007). Appendix M provides additional information on
3 the approach used.

4
5 Five bird species that could occur on or in the affected area of the SEZ are considered
6 focal species in the *Desert Bird Conservation Plan* (CalPIF 2009): ash-throated flycatcher
7 (*Myiarchus cinerascens*), burrowing owl (*Athene cunicularia*), common raven (*Corvus corax*),
8 ladder-backed woodpecker (*Picoides scalaris*), and Le Conte's thrasher (*Toxostoma lecontei*).
9 Habitats for most of these species are described in Table 11.7.11.2-1. Because of its special
10 species status, the burrowing owl is discussed in Section 11.7.12.

11 12 13 **Waterfowl, Wading Birds, and Shorebirds**

14
15 As discussed in Section 4.10.2.2.2,
16 waterfowl (ducks, geese, and swans), wading
17 birds (herons and cranes), and shorebirds
18 (avocets, gulls, plovers, rails, sandpipers, stilts,
19 and terns) are among the most abundant groups
20 of birds in the six-state solar study area.

21 However, within the proposed Millers SEZ,
22 waterfowl, wading birds, and shorebird species
23 would be mostly absent to uncommon. Playa and wash habitats within the SEZ may attract
24 shorebird species, but the larger dry lake habitats within 50 mi (80 km) of the SEZ would
25 provide more viable habitat for this group of birds. The killdeer (*Charadrius vociferus*) is the
26 shorebird species most likely to occur within the SEZ.

Desert Focal Bird Species

Bird species whose requirements define spatial attributes, habitat characteristics, and management regimes representative of a healthy desert system (Chase and Geupel 2005).

27 28 29 **Neotropical Migrants**

30
31 As discussed in Section 4.10.2.2.3, neotropical migrants represent the most diverse
32 category of birds within the six-state study area. Species expected to occur within the proposed
33 Millers SEZ include the ash-throated flycatcher, Bewick's wren (*Thryomanes bewickii*), common
34 poorwill (*Phalaenoptilus nuttallii*), common raven, greater roadrunner (*Geococcyx*
35 *californianus*), horned lark (*Eremophila alpestris*), ladder-backed woodpecker, Le Conte's
36 thrasher, lesser nighthawk (*Chordeiles acutipennis*), loggerhead shrike (*Lanius ludovicianus*),
37 northern mockingbird (*Mimus polyglottos*), rock wren (*Salpinctes obsoletus*), sage sparrow
38 (*Amphispiza belli*), Say's phoebe (*Sayornis saya*), and western kingbird (*Tyrannus verticalis*)
39 (USGS 2007).

40 41 42 **Birds of Prey**

43
44 Section 4.10.2.2.4 provides an overview of the birds of prey (raptors, owls, and vultures)
45 within the six-state study area. Raptor species that could occur within the proposed Millers SEZ

TABLE 11.7.11.2-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Bird Species That Could Occur on or in the Affected Area of the Proposed Millers SEZ

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Shorebirds</i>				
Killdeer (<i>Charadrius vociferus</i>)	Open areas such as fields, meadows, lawns, mudflats, and shores. Nests on ground in open dry or gravelly locations. About 122,100 acres ^g of potentially suitable habitat occurs within the SEZ region.	1,290 acres of potentially suitable habitat lost (1.1% of available potentially suitable habitat) during construction and operations	5,147 acres of potentially suitable habitat (4.2% of potentially suitable habitat)	Moderate overall impact. Wash and playa habitats should be avoided. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
<i>Neotropical Migrants</i>				
Ash-throated flycatcher (<i>Myiarchus cinerascens</i>)	Common in scrub and woodland habitats including desert riparian and desert washes. Requires hole/cavity for nesting. Uses shrubs or small trees for foraging perches. About 4,517,100 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	118,559 acres of potentially suitable habitat (2.6% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Bewick’s wren (<i>Thryomanes bewickii</i>)	Generally associated with dense, brushy habitats. A permanent resident of lowland deserts and pinyon-juniper forests of southern Utah. Breeding occurs in brushy areas of open woodlands and other open habitats. A cavity nester with nests constructed in small enclosed areas such as tree cavities, nesting boxes, rock crevices, or the center of a brush pile. About 2,356,400 acres of potentially suitable habitat occurs within the SEZ region.	4,576 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	31,246 acres of potentially suitable habitat (1.3% of available potentially suitable habitat)	Small overall impact. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.7.11.2-1 (Cont.)

		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants</i> <i>(Cont.)</i>				
Common poorwill (<i>Phalaenoptilus nuttallii</i>)	Scrubby and brushy areas, prairie, desert, rocky canyons, open woodlands, and broken forests. Mostly in arid and semi-arid habitats. Nests in open areas on a bare site. About 4,627,100 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	118,518 acres of potentially suitable habitat (2.6% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation also provided by the requirements of the Migratory Bird Treaty Act.
Common raven (<i>Corvus corax</i>)	Occurs in most habitats. Trees and cliffs provide cover. Roosts primarily in trees. Nests on cliffs, bluffs, tall trees, or human-made structures. Forages in sparse, open terrain. About 4,908,100 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,695 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.7.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants</i> <i>(Cont.)</i>				
Greater roadrunner (<i>Geococcyx californianus</i>)	Desert scrub, chaparral, edges of cultivated lands, and arid open areas with scattered brush. Fairly common in all desert habitats. Requires thickets, large bushes, or small trees for shade, refuge, and roosting. Usually nests low in trees, shrubs, or clumps of cactus. Rarely nests on ground. About 4,474,400 acres of potentially suitable habitat occurs in the SEZ region.	12,215 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	98,592 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Horned lark (<i>Eremophila alpestris</i>)	Common to abundant resident in a variety of open habitats. Breeds in grasslands, sagebrush, semidesert shrublands, and alpine tundra. During migration and winter, inhabits the same habitats other than tundra, and occurs in agricultural areas. Usually occurs where plant density is low and there are exposed soils. About 4,225,100 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	127,323 acres of potentially suitable habitat (3.0% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants</i> <i>(Cont.)</i>				
Ladder-backed woodpecker <i>(Picoides scalaris)</i>	Fairly common in Mojave and Colorado Deserts. Variety of habitats including deserts, arid scrub, riparian woodlands, mesquite, scrub oak, pinyon-juniper woodlands. Digs nest hole in rotted stub or dead or dying branches of various trees. Also nests in saguaro, agave, yucca, fence posts, and utility poles. Nests on ledges; branches of trees, shrubs, and cactus; and holes in trees or walls. About 3,307,300 acres of potentially suitable habitat occurs within the SEZ region.	12,215 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	94,412 acres of potentially suitable habitat (2.9% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Le Conte’s thrasher <i>(Toxostoma lecontei)</i>	Open desert wash, alkali desert scrub, and desert succulent shrub habitats. Prefers to nest and forage in arroyos and washes lined with dense stands of creosotebush and salt bush. About 2,600,100 acres of potentially suitable habitat occurs in the SEZ region.	12,215 acres of potentially suitable habitat lost (0.5% of available potentially suitable habitat) during construction and operations	93,489 acres of potentially suitable habitat (3.6% of available potentially suitable habitat)	Small overall impact. Avoid wash habitats; otherwise no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.7.11.2-1 (Cont.)

		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants</i> <i>(Cont.)</i>				
Lesser nighthawk (<i>Chordeiles acutipennis</i>)	Open country, desert regions, scrub, savanna, and cultivated areas. Usually near water including open marshes, salt ponds, large rivers, rice paddies, and beaches. Roosts on low perches or the ground. Nests in the open on bare sites. About 3,760,100 acres of potentially suitable habitat occurs within the SEZ region.	12,215 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	97,967 acres of potentially suitable habitat (2.6% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Loggerhead shrike (<i>Lanius ludovicianus</i>)	Open country with scattered trees and shrubs, savanna, desert scrub, desert riparian, Joshua tree, and occasionally, open woodland habitats. Perches on poles, wires, or fence posts (suitable hunting perches are important aspect of habitat). Nests in shrubs and small trees. About 4,848,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,661 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

		Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
Common Name (Scientific Name)	Habitat ^a	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants (Cont.)</i>				
Northern mockingbird (<i>Mimus polyglottos</i>)	Parkland, cultivated lands, second-growth habitats, desert scrub, and riparian areas at low elevations. Forages on ground in short, grassy to nearly barren substrates. About 4,932,900 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,098 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Rock wren (<i>Salpinctes obsoletus</i>)	Arid and semi-arid habitats. Breeds in areas with talus slopes, scrublands, or dry washes. Nests, constructed of plant materials, are located in rock crevices and the nest entrance is paved with small rocks and stones. About 4,593,300 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,780 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. Avoid wash habitats; otherwise no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Neotropical Migrants</i> <i>(Cont.)</i>				
Sage sparrow (<i>Amphispiza belli</i>)	Prefers shrubland, grassland, and desert habitats. The nest, constructed of twigs and grasses, is located either low in a shrub or on the ground. About 4,856,300 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,765 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Say’s phoebe (<i>Sayornis saya</i>)	Arid open country, deserts, sagebrush plains, dry barren foothills, canyons, cliffs, ranches, and rural homes. Nests in cliff crevices, holes in banks, sheltered ledges, tree cavities, under bridges and roofs, and in mines. About 1,428,800 acres of potentially suitable habitat occurs within the SEZ region.	3,153 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	23,843 acres of potentially suitable habitat (1.7% of potentially suitable habitat)	Small overall impact. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.
Western kingbird (<i>Tyrannus verticalis</i>)	Occurs in a variety of habitats including riparian forests and woodlands, savannahs, shrublands, agricultural lands, deserts, and urban areas. Nesting occurs in trees, bushes, and other raised areas, such as buildings. Migrates to Central America or the southeastern United States for the winter. About 4,074,900 acres of potentially suitable habitat occurs within the SEZ region.	12,352 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,778 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Migratory Bird Treaty Act.

TABLE 11.7.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Birds of Prey				
American kestrel (<i>Falco sparverius</i>)	Occurs in most open habitats, in various shrub and early successional forest habitats, forest openings, and various ecotones. Perches on trees, snags, rocks, utility poles and wires, and fence posts. Uses cavities in trees, snags, rock areas, banks, and buildings for nesting and cover. About 4,875,200 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,657 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Golden eagle (<i>Aquila chrysaetos</i>)	Grasslands, shrublands, pinyon-juniper woodlands, and ponderosa pine forests. Occasionally in most other habitats, especially during migration and winter. Nests on cliffs and sometimes trees in rugged areas, with breeding birds ranging widely over surrounding areas. About 4,862,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,661 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. Some measure of mitigation provided by the requirements of the Bald and Golden Eagle Protection Act.
Great horned owl (<i>Bubo virginianus</i>)	Needs large abandoned bird nest or large cavity for nesting. Usually lives on forest edges and hunts in open areas. In desert areas, requires wooded cliff areas for nesting. About 5,024,300 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,963 acres of potentially suitable habitat (2.6% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Birds of Prey (Cont.)				
Long-eared owl (<i>Asio otus</i>)	Nests and roosts in dense vegetation and hunts in open areas (e.g., creosotebush-bursage flats, desert scrub, grasslands, and agricultural fields). About 4,809,500 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,090 acres of potentially suitable habitat (2.5% of potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Red-tailed hawk (<i>Buteo jamaicensis</i>)	Wide variety of habitats from deserts, mountains, and populated valleys. Open areas with scattered, elevated perch sites such as scrub desert, plains and montane grassland, agricultural fields, pastures urban parklands, broken coniferous forests, and deciduous woodland. Nests on cliff ledges or in tall trees. About 3,305,900 acres of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	96,991 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Turkey vulture (<i>Cathartes aura</i>)	Occurs in open stages of most habitats that provide adequate cliffs or large trees for nesting, roosting, and resting. Migrates and forages over most open habitats. Roosts communally in trees, exposed boulders, and occasionally transmission line support towers. About 3,321,700 acres of potentially suitable habitat occurs in the SEZ region.	12,215 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	94,263 acres of potentially suitable habitat (2.8% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Upland Game Birds				
Chukar (<i>Alectoris chukar</i>)	Steep, semi-arid slopes with rocky outcrops and shrubs with a grass and forb understory. Sources of water are required during hot, dry periods, with most birds during the brooding period found within 0.25 mi (0.4 km) of water. About 4,727,900 acres of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,150 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	Small overall impact. Avoid wash and playa habitats; otherwise no species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects. However, avoidance of Ione Wash and an unnamed dry lake would protect potential occasional sources of water.
Gambel’s quail (<i>Callipepla gambelii</i>)	Deserts, especially in areas with brushy or thorny growth, and adjacent cultivated areas. Usually occurs near water. Nests on the ground under cover of small trees, shrubs, and grass tufts. About 1,467,600 acres of potentially suitable habitat occurs within the SEZ region.	3,290 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	26,088 acres of potentially suitable habitat (1.8% of potentially suitable habitat)	Small overall impact. Avoid wash and playa habitats.
Mourning dove (<i>Zenaida macroura</i>)	Habitat generalist, occurring in grasslands, shrublands, croplands, lowland and foothill riparian forests, ponderosa pine forests, deserts, and urban and suburban areas. Rarely in aspen and other forests, coniferous woodlands, and alpine tundra. Nests on ground or in trees. Winters mostly in lowland riparian forests adjacent to cropland. About 4,219,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	123,622 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.2-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Upland Game Bird (Cont.)				
Wild turkey (<i>Meleagris gallopavo</i>)	Lowland riparian forests, foothill shrubs, pinyon-juniper woodlands, foothill riparian forests, and agricultural areas. About 2,259,300 acres of potentially suitable habitat occurs within the SEZ region.	1,427 acres of potentially suitable habitat lost (0.06% of available potentially suitable habitat) during construction and operations	12,494 acres of potentially suitable habitat (0.6% of available potentially suitable habitat)	Small overall impact.

- ^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.
- ^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. A maximum of 13,430 acres of direct effects within the SEZ was assumed.
- ^c Direct effects within the SEZ consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
- ^d Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 13,340 acres of direct effects was also added to the area of indirect effects. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance from the SEZ.
- ^e Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: ≤1% of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but ≤10% of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: >10% of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^f Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ^g To convert to acres to km², multiply by 0.004047.

1 include the American kestrel (*Falco sparverius*), golden eagle (*Aquila chrysaetos*), great horned
2 owl (*Bubo virginianus*), long-eared owl (*Asio otus*), red-tailed hawk (*Buteo jamaicensis*), and
3 turkey vulture (*Cathartes aura*) (USGS 2007). Several other special status birds of prey are
4 discussed in Section 11.7.12.1, including the burrowing owl, ferruginous hawk (*Buteo regalis*),
5 prairie falcon (*Falco mexicanus*), and Swainson's hawk (*B. swainsoni*).
6
7

8 **Upland Game Birds**

9

10 Section 4.10.2.2.5 provides an overview of the upland game birds (primarily pheasants,
11 grouse, quail, and doves) that occur within the six-state study area. Upland game species that
12 could occur within the proposed Millers SEZ include the chukar (*Alectoris chukar*), Gambel's
13 quail (*Callipepla gambelii*), mourning dove (*Zenaida macroura*), and wild turkey (*Meleagris*
14 *gallopavo*) (USGS 2007).
15

16 Table 11.7.11.2-1 provides habitat information for representative bird species that could
17 occur within the proposed Millers SEZ. Special status bird species are discussed in
18 Section 11.7.12.
19
20

21 **11.7.11.2.2 Impacts**

22

23 The types of impacts that birds could incur from construction, operation, and
24 decommissioning of utility-scale solar energy facilities are discussed in Section 5.10.2.1. Any
25 such impacts would be minimized through the implementation of required programmatic design
26 features described in Appendix A, Section A.2.2, and through the applications of any additional
27 mitigation measures. Section 11.7.11.2.3, below, identifies design features of particular
28 relevance to the proposed Millers SEZ.
29

30 The assessment of impacts on bird species is based on available information on the
31 presence of species in the affected area, as presented in Section 11.7.11.2.1, following the
32 analysis approach described in Appendix M. Additional NEPA assessments and coordination
33 with federal or state natural resource agencies may be needed to address project-specific impacts
34 more thoroughly. These assessments and consultations could result in additional required actions
35 to avoid or mitigate impacts on birds (see Section 11.7.11.2.3).
36

37 In general, impacts on birds would result from habitat disturbance (i.e., habitat reduction,
38 fragmentation, and alteration) and from disturbance, injury, or mortality to individual birds.
39 Table 11.7.11.2-1 summarizes the magnitude of potential impacts on representative bird species
40 resulting from solar energy development in the proposed Millers SEZ. Direct impacts on
41 representative bird species would be moderate for the killdeer (loss of 1.1% of potentially
42 suitable habitat) and small for all other bird species (ranging from 0.06% for the wild turkey to
43 0.5% for Le Conte's thrasher (Table 11.7.11.2-1). Larger areas of potentially suitable habitat for
44 bird species occur within the area of potential indirect effects (e.g., up to 4.2% of potentially
45 suitable habitat for the killdeer). Other impacts on birds could result from collision with vehicles
46 and infrastructure (e.g., buildings and fences), surface water and sediment runoff from disturbed

1 areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species,
2 accidental spills, and harassment. Indirect impacts on areas outside the SEZ (e.g., impacts caused
3 by dust generation, erosion, and sedimentation) are expected to be negligible with
4 implementation of programmatic design features.

5
6 Decommissioning after operations cease could result in short-term negative impacts on
7 individuals and habitats within and adjacent to the SEZ. The negative impacts of
8 decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term
9 benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4
10 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of
11 particular importance for bird species would be the restoration of original ground surface
12 contours, soils, and native plant communities associated with semiarid shrublands.

13 14 15 ***11.7.11.2.3 SEZ-Specific Design Features and Design Feature Effectiveness***

16
17 The successful implementation of programmatic design features presented in
18 Appendix A, Section A.2.2, would reduce the potential for effects on birds, especially for those
19 species that depend on habitat types that can be avoided (e.g., washes and playas). Indirect
20 impacts could be reduced to negligible levels by implementing design features, especially those
21 engineering controls that would reduce runoff, sedimentation, spills, and fugitive dust. While
22 SEZ-specific design features important to reducing impacts on birds are best established when
23 project details are considered, some design features can be identified at this time:

- 24
25 • The requirements contained within the 2010 Memorandum of Understanding
26 between the BLM and USFWS to promote the conservation of migratory birds
27 will be followed.
- 28
29 • Take of golden eagles and other raptors should be avoided. Mitigation
30 regarding the golden eagle should be developed in consultation with the
31 USFWS and the NDOW. A permit may be required under the Bald and
32 Golden Eagle Protection Act.
- 33
34 • Wash and playa habitats should be avoided.

35
36 If these SEZ-specific design features are implemented in addition to the programmatic
37 design features, impacts on bird species could be reduced. However, because potentially suitable
38 habitats for a number of the bird species occur throughout much of the SEZ, additional species-
39 specific mitigation of direct effects for those species would be difficult or infeasible.

11.7.11.3 Mammals

11.7.11.3.1 Affected Environment

This section addresses mammal species that are known to occur, or for which potentially suitable habitat occurs, on or within the potentially affected area of the proposed Millers SEZ. The list of mammal species potentially present in the SEZ area was determined from the Nevada Natural Heritage Program (NDCNR 2002) and range maps and habitat information available from SWReGAP (USGS 2007). Land cover types suitable for each species were determined from SWReGAP (USGS 2004, 2005a, 2007). Appendix M provides additional information on the approach used.

More than 55 species of mammals have ranges that encompass the area of the proposed Millers SEZ (NDCNR 2002; USGS 2007); however, suitable habitats for a number of these species are limited or nonexistent within the SEZ (USGS 2007). Similar to the overview of mammals provided for the six-state study area (Section 4.6.2.3), the following discussion emphasizes big game and other mammal species that (1) have key habitats within or near the SEZ, (2) are important to humans (e.g., big game, small game, and furbearer species), and/or (3) are representative of other species that share important habitats.

Big Game

The big game species that could occur within the area of the proposed Millers SEZ include cougar (*Puma concolor*), elk (*Cervis canadensis*), mule deer (*Odocoileus hemionus*), Nelson's bighorn sheep (*Ovis canadensis nelsoni*), and pronghorn (*Antilocapra americana*) (USGS 2007). Because of its special species status, the Nelson's bighorn sheep is addressed in Section 11.7.12.1. Among the other big game species, potentially suitable habitat for the cougar, mule deer, and pronghorn occurs within the SEZ (Table 11.7.11.3-1). No potentially suitable habitat for elk occurs within the SEZ. Figures 11.7.11.3-1 and 11.7.11.3-2 show the location of the SEZ relative to mapped ranges of mule deer and pronghorn, respectively.

Other Mammals

A number of mid-size mammal species (e.g., carnivores and rabbits) occur within the area of the proposed Millers SEZ. Species that could occur within the area of the SEZ include the American badger (*Taxidea taxus*), black-tailed jackrabbit (*Lepus californicus*), bobcat (*Lynx rufus*), coyote (*Canis latrans*, common), desert cottontail (*Sylvilagus audubonii*), gray fox (*Urocyon cinereoargenteus*), kit fox (*Vulpes macrotis*), and red fox (*Vulpes vulpes*) (USGS 2007).

The nongame (small) mammals include bats, rodents, and shrews. Representative species for which potentially suitable habitat occurs within the proposed Millers SEZ include Botta's pocket gopher (*Thomomys bottae*), cactus mouse (*Peromyscus eremicus*), deer mouse

FIGURE 11.7.11.3-1 Location of the Proposed Millers SEZ Relative to the Mapped Range of Mule Deer (Source: NDOW 2010)

FIGURE 11.7.11.3-2 Location of the Proposed Millers SEZ Relative to the Mapped Range of Pronghorn (Source: NDOW 2010)

(*P. maniculatus*), desert shrew (*Notiosorex crawfordi*), desert woodrat (*Neotoma lepida*), little pocket mouse (*Perognathus longimembris*), long-tailed pocket mouse (*Chaetodipus formosus*), Merriam's pocket mouse (*Dipodomys merriami*), northern grasshopper mouse (*Onychomys leucogaster*), southern grasshopper mouse (*O. torridus*), western harvest mouse (*Reithrodontomys megalotis*), and white-tailed antelope squirrel (*Ammospermophilus leucurus*) (USGS 2007). Bat species that may occur within the area of the SEZ include the big brown bat (*Eptesicus fuscus*), Brazilian free-tailed bat (*Tadarida brasiliensis*), California myotis (*Myotis californicus*), hoary bat (*Lasiurus cinereus*), little brown myotis (*M. lucifugus*), long-legged myotis (*M. volans*), silver-haired bat (*Lasionycteris noctivagans*), and western pipistrelle (*Parastrellus hesperus*) (USGS 2007). However, roost sites for the bat species (e.g., caves, hollow trees, rock crevices, or buildings) would be limited to absent within the SEZ. Several other special status bat species that could occur within the SEZ area are described in Section 11.7.12.1.

Table 11.7.11.3-1 provides habitat information for representative mammal species that could occur within the proposed Millers SEZ. Special status mammal species are discussed in Section 11.7.12.

11.7.11.3.2 Impacts

The types of impacts that mammals could incur from construction, operation, and decommissioning of utility-scale solar energy facilities are discussed in Section 5.10.2.1. Any such impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2, and through the application of any additional mitigation measures. Section 11.7.11.3.3, below, identifies design features of particular relevance to mammals for the proposed Millers SEZ.

The assessment of impacts on mammal species is based on available information on the presence of species in the affected area, as presented in Section 11.7.11.3.1, following the analysis approach described in Appendix M. Additional NEPA assessments and coordination with state natural resource agencies may be needed to address project-specific impacts more thoroughly. These assessments and consultations could result in additional actions required to avoid or mitigate impacts on mammals (see Section 11.7.11.3.3). Table 11.7.11.3-1 summarizes the magnitude of potential impacts on representative mammal species resulting from solar energy development (with the inclusion of required programmatic design features) in the proposed Millers SEZ.

Cougar

Up to 12,352 acres (50 km²) of potentially suitable cougar habitat could be lost by solar energy development within the proposed Millers SEZ. This represents about 0.3% of potentially suitable cougar habitat within the SEZ region. About 100,800 acres (408 km²) of potentially suitable cougar habitat occurs within the area of indirect effects. Overall, impacts on cougar from solar energy development in the SEZ would be small.

TABLE 11.7.11.3-1 Habitats, Potential Impacts, and Potential Mitigation for Representative Mammal Species That Could Occur on or in the Affected Area of the Proposed Millers SEZ

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Big Game				
Cougar (<i>Puma concolor</i>)	Most common in rough, broken foothills and canyon country, often in association with montane forests, shrublands, and pinyon-juniper woodlands. About 4,795,400 acres ^g of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,837 acres of potentially suitable habitat (2.1% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Mule deer (<i>Odocoileus hemionus</i>)	Most habitats including coniferous forests, desert shrub, chaparral, and grasslands with shrubs. Greatest densities in shrublands on rough, broken terrain that provides abundant browse and cover. About 4,168,200 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	120,888 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Pronghorn (<i>Antilocapra americana</i>)	Grasslands and semidesert shrublands on rolling topography that affords good visibility. Most abundant in shortgrass or midgrass prairies and least common in xeric habitats. About 1,542,600 acres of potentially suitable habitat occurs in the SEZ region.	3,286 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	25,327 acres of potentially suitable habitat (1.6% of available potentially suitable habitat)	Small overall impact.
Small Game and Furbearers				
American badger (<i>Taxidea taxus</i>)	Open grasslands and deserts, meadows in subalpine and montane forests, alpine tundra. Digs burrows in friable soils. Most common in areas with abundant populations of ground squirrels, prairie dogs, and pocket gophers. About 4,950,600 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,098 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Small Game and Furbearers (Cont.)				
Black-tailed jackrabbit (<i>Lepus californicus</i>)	Open plains, fields, and deserts with scattered thickets or patches of shrubs. Also open, early stages of forests and chaparral habitats. Rests during the day in shallow depressions, and uses shrubs for cover. About 4,952,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,780 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Bobcat (<i>Lynx rufus</i>)	Most habitats except subalpine coniferous forest and montane meadow grasslands. Most common in rocky country from deserts through ponderosa forests. About 2,237,500 acres of potentially suitable habitat occurs in the SEZ region.	4,580 acres of potentially suitable habitat lost (0.2% of available potentially suitable habitat) during construction and operations	30,718 acres of potentially suitable habitat (1.4% of available potentially suitable habitat)	Small overall impact.
Coyote (<i>Canis latrans</i>)	All habitats at all elevations. Least common in dense coniferous forest. Where human control efforts occur, restricted to broken, rough country with abundant shrub cover and a good supply of rabbits or rodents. About 5,023,900 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	128,963 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Desert cottontail (<i>Sylvilagus audubonii</i>)	Abundant to common in grasslands, open forests, and desert shrub habitats. Can occur in areas with minimal vegetation as long as adequate cover (e.g., rock piles, fallen logs, fence rows) is present. Thickets and patches of shrubs, vines, and brush also used as cover. About 4,812,200 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,583 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
Small Game and Furbearers (Cont.)				
Gray fox (<i>Urocyon cinereoargenteus</i>)	Deserts, open forests and brush. Prefers wooded areas, broken country, brushlands, and rocky areas. Tolerant of low levels of residential development. About 3,716,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,877 acres of potentially suitable habitat (3.3% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Kit fox (<i>Vulpes macrotis</i>)	Desert and semidesert areas with relatively open vegetative cover and soft soils. Seeks shelter in underground burrows. About 4,127,100 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	105,416 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Red fox (<i>Vulpes vulpes</i>)	Most common in open woodlands, pasturelands, riparian areas, and agricultural lands. About 2,267,400 acres of potentially suitable habitat occurs in the SEZ region.	1,427 acres of potentially suitable habitat lost (0.06% of available potentially suitable habitat) during construction and operations	12,499 acres of potentially suitable habitat (0.6% of available potentially suitable habitat)	Small overall impact.
Nongame (small) Mammals				
Big brown bat (<i>Eptesicus fuscus</i>)	Most habitats from lowland deserts to timberline meadows. Roosts in hollow trees, rock crevices, mines, tunnels, and buildings. About 3,700,800 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,876 acres of potentially suitable habitat (3.3% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Nongame (small)</i>				
<i>Mammals (Cont.)</i>				
Botta’s pocket gopher (<i>Thomomys bottae</i>)	Variety of habitats including shortgrass plains, oak savanna, agricultural lands, and deserts. Burrows are more common in disturbed areas such as roadways and stream floodplains. About 3,559,800 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,494 acres of potentially suitable habitat (3.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Brazilian free-tailed bat (<i>Tadarida brasiliensis</i>)	Cliffs, deserts, grasslands, old fields, savannas, shrublands, woodlands, and suburban/urban areas. Roosts in buildings, caves, and hollow trees. May roost in rock crevices, bridges, signs, or cliff swallow nests during migration. Large maternity colonies inhabit caves, buildings, culverts, and bridges. About 4,260,900 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	124,380 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Cactus mouse (<i>Peromyscus eremicus</i>)	Variety of areas including desert scrub, semidesert chaparral, desert wash, semidesert grassland, and cliff and canyon habitats. About 982,800 acres of potentially suitable habitat occurs in the SEZ region.	3,290 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	21,963 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	Small overall impact. Avoid wash habitats.
California myotis (<i>Myotis californicus</i>)	Desertscrub, semidesert shrublands, lowland riparian, swamps, riparian suburban areas, plains grasslands, scrub-grasslands, woodlands, and forests. Roosts in caves, mine tunnels, hollow trees, and loose rocks. About 3,541,200 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,644 acres of potentially suitable habitat (3.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

		Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
Common Name (Scientific Name)	Habitat ^a	Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Nongame (small)</i>				
<i>Mammals (Cont.)</i>				
Deer mouse (<i>Peromyscus maniculatus</i>)	Tundra; alpine and subalpine grasslands; plains grasslands; open, sparsely vegetated deserts; warm temperate swamps and riparian forests; and Sonoran Desert scrub habitats. About 4,785,100 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,811 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Desert shrew (<i>Notiosorex crawfordi</i>)	Usually in arid areas with adequate cover such as semiarid grasslands, shortgrass plains, desert scrub, chaparral slopes, shortgrass plains, oak savannas and woodlands, and alluvial fans. About 3,079,400 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	122,995 acres of potentially suitable habitat (4.0% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Desert woodrat (<i>Neotoma lepida</i>)	Sagebrush scrub; chaparral; deserts and rocky slopes with scattered cactus, yucca, pine-juniper, or other low vegetation; creosotebush desert; Joshua tree woodlands; scrub oak woodlands, pinyon-juniper woodlands; and riparian zones. Most abundant in rocky areas with Joshua trees. Dens built of debris on ground, among cacti or yucca, along cliffs, among rocks, or occasionally in trees. About 4,863,900 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	121,661 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Hoary bat (<i>Lasiurus cinereus</i>)	Chaparral, shortgrass plains, scrub-grassland, desertscrub, forests and woodlands. Usually roosts in trees, also in caves, rock crevices, and houses. About 1,092,500 acres of potentially suitable habitat occurs in the SEZ region.	4,576 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	27,071 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Nongame (small)</i>				
<i>Mammals (Cont.)</i>				
Little pocket mouse (<i>Perognathus longimembris</i>)	Mostly sandy and gravelly soils, but also stony soils and rarely rocky sites. About 3,927,500 acres of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,207 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Long-legged myotis (<i>Myotis volans</i>)	Prefers pine forest, desert, and riparian habitats. Old buildings, rock crevices, and hollow trees used for daytime roosting and winter hibernation. It forages in open areas, such as forest clearings. About 3,794,200 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,728 acres of potentially suitable habitat (3.3% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Long-tailed pocket mouse (<i>Chaetodipus formosus</i>)	Common in sagebrush, desert scrub, and desert succulent shrub habitats with rocky or stony groundcover. About 3,964,100 acres of potentially suitable habitat occurs in the SEZ region.	12,352 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	100,778 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Merriam’s kangaroo rat (<i>Dipodomys merriami</i>)	Plains grasslands, scrub-grasslands, desertscrub, shortgrass plains, oak and juniper savannahs, mesquite dunes, and creosote flats. About 4,120,300 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	127,472 acres of potentially suitable habitat (3.1% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Nongame (small)</i>				
<i>Mammals (Cont.)</i>				
Northern grasshopper mouse (<i>Onychomys leucogaster</i>)	Occurs in grasslands, sagebrush deserts, overgrazed pastures, weedy roadside ditches, sand dunes, and other habitats with sandy soil and sparse vegetation. About 2,107,800 acres of potentially suitable habitat occurs within the SEZ region.	141 acres of potentially suitable habitat lost (<0.01% of available potentially suitable habitat) during construction and operations	6,818 acres of potentially suitable habitat (0.3% of available potentially suitable habitat)	Small overall impact.
Silver-haired bat (<i>Lasionycteris noctivagans</i>)	Urban areas, chaparral, alpine and subalpine grasslands, forests, scrub-grassland, oak savannah and desertscrub habitats. Roosts under bark, in hollow trees, caves and mines. Forages over clearings and open water. About 4,167,600 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat) during construction and operations	102,362 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Southern grasshopper mouse (<i>Onychomys torridus</i>)	Low, arid, shrub and semiscrub vegetation of deserts. About 2,774,100 acres of potentially suitable habitat occurs within the SEZ region.	12,352 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	95,883 acres of potentially suitable habitat (3.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Western harvest mouse (<i>Reithrodontomys megalotis</i>)	Various habitats, including scrub-grasslands, temperate swamps and riparian forests, salt marshes, shortgrass plains, oak savannah, dry fields, agricultural areas, deserts, and desertscrub. Grasses are the preferred cover. About 3,658,700 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	123,691 acres of potentially suitable habitat (3.4% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

TABLE 11.7.11.3-1 (Cont.)

Common Name (Scientific Name)	Habitat ^a	Maximum Area of Potential Habitat Affected ^b		Overall Impact Magnitude ^e and Species-Specific Mitigation ^f
		Within SEZ (Direct Effects) ^c	Outside SEZ (Indirect Effects) ^d	
<i>Nongame (small)</i>				
<i>Mammals (Cont.)</i>				
Western pipistrelle (<i>Parastrellus hesperus</i>)	Deserts and lowlands, desert mountain ranges, desert scrub flats, and rocky canyons. Roosts mostly in rock crevices, sometimes in mines and caves, and rarely in buildings. Suitable roosts occur in rocky canyons and cliffs. Most abundant bat in desert regions. About 3,550,400 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	124,177 acres of potentially suitable habitat (3.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
White-tailed antelope squirrel (<i>Ammospermophilus leucurus</i>)	Low deserts, semidesert and montane shrublands, plateaus, and foothills in areas with sparse vegetation and hard gravelly surfaces. Spends nights and other periods of inactivity in underground burrows. About 3,646,800 acres of potentially suitable habitat occurs within the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	126,782 acres of potentially suitable habitat (3.5% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.
Yuma myotis (<i>Myotis yumanensis</i>)	Riparian areas, grasslands, semidesert shrubland, mountain brush, woodlands, and deserts. Occurs where there is open water, regardless of the habitat. Roosts in caves, mines, cliffs, crevices, buildings, and swallow nests. About 3,463,900 acres of potentially suitable habitat occurs in the SEZ region.	13,430 acres of potentially suitable habitat lost (0.4% of available potentially suitable habitat) during construction and operations	101,742 acres of potentially suitable habitat (2.9% of available potentially suitable habitat)	Small overall impact. No species-specific mitigation of direct effects is feasible, because suitable habitat is widespread in the area of direct effects.

^a Potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.

^b Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. A maximum of 13,430 acres of direct effects within the SEZ was assumed.

Footnotes continued on next page

TABLE 11.7.11.3-1 (Cont.)

-
- ^c Direct effects within the SEZ consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
 - ^d Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary. Potentially suitable habitat within the SEZ greater than the maximum of 13,430 acres of direct effects was also added to the area of indirect effects. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from the SEZ, but do not include ground-disturbing activities. The potential degree of indirect effects would decrease with increasing distance away from the SEZ.
 - ^e Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects, because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
 - ^f Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
 - ^g To convert acres to km^2 , multiply by 0.004047.

Sources: CDFG (2008); NatureServe (2010); NDCNR (2002); USGS (2004, 2005a, 2007).

Elk

Potentially suitable elk habitat does not occur within the proposed Millers SEZ. Thus, solar energy development would not directly affect elk habitat. About 4,330 acres (17.5 km²) of potentially suitable elk habitat occurs within the area of indirect effects. This is only about 0.3% of potentially suitable elk habitat within the SEZ region. No mapped elk ranges occur within 23 mi (37 km) of the SEZ (NDOW 2010). Overall, impacts on elk from solar energy development in the SEZ would be small.

Mule Deer

Based on land cover analyses, up to 13,430 acres (54.3 km²) of potentially suitable mule deer habitat could be lost by solar energy development within the proposed Millers SEZ. This represents about 0.3% of potentially suitable mule deer habitat within the SEZ region. About 120,900 acres (489.3 km²) of potentially suitable mule deer habitat occurs within the area of indirect effects. No mapped mule deer ranges occur within the SEZ. The closest year-round habitat is about 5 mi (8 km) from the SEZ. The closest summer, winter, and crucial winter ranges are over 20 mi (324 km) from the SEZ (Figure 11.7.11.3-1). Thus, no direct or indirect effect to these mule deer ranges would occur. Overall, impacts on mule deer from solar energy development in the SEZ would be small.

Pronghorn

Based on land cover analyses, up to 3,286 acres (13.3 km²) of potentially suitable pronghorn habitat could be lost by solar energy development within the proposed Millers SEZ. This represents about 0.2% of potentially suitable mule deer habitat within the SEZ region. About 25,325 acres (102.5 km²) of potentially suitable pronghorn habitat occurs within the area of indirect effects. Based on mapped range, year-round pronghorn habitat occurs within the SEZ (Figure 11.7.11.3-2). About 5,215 acres (21.1 km²) of year-round habitat occurs within the SEZ. Loss of this range would total about 0.2% of the year-round pronghorn range within the SEZ region. About 60,445 acres (244.6 km²) of year-round pronghorn habitat occurs within the area of indirect effect. This is about 2.3% of the year-round pronghorn habitat within the SEZ region. Overall, impacts on pronghorn from solar energy development in the SEZ would be small.

Other Mammals

Direct impacts on all other representative mammal species would be small, because 0.4% or less of their potentially suitable habitat within the proposed Millers SEZ region would be lost (Table 11.7.11.3-1). Larger areas of potentially suitable habitat for these species occur within the area of potential indirect effects (e.g., up to 4.0% of potentially suitable habitat for the desert shrew).

Summary of Impacts

Overall, direct impacts on mammal species from habitat loss would be small (Table 11.7.11.3-1). Other impacts on mammals could result from collision with vehicles and infrastructure (e.g., fences), surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, noise, lighting, spread of invasive species, accidental spills, and harassment. Indirect impacts on areas outside the SEZ (e.g., impacts caused by dust generation, erosion, and sedimentation) would be negligible with implementation of programmatic design features.

Decommissioning after operations cease could result in short-term negative impacts on individuals and habitats within and adjacent to the SEZ. The negative impacts of decommissioning would be reduced or eliminated as reclamation proceeds. Potentially long-term benefits could accrue as habitats are restored in previously disturbed areas. Section 5.10.2.1.4 provides an overview of the impacts of decommissioning and reclamation on wildlife. Of particular importance for mammal species would be the restoration of original ground surface contours, soils, and native plant communities associated with semi-arid shrublands.

11.7.11.3.3 SEZ-Specific Design Features and Design Feature Effectiveness

The implementation of required programmatic design features presented in Appendix A, Section A.2.2, would reduce the potential for effects on mammals. Indirect impacts would be reduced to negligible levels by implementing design features, especially those engineering controls that would reduce runoff, sedimentation, spills, and fugitive dust. While SEZ-specific design features important for reducing impacts on mammals are best established when considering specific project details, design features that can be identified at this time are:

- The fencing around the solar energy development should not block the free movement of mammals, particularly big game species.
- Wash and playa habitats should be avoided.

If these SEZ-specific design features are implemented in addition to the programmatic design features, impacts on mammals could be reduced. However, potentially suitable habitats for a number of the mammal species occur throughout much of the SEZ; therefore, species-specific mitigation of direct effects for those species would be difficult or infeasible.

11.7.11.4 Aquatic Biota

11.7.11.4.1 Affected Environment

This section addresses aquatic habitats and biota known to occur on the proposed Millers SEZ itself or within an area that could be affected, either directly or indirectly, by activities

1 associated with solar energy development within the SEZ. There are no permanent streams or
2 water bodies within the proposed Millers SEZ. There is one intermittent/ephemeral wash
3 (Ione Wash), which runs for approximately 3 mi (5 km) through the center of the proposed SEZ.
4 Several other ephemeral washes also cross the Millers SEZ, but based on site visits these
5 drainages contain water only for brief periods following rainfall and do not support wetland or
6 riparian habitats. Ione Wash does not drain into any permanent surface waters and therefore does
7 not provide habitat for fish populations from perennial waters. There are also wetlands along the
8 southern edge of the SEZ. However, wetlands in the southwest rarely have surface water or
9 contain water for only brief periods and typically do not support aquatic communities. The
10 assumed access road corridor does not intersect any intermittent or permanent surface water
11 features. Overall, aquatic habitat and communities are not likely to be present in ephemeral and
12 intermittent desert wetland and surface water features. However, opportunistic crustaceans and
13 aquatic insect larvae adapted to desert conditions may be present even under dry conditions.
14 More detailed site survey data is needed to characterize the aquatic biota, if present, in Millers
15 SEZ.

16
17 Six miles (10 km) of Ione Wash and 29 mi (47 km) of additional unnamed intermittent
18 washes are located within the area of indirect effects, as are wetlands along the southern border
19 of the proposed SEZ. The washes are typically dry and are not expected to contain permanent
20 aquatic habitat or communities. Like Ione Wash, the intermittent washes in the area of indirect
21 effects do not connect to any permanent water bodies but rather terminate in dry lakes.

22
23 Outside of the area of indirect effects, but within 50 mi (80 km) of the proposed Millers
24 SEZ, are 63,486 acres (257 km²) of dry lakes, 43 mi (69 km) of perennial streams, and 434 mi
25 (698 km) of intermittent streams. Intermittent streams are the only surface water feature present
26 in the area of direct and indirect effects and account for about 8% of the total amount of
27 intermittent stream present in the SEZ region.

28 29 30 **11.7.11.4.2 Impacts**

31
32 Because surface water habitats are a unique feature in the arid landscape in the vicinity
33 of the proposed Millers SEZ, the maintenance and protection of such habitats is important to
34 the survival of aquatic and terrestrial organisms. The types of impacts that aquatic habitats and
35 biota could incur from the development of utility-scale solar energy facilities are described in
36 detail in Section 5.10.3. Aquatic habitats present on or near the locations selected for
37 construction of solar energy facilities could be affected in a number of ways, including (1) direct
38 disturbance, (2) deposition of sediments, (3) changes in water quantity, and (4) degradation of
39 water quality.

40
41 The intermittent Ione Wash is present in the proposed Millers SEZ, and direct effects
42 such as ground disturbance are possible. However, Ione Wash is typically dry and impacts on
43 aquatic habitat and communities are not likely. Sediment deposition into intermittent/ephemeral
44 washes in the area of direct and indirect effects is possible via runoff and airborne particulate
45 deposition, especially if ground disturbance occurs near Ione Wash and the intermittent streams
46 and wetlands. However, no aquatic habitats or aquatic communities are present. Although

ephemeral and intermittent surface waters are not likely to contain aquatic habitat, more detailed site surveys for biota in would be necessary to determine whether solar energy development activities would result in direct or indirect impacts to aquatic biota. The streams and wetlands in the SEZ and area of indirect effects are not connected to any permanent surface water features, and the nearest perennial surface water feature is greater than 35 mi (56 km) from the Millers SEZ. Therefore, impacts from runoff on aquatic habitat and communities outside of the area of direct and indirect effects are not likely.

In arid environments, reductions in the quantity of water in aquatic habitats are of particular concern. Water quantity in aquatic habitats could also be affected if significant amounts of surface water or groundwater were utilized for power plant cooling water, for washing mirrors, or for other needs. The greatest need for water would occur if technologies employing wet cooling, such as parabolic trough or power tower, were developed at the site; the associated impacts would ultimately depend on the water source used (including groundwater from aquifers at various depths). Obtaining cooling water from other perennial surface water features in the region could affect water levels and, as a consequence, aquatic organisms in those water bodies located outside the SEZ. Additional details on the volume of water required and the types of organisms present in potentially affected water bodies would be required in order to further evaluate the potential for impacts from water withdrawals.

As identified in Section 5.10.3, water quality in aquatic habitats could be affected by the introduction of contaminants such as fuels, lubricants, or pesticides/herbicides during site characterization, construction, operation, or decommissioning for a solar energy facility. There is the potential for contaminants to enter intermittent streams and wetlands, especially if heavy machinery is used in or nearby these surface water features. Thus, the introduction of contaminants can be minimized by avoiding construction near intermittent streams like Ione Wash. The intermittent streams within the SEZ region are typically dry, do not support aquatic communities, and are not connected to any permanent surface water features. Therefore contaminant effects on aquatic habitat and biota inside and outside of the area of direct and indirect effects are not likely.

11.7.11.4.3 SEZ-Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features are identified at this time. If programmatic project design features described in Appendix A, Section A.2.2, are implemented as needed and if the utilization of water from groundwater or surface water sources is adequately controlled to maintain sufficient water levels in aquatic habitats, the potential impacts on aquatic biota and habitats from solar energy development at the proposed Millers SEZ would be negligible.

11.7.12 Special Status Species (Threatened, Endangered, Sensitive, and Rare Species)

This section addresses special status species that are known to occur, or for which suitable habitat occurs, within the potentially affected area of the proposed Millers SEZ. Special status species include the following types of species:³

- Species listed as threatened or endangered under the ESA;
- Species that are proposed for listing, under review, or are candidates for listing under the ESA;
- Species that are listed by the BLM as sensitive;
- Species that are listed by the State of Nevada;⁴ and
- Species that have been ranked by the State of Nevada as S1 or S2, or species of concern by the State of Nevada or the USFWS; hereafter referred to as “rare” species.

Special status species known to occur within 50 mi (80 km) of the center of the proposed Millers SEZ (i.e., the SEZ region) were determined from natural heritage records available through NatureServe Explorer (NatureServe 2010), information provided by the NDOW, the NNHP (Miskow 2009; NDCNR 2004, 2005, 2009a,b), SWReGAP (USGS 2004, 2005a, 2007), and the USFWS Environmental Conservation Online System (ECOS) (USFWS 2010). Information reviewed consisted of county-level occurrences as determined from Nature Serve, element occurrences provided by the NNHP, as well as modeled land cover types and predicted suitable habitats for the species within the 50-mi (80-km) region as determined from SWReGAP. The 50-mi (80-km) SEZ region intersects Esmeralda, Mineral, and Nye Counties, Nevada. However, the SEZ occurs only in Esmeralda County, Nevada. The affected area occurs within Esmeralda and Nye Counties, Nevada. See Appendix M for additional information on the approach used to identify species that could be affected by development within the SEZ.

11.7.12.1 Affected Environment

The affected area considered in this assessment included the areas of direct and indirect effects for solar development within the proposed SEZ. The area of direct effects was defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur). For the proposed Millers SEZ, the area of direct effect was limited to the SEZ itself. Due to the proximity of existing infrastructure, the impacts of

³ See Section 4.6.4 for definitions of these species categories. Note that some of the categories of species included here do not fit BLM’s definition of special status species as defined in BLM Manual 6840 (BLM 2008b). These species are included here to ensure broad consideration of species that may be most vulnerable to impacts.

⁴ State listed species for the state of Nevada are those protected under NRS 501.110 (animals) or NRS 527 (plants).

1 construction and operation of transmission lines outside of the SEZ are not assessed, assuming
2 that the existing transmission infrastructure might be used to connect some new solar facilities to
3 load centers, and that additional project-specific analysis would be conducted for new
4 transmission construction or line upgrades. Similarly, the impacts of construction or upgrades to
5 access roads were not assessed for this SEZ due to the proximity of an existing federal highway
6 (see Section 11.7.1.2 for a discussion of development assumptions for this SEZ). The area of
7 indirect effects was defined as the area within 5 mi [8 km] of the SEZ boundary where ground-
8 disturbing activities would not occur but that could be indirectly affected by activities in the area
9 of direct effect. Indirect effects considered in the assessment included effects from surface
10 runoff, dust, noise, lighting, and accidental spills from the SEZ, but do not include ground
11 disturbing activities. The potential magnitude of indirect effects would decrease with increasing
12 distance from the SEZ. This area of indirect effect was identified on the basis of professional
13 judgment and was considered sufficiently large to bound the area that would potentially be
14 subject to indirect effects.

15
16 The primary land cover habitat type within the affected area is inter-mountain basins
17 mixed salt desert scrub (see Section 11.7.10). Potentially unique habitats in the affected area in
18 which special status species may reside include desert dune, cliff and rock outcrop, wash, and
19 playa habitats. Aquatic habitats that occur on the SEZ and the area of indirect effects include
20 unnamed playa habitats and the Ione Wash, Peavine Creek, Slime Wash, and an unnamed
21 intermittent stream (Figure 11.7.12.1-1).

22
23 All special status species that are known to occur within the proposed Millers SEZ region
24 (i.e., the area within 50 mi [80 km] of the center of the SEZ) are listed, along with their status,
25 nearest recorded occurrence, and habitats in Appendix J. Nineteen of those species could be
26 affected by solar energy development on the SEZ, based on recorded occurrences or the presence
27 of potentially suitable habitat in the area. These species, their status, and their habitats are
28 presented in Table 11.7.12.1-1. The predicted potential occurrence in the affected area of many
29 of the species listed in the table (especially plants and invertebrates), is based only on a general
30 correspondence between mapped SWReGAP land cover types and descriptions of species habitat
31 preferences. This overall approach to identifying species potentially present in the affected area
32 probably overestimates the number of species that actually occur there. For many of the species
33 identified as having potentially suitable habitat in the affected area, the nearest known actual
34 occurrence is more than 20 mi (32 m) away from the SEZ.

35
36 Based on NNHP records, two special status species are known to occur within the
37 affected area of the proposed Millers SEZ: Tonopah milkvetch and western small-footed bat.
38 The Tonopah milkvetch is considered a rare species (state rank S2 in Nevada); the western
39 small-footed bat is a BLM-designated sensitive species (the USFWS considers it a species of
40 concern). There are no groundwater-dependent species in the vicinity of the SEZ based upon
41 NNHP records, comments provided by the USFWS (Stout 2009), and the evaluation of
42 groundwater resources in the Millers SEZ region (Section 11.7.9).

FIGURE 11.7.12.1-1 Known or Potential Occurrences of Species Listed as Endangered or Threatened under the ESA, Candidate for Listing under the ESA, or Species under Review for ESA Listing in the Affected Area of the Proposed Millers SEZ (Sources: Miskow 2009; NDCNR 2005; USFWS 2010; USGS 2007)

TABLE 11.7.12.1-1 Habitats, Potential Impacts, and Potential Mitigation for Special Status Species That Could be Affected by Solar Energy Development on the Proposed Millers SEZ

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c		Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Plants						
Eastwood milkweed	<i>Asclepias eastwoodiana</i>	BLM-S; FWS-SC; NV-S2	Endemic to Nevada from public and private lands in Esmeralda, Lander, Lincoln, and Nye Counties in open areas on a wide variety of basic (pH usually >8) soils, including calcareous clay knolls, sand, carbonate or basaltic gravels, or shale outcrops, generally barren and lacking competition. Frequently in small washes or other moisture-accumulating microsites at elevations between 4,700 and 7,100 ft ^h . Nearest recorded occurrence is 12 mi ⁱ southeast of the SEZ. About 379,398 acres ^j of potentially suitable habitat occurs within the SEZ region.	3,300 acres of potentially suitable habitat lost (0.9% of available potentially suitable habitat)	22,000 acres of potentially suitable habitat (5.8% of available potentially suitable habitat)	Small overall impact. Pre-disturbance surveys and avoidance or minimization of disturbance to occupied habitats in the areas of direct effect; translocation of individuals from areas of direct effect; or compensatory mitigation of direct effects on occupied habitats could reduce impacts. Note that these same potential mitigations apply to all special status plants.
Nevada dune beardtongue	<i>Penstemon arenarius</i>	BLM-S; FWS-SC; NV-S2	Endemic to western Nevada on sand dunes or deep sand occurring on deep, loose, sandy soils of valley bottoms, aeolian deposits, and dune skirts, often in alkaline areas, sometimes on road banks and other recovering disturbances crossing such soils, in shadscale communities. Nearest recorded occurrence is along Peavine Creek, approximately 17 mi northeast of the SEZ. About 97,638 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	150 acres of potentially suitable habitat (6.5% of available potentially suitable habitat)	Small overall impact; no direct effect. No species-specific mitigation is warranted.

				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Plants (Cont.)						
Ripley biscuitroot	<i>Cymopterus ripleyi</i> var. <i>ripleyi</i>	FWS-SC; NV-S2	Restricted to southeastern California and western Nevada in deep loose, sandy soils of stabilized dunes, dune skirt areas, aeolian deposits, and alluvial drainage areas at elevations between 4,400 and 6,000 ft. Nearest recorded occurrence is 14 mi northeast of the SEZ. About 2,281 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	150 acres of potentially suitable habitat (6.5% of available potentially suitable habitat)	Small overall impact; no direct effect. No species-specific mitigation is warranted.
Sanicle biscuitroot	<i>Cymopterus ripleyi</i> var. <i>saniculoides</i>	BLM-S; FWS-SC	Endemic to Nevada on loose, sandy to gravelly, often somewhat alkaline soils on volcanic tuff deposits and mixed valley alluvium within blackbrush, mixed-shrub, sagebrush, and lower pinyon-juniper communities. Elevation ranges between 3,150 and 6,700 ft. Nearest recorded occurrence is 12 mi northeast of the SEZ. About 4,039,523 acres of potentially suitable habitat occurs within the SEZ region.	13,475 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat)	102,500 acres of potentially suitable habitat (2.5% of available potentially suitable habitat)	Small overall impact. See Eastwood milkweed for a list of other potential mitigations.

				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Plants (Cont.)						
Squalid milkvetch	<i>Astragalus sereno</i> var. <i>sordescens</i>	NV-S2	Endemic to Nevada on dry, open, gravelly or sandy soils along gentle slopes of alluvial fans or light-colored clay hills, within mixed-shrub, sagebrush, and lower pinyon-juniper communities at elevations between 5,000 and 6,800 ft. Nearest recorded occurrence is from the Toiyabe National Forest, about 17 mi northeast of the SEZ. About 4,416,115 acres of potentially suitable habitat occurs within the SEZ region.	12,175 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat)	97,800 acres of potentially suitable habitat (2.2% of available potentially suitable habitat)	Small overall impact. See Eastwood milkweed for a list of other potential mitigations.
Tonopah milkvetch^k	<i>Astragalus pseudiodanthus</i>	NV-S2	Restricted to southeastern California and western Nevada in deep, loose, sandy soils of stabilized and active dune margins, old beaches, valley floors, or drainages at elevations between 4,500 and 6,000 ft. Nearest recorded occurrence is 4 mi southeast of the SEZ. About 2,281 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	150 acres of potentially suitable habitat (6.5% of available potentially suitable habitat)	Small overall impact; no direct effect. No species-specific mitigation is warranted.
Toquima milkvetch	<i>Astragalus toquimanus</i>	BLM-S; NV-S2	Endemic to Nevada on dry, stiff, sandy to gravelly, basic or calcareous soils along gentle slopes or flats at elevations between 6,500 and 7,500 ft. Nearest recorded occurrence is 21 mi east of the SEZ. About 1,156,759 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	4,320 acres of potentially suitable habitat (0.4% of available potentially suitable habitat)	Small overall impact; no direct effect. No species-specific mitigation is warranted.

TABLE 11.7.12.1-1 (Cont.)

				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Invertebrates						
Crescent Dunes aegialian scarab beetle	<i>Aegialia crescenta</i>	ESA-UR; BLM-S; NV-S1	Sand dune obligate species endemic to Nevada on the Crescent Dunes and possibly also to the San Antonio and Game Range Dunes. Nearest recorded occurrence is from the Crescent Dunes SRMA, about 6 mi east of the SEZ. About 2,281 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	150 acres of potentially suitable habitat (6.5% of available potentially suitable habitat)	Small overall impact; no direct effect. A review of mitigation effectiveness to avoid indirect effects (e.g., site runoff and erosion, disruption of sand transport systems) on this species should be conducted during the project design phase and in coordination with the USFWS and NDOW. Coordination would identify the need for mitigation, which may include avoidance, minimization, translocation, or compensation.
Crescent Dunes serican scarab beetle	<i>Serica ammomenisco</i>	ESA-UR; BLM-S; NV-S1	Sand dune obligate species endemic to Nevada on the Crescent Dunes. Nearest recorded occurrence is from the Crescent Dunes SRMA, approximately 6 mi east of the SEZ. About 2,281 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	150 acres of potentially suitable habitat (6.5% of available potentially suitable habitat)	Small overall impact; no direct effect. A review of mitigation effectiveness to avoid indirect effects (e.g., site runoff and erosion, disruption of sand transport systems) on this species should be conducted during the project design phase and in coordination with the USFWS and NDOW. Coordination would identify the need for mitigation, which may include avoidance, minimization, translocation, or compensation.

TABLE 11.7.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c		Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Birds						
Ferruginous hawk	<i>Buteo regalis</i>	BLM-S; NV-P; FWS-SC	Year-round resident in the SEZ region. Grasslands, sagebrush, and saltbrush habitats, as well as the periphery of pinyon-juniper woodland. Nests in tall trees or on rock outcrops along cliff faces. Known to occur in Esmeralda County, Nevada. About 1,403,676 acres of potentially suitable habitat occurs within the SEZ region.	3,125 acres of potentially suitable foraging habitat lost (0.2% of available potentially suitable habitat)	24,000 acres of potentially suitable foraging and nesting habitat (1.7% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.
Greater sage-grouse	<i>Centrocercus urophasianus</i>	ESA-C; BLM-S	Plains, foothills, and mountain valleys dominated by sagebrush. Lek sites are located in relatively open areas surrounded by sagebrush or in areas where sagebrush density is low. Nesting usually occurs on the ground where sagebrush density is higher. Some populations may travel up to 60 mi between summer and winter habitats. Known to occur in Esmeralda County, Nevada. About 1,264,279 acres of potentially suitable habitat occurs within the SEZ region.	125 acres of potentially suitable habitat lost (<0.1% of available potentially suitable habitat)	6,450 acres of potentially suitable habitat (0.5% of available potentially suitable habitat)	Small overall impact. Pre-disturbance surveys and avoidance or minimization of disturbance to occupied and/or suitable leks and nesting sites in the areas of direct effect or compensatory mitigation of direct effects on occupied habitats could reduce impacts. The potential for impact and need for mitigation should be determined in coordination with the USFWS and NDOW.

				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Birds (Cont.)						
Prairie falcon	<i>Falco mexicanus</i>	BLM-S	Year-round resident in open habitats in mountainous areas, steppe, grasslands, or cultivated areas. Nests in well-sheltered ledges of rocky cliffs and outcrops. Known to occur in Esmeralda County, Nevada. About 3,612,314 acres of potentially suitable habitat occurs within the SEZ region.	12,050 acres of potentially suitable foraging habitat lost (0.3% of available potentially suitable habitat)	100,300 acres of potentially suitable foraging and nesting habitat (2.8% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.
Swainson’s hawk	<i>Buteo swainsoni</i>	BLM-S; NV-P; NV-S2	Summer breeding resident in the SEZ region. Savanna, open pine-oak woodlands, grasslands, and cultivated lands. Nests in solitary trees, bushes, or small groves. Known to occur in Esmeralda County, Nevada. About 847,596 acres of potentially suitable habitat occurs within the SEZ region.	125 acres of potentially suitable foraging habitat lost (<0.1% of available potentially suitable habitat)	2,225 acres of potentially suitable foraging and nesting habitat (0.3% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.
Western burrowing owl	<i>Athene cunicularia hypugaea</i>	BLM-S; FWS-SC	Summer breeding resident in SEZ region in open grasslands and prairies, as well as disturbed sites such as golf courses, cemeteries, and airports. Nests in burrows constructed by mammals (prairie dog, badger, etc.). Known to occur in Esmeralda County, Nevada. About 4,035,785 acres of potentially suitable habitat occurs within the SEZ region.	13,600 acres of potentially suitable habitat lost (0.3% of available potentially suitable habitat)	105,600 acres of potentially suitable habitat (2.6% of available potentially suitable habitat)	Small overall impact on foraging and nesting habitat. Pre-disturbance surveys and avoidance or minimization of disturbance to occupied burrows in the area of direct effect or compensatory mitigation of direct effects on occupied habitats could reduce impacts.

				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Mammals						
Fringed myotis	<i>Myotis thysanodes</i>	BLM-S; NV-P; FWS-SC; NV-S2	Year-round resident in SEZ region in wide range of habitats, including lowland riparian, desert shrub, pinyon-juniper, and sagebrush habitats. Roosts in buildings and caves. Known to occur in Esmeralda County, Nevada. About 4,549,929 acres of potentially suitable habitat occurs within the SEZ region.	15,200 acres of potentially suitable foraging habitat lost (0.3% of available potentially suitable habitat)	119,600 acres of potentially suitable foraging and roosting habitat (2.6% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.
Nelson’s bighorn sheep	<i>Ovis canadensis nelsoni</i>	BLM-S; FWS-SC	Open, steep rocky terrain in mountainous habitats of the eastern Mojave and Sonoran Deserts in California. Uses desert lowland as corridors for travel between mountain ranges. Known to occur in Esmeralda County, Nevada. About 1,866,606 acres of potentially suitable habitat occurs within the SEZ region.	0 acres	17,250 acres of potentially suitable habitat (0.9% of available potentially suitable habitat)	Small overall impact; no direct effect. Pre-disturbance surveys and avoidance or minimization of disturbance of habitats within the area of direct effects that serve as movement corridors could further reduce impacts.
Spotted bat	<i>Euderma maculatum</i>	BLM-S; NV-P; FWS-SC; NV-S2	Year-round resident in SEZ region near forests and shrubland habitats. Roosts and hibernates in caves and rock crevices. Nearest recorded occurrence is 30 mi south of the SEZ. About 3,863,972 acres of potentially suitable habitat occurs within the SEZ region.	15,075 acres of potentially suitable foraging habitat lost (0.4% of available potentially suitable habitat)	114,000 acres of potentially suitable foraging and roosting habitat (2.9% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.

TABLE 11.7.12.1-1 (Cont.)

Common Name	Scientific Name	Listing Status ^a	Habitat ^b	Maximum Area of Potential Habitat Affected ^c		Overall Impact Magnitude ^f and Species-Specific Mitigation ^g
				Within SEZ (Direct Effects) ^d	Outside SEZ (Indirect Effects) ^e	
Mammals (Cont.)						
Townsend's big-eared bat	<i>Corynorhinus townsendii</i>	BLM-S; NV-P; NV-S2	Year-round resident in SEZ region near forests and shrubland habitats below 9,000 ft elevation. Roosts and hibernates in caves, mines, and buildings. Nearest recorded occurrence is 7 mi south of the SEZ. About 3,580,069 acres of potentially suitable habitat occurs within the SEZ region.	13,600 acres of potentially suitable foraging habitat lost (0.4% of available potentially suitable habitat)	102,100 acres of potentially suitable foraging and roosting habitat (2.9% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.
Western small-footed bat	<i>Myotis ciliolabrum</i>	BLM-S; FWS-SC	Year-round resident in woodlands and riparian habitats at elevations below 9,000 ft (2,750 m). Roosts in caves, buildings, mines, and crevices of cliff faces. Nearest recorded occurrence is 4 mi north of the SEZ. About 4,949,592 acres of potentially suitable habitat occurs within the SEZ region	16,725 acres of potentially suitable foraging habitat lost (0.3% of available potentially suitable habitat)	125,275 acres of potentially suitable foraging and roosting habitat (2.5% of available potentially suitable habitat)	Small overall impact. Direct impact on foraging habitat only. Avoidance of direct impacts on all foraging habitat is not feasible because suitable foraging habitat is widespread in the area of direct effect.

^a BLM-S = listed as a sensitive species by the BLM; ESA-E = listed as endangered under the ESA; ESA-T = listed as threatened under the ESA; ESA-UR = under review for listing under the ESA; FWS-SC = USFWS species of concern; NV-P = protected in the state of Nevada under NRS 501.110 (animals) or NRS 527 (plants); NV-S1 = ranked as S1 in the state of Nevada; NV-S2 = ranked as S2 in the state of Nevada.

^b For plant species, potentially suitable habitat was determined by using SWReGAP land cover types. For terrestrial vertebrate species, potentially suitable habitat was determined by using SWReGAP habitat suitability and land cover models. Area of potentially suitable habitat for each species is presented for the SEZ region, which is defined as the area within 50 mi (80 km) of the SEZ center.

^c Maximum area of potentially suitable habitat that could be affected relative to availability within the SEZ region. Habitat availability for each species within the region was determined by using SWReGAP habitat suitability and land cover models. This approach probably overestimates the amount of suitable habitat in the project area. Impacts of access road and transmission line construction, upgrade, or operation are not assessed in this evaluation due to the proximity of existing infrastructure to the SEZ.

Footnotes continued on next page.

TABLE 11.7.12.1-1 (Cont.)

-
- ^d Direct effects within the SEZ consist of the ground-disturbing activities associated with construction and the maintenance of an altered environment associated with operations.
- ^e Area of indirect effects was assumed to be the area adjacent to the SEZ within 5 mi (8 km) of the SEZ boundary and the portions of the road and transmission corridors where ground disturbing activities would not occur. Indirect effects include effects from surface runoff, dust, noise, lighting, etc. from projects. The potential degree of indirect effects would decrease with increasing distance from the SEZ. Indirect effects on groundwater-dependent species were considered outside these defined areas.
- ^f Overall impact magnitude categories were based on professional judgment and are as follows: (1) *small*: $\leq 1\%$ of the population or its habitat would be lost and the activity would not result in a measurable change in carrying capacity or population size in the affected area; (2) *moderate*: >1 but $\leq 10\%$ of the population or its habitat would be lost and the activity would result in a measurable but moderate (not destabilizing) change in carrying capacity or population size in the affected area; (3) *large*: $>10\%$ of a population or its habitat would be lost and the activity would result in a large, measurable, and destabilizing change in carrying capacity or population size in the affected area. Note that much greater weight was given to the magnitude of direct effects because those effects would be difficult to mitigate. Programmatic design features would reduce most indirect effects to negligible levels.
- ^g Species-specific mitigations are suggested here, but final mitigations should be developed in consultation with state and federal agencies and should be based on pre-disturbance surveys.
- ^h To convert ft to m, multiply by 0.3048.
- ⁱ To convert mi to km, multiply by 1.609.
- ^j To convert acres to km², multiply by 0.004047.
- ^k Species in bold text have been recorded or have designated critical habitat within 5 mi (8 km) of the SEZ boundary.

1 **11.7.12.1.1 Species Listed under the Endangered Species Act That Could**
2 **Occur in the Affected Area**
3

4 In their scoping comments on the proposed Millers SEZ, the USFWS (Stout 2009) did
5 not express concern for impacts of project development within the SEZ on any species listed as
6 threatened or endangered under the ESA. There are no NNHP records of or potentially suitable
7 habitats for any ESA-listed species within the affected area. According to SWReGAP and USGS
8 habitat suitability models, potentially suitable habitat for the desert tortoise, a species listed as
9 threatened under the ESA, does not occur within the affected area of the proposed Millers SEZ.
10

11
12 **11.7.12.1.2 Species That Are Candidates for Listing under the ESA**
13

14 In their scoping comments on the proposed Millers SEZ, the USFWS did not identify any
15 candidate species for listing under the ESA that may be directly or indirectly affected by solar
16 energy development on the SEZ (Stout 2009). However, one candidate species, the greater sage-
17 grouse, may occur within the affected area. This species inhabits primarily sagebrush habitats in
18 plains, foothills, and mountain valley regions. This species occurs in Esmeralda County, Nevada,
19 and potentially suitable year-round sagebrush habitat is expected to occur within the SEZ and
20 other portions of the affected area (Figure 11.7.12.1-1). According to the SWReGAP habitat
21 suitability model, about 125 acres (0.5 km²) of potentially suitable habitat for this species occurs
22 on the SEZ; about 6,450 acres (26 km²) of potentially suitable habitat occurs in the area of
23 indirect effects (Table 11.7.12.1-1). Additional basic information on life history, habitat needs,
24 and threats to populations of the greater sage-grouse is provided in Appendix J.
25

26
27 **11.7.12.1.3 Species That Are under Review for Listing under the ESA**
28

29 In their scoping comments on the proposed Millers SEZ, the USFWS did not identify
30 any species under ESA review that may be directly or indirectly affected by solar energy
31 development on the SEZ (Stout 2009). However, on the basis of occurrence records, two such
32 species, the Crescent Dunes aegialian scarab beetle and the Crescent Dunes serican scarab beetle,
33 may occur within the affected area. These species are sand dune obligates endemic to Nevada,
34 where they are restricted primarily to the Crescent Dunes in Esmeralda County. The nearest
35 recorded occurrences of these two species are from the Crescent Dunes, approximately 6 mi
36 (10 km) east of the SEZ (Figure 11.7.12.1-1). According to the SWReGAP land cover model,
37 potentially suitable sand dune habitat for these species does not occur on the SEZ; however,
38 approximately 150 acres (0.6 km²) of potentially suitable sand dune habitat occurs in the area of
39 indirect effects (Table 11.7.12.1-1). Additional basic information on life history, habitat needs,
40 and threats to populations of these species is provided in Appendix J.
41

42
43 **11.7.12.1.4 BLM-Designated Sensitive Species**
44

45 There are 16 BLM-designated sensitive species that may occur in the affected area of the
46 proposed Millers SEZ (Table 11.7.12.1-1). These BLM-designated sensitive species include the

1 following (1) plants: Eastwood milkweed, Nevada dune beardtongue, sanicle biscuitroot, and
2 Toquima milkvetch; (2) invertebrates: Crescent Dunes aegialian scarab beetle and Crescent
3 Dunes serican scarab beetle; (3) birds: ferruginous hawk, greater sage-grouse, prairie falcon,
4 Swainson's hawk, and western burrowing owl; and (3) mammals: fringed myotis, Nelson's
5 bighorn sheep, spotted bat, Townsend's big-eared bat, and western small-footed bat. Of these
6 BLM-designated sensitive species with potentially suitable habitat in the affected area, only the
7 western small-footed bat has been recorded within 5 mi (8 km) of the SEZ boundary. Habitats in
8 which BLM-designated sensitive species are found, the amount of potentially suitable habitat for
9 each in the affected area, and known locations of the species relative to the SEZ are presented in
10 Table 11.7.12.1-1. Three of these species—Crescent Dunes aegialian scarab beetle, Crescent
11 Dunes serican scarab beetle, and greater sage-grouse—were discussed above because of their
12 known or pending status under the ESA (Sections 11.7.12.1.2 and 11.7.12.1.3). The remaining
13 species as related to the SEZ are described in the remainder of this section. Additional life
14 history information for these species is provided in Appendix J.

15 16 17 **Eastwood Milkweed**

18
19 The Eastwood milkweed is a perennial forb endemic to Nevada found on public and
20 private lands in Esmeralda, Lander, Lincoln, and Nye Counties. It occurs in open areas on a wide
21 variety of basic (pH usually >8) soils, including calcareous clay knolls, sand, carbonate or
22 basaltic gravels, washes, or shale outcrops at elevations between 4,700 and 7,100 ft (1,430 and
23 2,150 m). The species is known to occur about 12 mi (19 km) southeast of the SEZ. Although it
24 is not known to occur in the affected area, potentially suitable shrubland and desert wash habitat
25 may occur in the SEZ and other portions of the affected area (Table 11.7.12.1-1).

26 27 28 **Nevada Dune Beardtongue**

29
30 The Nevada dune beardtongue is a perennial forb endemic to sandy habitats in western
31 Nevada. The species occurs primarily on dunes or deep sand in valley bottoms, alkaline areas,
32 or road banks. Nearest recorded occurrences are from Peavine Creek, about 17 mi (27 km)
33 northeast of the SEZ. The species is not known to occur within the affected area of the SEZ, and
34 potentially suitable habitat does not occur on the SEZ. However, potentially suitable dune habitat
35 may occur in the area of indirect effects (Table 11.7.12.1-1).

36 37 38 **Sanicle Biscuitroot**

39
40 The sanicle biscuitroot is a perennial forb endemic to Nevada occurring in mixed desert
41 scrub and pinyon-juniper woodland communities on sandy to gravelly alkaline substrates and
42 volcanic deposits. The nearest recorded occurrences are about 12 mi (19 km) northeast of the
43 SEZ. Although it is not known to occur in the affected area, potentially suitable desert scrub
44 habitats may occur in the SEZ and other portions of the affected area (Table 11.7.12.1-1).

Toquima Milkvetch

The Toquima milkvetch is a perennial forb endemic to Nevada on sandy to gravelly slopes or flats at elevations between 6,500 and 7,500 ft (1,980 and 2,280 m). The nearest recorded occurrences are about 21 mi (34 km) east of the SEZ. This species is not known to occur in the affected area, and potentially suitable habitat does not occur on the SEZ. However, potentially suitable sagebrush habitat may occur in the area of indirect effects (Table 11.7.12.1-1).

Ferruginous Hawk

The ferruginous hawk occurs throughout the western United States. According to the SWReGAP habitat suitability model, potentially suitable year-round habitat for the ferruginous hawk may occur within the affected area of the proposed Millers SEZ. This species inhabits open grasslands, sagebrush flats, desert scrub, and the edges of pinyon-juniper woodlands. It occurs in Esmeralda County, Nevada, and potentially suitable foraging habitat occurs on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On the basis of an evaluation of SWReGAP land cover types, no suitable nesting habitat occurs within the area of direct effects, but about 54 acres (0.2 km²) of pinyon-juniper woodlands and 720 acres (3 km²) of cliffs and rock outcrops that may be potentially suitable nesting habitat occur in the area of indirect effects.

Prairie Falcon

The prairie falcon occurs throughout the western United States. According to the SWReGAP habitat suitability model, potentially suitable year-round habitat for the prairie falcon may occur within the affected area of the proposed Millers SEZ. The species occurs in open habitats in mountainous areas, sagebrush-steppe, grasslands, or cultivated areas. Nests are typically constructed in well-sheltered ledges of rocky cliffs and outcrops. This species occurs in Esmeralda County, Nevada, and potentially suitable foraging habitat occurs on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On the basis of an evaluation of SWReGAP land cover types, there is no suitable nesting habitat within the area of direct effects, but about 720 acres (3 km²) of cliff and rock outcrop habitat that may be potentially suitable nesting habitat occurs in the area of indirect effects.

Swainson's Hawk

The Swainson's hawk occurs throughout the southwestern United States. According to the SWReGAP habitat suitability model, only potentially suitable summer foraging and nesting habitat occurs in the affected area of the proposed Millers SEZ. This species inhabits desert, savanna, open pine-oak woodland, grassland, and cultivated habitats. Nests are typically constructed in solitary trees, bushes, or small groves. This species occurs in Esmeralda County, Nevada, and potentially suitable foraging habitat occurs on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On the basis of an evaluation of SWReGAP land cover types,

1 there is no suitable nesting habitat (solitary trees) within the area of direct effects, but about
2 54 acres (0.2 km²) of pinyon-juniper woodland that may be potentially suitable nesting habitat
3 occurs in the area of indirect effects.

6 **Western Burrowing Owl**

8 According to the SWReGAP habitat suitability model for the western burrowing owl,
9 only potentially suitable summer breeding habitat may occur in the affected area of the proposed
10 Millers SEZ. The species forages in grasslands, shrublands, open disturbed areas, and nests in
11 burrows typically constructed by mammals. The species occurs in Esmeralda County, Nevada,
12 and potentially suitable breeding habitat is expected to occur in the SEZ and in other portions of
13 the affected area (Table 11.7.12.1-1). The availability of nest sites (burrows) within the affected
14 area has not been determined, but shrubland habitat that may be suitable for either foraging or
15 nesting occurs throughout the affected area.

18 **Fringed Myotis**

20 The fringed myotis is a year-round resident in the proposed Millers SEZ region. It
21 occurs in a variety of habitats, including riparian, shrubland, sagebrush, and pinyon-juniper
22 woodlands. The species roosts in buildings and caves. It occurs in Esmeralda County, Nevada,
23 and the SWReGAP habitat suitability model for the species indicates that potentially suitable
24 foraging habitat may occur on the SEZ and in other portions of the affected area
25 (Table 11.7.12.1-1). On the basis of an evaluation of SWReGAP land cover types, no suitable
26 roosting habitat occurs within the SEZ, but about 720 acres (3 km²) of cliff and rock outcrop
27 habitat that may be potentially suitable roosting habitat occurs in the area of indirect effects.

30 **Nelson's Bighorn Sheep**

32 The Nelson's bighorn sheep (also called the desert bighorn sheep) is a subspecies of
33 bighorn sheep known to occur in the proposed Millers SEZ region. This species occurs in desert
34 mountain ranges in Arizona, California, Nevada, Oregon, and Utah. The Nelson's bighorn sheep
35 uses primarily montane shrubland, forest, and grassland habitats, and may utilize desert valleys
36 as corridors for travel between range habitats. It occurs in Esmeralda County, Nevada. According
37 to the SWReGAP habitat suitability model for the species, potentially suitable habitat does not
38 occur on the SEZ; but portions of the affected area may provide important range and migratory
39 habitat for the Nelson's bighorn sheep (Table 11.7.12.1-1).

42 **Spotted Bat**

44 The spotted bat is a year-round resident in the proposed Millers SEZ region, where it
45 occurs in a variety of forested and shrubland habitats. It roosts in caves and rock crevices. The
46 species occurs about 30 mi (56 km) south of the SEZ. Potentially suitable foraging habitat may

1 occur on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On the basis of
2 an evaluation of SWReGAP land cover types, there is no suitable roosting habitat within the
3 SEZ, but about 720 acres (3 km²) of cliff and rock outcrop habitat that may be potentially
4 suitable roosting habitat occurs in the area of indirect effects.
5
6

7 **Townsend's Big-Eared Bat**

8

9 The Townsend's big-eared bat is a year-round resident in the proposed Millers SEZ
10 region, where it forages in a wide variety of desert and non-desert habitats. The species roosts
11 in caves, mines, tunnels, buildings, and other man-made structures. The nearest recorded
12 occurrences of this species are about 7 mi (11 km) south of the SEZ. Potentially suitable foraging
13 habitat may occur on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On
14 the basis of an evaluation of SWReGAP land cover types, no suitable roosting habitat occurs
15 within the SEZ, but about 720 acres (3 km²) of cliff and rock outcrop habitat that may be
16 potentially suitable roosting habitat occurs in the area of indirect effects.
17
18

19 **Western Small-Footed Bat**

20

21 The western small-footed bat is a year-round resident in the proposed Millers SEZ region,
22 where it occupies a wide variety of desert and non-desert habitats. including cliffs and rock
23 outcrops, grasslands, shrubland, and mixed woodlands. The species roosts in caves, mines,
24 tunnels, buildings, and other man-made structures and beneath boulders or loose bark. The
25 species is known to occur as near as 4 mi (6 km) north of the SEZ. Potentially suitable foraging
26 habitat may occur on the SEZ and in other portions of the affected area (Table 11.7.12.1-1). On
27 the basis of an evaluation of SWReGAP land cover types, no suitable roosting habitat occurs
28 within the SEZ, but about 720 acres (3 km²) of cliff and rock outcrop habitat that may be
29 potentially suitable roosting habitat occurs in the area of indirect effects.
30
31

32 **11.7.12.1.5 State-Listed Species**

33

34 There are 5 species listed by the State of Nevada that may occur in the proposed Millers
35 SEZ affected area (Table 11.7.12.1-1). These species are (1) birds: ferruginous hawk and
36 Swainson's hawk; and (2) mammals: fringed myotis, spotted bat, and Townsend's big-eared bat.
37 All of these species are protected in the state of Nevada under NRS 501.110. Each of these
38 species has been previously discussed because of its status under the BLM (Section 11.7.12.1.4).
39 Appendix J provides additional life history information for these species.
40
41

42 **11.7.12.1.6 Rare Species**

43

44 There are 17 rare species (i.e., state rank of S1 or S2 in Nevada or a species of concern by
45 the State of Nevada or USFWS) that may be affected by solar energy development on the
46 proposed Millers SEZ (Table 11.7.12.1-1). Of these species, three rare plants have not been

discussed previously—Ripley biscuitroot, squalid milkvetch, and Tonopah milkvetch. The only rare species known to occur within 5 mi (8 km) of the proposed Millers SEZ are the Tonopah milkvetch and western small-footed bat (Table 11.7.12.1-1).

11.7.12.2 Impacts

The potential for impacts on special status species from utility-scale solar energy development within the proposed Millers SEZ is discussed in this section. The types of impacts that special status species could incur from construction and operation of utility-scale solar energy facilities are discussed in Section 5.10.4.

The assessment of impacts to special status species is based on available information on the presence of species in the affected area as presented in Section 11.7.12.1 following the analysis approach described in Appendix M. It is assumed that pre-disturbance surveys would be conducted to determine the presence of special status species and their habitats in and near areas where ground-disturbing activities would occur. Additional NEPA assessments, ESA consultations, and coordination with state natural resource agencies may be needed to address project-specific impacts more thoroughly. These assessments and consultations could result in additional required actions to avoid, minimize, or mitigate impacts on special status species (see Section 11.7.12.3).

Solar energy development within the proposed Millers SEZ could affect a variety of habitats (see Sections 11.7.9 and 11.7.10). These impacts on habitats could in turn affect special status species dependent on those habitats. Based on NNHP records, two special status species are known to occur within 5 mi (8 km) of the proposed Millers SEZ boundary: Tonopah milkvetch and western small-footed bat (listed in bold in Table 11.7.12.1-1). Other special status species may occur on the SEZ or within the affected area based on the presence of potentially suitable habitat. As discussed in Section 11.7.12.1, this approach to identifying the species that could occur in the affected area probably overestimates the number of species that actually occur there and, therefore, may overestimate impacts to some special status species.

Impacts on special status species could occur during all phases of development (construction, operation, and decommissioning and reclamation) of a utility-scale solar energy project within the SEZ. Construction and operation activities could result in short- or long-term impacts on individuals and their habitats, especially if those activities are sited in areas where special status species are known to or could occur. As presented in Section 11.7.1.2, impacts of access road and transmission line construction, upgrade, or operation are not assessed in this evaluation due to the proximity of existing infrastructure to the SEZ.

Direct impacts would result from habitat destruction or modification. It is assumed that direct impacts would occur only within the SEZ where ground disturbing activities are expected to occur. Indirect impacts could result from depletion of groundwater resources, surface water and sediment runoff from disturbed areas, fugitive dust generated by project activities, accidental spills, harassment, and lighting. No ground disturbing activities associated with projects are anticipated to occur within the area of indirect effects. Decommissioning of facilities and

1 reclamation of disturbed areas after operations cease could result in short-term negative impacts
2 to individuals and habitats adjacent to project areas, but long-term benefits would accrue if
3 original land contours and native plant communities were restored in previously disturbed areas.
4

5 The successful implementation of programmatic design features (discussed in
6 Appendix A, Section A.2.2) would reduce direct impacts on some special status species,
7 especially those that depend on habitat types that can be easily avoided (e.g., dunes and playa
8 habitats). Indirect impacts on special status species could be reduced to negligible levels by
9 implementing programmatic design features, especially those engineering controls that would
10 reduce groundwater consumption, runoff, sedimentation, spills, and fugitive dust.
11

12 13 ***11.7.12.2.1 Impacts on Species Listed under the ESA*** 14

15 In their scoping comments on the proposed Millers SEZ, the USFWS did not express
16 concern for impacts of project development within the SEZ on any species listed as threatened
17 or endangered under the ESA (Stout 2009). There are no NNHP records or potentially suitable
18 habitats for any ESA-listed species within the affected area. For these reasons, solar energy
19 development within the proposed Millers SEZ is not likely to affect any species currently listed
20 under the ESA.
21

22 23 ***11.7.12.2.2 Impacts on Species That Are Candidates for Listing under the ESA*** 24

25 The greater sage-grouse is the only ESA candidate species that could occur in the
26 affected area of the proposed Millers SEZ, based upon information provided by the NNHP
27 (NDCNR 2004, 2005) and SWReGAP (USGS 2007). This species is known to occur in
28 Esmeralda County, Nevada, and potentially suitable year-round sagebrush habitat is expected to
29 occur within the SEZ and other portions of the affected area (Figure 11.7.12.1-1). According to
30 the SWReGAP habitat suitability model, about 125 acres (0.5 km²) of potentially suitable habitat
31 on the SEZ could be directly affected by construction and operations (Table 11.7.12.1-1). This
32 direct effects area represents less than 0.1% of available suitable habitat for the greater sage-
33 grouse in the SEZ region. About 6,450 acres (26 km²) of suitable habitat occurs in the area of
34 potential indirect effects; this area represents about 0.5% of the available suitable habitat in the
35 SEZ region (Table 11.7.12.1-1).
36

37 The overall impact on the greater sage-grouse from construction, operation, and
38 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
39 considered small because the amount of potentially suitable habitat for this species in the area
40 of direct effects represents less than 1% of potentially suitable habitat in the SEZ region. The
41 implementation of programmatic design features alone may not be sufficient to reduce impacts
42 because potentially suitable sagebrush habitats may not be avoided in the area of direct effects.
43

44 Efforts to mitigate the impacts of solar energy facilities in the proposed Millers SEZ on
45 the greater sage-grouse should be developed in consultation with the USFWS and NDOW
46 following the *Strategic Plan for Management of Sage Grouse* (UDWR 2002) and *Guidelines to*

1 *Manage Sage Grouse Populations and Their Habitats* (Connelly et al. 2000). Impacts could be
2 reduced by conducting pre-disturbance surveys and avoiding or minimizing disturbance to
3 occupied habitats in the areas of direct effects. If avoidance or minimization is not feasible, a
4 compensatory mitigation plan could be developed and implemented to mitigate direct effects on
5 occupied habitats. Compensation could involve the protection and enhancement of existing
6 occupied or suitable habitats to compensate for habitats lost to development. Any mitigation
7 plans should be developed in coordination with the USFWS and NDOW.
8
9

10 ***11.7.12.2.3 Impacts on Species That Are under Review for Listing under the ESA***

11

12 Two species under review for ESA listing may occur in the affected area of the proposed
13 Millers SEZ: Crescent Dunes aegialian scarab beetle and Crescent Dunes serican scarab beetle.
14 Both species are sand dune obligates, and they are restricted primarily to the Crescent Dunes,
15 about 6 mi (10 km) east of the SEZ (Figure 11.7.12.1-1). According to the SWReGAP land
16 cover model, potentially suitable sand dune habitat for these species does not occur on the SEZ.
17 However, about 150 acres (0.6 km²) of dune habitat occurs in the area of indirect effects; this
18 area represents about 0.5% of the available suitable habitat for both of these species in the SEZ
19 region (Table 11.7.12.1-1).
20

21 The overall impact on the Crescent Dunes aegialian scarab beetle and Crescent Dunes
22 serican scarab beetle from construction, operation, and decommissioning of utility-scale solar
23 energy facilities within the proposed Millers SEZ is considered small because no potentially
24 suitable habitat for this species occurs in the area of direct effects, and only indirect effects are
25 possible. The implementation of programmatic design features is expected to be sufficient to
26 reduce indirect impacts to negligible levels. However, given the location of these species and
27 their habitat adjacent to the SEZ boundary, a review of mitigation effectiveness to avoid indirect
28 effects (e.g., site runoff and erosion, disruption of sand transport systems) on these species
29 should be conducted during the project design phase and in coordination with the USFWS and
30 NDOW. Coordination would identify the need for mitigation, which may include avoidance,
31 minimization, translocation, or compensation.
32
33

34 ***11.7.12.2.4 Impacts on BLM-Designated Sensitive Species***

35

36 BLM-designated sensitive species that may be affected by solar energy development on
37 the proposed Millers SEZ and that have not previously been discussed are discussed below.
38
39

40 ***Eastwood Milkweed***

41

42 The Eastwood milkweed is not known to occur in the affected area of the proposed
43 Millers SEZ; however, about 3,300 acres (13 km²) of potentially suitable habitat on the SEZ
44 could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact
45 area represents about 0.9% of potentially suitable habitat in the SEZ region. About 22,000 acres

(89 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 5.8% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1).

The overall impact on the Eastwood milkweed from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because the amount of potentially suitable habitat for this species in the area of direct effects represents less than 1% of potentially suitable habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts to negligible levels.

Avoidance of all potentially suitable habitats is not a feasible option for mitigating impacts on the Eastwood milkweed because potentially suitable sagebrush and mixed shrubland habitat is widespread throughout the area of direct effects. For this species and other special status plants, impacts could be reduced by conducting pre-disturbance surveys and avoiding or minimizing disturbance to occupied habitats in the area of direct effects. If avoidance or minimization is not feasible, plants could be translocated from the area of direct effects to protected areas that would not be affected directly or indirectly by future development. Alternatively, or in combination with translocation, a compensatory mitigation plan could be developed and implemented to mitigate direct effects on occupied habitats. Compensation could involve the protection and enhancement of existing occupied or suitable habitats to compensate for habitats lost to development. A comprehensive mitigation strategy that used one or more of these options could be designed to completely offset the impacts of development.

Nevada Dune Beardtongue

The Nevada dune beardtongue is not known to occur in the affected area of the proposed Millers SEZ, and potentially suitable sand dune habitat does not occur in the area of direct effects. However, about 150 acres (0.6 km²) of potentially suitable sand dune habitat occurs in the area of indirect effects; this area represents about 0.4% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1).

The overall impact on the Nevada dune beardtongue from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because no potentially suitable habitat for this species occurs in the area of direct effects, and only indirect effects are possible. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts to negligible levels.

Sanicle Biscuitroot

The sanicle biscuitroot is not known to occur in the affected area of the proposed Millers SEZ; however, about 13,475 acres (55 km²) of potentially suitable habitat on the SEZ could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact area represents about 0.3% of potentially suitable habitat in the SEZ region. About 102,500 acres

(415 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 2.5% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1).

The overall impact on the sanicle biscuitroot from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because the amount of potentially suitable habitat for this species in the area of direct effects represents less than 1% of potentially suitable habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts to negligible levels.

Avoidance of all potentially suitable habitats is not a feasible option for mitigating impacts on the sanicle biscuitroot because potentially suitable shrubland habitat is widespread throughout the area of direct effect. However, impacts could be reduced with the implementation of programmatic design features and the mitigation options described previously for the Eastwood milkweed. The need for mitigation, other than programmatic design features, should be determined by conducting pre-disturbance surveys for the species and its habitat on the SEZ.

Toquima Milkvetch

The Toquima milkvetch is not known to occur in the affected area of the proposed Millers SEZ and potentially suitable sand dune habitat does not occur in the area of direct effects. However, approximately 150 acres (0.6 km²) of potentially suitable sand dune habitat occurs in the area of indirect effects; this area represents about 0.4% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1).

The overall impact on the Toquima milkvetch from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because no potentially suitable habitat for this species occurs in the area of direct effects, and only indirect effects are possible. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts to negligible levels.

Ferruginous Hawk

According to the SWReGAP habitat suitability model, potentially suitable year-round habitat for the ferruginous hawk exists in the affected area of proposed Millers SEZ. About 3,125 acres (13 km²) of potentially suitable habitat on the SEZ could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact area represents 0.2% of potentially suitable habitat in the SEZ region. About 24,000 acres (97 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 1.7% of the available suitable habitat in the SEZ region (Table 11.7.12.1-1). Most of the suitable habitat in the affected area could serve as foraging habitat (open shrublands). On the basis of SWReGAP land cover data, suitable nesting habitat (large trees and rock outcrops) does not occur on the SEZ. However, about 54 acres (0.2 km²) of woodland habitat (pinyon-juniper) and 720 acres

(0.6 km²) of cliffs and rock outcrops that may be potentially suitable nesting habitat occurs in the area of indirect effects.

The overall impact on the ferruginous hawk from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts on this species to negligible levels. Avoidance of all potentially suitable foraging habitats (desert shrublands) is not a feasible option for mitigating impacts on this species because potentially suitable habitat is widespread throughout the area of direct effects and in other portions of the SEZ region.

Prairie Falcon

The prairie falcon is a year-round resident in the proposed Millers SEZ region, and potentially suitable foraging habitat is expected to occur in the affected area. About 12,050 acres (49 km²) of potentially suitable habitat on the SEZ could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact area represents 0.3% of potentially suitable habitat in the SEZ region. About 100,300 acres (406 km²) of potentially suitable habitat occurs in the area of indirect effects; this area represents about 2.8% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1). Most of this area could serve as foraging habitat (open shrublands). On the basis of SWReGAP land cover data, potentially suitable nesting habitat (cliffs and rock outcrops) does not occur on the SEZ. However, about 720 acres (3 km²) of cliff and rock outcrop habitat that may be potentially suitable nesting habitat occurs in the area of indirect effects.

The overall impact on the prairie falcon from construction, operation, and decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is considered small because the amount of potentially suitable foraging habitat for this species in the area of direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region. The implementation of programmatic design features is expected to be sufficient to reduce indirect impacts on this species to negligible levels. Avoidance of all potentially suitable foraging habitats (desert shrublands) is not a feasible option for mitigating impacts on this species because potentially suitable habitat is widespread throughout the area of direct effects and in other portions of the SEZ region.

Swainson's Hawk

Potentially suitable summer foraging and nesting habitat for the Swainson's hawk is expected to occur throughout much of the proposed Millers SEZ region, and potentially suitable habitat is expected to occur in the affected area. About 125 acres (0.5 km²) of potentially suitable foraging habitat on the SEZ could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact area represents <0.1% of potentially suitable habitat in

1 the SEZ region. About 2,225 acres (9 km²) of potentially suitable habitat occurs in the area of
2 indirect effects; this area represents about 0.3% of the available suitable foraging habitat in the
3 SEZ region (Table 11.7.12.1-1). On the basis of SWReGAP land cover data, potentially suitable
4 nesting habitat (solitary trees) does not occur on the SEZ. However, about 54 acres (0.2 km²) of
5 woodland habitat (pinyon-juniper) that may be potentially suitable nesting habitat occurs in the
6 area of indirect effects.

7
8 The overall impact on the Swainson's hawk from construction, operation, and
9 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
10 considered small because the amount of potentially suitable habitat for this species in the area of
11 direct effects represents less than 1% of potentially suitable foraging habitat in the SEZ region.
12 The implementation of programmatic design features is expected to be sufficient to reduce
13 indirect impacts on this species to negligible levels. Avoidance of all potentially suitable
14 foraging habitats (desert shrublands) is not a feasible option for mitigating impacts on this
15 species because potentially suitable habitat is widespread throughout the area of direct effects
16 and in other portions of the SEZ region.

17 18 19 **Western Burrowing Owl**

20
21 Potentially suitable breeding habitat for the western burrowing owl occurs throughout
22 much of the proposed Millers SEZ region, and potentially suitable habitat is expected to occur in
23 the affected area. About 13,600 acres (55 km²) of potentially suitable habitat on the SEZ could
24 be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact area
25 represents 0.3% of potentially suitable habitat in the SEZ region. About 105,600 acres (427 km²)
26 of potentially suitable habitat occurs in the area of indirect effects; this area represents about
27 2.6% of the potentially suitable habitat in the SEZ region (Table 11.7.12.1-1). Most of this area
28 could serve as foraging and nesting habitat (shrublands). The abundance of burrows suitable for
29 nesting on the SEZ and in the area of indirect effects has not been determined.

30
31 The overall impact on the western burrowing owl from construction, operation, and
32 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
33 considered small because the amount of potentially suitable habitat for this species in the area of
34 direct effects represents less than 1% of potentially suitable habitat in the SEZ region. The
35 implementation of programmatic design features is expected to be sufficient to reduce indirect
36 impacts on this species to negligible levels.

37
38 Avoidance of all potentially suitable habitats is not a feasible option for mitigating
39 impacts on the western burrowing owl because potentially suitable desert scrub habitats are
40 widespread throughout the area of direct effect and readily available in other portions of the SEZ
41 region. Impacts on the western burrowing owl could be reduced to negligible levels through the
42 implementation of programmatic design features and by conducting pre-disturbance surveys and
43 avoiding or minimizing disturbance to occupied burrows on the SEZ. If avoidance or
44 minimization is not feasible, a compensatory mitigation plan could be developed and
45 implemented to mitigate direct effects on occupied habitats. Compensation could involve the
46 protection and enhancement of existing occupied or suitable habitats to compensate for habitats

1 lost to development. A comprehensive mitigation strategy that used one or both of these options
2 could be designed to completely offset the impacts of development. The need for mitigation,
3 other than programmatic design features, should be determined by conducting pre-disturbance
4 surveys for the species and its habitat on the SEZ.

5 6 7 **Fringed Myotis** 8

9 The fringed myotis is a year-round resident within the proposed Millers SEZ region. On
10 the basis of SWReGAP land cover data, suitable roosting habitats (caves) do not occur on the
11 SEZ. However, about 720 acres (3 km²) of cliff and rock outcrop habitat that may be potentially
12 suitable roosting habitat occurs in the area of indirect effects. About 15,200 acres (62 km²) of
13 potentially suitable foraging habitat on the SEZ could be directly affected by construction and
14 operations (Table 11.7.12.1-1). This direct impact area represents about 0.3% of potentially
15 suitable foraging habitat in the region. About 119,600 acres (484 km²) of potentially suitable
16 foraging habitat occurs in the area of indirect effect; this area represents about 2.6% of the
17 available suitable foraging habitat in the region (Table 11.7.12.1-1). Most of the suitable habitat
18 in the affected area could serve as foraging habitat (open shrublands). On the basis of SWReGAP
19 land cover data, potentially suitable roosting habitat (cliffs and rock outcrops) does not occur on
20 the SEZ. However, about 720 acres (3 km²) of potentially suitable roosting habitat occurs in the
21 area of indirect effects.

22
23 The overall impact on the fringed myotis from construction, operation, and
24 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
25 considered small because the amount of potentially suitable habitat for this species in the
26 area of direct effects represents less than 1% of potentially suitable habitat in the region. The
27 implementation of programmatic design features may be sufficient to reduce indirect impacts on
28 this species to negligible levels. Avoidance of all potentially suitable foraging habitats (desert
29 shrublands) is not a feasible option for mitigating impacts on this species because potentially
30 suitable habitat is widespread throughout the area of direct effects and in other portions of the
31 SEZ region.

32 33 34 **Nelson's Bighorn Sheep** 35

36 The Nelson's bighorn sheep is not known to occur on the proposed Millers SEZ and
37 potentially suitable habitat does not occur on the site. However, about 17,250 acres (70 km²)
38 of potentially suitable habitat occurs within the area of indirect effect; this area represents
39 about 0.9% of the potentially suitable habitat in the region (Table 11.7.12.1-1).

40
41 The overall impact on the Nelson's bighorn sheep from construction, operation, and
42 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
43 considered small because no potentially suitable habitat for this species has been identified in the
44 area of direct effects, and only indirect effects are possible. The implementation of programmatic
45 design features is expected to be sufficient to reduce indirect impacts to negligible levels.
46 Impacts on the Nelson's bighorn sheep may be reduced by conducting pre-disturbance surveys

1 and avoiding or minimizing disturbance to important movement corridors within the area of
2 direct effects.

3 4 5 **Spotted Bat**

6
7 The spotted bat is a year-round resident within the proposed Millers SEZ region. On the
8 basis of SWReGAP land cover data, suitable roosting habitats (caves and rock outcrops) do not
9 occur on the SEZ. However, about 720 acres (3 km²) of cliff and rock outcrop habitat that may
10 be potentially suitable roosting habitat occurs in the area of indirect effects. About 15,075 acres
11 (61 km²) of potentially suitable foraging habitat on the SEZ could be directly affected by
12 construction and operations (Table 11.7.12.1-1). This direct impact area represents about 0.4% of
13 potentially suitable foraging habitat in the region. About 114,000 acres (461 km²) of potentially
14 suitable foraging habitat occurs in the area of indirect effect; this area represents about 2.9% of
15 the potentially suitable foraging habitat in the region (Table 11.7.12.1-1). Most of the suitable
16 habitat in the affected area could serve as foraging habitat (open shrublands). On the basis of
17 SWReGAP land cover data, potentially suitable roosting habitat (cliffs and rock outcrops) does
18 not occur on the SEZ. However, about 720 acres (3 km²) of potentially suitable roosting habitat
19 occurs in the area of indirect effects.

20
21 The overall impact on the spotted bat from construction, operation, and decommissioning
22 of utility-scale solar energy facilities within the proposed Millers SEZ is considered small
23 because the amount of potentially suitable foraging habitat for this species in the area of direct
24 effects represents less than 1% of potentially suitable habitat in the region. The implementation
25 of programmatic design features may be sufficient to reduce indirect impacts on this species to
26 negligible levels. Avoidance of all potentially suitable foraging habitats (desert shrublands) is not
27 a feasible option for mitigating impacts on this species because potentially suitable habitat is
28 widespread throughout the area of direct effects and in other portions of the SEZ region.

29 30 31 **Townsend's Big-Eared Bat**

32
33 The Townsend's big-eared bat is a year-round resident within the proposed Millers SEZ
34 region. On the basis of SWReGAP land cover data, suitable roosting habitats (caves) do not
35 occur on the SEZ. However, about 720 acres (3 km²) of cliff and rock outcrop habitat that may
36 be potentially suitable roosting habitat occurs in the area of indirect effects. About 13,600 acres
37 (55 km²) of potentially suitable foraging habitat on the SEZ could be directly affected by
38 construction and operations (Table 11.7.12.1-1). This direct impact area represents about 0.4% of
39 potentially suitable foraging habitat in the region. About 102,100 acres (413 km²) of potentially
40 suitable foraging habitat occurs in the area of indirect effect; this area represents about 2.9% of
41 the potentially suitable foraging habitat in the region (Table 11.7.12.1-1). Most of the suitable
42 habitat in the affected area could serve as foraging habitat (open shrublands). On the basis of
43 SWReGAP land cover data, potentially suitable roosting habitat (cliffs and rock outcrops) does
44 not occur on the SEZ. However, about 720 acres (3 km²) of potentially suitable roosting habitat
45 occurs in the area of indirect effects.

1 The overall impact on the Townsend's big-eared bat from construction, operation, and
2 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
3 considered small because the amount of potentially suitable habitat for this species in the area
4 of direct effects represents less than 1% of potentially suitable habitat in the region. The
5 implementation of programmatic design features may be sufficient to reduce indirect impacts on
6 this species to negligible levels. Avoidance of all potentially suitable foraging habitats (desert
7 shrublands) is not a feasible option for mitigating impacts on this species because potentially
8 suitable habitat is widespread throughout the area of direct effects and in other portions of the
9 SEZ region.

12 **Western Small-Footed Bat**

14 The western small-footed bat is a year-round resident within the proposed Millers SEZ
15 region. On the basis of SWReGAP land cover data, suitable roosting habitats (caves, rock
16 outcrops, and buildings) do not occur on the SEZ. However, about 720 acres (3 km²) of cliff
17 and rock outcrop habitat that may be potentially suitable roosting habitat occurs in the area of
18 indirect effects. About 16,725 acres (68 km²) of potentially suitable foraging habitat on the SEZ
19 could be directly affected by construction and operations (Table 11.7.12.1-1). This direct impact
20 area represents about 0.3% of potentially suitable foraging habitat in the region. About
21 125,275 acres (507 km²) of potentially suitable foraging habitat occurs in the area of indirect
22 effect; this area represents about 2.5% of the potentially suitable foraging habitat in the region
23 (Table 11.7.12.1-1). Most of the suitable habitat in the affected area could serve as foraging
24 habitat (open shrublands). On the basis of SWReGAP land cover data, potentially suitable
25 roosting habitat (cliffs and rock outcrops) does not occur on the SEZ. However, about 720 acres
26 (3 km²) of potentially suitable roosting habitat occurs in the area of indirect effects.

28 The overall impact on the western small-footed bat from construction, operation, and
29 decommissioning of utility-scale solar energy facilities within the proposed Millers SEZ is
30 considered small because the amount of potentially suitable habitat for this species in the area
31 of direct effects represents less than 1% of potentially suitable habitat in the region. The
32 implementation of programmatic design features may be sufficient to reduce indirect impacts on
33 this species to negligible levels. Avoidance of all potentially suitable foraging habitats (desert
34 shrublands) is not a feasible option for mitigating impacts on this species because potentially
35 suitable habitat is widespread throughout the area of direct effects and in other portions of the
36 SEZ region.

39 **11.7.12.2.5 Impacts on State-Listed Species**

41 There are five species listed by the State of Nevada that may occur in the proposed
42 Millers SEZ affected area or may be affected by solar energy development on the SEZ
43 (Table 11.7.12.1-1). Impacts to these species have been previously discussed because of their
44 designation by the BLM as sensitive species (Section 11.7.12.2.4).

11.7.12.2.6 Impacts on Rare Species

There are 17 rare species (state rank of S1 or S2 in Nevada or listed as a species of concern by the State of Nevada or USFWS) that may be affected by solar energy development on the proposed Millers SEZ. Impacts have been previously discussed for 14 of these species that are under review for ESA listing (Section 11.7.12.2.3) or that are BLM-designated sensitive (Section 11.7.12.2.4). Impacts to the following three rare species have not been previously discussed: Ripley biscuitroot, squalid milkvetch, and Tonopah milkvetch. Impacts and potentially applicable mitigation measures (if necessary) for each of these species are provided in Table 11.7.12.1-1.

11.7.12.3 SEZ-Specific Design Features and Design Feature Effectiveness

The implementation of required programmatic design features described in Appendix A, Section A.2.2, would greatly reduce or eliminate the potential for effects of utility-scale solar energy development on special status species. While some SEZ-specific design features are best established when project details are being considered, some design features can be identified at this time, including the following:

- Pre-disturbance surveys should be conducted within the SEZ to determine the presence and abundance of special status species, including those identified in Table 11.7.12.1-1; disturbance to occupied habitats for these species should be avoided or minimized to the extent practicable. If avoiding or minimizing impacts on occupied habitats is not possible, translocation of individuals from areas of direct effects, or compensatory mitigation of direct effects on occupied habitats could reduce impacts. A comprehensive mitigation strategy for special status species that used one or more of these options to offset the impacts of development should be developed in coordination with the appropriate federal and state agencies
- Coordination should be conducted with the USFWS and NDOW for the Crescent Dunes aegialian scarab beetle, Crescent Dunes serican scarab beetle, and greater sage-grouse – species that are candidates or under review for ESA listing. Coordination would identify an appropriate survey protocol, and mitigation requirements, which may include avoidance, minimization, translocation, or compensation.
- Harassment or disturbance of special status species and their habitats in the affected area should be avoided or minimized. This can be accomplished by identifying any additional sensitive areas and implementing necessary protection measures based upon consultation with the USFWS and NDOW.

If these SEZ-specific design features are implemented in addition to required programmatic design features, impacts on the special status and rare species could be reduced.

11.7.13 Air Quality and Climate

11.7.13.1 Affected Environment

11.7.13.1.1 Climate

The proposed Millers SEZ is located in southwestern Nevada, in the northern portion of Esmeralda County. Nevada lies on the eastern lee side of the Sierra Nevada Range, which markedly influences the climate of the state under the prevailing westerlies (NCDC 2010a). In addition, the mountains east and north of Nevada act as barriers to the cold arctic air masses; thus making long periods of extremely cold weather uncommon. The SEZ lies at an average elevation of about 4,830 ft (1,470 m) in the southwestern portion of the Great Basin Desert, which has an high desert climate marked by pleasant weather (mild winters and warm summers) with large daily temperature swings due to dry air, scant precipitation, low relative humidity, and abundant sunshine. Meteorological data collected at the Tonopah Airport, about 20 mi (32 km) east-southeast of the Millers SEZ boundary, are summarized below.

A wind rose from the Tonopah Airport for the 5-year period 2005 to 2009, taken at a level of 33 ft (10 m), is presented in Figure 11.7.13.1-1 (NCDC 2010b). During this period, the annual average wind speed at the airport was about 9.6 mph (4.3 m/s), with a prevailing wind direction from the north (about 19.7% of the time) and secondarily from the north-northwest (about 16.4% of the time). The northerly wind component predominates, with about 46.7% of wind directions from the northwest clockwise to north. Winds blew predominantly from the north every month throughout the year, except in January and April, when wind blew more frequently from the north-northwest. Wind speeds categorized as calm (less than 1.1 mph [0.5 m/s]) occurred frequently (about 10% of the time) because of the stable conditions caused by strong radiative cooling from late night to sunrise. Average wind speeds by season were relatively uniform: the highest in spring at 11.2 mph (5.0 m/s); lower in summer and fall at 9.2 mph (4.1 m/s); and lowest in winter at 9.0 mph (4.0 m/s).

For the 1954 to 2009 period, the annual average temperature at Tonopah Airport was 51.6°F (10.9°C) (WRCC 2010e). January was the coldest month, with an average minimum temperature of 19.1°F (−7.2°C), and July was the warmest month with an average maximum of 91.5°F (33.1°C). In summer, daytime maximum temperatures were frequently in the 90s, and minimums were in the 50s. The minimum temperatures recorded were below freezing (≤32°F [0°C]) during the colder months (most days from November through March), but subzero temperatures were recorded about 2 days per year, mostly in December and January. During the same period, the highest temperature, 104°F (40.0°C), was reached in July 1960, and the lowest, −15°F (−26.1°C), in January 1962. In a typical year, about 50 days had a maximum temperature of ≥90°F (32.2°C), while about 158 days had minimum temperatures at or below freezing.

FIGURE 11.7.13.1-1 Wind Rose at 33 ft (10 m) at Tonopah Airport, Nevada, 2005 to 2009 (Source: NCDC 2010b)

1 Along with prevailing westerlies, Pacific air masses lose most of their moisture on
2 the windward side of the Sierra Nevada Range parallel to Nevada's western boundary with
3 California (NCDC 2010a). Thus, leeward areas like the Millers SEZ vicinity experience a lack of
4 precipitation. For 1954 to 2009, annual precipitation at Tonopah Airport averaged about 5.08 in.
5 (12.9 cm) (WRCC 2010e). On average, 36 days annually have measurable precipitation (0.01 in.
6 [0.025 cm] or higher). Precipitation is relatively evenly distributed by season, although it is
7 slightly higher in spring and summer than in winter and fall. Snow falls as early as October and
8 continues as late as May; most of the snow falls from December to March. The annual average
9 snowfall at Tonopah Airport is about 13.0 in. (33.0 cm).

10
11 Because the area surrounding the proposed Millers SEZ is far from major water bodies
12 (more than 250 mi [402 km]) and because surrounding mountain ranges block air masses from
13 penetrating into the area, severe weather events, such as thunderstorms and tornadoes, are rare.

14
15 In Nevada, flooding could occur from melting of heavy snowpack. On occasion, heavy
16 summer thunderstorms also cause flooding of local streams, usually in sparsely populated
17 mountainous areas, but these are seldom destructive (NCDC 2010a). Since 1997, four flash
18 floods have been reported in Esmeralda County, all of which occurred far from the SEZ and one
19 of which caused minor property damage.

20
21 In Esmeralda County, no hail storms have been reported (NCDC 2010c). Forty-two high-
22 wind events have been reported since 1999, which caused some property damage. Such events,
23 with a maximum wind speed of up to 127 mph (57 m/s), have occurred any time of the year, with
24 peaks in March and June (NCDC 2010c). In addition, one thunderstorm wind event with a
25 maximum wind speed of 52 mph (23 m/s) was reported in 2010, which caused minor property
26 damage.

27
28 No dust storm events have been reported in Esmeralda County (NCDC 2010c). However,
29 the SEZ is covered primarily with gravelly sands and sandy loams, which have a relatively low
30 dust storm potential. On occasion, high winds and dry soil conditions result in blowing dust in
31 Esmeralda County. Dust storms can deteriorate air quality and visibility and have adverse effects
32 on health.

33
34 Hurricanes and tropical storms formed off the coast of Central America and Mexico
35 weaken over the cold waters off the California coast. Accordingly, hurricanes never hit Nevada.
36 Historically, no tropical storm has passed within 100 mi (160 km) of the proposed Millers SEZ
37 (CSC 2010). Tornadoes in Esmeralda County, which encompasses the proposed Millers SEZ,
38 occur infrequently. Only one tornado has been reported; it occurred in 1982 (NCDC 2010c).
39 However, the tornado occurred far from the SEZ and was relatively weak (i.e., F1 on the Fujita
40 tornado scale). It did not cause property damage, injuries, or deaths.

41 42 43 **11.7.13.1.2 Existing Air Emissions** 44

45 Esmeralda County has a few industrial emission sources, related to minerals and mining,
46 but their emissions are relatively small. All industrial sources are located far from the proposed

Millers SEZ. Because of the sparse population, only a handful of major roads, such as U.S. 6 and U.S. 95 and several State Routes (264, 265, 266, and 773) are present in Esmeralda County. Thus, onroad mobile source emissions are not substantial. Data on annual emissions of criteria pollutants and volatile organic compounds (VOCs) in Esmeralda County are presented in Table 11.7.13.1-1 for 2002 (WRAP 2009). Emission data are classified into six source categories: point, area, onroad mobile, nonroad mobile, biogenic, and fire (wildfires, prescribed fires, agricultural fires, structural fires). In 2002, point sources were major contributors to total emissions of SO₂ (about 78%). Biogenic sources (i.e., vegetation—including trees, plants, and crops—and soils) that release naturally occurring emissions primarily contributed to NO_x and CO emissions (about 62% and 64%, respectively) and accounted for most of VOC emissions (about 99%). Area sources were major contributors to total emissions of PM₁₀ (about 96%) and PM_{2.5} (about 91%), and secondary contributors to SO₂ emissions (about 20%). Onroad sources were secondary contributors to NO_x and CO emissions (about 30% and 35%, respectively). In Esmeralda County, nonroad sources were minor contributors to criteria pollutants and VOCs. (Fire emissions were not estimated in Esmeralda County in 2002.)

TABLE 11.7.13.1-1 Annual Emissions of Criteria Pollutants and VOCs in Esmeralda County, Nevada, Encompassing the Proposed Millers SEZ, 2002^a

Pollutant	Emissions (tons/yr)
SO ₂	106
NO _x	1,116
CO	13,832
VOCs	59,144
PM ₁₀	937
PM _{2.5}	202

^a Includes point, area, onroad and nonroad mobile, biogenic, and fire emissions.

^b Notation: CO = carbon monoxide; NO_x = nitrogen oxides; PM_{2.5} = particulate matter with a diameter of ≤2.5 μm; PM₁₀ = particulate matter with a diameter of ≤10 μm; SO₂ = sulfur dioxide; and VOCs = volatile organic compounds.

Source: WRAP (2009).

In 2005, Nevada produced about 56.3 MMt of *gross*⁵ carbon dioxide equivalent (CO₂e)⁶ emissions, which is about 0.8% of total U.S. GHG emissions in that year (NDEP 2008). Gross GHG emissions in Nevada increased by about 65% from 1990 to 2005 because of Nevada's rapid population growth, compared to 16.3% growth in U.S. GHG emissions during the same period. In 2005, electrical generation (48%) and transportation (30%) were the primary contributors to gross GHG emission sources in Nevada. Fuel use in the residential, commercial, and industrial sectors combined accounted for about 12% of total state emissions. Nevada's *net* emissions were about 51.3 MMt CO₂e, considering carbon sinks from forestry activities and agricultural soils throughout the state. The EPA (2009a) also estimated 2005 emissions in Nevada. Its estimate of CO₂ emissions from fossil fuel combustion was 49.6 MMt, which was comparable to the state's estimate. Electric power generation and transportation accounted for about 52.7% and 33.6% of the CO₂ emissions total, respectively, while the residential, commercial, and industrial sectors accounted for the remainder (about 13.7%).

⁵ Excluding GHG emissions removed as a result of forestry and other land uses and excluding GHG emissions associated with exported electricity.

⁶ A measure used to compare the emissions from various GHGs on the basis of their global warming potential, defined as the cumulative radiative forcing effects of a gas over a specified time horizon resulting from the emission of a unit mass of gas relative to a reference gas, CO₂. The CO₂e for a gas is derived by multiplying the mass of the gas by the associated global warming potential.

11.7.13.1.3 Air Quality

The EPA set National Ambient Air Quality Standards (NAAQS) for six criteria pollutants (EPA 2010a): SO₂, NO₂, CO, O₃, PM (PM₁₀ and PM_{2.5}), and Pb. Nevada has its own State Ambient Air Quality Standards (SAAQS), which are generally similar to the NAAQS but with some differences (NAC 445B.22097). In addition, Nevada has set standards for 1-hour H₂S emissions, which are not addressed by the NAAQS. The NAAQS and Nevada SAAQS for criteria pollutants are presented in Table 11.7.13.1-2.

Esmeralda County is located administratively in the Nevada Intrastate AQCR, along with 10 other counties in Nevada. Not included are Las Vegas Intrastate AQCR, including Clark County only, which encompasses Las Vegas; and Northwest Nevada Intrastate AQCR, including five northwest counties, which encompasses Reno. Currently, the area surrounding the proposed SEZ is designated as being in unclassifiable/attainment of NAAQS for all criteria pollutants (Title 40, Part 81, Section 329 of the *Code of Federal Regulations* [40 CFR 81.329]).

Because of Esmeralda County's low population density, it has no significant emission sources of its own and only minor mobile emissions along major highways. Accordingly, ambient air quality in Esmeralda County is relatively good. No ambient air-monitoring stations are located in Esmeralda County. To characterize ambient air quality around the SEZ, one monitoring station in Clark County was chosen: Jean, about 200 mi (322 km) southeast of the SEZ. The Jean station, which is located upwind of the Las Vegas area, can be considered representative of the proposed SEZ, although its air quality is, to some extent, influenced by transport of air pollutants from the South Coast Air Basin, which includes Los Angeles, along with prevailing westerlies. Ambient concentrations of NO₂, O₃, PM₁₀, and PM_{2.5} are recorded at Jean. The East Sahara Avenue station, which is on the outskirts of Las Vegas, has only one SO₂ monitor in the area. The CO concentrations at the East Tonopah Avenue station in Las Vegas, which is the farthest downwind of Las Vegas among CO monitoring stations, were presented. No Pb measurements have been made in the state of Nevada because of low Pb concentration levels after the phase-out of leaded gasoline. The background concentrations of criteria pollutants at these stations for the period 2004 to 2008 are presented in Table 11.7.13.1-2 (EPA 2010b). Monitored concentration levels at either station were lower than their respective standards (up to 44%), except O₃, which approaches the 1-hour NAAQS/SAAQS and exceeds the 8-hour NAAQS. However, ambient concentrations around the SEZ are anticipated to be lower than those presented in the table, except PM₁₀ and PM_{2.5}, which can be either higher or lower.

The Prevention of Significant Deterioration (PSD) regulations (see 40 CFR 52.21), which are designed to limit the growth of air pollution in clean areas, apply to a major new source or modification of an existing major source within an attainment or unclassified area (see Section 4.11.2.3). As a matter of policy, EPA recommends that the permitting authority notify the Federal Land Managers when a proposed PSD source would locate within 62 mi (100 km) of a sensitive Class I area. Several Class I areas are located around the Millers SEZ, but none of these is situated within 62-mi (100-km) distance in Nevada and California. The nearest Class I area is the John Muir WA in California (40 CFR 81.405), about 73 mi (118 km) southwest of the proposed Millers SEZ. This Class I area is not located downwind of prevailing

TABLE 11.7.13.1-2 NAAQS, SAAQS, and Background Concentration Levels Representative of the Proposed Millers SEZ in Esmeralda County, Nevada, 2004 to 2008

Pollutant ^a	Averaging Time	NAAQS	SAAQS	Background Concentration Level	
				Concentration ^{b,c}	Data Source ^d
SO ₂	1-hour	75 ppb ^e	– ^f	–	–
	3-hour	0.5 ppm	0.5 ppm	0.009 ppm (1.8%)	Las Vegas, 2005
	24-hour	0.14 ppm	0.14 ppm	0.008 ppm (5.7%)	Las Vegas, 2005
	Annual	0.030 ppm	0.030 ppm	0.006 ppm (20%)	Las Vegas, 2005
NO ₂	1-hour	100 ppb ^g	–	–	–
	Annual	0.053 ppm	0.053 ppm	0.004 ppm (7.5%)	Jean Station, 2007
CO	1-hour	35 ppm	35 ppm	5.7 ppm (16%)	Las Vegas, 2004
	8-hour	9 ppm	9 ppm	3.9 ppm (43%)	Las Vegas, 2005
O ₃	1-hour	0.12 ppm ^h	0.12 ppm	0.098 ppm (82%)	Jean, 2005
	8-hour	0.075 ppm	–	0.083 ppm (111%)	Jean, 2007
PM ₁₀	24-hour	150 µg/m ³	150 µg/m ³	66 µg/m ³ (44%)	Jean, 2008
	Annual	–	50 µg/m ³	17 µg/m ³ (34%)	Jean, 2005
PM _{2.5}	24-hour	35 µg/m ³	–	12.9 µg/m ³ (37%)	Jean, 2008
	Annual	15.0 µg/m ³	–	4.93 µg/m ³ (33%)	Jean, 2008
Pb	30-day	–	1.5 µg/m ³	–	–
	Calendar quarter	1.5 µg/m ³	–	–	–
	Rolling 3-month	0.15 µg/m ³ ⁱ	–	–	–

^a Notation: CO = carbon monoxide; NO₂ = nitrogen dioxide; O₃ = ozone; Pb = lead; PM_{2.5} = particulate matter with a diameter of ≤2.5 µm; PM₁₀ = particulate matter with a diameter of ≤10 µm; and SO₂ = sulfur dioxide.

^b Monitored concentrations are the second-highest for all averaging times less than or equal to 24-hour averages, except fourth-highest daily maximum for 8-hour O₃ and the 98th percentile for 24-hour PM_{2.5}; and arithmetic mean for annual SO₂, NO₂, PM₁₀, and PM_{2.5}.

^c Values in parentheses are background concentration levels as a percentage of NAAQS or SAAQS. Calculation of 1-hour SO₂ and NO₂ compared to NAAQS was not made, because no measurement data based on new NAAQS are available.

^d All air monitoring stations listed are located in Clark County.

^e Effective August 23, 2010.

^f A hyphen denotes not applicable or not available.

^g Effective April 12, 2010.

^h The EPA revoked the 1-hour O₃ standard in all areas, although some areas have continuing obligations under that standard (“anti-backsliding”).

ⁱ Effective January 12, 2009.

Sources: EPA (2010a,b); NAC 445B.22097.

winds at the Millers SEZ (Figure 11.7.13.1-1). The next nearest Class I areas are Ansel Adams WA, Kings Canyon NP, Yosemite NP, and Hoover WA, which are about 86 mi (139 km) west-southwest, 88 mi (141 km) southwest, 89 mi (143 km) west, and 91 mi (146 km) west of the Millers SEZ, respectively.

11.7.13.2 Impacts

Potential impacts on ambient air quality associated with a solar project would be of most concern during the construction phase. Impacts on ambient air quality from fugitive dust emissions resulting from soil disturbances are anticipated, but they would be of short duration. During the operations phase, only a few sources with generally low-level emissions would exist for any of the four types of solar technologies evaluated. A solar facility would either not burn fossil fuels or burn only small amounts during operation. (For facilities using heat transfer fluids [HTFs], fuel could be used to maintain the temperature of the HTFs for more efficient daily start-up.) Conversely, solar facilities could displace air emissions that would otherwise be released from fossil fuel power plants to generate an equivalent amount of electricity.

Air quality impacts shared by all solar technologies are discussed in detail in Section 5.11.1, and technology-specific impacts are discussed in Section 5.11.2. Impacts specific to the proposed Millers SEZ are presented in the following sections. Any such impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2, and through the application of any additional mitigation measures. Section 11.7.13.3 below identifies SEZ-specific design features of particular relevance to the Millers SEZ.

11.7.13.2.1 Construction

The Millers SEZ has a relatively flat terrain; thus only a minimum number of site preparation activities, perhaps with no large-scale earthmoving operations, would be required. However, fugitive dust emissions from soil disturbances during the entire construction phase would be a major concern because of the large areas that would be disturbed in a region that experiences windblown dust problems. Fugitive dusts, which are released near ground level, typically have more localized impacts than emissions from an elevated stack with additional plume rise induced by buoyancy and momentum effects.

Methods and Assumptions

Air quality modeling for PM₁₀ and PM_{2.5} emissions associated with construction activities was performed using the EPA-recommended AERMOD model (EPA 2009b). Details for emissions estimation, the description of AERMOD, input data processing procedures, and modeling assumption are described in Section M.13 of Appendix M. Estimated air concentrations were compared with the applicable NAAQS/SAAQS levels at the site boundaries and nearby communities and with Prevention of Significant Deterioration (PSD) increment

1 levels at nearby Class I areas.⁷ However, no receptors were modeled for PSD analysis at the
2 nearest Class I area, John Muir WA in California, because it is about 73 mi (118 km) from the
3 SEZ, which is over the maximum modeling distance of 31 mi (50 km) for the AERMOD. Rather,
4 several regularly spaced receptors in the direction of the John Muir WA were selected as
5 surrogates for the PSD analysis. For the Millers SEZ, the modeling was conducted based on the
6 following assumptions and input:

- 7
- 8 • Uniformly distributed emissions of 3,000 acres (12.1 km²) each and
9 6,000 acres (24.3 km²) in total, in the southeastern portion of the SEZ, close
10 to the nearest residences and the town of Tonopah,
11
- 12 • Surface hourly meteorological data from Tonopah Airport⁸ and upper air
13 sounding data from the Mercury/Desert Rock Airport for the 2005 to 2009
14 period, and
15
- 16 • A regularly spaced receptor grid over a modeling domain of 62 × 62 mi
17 (100 km × 100 km) centered on the proposed SEZ, and additional discrete
18 receptors at the SEZ boundaries.
19

20 21 **Results**

22
23 The modeling results for both PM₁₀ and PM_{2.5} concentration increments and total
24 concentrations (modeled plus background concentrations) that would result from construction-
25 related fugitive emissions are summarized in Table 11.7.13.2-1. Maximum 24-hour PM₁₀
26 concentration increments modeled to occur at the site boundaries would be an estimated
27 539 µg/m³, which far exceeds the relevant standard level of 150 µg/m³. Total 24-hour PM₁₀
28 concentrations of 605 µg/m³ would also exceed the standard level at the SEZ boundary.
29 However, high PM₁₀ concentrations would be limited to the immediate areas surrounding the
30 SEZ boundary and would decrease quickly with distance. Predicted maximum 24-hour PM₁₀
31 concentration increments would be about 15 µg/m³ at the Silver Peak (about 26 mi [42 km]
32 south-southwest from the SEZ), about 4 µg/m³ at Coaldale, and about 2 µg/m³ at Tonopah (the
33 closest town, about 11 mi [18 km] east-southeast of the SEZ boundary). Annual average modeled
34 PM₁₀ concentration increments and total concentration (increment plus background) at the SEZ
35 boundary would be about 75.8 µg/m³ and 92.8 µg/m³, respectively, which are much higher than

⁷ To provide a quantitative assessment, the modeled air impacts of construction were compared to the NAAQS/SAAQS levels and the PSD Class I increment levels. Although the Clean Air Act exempts construction activities from PSD requirements, a comparison with the Class I increment levels was used to quantify potential impacts. Only monitored data can be used to determine the attainment status. Modeled data are used to assess potential problems and as a consideration in the permitting process.

⁸ The number of missing hours at the Tonopah Airport amounts to about 17.6% of the total hours, which may not be acceptable for regulatory applications because that percentage exceeds the 10% limit defined by the EPA. However, because the wind patterns at Tonopah Airport are more representative of wind at the Millers SEZ than the wind patterns at other airports (which have more complete data but are located in different topographic features), the former values were used for the screening analysis.

TABLE 11.7.13.2-1 Maximum Air Quality Impacts from Emissions Associated with Construction Activities for the Proposed Millers SEZ

Pollutant ^a	Averaging Time	Rank ^b	Concentration (µg/m ³)				Percentage of NAAQS/SAAQS	
			Maximum Increment ^b	Background ^c	Total	NAAQS/SAAQS	Increment	Total
PM ₁₀	24 hours	H6H	539	66	605	150	359	403
	Annual	— ^d	75.8	17	92.8	50	152	186
PM _{2.5}	24 hours	H8H	34.9	12.9	47.8	35	100	136
	Annual	—	7.6	4.9	12.5	15.0	51	83

^a PM_{2.5} = particulate matter with a diameter of ≤2.5 µm; PM₁₀ = particulate matter with a diameter of ≤10 µm.

^b Concentrations for attainment demonstration are presented. H6H = highest of the sixth-highest concentrations at each receptor over the 5-year period. H8H = highest of the multiyear average of the eighth-highest concentrations at each receptor over the 5-year period. For the annual average, multiyear averages of annual means over the 5-year period are presented. Maximum concentrations are predicted to occur at the site boundaries.

^c See Table 11.7.13.1-2.

^d A dash indicates not applicable.

the SAAQS level of 50 µg/m³. Annual PM₁₀ increments would be much lower, about 0.3 µg/m³ at Silver Peak, about 0.1 µg/m³ at Tonopah, and lower than 0.1 µg/m³ at Coaldale. Total 24-hour PM_{2.5} concentrations would be 48 µg/m³ at the SEZ boundary, which is higher than the NAAQS level of 35 µg/m³; modeled increments contribute about three times more than background concentration to this total. The total annual average PM_{2.5} concentration would be 12.5 µg/m³, which is below the NAAQS level of 15.0 µg/m³. At Silver Peak, predicted maximum 24-hour and annual PM_{2.5} concentration increments would be about 0.3 and 0.03 µg/m³, respectively.

Predicted 24-hour and annual PM₁₀ concentration increments at the surrogate receptors for the nearest Class I Area—John Muir WA in California—would be about 8.7 and 0.2 µg/m³, or 109% and 5% of the PSD increments for Class I area, respectively. These surrogate receptors are more than 36 mi (58 km) from the John Muir WA, and thus predicted concentrations in John Muir WA would be much lower than the above values (about 55% of the PSD increments for 24-hour PM₁₀), considering the same decay ratio with distance.

In conclusion, predicted 24-hour and annual PM₁₀ and 24-hour PM_{2.5} concentration levels could exceed the standard levels used as guidelines at the SEZ boundaries and in the immediate surrounding areas during the construction of solar facilities. To reduce potential impacts on ambient air quality and in compliance with programmatic design features, aggressive dust control measures would be used. Potential air quality impacts on nearby communities would be much lower. Predicted total concentrations for annual PM_{2.5} would be below the respective standard levels. Modeling indicates that emissions from construction activities are not anticipated

1 to exceed Class I PSD PM₁₀ increments at the nearest federal Class I area (John Muir WA in
2 California). Construction activities are not subject to the PSD program, and the comparison
3 provides only a screen for gauging the size of the impact. Accordingly, it is anticipated that
4 impacts of construction activities on ambient air quality would be moderate and temporary.

5
6 Construction emissions from the engine exhaust from heavy equipment and vehicles
7 could cause impacts on AQRVs (e.g., visibility and acid deposition) at the nearby federal Class I
8 areas. The SO_x emissions from engine exhaust would be very low, because programmatic design
9 features would require ultra-low-sulfur fuel with a sulfur content of 15 ppm. The NO_x emissions
10 from engine exhaust would be primary contributors to potential impacts on AQRVs.
11 Construction-related emissions are temporary in nature and thus would cause some unavoidable
12 but short-term impacts.

13
14 For this analysis, the impacts of construction and operation of transmission lines outside
15 of the SEZ were not assessed, assuming that the existing regional 120-kV transmission line
16 might be used to connect some new solar facilities to load centers, and that additional project-
17 specific analysis would be done for new transmission construction or line upgrades. However,
18 some construction of transmission lines could occur within the SEZ. Potential impacts on
19 ambient air quality would be a minor component of construction impacts in comparison with
20 solar facility construction and would be temporary.

21 22 23 **11.7.13.2.2 Operations**

24
25 Emission sources associated with the operation of a solar facility would include auxiliary
26 boilers; vehicle traffic (commuter, visitor, support, and delivery); maintenance (e.g., mirror
27 cleaning and repair and replacement of damaged mirrors); and drift from cooling towers for the
28 parabolic trough or power tower technology if wet cooling was implemented (drift comprises
29 low-level PM emissions).

30
31 The type of emission sources caused by and offset by operation of a solar facility are
32 discussed in Appendix M, Section M.13.4.

33
34 Potential air emissions displaced by the solar project development at the proposed Millers
35 SEZ are presented in Table 11.7.13.2-2. Total power generation capacity ranging from 1,492 to
36 2,686 MW is estimated for the proposed Millers SEZ for various solar technologies
37 (see Section 11.7.2). The estimated amount of emissions avoided for the solar technologies
38 evaluated depends only on the megawatts of conventional fossil fuel-generated power displaced,
39 because a composite emission factor per megawatt-hour of power by conventional technologies
40 is assumed (EPA 2009c). Full development of solar power in the SEZ could result in substantial
41 avoided air emissions—ranging from 6.9 to 12% of total emissions of SO₂, NO_x, Hg, and CO₂
42 from electric power systems in the state of Nevada (EPA 2009c). Avoided emissions could be up
43 to 2.6% of total emissions from electric power systems in the six-state study area. When
44 compared with all source categories, power production from the same solar facilities could
45 displace up to 10% of SO₂, 3.8% of NO_x, and 6.7% of CO₂ emissions in the state of Nevada
46 (EPA 2009a; WRAP 2009). These emissions could be up to 1.4% of total emissions from all

TABLE 11.7.13.2-2 Annual Emissions from Combustion-Related Power Generation Avoided by Full Solar Development of the Proposed Millers SEZ

Area Size (acres)	Capacity (MW) ^a	Power Generation (GWh/yr) ^b	Emissions Displaced (tons/yr; 10 ³ tons/yr for CO ₂) ^c			
			SO ₂	NO _x	Hg	CO ₂
16,787	1,492–2,686	2,614–4,706	3,689–6,639	3,164–5,695	0.021–0.038	2,030–3,655
Percentage of total emissions from electric power systems in Nevada ^d			6.9–12%	6.9–12%	6.9–12%	6.9–12%
Percentage of total emissions from all source categories in Nevada ^e			5.6–10%	2.1–3.8%	– ^f	3.7–6.7%
Percentage of total emissions from electric power systems in the six-state study area ^d			1.5–2.6%	0.86–1.5%	0.72–1.3%	0.77–1.4%
Percentage of total emissions from all source categories in the six-state study area ^e			0.78–1.4%	0.12–0.21%	–	0.24–0.44%

^a It is assumed that the SEZ would eventually have development on 80% of the lands and that a range of 5 acres (0.020 km²) per MW (for parabolic trough technology) to 9 acres (0.036 km²) per MW (power tower, dish engine, and PV technologies) would be required.

^b Assumed capacity factor of 20%.

^c Composite combustion-related emission factors for SO₂, NO_x, Hg, and CO₂ of 2.82, 2.42, 1.6 × 10⁻⁵, and 1,553 lb/MWh, respectively, were used for the state of Nevada.

^d Emission data for all air pollutants are for 2005.

^e Emission data for SO₂ and NO_x are for 2002, while those for CO₂ are for 2005.

^f A dash indicates not estimated.

Sources: EPA (2009a,c); WRAP (2009).

source categories in the six-state study area. Power generation from fossil fuel-fired power plants accounts for about 93% of the total electric power generated in Nevada for which contribution of natural gas and coal combustion is comparable (EPA 2009c). Thus, solar facilities to be built in the Millers SEZ could be more important than those built in other states in terms of reducing fuel combustion-related emissions.

As discussed in Section 5.11.1.5, the operation of associated transmission lines would generate some air pollutants from activities such as periodic site inspections and maintenance. However, these activities would occur infrequently, and the amount of emissions would be small. In addition, transmission lines could produce minute amounts of O₃ and its precursor NO_x associated with corona discharge (i.e., the breakdown of air near high-voltage conductors), which is most noticeable for high-voltage lines during rain or very humid conditions. Since the Millers SEZ is located in an arid desert environment, these emissions would be small, and

1 potential impacts on ambient air quality associated with transmission lines would be negligible,
2 considering the infrequent occurrences and small amount of emissions from corona discharges.
3
4

5 **11.7.13.2.3 Decommissioning/Reclamation**

6

7 As discussed in Section 5.11.1.4, decommissioning/reclamation activities are similar to
8 construction activities but are on a more limited scale and of shorter duration. Potential impacts
9 on ambient air quality would be correspondingly less than those from construction activities.
10 Decommissioning activities would last for a short period, and their potential impacts would be
11 moderate and temporary. The same mitigation measures adopted during the construction phase
12 would also be implemented during the decommissioning phase (Section 5.11.3).
13
14

15 **11.7.13.3 SEZ-Specific Design Features and Design Feature Effectiveness**

16

17 No SEZ-specific design features are required. Limiting dust generation during
18 construction and operations at the proposed Millers SEZ (such as increased watering frequency
19 or road paving or treatment) is a required design feature under BLM's Solar Energy Program.
20 These extensive fugitive dust control measures would keep off-site PM levels as low as possible
21 during construction.
22

11.7.14 Visual Resources

11.7.14.1 Affected Environment

The proposed Millers SEZ is located in Esmeralda County in southwestern Nevada, 44 mi (71 km) east of the California border. The SEZ occupies 16,787 acres (67.9 km²) within the Big Smoky Valley and extends about 7.7 mi (12.4 km) east to west and nearly 5.8 mi (9.3 km) north to south. The SEZ ranges in elevation from 4,778 ft (1,456 m) in the southwest portion to 4,892 ft (1,491 m) in the northwest portion.

The SEZ lies within the Central Basin and Range Level III ecoregion, which consists of northerly trending fault-block ranges and intervening drier basins. Valleys, lower slopes, and alluvial fans are either shrub- and grass-covered or shrub-covered. Higher elevation mountain slopes support woodland, mountain brush, and scattered forests. The land is primarily used for grazing, with some irrigated cropland found in valleys near mountain water sources. Millers SEZ is located within two Level IV ecoregions. The southwest corner of the SEZ is within the nearly level and mostly barren Lahontan and Tonopah Playas Level IV ecoregion. The playas contain mud flats, alkali flats, and intermittent saline lakes. Playas occur at the lowest elevations in the Lahontan Basin and fill with seasonal runoff from surrounding mountain ranges during winter, providing habitat for migratory birds. (Bryce et al. 2003). The rest of the SEZ is within the *Tonopah Basin* Level IV ecoregion, which is a transition between the Great Basin and the more southerly Mojave Desert. It is typified by broad, nearly flat to rolling valleys containing lake plains, scattered hills, alluvial fans, bajadas, sand dunes, and hot springs. Ephemeral washes occur. Surface water comes from springs and sporadic foothill precipitation events, but is generally scarce.

The SEZ is located within a very flat treeless plain of the broad Big Smoky Valley, resulting in a very strong horizon line. The SEZ is bounded by mountain ranges on the east, south, and west, with open views to the northeast and southwest. Lone Mountain rises 5.5 mi (8.9 km) south of the SEZ. The Monte Cristo Range is located about 3 mi (5 km) west of the SEZ. The San Antonio Mountains to the east are more distant, rising about 9 mi (15 km) from the SEZ. These ranges include peaks generally between 6,000 and 8,000 ft (1,829 and 2,438 m) in elevation, with the peak of Lone Mountain at 9,108 ft (2,776 m). From the northeast to the southwest, the Big Smoky Valley extends 50 mi (81 km) and is about 12 mi (19 km) wide. The SEZ and surrounding mountain ranges are shown in Figure 11.7.14.1-1.

The overall visual impression of the SEZ and its surroundings is of a vast, light-colored plain rising abruptly to rugged mountains to the south and west, with more distant mountains to the east, and generally open views to the north and southwest. The mountains to the south (Lone Mountain) are dark, while the mountains to the west (Monte Cristo Range) present a range of colors from nearly white through rusty red to darker grays and browns. The light soils and lack of vegetation in playas add some visual interest, and in other, scattered, smaller areas, black, featureless, and nearly perfectly flat desert pavement provides striking visual contrasts in color and texture with surrounding vegetation and soils.

FIGURE 11.7.14.1-1 Proposed Millers SEZ and Surrounding Lands

1 Vegetation is generally sparse in much of the SEZ, with widely spaced low shrubs
2 generally less than 3 ft (1 m) tall, and much bare soil, particularly in the playas. The vegetation is
3 predominantly greasewood-shadscale. During an August 2009 site visit, the vegetation presented
4 a limited range of light greens, tans, and grays, with medium to coarse textures, and generally
5 low visual interest.

6
7 There is no permanent surface water within the SEZ. A number of washes, including Ione
8 Wash, cross the SEZ in a generally north-south direction.

9
10 Cultural disturbances visible within the SEZ include existing transmission lines, fences,
11 and roads. There is evidence of OHV use in some areas, but in general, the level of cultural
12 disturbance is low. These cultural modifications generally detract from the scenic quality of the
13 SEZ; however, the SEZ is so large that from many locations within the SEZ, these features are
14 either not visible or are so distant as to have minimal effect on views. From most locations
15 within the SEZ, the landscape is generally natural in appearance, with little disturbance visible.

16
17 Off-site cultural disturbances visible from the SEZ include U.S. 6, just south of the SEZ
18 and generally paralleling the southern boundary of the SEZ. Traffic on the highway would be
19 plainly visible from many locations within the SEZ. The Millers rest stop on U.S. 6 includes
20 fences, cleared areas roads, groves of trees, a few low buildings, and a communications tower
21 that is visible for long distances, including from within the SEZ. Transmission towers and lines
22 are visible along U.S. 6 and also between the highway and the SEZ.

23
24 The general lack of topographic relief, water, and variety results in low scenic value
25 within the SEZ itself; however, because of the flatness of the landscape, the lack of trees, and the
26 breadth of the Big Smoky Valley, the SEZ presents a vast panoramic landscape with sweeping
27 views of the surrounding mountains that add to the scenic values within the SEZ viewshed. In
28 general, the mountains appear to be devoid of vegetation, and their jagged, irregular forms, and
29 varied colors provide dramatic visual contrasts to the strong horizontal line, light-colored
30 vegetation, the light playa soils and dark desert pavement areas of the valley floor, particularly
31 when viewed from nearby locations within the SEZ. The mountain slopes and peaks to the east,
32 south, and west of the SEZ are, in general, visually pristine. Panoramic views of the SEZ are
33 shown in Figures 11.7.14.1-2, 11.7.14.1-3 and 11.7.14.1-4.

34
35 The BLM conducted a VRI for the SEZ and surrounding lands in 2004. The VRI
36 evaluates BLM-administered lands based on scenic quality; sensitivity level in terms of public
37 concern for preservation of scenic values in the evaluated lands; and distance from travel routes
38 or KOPs. Based on these three factors, BLM-administered lands are placed into one of four VRI
39 Classes, which represent the relative value of the visual resources. Class I and II are the most
40 valued; Class III represents a moderate value; and Class IV represents the least value. Class I is
41 reserved for specially designated areas, such as national wildernesses and other congressionally
42 and administratively designated areas for which decisions have been made to preserve a natural
43 landscape. Class II is the highest rating for lands without special designation. More information
44 about VRI methodology is presented in Section 5.12 and in *Visual Resource Inventory*, BLM
45 Manual Handbook 8410-1 (BLM 1986a).

FIGURE 11.7.14.1-4 Approximately 120° Panoramic View of the Proposed Millers SEZ, Facing South toward Lone Mountain from West-Central Portion of the SEZ

13

1 The VRI values for the SEZ are VRI Class 4, indicating low relative visual values. Most
2 of the immediate surroundings are also VRI Class 4, with the exception of the area immediately
3 to the east of the SEZ. This is VRI Class 3 (BLM 2009c). The BLM conducted a new VRI for
4 the SEZ and surrounding lands in 2010, ; however, the VRI was not completed in time for the
5 new data to be included in this draft PEIS. The new VRI data will be incorporated into the
6 analyses presented in the final PEIS. More information about VRI methodology is presented in
7 Section 5.12 and in *Visual Resource Inventory*, BLM Manual Handbook 8410-1 (BLM 1986a).

8
9 The Tonopah Resource Management Plan (BLM 1997) indicates that the SEZ and
10 surrounding area is managed as VRM Class IV, which permits major modification of the existing
11 character of the landscape. More information about the BLM VRM program is presented in
12 Section 5.12 and in *Visual Resource Management*, BLM Manual Handbook 8400 (BLM 1984).

13 14 15 **11.7.14.2 Impacts** 16

17 The potential for impacts from utility-scale solar energy development on visual
18 resources within the proposed Millers SEZ and surrounding lands, as well as the impacts
19 of related projects (e.g., access roads and transmission lines) outside of the SEZ, is presented in
20 this section.

21
22 Site-specific impact assessment is needed to systematically and thoroughly assess visual
23 impact levels for a particular project. Without precise information about the location of a project
24 and a relatively complete and accurate description of its major components and their layout, it is
25 not possible to assess precisely the visual impacts associated with the facility. However, if the
26 general nature and location of a facility are known, a more generalized assessment of potential
27 visual impacts can be made by describing the range of expected visual changes and discussing
28 contrasts typically associated with these changes. In addition, a general analysis can identify
29 sensitive resources that may be at risk if a future project is sited in a particular area. Detailed
30 information about the methodology employed for the visual impact assessment used in this PEIS,
31 including assumptions and limitations, is presented in Appendix M.

32
33
34 *Potential Glint and Glare Impacts.* Similarly, the nature and magnitude of potential glint-
35 and glare-related visual impacts for a given solar facility is highly dependent on viewer position,
36 sun angle, the nature of the reflective surface and its orientation relative to the sun and the
37 viewer, atmospheric conditions and other variables. The determination of potential impacts from
38 glint and glare from solar facilities within a given proposed SEZ would require precise
39 knowledge of these variables, and is not possible given the scope of the PEIS. Therefore, the
40 following analysis does not describe or suggest potential contrast levels arising from glint and
41 glare for facilities that might be developed within the SEZ. However, it should be assumed that
42 glint and glare are possible visual impacts from *any* utility-scale solar facility, regardless of size,
43 landscape setting, or technology type. The occurrence of glint and glare at solar facilities could
44 potentially cause large though temporary increases in brightness and visibility of the facilities.
45 The visual contrast levels projected for sensitive visual resource areas discussed in the following
46 analysis do not account for potential glint and glare effects; however, these effects would be

1 incorporated into a future site-and project-specific assessment that would be conducted for
2 specific proposed utility-scale solar energy projects. For more information about potential glint
3 and glare impacts associated with utility-scale solar energy facilities, see Section 5.12 of this
4 PEIS.

7 ***11.7.14.2.1 Impacts on the Proposed Millers SEZ***

9 Some or all of the SEZ could be developed for one or more utility-scale solar energy
10 projects, utilizing one or more of the solar energy technologies described in Appendix F.
11 Because of the industrial nature and large size of utility-scale solar energy facilities, large visual
12 impacts on the SEZ would occur as a result of the construction, operation, and decommissioning
13 of solar energy projects. In addition, large impacts could occur at solar facilities utilizing highly
14 reflective surfaces or major light-emitting facility components (solar dish, parabolic trough, and
15 power tower technologies) , with lesser impacts associated with reflective surfaces expected
16 from PV facilities. These impacts would be expected to involve major modification of the
17 existing character of the landscape and would likely dominate the views nearby. Additional, and
18 potentially large, impacts would occur as a result of the construction, operation, and
19 decommissioning of related facilities, such as access roads and electric transmission lines. While
20 the primary visual impacts associated with solar energy development within the SEZ would
21 occur during daylight hours, lighting required for utility-scale solar energy facilities would be a
22 potential source of visual impacts at night, both within the SEZ and on surrounding lands.

24 Common and technology-specific visual impacts from utility-scale solar energy
25 development, as well as impacts associated with electric transmission lines, are discussed in
26 Section 5.12 of this PEIS. Impacts would last throughout construction, operation, and
27 decommissioning, and some impacts could continue after project decommissioning. Visual
28 impacts resulting from solar energy development in the SEZ would be in addition to impacts
29 from solar energy development and other development that may occur on other public or private
30 lands within the SEZ viewshed, and are subject to cumulative effects. For discussion of
31 cumulative impacts, see Section 11.7.22.4.13 of this PEIS.

33 The changes described above would be expected to be consistent with BLM VRM
34 objectives for VRM Class IV (as seen from nearby KOPs), the current VRM class designated for
35 the SEZ. More information about impact determination using the BLM VRM program is
36 presented in Section 5.12 and in *Visual Resource Contrast Rating*, BLM Manual
37 Handbook 8431-1 (BLM 1986b).

39 Implementation of the programmatic design features intended to reduce visual impacts
40 (described in Appendix A, Section A.2.2) would be expected to reduce visual impacts associated
41 with utility-scale solar energy development within the SEZ; however, the degree of effectiveness
42 of these design features could be assessed only at the site- and project-specific level. Given the
43 large scale, reflective surfaces, and strong regular geometry of utility-scale solar energy facilities
44 and the lack of screening vegetation and landforms within the SEZ viewshed, siting the facilities
45 away from sensitive visual resource areas and other sensitive viewing areas would be the primary
46 means of mitigating visual impacts. The effectiveness of other visual impact mitigation measures

1 would generally be limited, but would be important to reduce visual contrasts to the greatest
2 extent possible.

3 4 5 **11.7.14.2.2 Impacts on Lands Surrounding the Proposed Millers SEZ** 6

7 Because of the large size of utility-scale solar energy facilities and the generally flat,
8 open nature of the proposed SEZ, lands outside the SEZ would be subjected to visual impacts
9 related to construction, operation, and decommissioning of utility-scale solar energy facilities.
10 The affected areas and extent of impacts would depend on a number of visibility factors and
11 viewer distance. (For a detailed discussion of visibility and related factors, see Section 5.12).
12 The intervisibility between the project and potentially affected lands is a key component in
13 determining impact levels; if topography, vegetation, or structures screen the project from
14 viewer locations, there is no impact.

15
16 Preliminary viewshed analyses were conducted to identify which lands surrounding the
17 proposed SEZ are visible from the SEZ (see Appendix M for information on assumptions and
18 limitations of the methods used). Four viewshed analyses were conducted, assuming four
19 different equipment heights representative of project elements associated with potential solar
20 energy technologies: PV and parabolic trough arrays (24.6 ft [7.5 m]), solar dishes and power
21 blocks for CSP technologies (38 ft [11.6 m]), transmission towers and short solar power towers
22 (150 ft [45.7 m]), and tall solar power towers (650 ft [198.1 m]). Viewshed maps for the SEZ for
23 all four solar technology heights are presented in Appendix N.

24
25 Figure 11.7.14.2-1 shows the combined results of the viewshed analyses for all four solar
26 technologies. The colored segments indicate areas with clear lines of sight to one or more areas
27 within the SEZ and from which solar facilities within these areas of the SEZ would be expected
28 to be visible, assuming the absence of screening vegetation or structures and adequate lighting
29 and other atmospheric conditions. The light brown areas are locations from which PV and
30 parabolic trough arrays located in the SEZ could be visible. Solar dishes and power blocks for
31 CSP technologies would be visible from the areas shaded in light brown and the additional areas
32 shaded in light purple. Transmission towers and short solar power towers would be visible from
33 the areas shaded light brown, light purple, and the additional areas shaded in dark purple. Power
34 tower facilities located in the SEZ could be visible from areas shaded light brown, light purple,
35 and dark purple, and at least the upper portions of power tower receivers could be visible from
36 the additional areas shaded in medium brown.

37
38 For the following visual impact discussion, the tall solar power tower (650 ft [198.1 m])
39 and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds are shown in figures and
40 discussed in the text. These heights represent the maximum and minimum landscape visibility
41 for solar energy technologies analyzed in the PEIS. Viewsheds for solar dish and CSP
42 technology power blocks (38 ft [11.6 m]), and transmission towers and short solar power towers
43 (150 ft [45.7 m]) are presented in Appendix N. The visibility of these facilities would fall
44 between that for tall power towers and PV and parabolic trough arrays.
45

FIGURE 11.7.14.2-1 Viewshed Analyses for the Proposed Millers SEZ and Surrounding Lands, Assuming Solar Technology Heights of 24.6 ft (7.5 m), 38 ft (11.6 m), 150 ft (45.7 m), and 650 ft (198.1 m) (shaded areas indicate lands from which solar development within the SEZ could be visible)

Impacts on Selected Federal-, State-, and BLM-Designated Sensitive Visual Resource Areas

A GIS analysis was conducted that overlaid selected federal, state, and BLM-designated sensitive visual resource areas onto the combined tall solar power tower (650 ft [198.1 m]) and PV and parabolic trough array (24.6 ft [7.5 m]) viewsheds. This was done in order to identify which of these sensitive visual resource areas would have views of solar facilities within the SEZ and, therefore, would potentially be subject to visual impacts from those facilities.

The scenic resources included in the analysis were as follows:

- National Parks, National Monuments, National Recreation Areas, National Preserves, National Wildlife Refuges, National Reserves, National Conservation Areas, National Historic Sites;
- Congressionally authorized Wilderness Areas;
- Wilderness Study Areas;
- National Wild and Scenic Rivers;
- Congressionally authorized Wild and Scenic Study Rivers;
- National Scenic Trails and National Historic Trails;
- National Historic Landmarks and National Natural Landmarks;
- All-American Roads, National Scenic Byways, State Scenic Highways; and BLM- and USFS-designated scenic highways/byways;
- BLM-designated Special Recreation Management Areas; and
- ACECs designated because of outstanding scenic qualities.

The results of the GIS analysis demonstrate that none of these types of scenic resources are located within the 25-mi (40-km) viewshed of the Millers SEZ.

Additional scenic resources exist at the national, state, and local levels, and impacts may occur on both federal and nonfederal lands, including sensitive traditional cultural properties important to Tribes. In addition to the resource types and specific resources analyzed in this PEIS, future site-specific NEPA analyses would include state and local parks, recreation areas, other sensitive visual resources, and communities close enough to the proposed project to be affected by visual impacts. Selected other lands and resources are included in the discussion below. Further discussion of impacts on these areas is presented in Sections 11.7.3 (Specially Designated Areas and Lands with Wilderness Characteristics) and Section 11.7.17 (Cultural Resources) of this PEIS.

1 In addition to impacts associated with the solar energy facilities themselves, sensitive
2 visual resources could be affected by facilities that would be built and operated in conjunction
3 with the solar facilities. With respect to visual impacts, the most important associated facilities
4 would be access roads and transmission lines, the precise location of which cannot be determined
5 until a specific solar energy project is proposed. There is currently a 120-kV transmission line
6 within the proposed SEZ, so construction and operation of a transmission line outside the
7 proposed SEZ would not be required; however, transmission lines to connect facilities to the
8 existing line would be required. For this analysis, the impacts of construction and operation of
9 transmission lines outside of the SEZ were not assessed, assuming that the existing 120-kV
10 transmission line might be used to connect some new solar facilities to load centers, and that
11 additional project-specific analysis would be done for new transmission construction or line
12 upgrades. Depending on project- and site-specific conditions, visual impacts associated with
13 access roads, and particularly transmission lines, could be large. Detailed information about
14 visual impacts associated with transmission lines is presented in Section 5.12.1. A detailed site-
15 specific NEPA analysis would be required to determine visibility and associated impacts
16 precisely for any future solar projects, based on more precise knowledge of facility location and
17 characteristics.

18
19 The following visual impact analysis describes *visual contrast levels* rather than *visual*
20 *impact levels*. *Visual contrasts* are changes in the landscape seen by the viewer, including
21 changes in the forms, lines, colors, and textures of objects. A measure of *visual impact* includes
22 potential human reactions to the visual contrasts arising from a development activity, based on
23 viewer characteristics, including attitudes and values, expectations, and other characteristics that
24 that are viewer- and situation-specific. Accurate assessment of visual impacts requires
25 knowledge of the potential types and numbers of viewers for a given development and their
26 characteristics and expectations; specific locations where the project might be viewed from; and
27 other variables that were not available or not feasible to incorporate in the PEIS analysis. These
28 variables would be incorporated into a future site-and project-specific assessment that would be
29 conducted for specific proposed utility-scale solar energy projects. For more discussion of visual
30 contrasts and impacts, see Section 5.12 of the PEIS.

31 32 33 **Impacts on Selected Other Lands and Resources** 34 35

36 **U.S. 6.** About 31 mi (50 km) of U.S. 6 is within the SEZ 25 mi (40 km) viewshed. As
37 shown in Figure 11.7.14.2-1, at the point of closest approach, U.S. 6 passes within 0.2 mi
38 (0.3 km) of the southern boundary of the Millers SEZ and approaches the SEZ from the direction
39 of Tonopah (southeast) and Coaldale (southwest). The AADT value for U.S. 6 just west of
40 Tonopah was 3,900 vehicles in 2009 (NV DOT 2010), although traffic would increase slightly as
41 a result of solar energy development within the SEZ.

42
43 For westbound travelers on U.S. 6, solar facilities within the SEZ would come into view
44 just west of Tonopah and would be in full view as vehicles descended the approximately 14-mi
45 (23-km) slope from Tonopah. Near Tonopah, U.S. 6 is elevated nearly 1,000 ft [300 m] above
46 the SEZ elevation, but because of the long distance to the SEZ, the vertical angle of view is low.

GOOGLE EARTH™ VISUALIZATIONS

The visual impact analysis discussion in this section utilizes three-dimensional Google Earth™ perspective visualizations of hypothetical solar facilities placed within the SEZ. The visualizations include simplified wireframe models of a hypothetical solar power tower facility. The models were placed at various locations within the SEZ as visual aids for assessing the approximate size and viewing angle of utility-scale solar facilities. The visualizations are intended to show the apparent size, distance, and configuration of the SEZ, as well as the apparent size of a typical utility-scale solar power tower project and its relationship to the surrounding landscape, as viewed from potentially sensitive visual resource areas within the viewshed of the SEZ.

The visualizations are not intended to be realistic simulations of the actual appearance of the landscape or of proposed utility-scale solar energy projects. The placement of models within the SEZ did not reflect any actual planned or proposed projects within the SEZ, and did not take into account engineering or other constraints that would affect the siting or choice of facilities for this particular SEZ. The number of facility models placed in the SEZ does not reflect the 80% development scenario analyzed in the PEIS, but it should be noted that the discussion of expected visual contrast levels does account for the 80% development scenario. A solar power tower was chosen for the models because the unique height characteristics of power tower facilities make their visual impact potential extend beyond other solar technology types.

The angle of view would decrease as travelers approached the SEZ, but the facilities within the SEZ would increase in apparent size. The SEZ would be visible directly in front of vehicles on the upper portions of the slope, but would gradually appear to shift to the right as westbound travelers approached the SEZ to pass it on its southern side. At highway speeds, the SEZ would be in view for about 15 minutes for westbound travelers as they approached and passed it.

Figure 11.7.14.2-2 is a Google Earth visualization of the SEZ (highlighted in orange) as seen from U.S. 6, on the western outskirts of Tonopah about 12.4 mi (20.0 km) from the southeast corner of the SEZ. The visualization includes simplified wireframe models of a hypothetical solar power tower facility. The models were placed within the SEZ as a visual aid for assessing the approximate size and viewing angle of utility-scale solar facilities. The receiver towers depicted in the visualization are properly scaled models of a 459-ft (139.9-m) tall power tower with an 867-acre (3.5-km²) field of 12-ft (3.7-m) tall heliostats, each representing about 100 MW of electric generating capacity. Four models were placed in the SEZ for this and other visualizations shown in this section of the PEIS. In the visualization, the SEZ area is depicted in orange, the heliostat fields in blue.

The visualization suggests that from this distance and viewing angle, irregularities in the gentle downward sloping terrain toward the SEZ would screen parts of the SEZ from view, although most of it would be visible. The SEZ would occupy a substantial portion of the horizontal field of view, but solar facilities within the SEZ would be seen nearly edge on, so that the collector/reflector arrays would appear as thin lines at the base of the Monte Cristo Range. The edge-on view of the facilities would reduce the visible surface area, conceal the strong regular geometry of the collector arrays, and repeat the strong horizon line, all of which would tend to reduce associated visual contrasts, although there could be glinting or glare from the collectors or ancillary facilities that might attract visual attention. The receivers of operating power towers within the SEZ would likely be visible as bright point light sources against the

FIGURE 11.7.14.2-2 Google Earth Visualization of the Proposed Millers SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Models as Seen from U.S. 6, just West of Tonopah, Nevada

backdrop of the valley floor or the bajadas of the Monte Cristo Range. The tower structures would likely be visible underneath the receiver “glow.” Under the 80% development scenario analyzed in the PEIS and depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, weak to moderate visual contrasts from solar energy development within the SEZ could be expected at this location.

Figure 11.7.14.2-3 is a Google Earth visualization of the SEZ as seen from U.S. 6 about 5 mi (8 km) from the southeast corner of the SEZ, the outer limit of the BLM VRM Program’s foreground-middleground distance. From this viewpoint, the SEZ would occupy most of the horizontal field of view. Solar facilities within the SEZ would be seen edge on, but any ancillary facilities, such as STGs, cooling towers, substations, etc. would likely be visible projecting above the collector arrays, and adding contrasts in form, line, texture, and color, with the possibility and glinting and glare from any reflective surfaces associated with those project components. The light from operating power tower receivers in the SEZ could appear as very bright non-point light sources as viewed from the road and would be expected to strongly attract visual attention. Under the 80% development scenario analyzed in the PEIS, solar facilities within the SEZ would likely command visual attention and could potentially dominate views from U.S. 6. Depending on project location within the SEZ, the types of solar facilities and their designs, and other visibility factors, strong visual contrasts from solar energy development within the SEZ could be expected at this location.

Figure 11.7.14.2-4 is a Google Earth visualization of the SEZ as seen from U.S. 6 about 0.4 mi (0.7 km) from the southern boundary of the SEZ. From this viewpoint, the SEZ could not be encompassed in a single view; viewers would have to turn their heads to see the entire SEZ. Solar facilities within the SEZ would be seen edge on, but if they were located in closer parts of the SEZ, they could be too large to appear as lines. Depending on the technology, project layout, and location, facilities could block views of the surrounding mountains and dominate views from the roadway.

Taller ancillary facilities, such as buildings, transmission structures, and cooling towers, and plumes (if present) would likely be visible projecting above the collector/reflector arrays, and their structural details could be evident, at least for nearby facilities. The ancillary facilities could create form and line contrasts with the strongly horizontal, regular, and repeating forms and lines of the collector/reflector arrays. Color and texture contrasts would also be likely, but their extent would depend on the materials and surface treatments utilized in the facilities.

If power tower facilities were located in the SEZ in close proximity to the highway, when operating, the receivers could appear as brilliant white no-point (i.e. having visible cylindrical or rectangular surfaces) light sources as viewed from the highway, and if sufficiently close to the road, would likely strongly attract visual attention. Also, under certain viewing conditions, sunlight on dust particles in the air might result in the appearance of light streaming down from the tower. At night, if more than 200 ft (61 m) tall, power towers would have hazard navigation lights that could potentially be visible from this location. The lights could be red flashing lights or red or white strobe lights, and the light could be visible from U.S. 6. Other lighting associated with solar facilities could be visible as well.

FIGURE 11.7.14.2-3 Google Earth Visualization of the Proposed Millers SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Models as Seen from U.S. 6 approximately 5 mi (8 km) Southeast of the SEZ

FIGURE 11.7.14.2-4 Google Earth Visualization of the Proposed Millers SEZ (shown in orange tint) and Surrounding Lands, with Power Tower Wireframe Models as Seen from U.S. 6, 0.4 mi (0.7 km) from the SEZ

1 As travelers approached and passed by the SEZ, depending on lighting conditions, the
2 solar technologies present, facility layout, and mitigation measures employed, there would be the
3 potential for reflections from facility components. These effects could potentially distract drivers
4 and/or impair views toward the facilities. These potential impacts could be reduced by siting
5 reflective components away from the roadways, employing various screening mechanisms,
6 and/or adjusting the mirror operations to reduce potential impacts; however, it could be difficult
7 to screen power towers from view, because of their height. Under the 80% development scenario
8 analyzed in the PEIS, the various solar facilities within the SEZ would likely dominate views
9 from the roadway and would be expected to create strong visual contrasts as seen from this
10 viewpoint on U.S. 6.

11
12 Eastbound travelers on U.S. 6 would have roughly similar visual experiences to
13 westbound travelers in terms of impact magnitude; however, because U.S. 6 essentially does
14 not slope downward toward the SEZ as it approaches the SEZ from the east, there are no
15 elevated views of the SEZ, so the general level of visual contrasts created would likely be
16 somewhat less than for westbound travelers. The SEZ would first come into view about 11 mi
17 (18 km) west of the SEZ. At highway speeds, the SEZ would be in view for about 15 minutes
18 for eastbound travelers as they approached and passed it.

19
20 In summary, under the 80% development scenario analyzed in the PEIS and depending
21 on project location within the SEZ, the types of solar facilities and their designs, and other
22 visibility factors, weak to strong visual contrasts from solar energy development within the SEZ
23 would be expected for travelers on U.S. 6.

24
25
26 **Town of Tonopah.** The viewshed analyses indicate visibility of the SEZ from the town of
27 Tonopah (approximately 13 mi [20.9 km] southeast of the SEZ). Tonopah is more than 1,000 ft
28 (305 m) higher in elevation than the SEZ, so portions of the SEZ would be visible. A detailed
29 future site-specific NEPA analysis is required to determine visibility precisely, but a site visit in
30 2009 determined that views of the SEZ are screened in most of Tonopah by trees, structures, and
31 small variations in local topography. Visibility of the SEZ is more likely in the far western
32 portions of Tonopah, where the density of structures and planted vegetation diminishes.
33 Figure 11.7.14.2-2 (see above) is a Google Earth visualization of the SEZ with hypothetical solar
34 power tower facilities as seen from the far western outskirts of Tonopah. As noted above, the
35 visualization suggests that from this distance and viewing angle, under the 80% development
36 scenario analyzed in the PEIS, weak levels of visual contrasts would be expected to arise from
37 solar facilities located within the Millers SEZ.

38
39
40 **Other Impacts.** In addition to the impacts described for the resource areas above, nearby
41 residents and visitors to the area may experience visual impacts from solar energy facilities
42 located within the SEZ (as well as any associated access roads and transmission lines) from their
43 residences, or as they travel area roads. The range of impacts experienced would be highly
44 dependent on viewer location, project types, locations, sizes, and layouts, as well as the presence
45 of screening, but under the 80% development scenario analyzed in the PEIS, from some

1 locations, strong visual contrasts from solar development within the SEZ could potentially be
2 observed.

3 4 5 **11.7.14.2.3 Summary of Visual Resource Impacts for the Proposed Millers SEZ** 6

7 Under the 80% development scenario analyzed in the PEIS, the SEZ could contain
8 multiple solar facilities utilizing differing solar technologies, as well as a variety of roads and
9 ancillary facilities. The array of facilities could create a visually complex landscape that would
10 contrast strongly with the strongly horizontal landscape of the flat valley in which the SEZ is
11 located. Large visual impacts on the SEZ and surrounding lands within the SEZ viewshed would
12 be associated with solar energy development due to major modification of the character of the
13 existing landscape. The potential exists for additional impacts from construction and operation of
14 transmission lines and access roads within the SEZ.

15
16 The SEZ is in an area of low scenic quality. Residents of Tonopah and nearby areas,
17 workers, and visitors to the area may experience visual impacts from solar energy facilities
18 located within the SEZ (as well as any associated access roads and transmission lines) as they
19 travel area roads. The residents nearest to the SEZ could be subjected to large visual impacts
20 from solar energy development within the SEZ. U.S. 6 passes very close to the SEZ, and
21 travelers on that road could be subjected to strong visual contrasts from solar development within
22 the SEZ, but typically their exposure would be brief. Utility-scale solar energy development
23 within the proposed Millers SEZ could cause weak levels of visual contrast for some residents of
24 Tonopah, generally for persons in the westernmost parts of the community.

25 26 27 **11.7.14.3 SEZ-Specific Design Features and Design Features Effectiveness** 28

29 No SEZ-specific design features have been identified to protect visual resources for the
30 proposed Millers SEZ. As noted in Section 5.12, the presence and operation of large-scale solar
31 energy facilities and equipment would introduce major visual changes into non-industrialized
32 landscapes and could create strong visual contrasts in line, form, color, and texture that could not
33 easily be mitigated substantially. Implementation of programmatic design features intended to
34 reduce visual impacts (described in Appendix A, Section A.2.2) would be expected to reduce
35 visual impacts associated with utility-scale solar energy development within the SEZ; however,
36 the degree of effectiveness of these design features could be assessed only at the site- and
37 project-specific level. Given the large scale, reflective surfaces, strong regular geometry of
38 utility-scale solar energy facilities, and the lack of screening vegetation and landforms within the
39 SEZ viewshed, siting the facilities away from sensitive visual resource areas and other sensitive
40 viewing areas is the primary means of mitigating visual impacts. The effectiveness of other
41 visual impact mitigation measures would generally be limited.

11.7.15 Acoustic Environment

11.7.15.1 Affected Environment

The proposed Millers SEZ is located in the northern portion of Esmeralda County in southwestern Nevada. Neither the State of Nevada nor Esmeralda County has established quantitative noise-limit regulations.

The proposed Millers SEZ is in an undeveloped area, the overall character of which is rural. U.S. 6/95 extends east–west as close as 800 ft (244 m) south of the SEZ, while State Route 89 extends north–south as close as 2.5 mi (4.0 km) east of the SEZ. Numerous dirt roads cross the SEZ. The nearest railroad is in Luning in neighboring Mineral County, about 40 mi (64 km) northwest of the SEZ. Nearby airports include: Coaldale Airport, about 19 mi (30 km) west-southwest of the SEZ; Tonopah Airport in Nye County, about 20 mi (32 km) east–southeast; Goldfield Airport in Esmeralda County, about 32 mi (51 km) south–southeast; and Mina Airport in Mineral County, about 33 mi (53 km) west–northwest. Small-scale irrigated agricultural lands are situated about 10 mi (16 km) north of the SEZ. No industrial or commercial activities are located around the SEZ; grazing is about the only agricultural activity in the immediate vicinity of the SEZ. Millers, a ghost town, is about 0.8 mi (1.3 km) from the southeast corner of the SEZ. No sensitive receptors (e.g., residences, hospitals, schools, or nursing homes) exist around the proposed Millers SEZ. The closest population center with schools is Tonopah, the county seat of Nye County. It is about 11 mi (18 km) east–southeast of the SEZ.

Accordingly, noise sources around the SEZ include road traffic, aircraft flyovers, and cattle grazing. Other noise sources are associated with current land use around the SEZ include occasional OHV races, but not much other recreational use occurs in the area. To date, no environmental noise survey has been conducted around the proposed Millers SEZ. On the basis of the population density, the day-night average noise level (L_{dn} or DNL) is estimated to be 17 dBA for Esmeralda County, well below the 33 to 47 dBA L_{dn} range level typical of a rural area (Eldred 1982; Miller 2002).⁹

11.7.15.2 Impacts

Potential noise impacts associated with solar projects in the Millers SEZ would occur during all phases of the projects. During the construction phase, potential noise impacts on the nearest residences (about 11 mi [18 km] east-southeast of the SEZ boundary) from operation of heavy equipment would be expected to be minimal because of the considerable separation distance. During the operations phase, potential noise impacts on the nearest residences also would be expected to be minimal. However, if the Millers SEZ is fully developed, potential noise

⁹ Rural and undeveloped areas have sound levels in the range of 33 to 47 dBA as L_{dn} (Eldred 1982). Typically, the nighttime level is 10 dBA lower than daytime level, and it can be interpreted as 33 to 47 dBA (mean 40 dBA) during the daytime hours and 23 to 37 dBA (mean 30 dBA) during nighttime hours.

1 impacts on residences along the roads would be likely because of vehicular traffic (commuters,
2 visitors, support, and deliveries) to and from the SEZ. Noise impacts shared by all solar
3 technologies are discussed in detail in Section 5.13.1, and technology-specific impacts are
4 presented in Section 5.13.2. Impacts specific to the proposed Millers SEZ are presented in this
5 section. Any such impacts would be minimized through the implementation of required
6 programmatic design features described in Appendix A, Section A.2.2, and through the
7 application of any additional SEZ-specific design features applied (see Section 11.7.15.3 below).
8 This section primarily addresses potential noise impacts on humans, although potential impacts
9 on wildlife at nearby sensitive areas are discussed. Additional discussion on potential noise
10 impacts on wildlife is presented in Section 5.10.2.

11 12 13 **11.7.15.2.1 Construction** 14

15 The proposed Millers SEZ has a relatively flat terrain; thus, minimal site preparation
16 activities would be required, and associated noise levels would be lower than those during
17 general construction (e.g., erecting building structures and installing equipment, piping, and
18 electrical).

19
20 For the parabolic trough and power tower technologies, the highest construction noise
21 levels would occur at the power block area, where key components (e.g., steam turbine/
22 generator) needed to generate electricity would be located. A maximum of 95 dBA at a distance
23 of 50 ft (15 m) is assumed, if impact equipment such as pile drivers or rock drills is not being
24 used. Typically, the power block area is located in the center of the solar facility, at a distance
25 of more than 0.5 mi (0.8 km) from the facility boundary. Noise levels from construction of the
26 solar array would be lower than 95 dBA. When geometric spreading and ground effects are
27 considered, as explained in Section 4.13.1, noise levels would attenuate to about 40 dBA at a
28 distance of 1.2 mi (1.9 km) from the power block area. This noise level is typical of daytime
29 mean rural background level. In addition, mid- and high-frequency noise from construction
30 activities is significantly attenuated by atmospheric absorption under the low-humidity
31 conditions typical of an arid desert environment and by temperature lapse conditions typical of
32 daytime hours. Therefore, noise attenuation to a 40-dBA level would occur at distances
33 somewhat shorter than 1.2 mi (1.9 km). If a 10-hour daytime work schedule is considered, the
34 EPA guideline level of 55 dBA L_{dn} for residential areas (EPA 1974) would occur at about
35 1,200 ft (370 m) from the power block area, which would be well within the facility boundary.
36 For construction activities occurring near the southeastern SEZ boundary (the closest SEZ
37 boundary to the nearest residences), estimated noise levels at the nearest residences would be
38 about 15 dBA. This noise level is well below a typical daytime mean rural background level of
39 40 dBA. In addition, an estimated 40-dBA L_{dn} ¹⁰ at these residences (i.e., no contribution from
40 construction activities) is well below the EPA guidance of 55 dBA L_{dn} for residential areas.

41
42 It is assumed that a maximum of two projects would be developed at any one time for
43 SEZs greater than 10,000 acres (40.47 km²) but less than 30,000 acres (121.4 km²), such as the

¹⁰ For this analysis, background levels of 40 and 30 dBA for daytime and nighttime hours, respectively, are assumed, which result in day-night average noise level (L_{dn}) of 40 dBA.

1 Millers SEZ. If two projects were to be built in the southeastern portion of the SEZ near the
2 nearest residences, noise levels would be about 18 dBA, 3 dBA higher than the value for one
3 project. These levels would be still well below the typical daytime mean rural background level,
4 and thus their contribution to the existing L_{dn} would be minimal.

5
6 There are no specially designated areas within 25 mi (40 km) of the proposed Millers
7 SEZ. Thus, noise impacts for nearby specially designated areas were not modeled.

8
9 Depending on the soil conditions, pile driving might be required for installation of
10 solar dish engines. However, the pile drivers used, such as vibratory or sonic drivers, would be
11 relatively small and quiet rather than the impulsive impact pile drivers frequently seen at large-
12 scale construction sites. Potential impacts on the nearest residences would be anticipated to be
13 negligible, considering the distance to the nearest residences (about 11 mi [18 km] from the SEZ
14 boundary).

15
16 It is assumed that most construction activities would occur during the day, when noise is
17 better tolerated than at night because of the masking effects of background noise. In addition,
18 construction activities for a utility-scale facility are temporary in nature (typically a few years).
19 Construction within the proposed Millers SEZ would cause negligible unavoidable but localized
20 short-term noise impacts on neighboring communities, even when construction activities would
21 occur near the southeastern SEZ boundary, the SEZ boundary closest to the nearest residences.

22
23 Construction activities could result in various degrees of ground vibration, depending on
24 the construction equipment and methods employed. All construction equipment causes ground
25 vibration to some degree, but activities that typically generate the most severe vibrations are
26 high-explosive detonations and impact pile driving. As is the case for noise, vibration would
27 diminish in strength with distance. For example, vibration levels at receptors beyond 140 ft
28 (43 m) from a large bulldozer (87 VdB at 25 ft [7.6 m]) would diminish below the threshold of
29 perception for humans, which is about 65 VdB (Hanson et al. 2006). During the construction
30 phase, no major construction equipment that can cause ground vibration would be used, and no
31 residences or sensitive structures are located in close proximity. Therefore, no adverse vibration
32 impacts are anticipated from construction activities, including pile driving for dish engines.

33
34 For this analysis, the impacts of construction and operation of transmission lines outside
35 of the SEZ were not assessed, assuming that the existing regional 120-kV transmission line
36 might be used to connect some new solar facilities to load centers, and that additional project-
37 specific analysis would be done for new transmission construction or line upgrades. However,
38 some construction of transmission lines could occur within the SEZ. Potential noise impacts on
39 nearby residences would be a negligible component of construction impacts and would be
40 temporary in nature.

41 42 43 **11.7.15.2.2 Operations**

44
45 Noise sources common to all or most types of solar technologies include equipment
46 motion from solar tracking, maintenance and repair activities (e.g., washing mirrors or replacing

1 broken mirrors) at the solar array area, commuter/visitor/support/delivery traffic within and
2 around the solar facility, and control/administrative buildings, warehouses, and other auxiliary
3 buildings/structures. Diesel-fired emergency power generators and firewater pump engines
4 would be additional sources of noise, but their operations would be limited to several hours per
5 month (for preventive maintenance testing).
6

7 With respect to the main solar energy technologies, noise-generating activities in the
8 PV solar array area would be minimal, related mainly to solar tracking, if used. On the other
9 hand, dish engine technology, which employs collector and converter devices in a single unit,
10 generally has the strongest noise sources.
11

12 For the parabolic trough and power tower technologies, most noise sources during
13 operations would be in the power block area, including the turbine generator (typically in an
14 enclosure), pumps, boilers, and dry- or wet-cooling systems. The power block is typically
15 located in the center of the facility. On the basis of a 250-MW parabolic trough facility with a
16 cooling tower (Beacon Solar, LLC 2008), simple noise modeling indicates that noise levels
17 around the power block would be more than 85 dBA, but about 51 dBA at the facility boundary,
18 about 0.5 mi (0.8 km) from the power block area. For a facility located near the southeastern
19 SEZ boundary, the predicted noise level would be about 21 dBA at the nearest residences,
20 located about 11 mi (18 km) from the SEZ boundary. This noise level is much lower than typical
21 daytime mean rural background level of 40 dBA. If TES was not used (i.e., if the operation was
22 limited to daytime, 12 hours only¹¹), the EPA guideline level of 55 dBA (as L_{dn} for residential
23 areas) would occur at about 1,370 ft (420 m) from the power block area and thus would not be
24 exceeded outside of the proposed SEZ boundary. At the nearest residences, about 40 dBA L_{dn}
25 (i.e., no contribution from facility operation) would be estimated, which is well below the EPA
26 guideline of 55 dBA L_{dn} for residential areas. As for construction, if two parabolic trough and/or
27 power tower facilities were operating at the same time, combined noise levels at the nearest
28 residences would be about 24 dBA, 3 dBA higher than the value for a single facility. These
29 levels are still well below the typical daytime mean rural background level of 40 dBA, and their
30 contribution to existing L_{dn} level would be minimal. However, day-night average noise levels
31 higher than those estimated above by using the simple noise modeling would be anticipated if
32 TES was used during nighttime hours, as explained below and in Section 4.13.1.
33

34 On a calm, clear night typical of the proposed Millers SEZ setting, the air temperature
35 would likely increase with height (temperature inversion) because of strong radiative cooling.
36 Such a temperature profile tends to focus noise down toward the ground. There would be little, if
37 any, shadow zone¹² within 1 or 2 mi (1.6 or 3 km) of the noise source in the presence of a strong
38 temperature inversion (Beranek 1988). In particular, such conditions add to the effect of noise
39 being more discernable during nighttime hours, when the background noise levels are lowest. To
40 estimate the day-night average noise level (L_{dn}), 6-hour nighttime generation with TES is
41 assumed after 12-hour daytime generation. For nighttime hours under temperature inversion,
42 10 dB is added to noise levels estimated from the uniform atmosphere (see Section 4.13.1). On

11 Maximum possible operating hours at the summer solstice, but limited to 7 to 8 hours at the winter solstice.

12 A shadow zone is defined as the region in which direct sound does not penetrate because of upward diffraction.

1 the basis of these assumptions, the estimated nighttime noise level at the nearest residences
2 (about 11 mi [18 km] from the SEZ boundary) would be 31 dBA, which is comparable to the
3 typical nighttime mean rural background level of 30 dBA. However, the noise level would be
4 much lower than this value if considering air absorption among other attenuation mechanisms.
5 The day-night average noise level is estimated to be about 41 dBA L_{dn} , which is well below the
6 EPA guideline of 55 dBA L_{dn} for residential areas. The assumptions are conservative in terms of
7 operating hours, and no credit was given to other attenuation mechanisms, so it is likely that
8 noise levels would be lower than 41 dBA L_{dn} at the nearest residences, even if TES was used at a
9 solar facility. In consequence, operating parabolic trough or power tower facilities using TES
10 and located near the SEZ boundary could result in minimal adverse noise impacts on the nearest
11 residences, depending on background noise levels and meteorological conditions..
12

13 The solar dish engine is unique among CSP technologies because it generates electricity
14 directly and does not require a power block. A single, large solar dish engine has relatively low
15 noise levels, but a solar facility might use tens of thousands of dish engines, which would cause
16 high noise levels around such a facility. For example, the proposed 750-MW SES Solar Two
17 dish engine facility in California would employ as many as 30,000 dish engines (SES Solar Two,
18 LLC 2008). At the proposed Millers SEZ, on the basis of the assumption of dish engine facilities
19 of up to 1,492 MW total capacity (covering 80% of the total area, or 13,430 acres [54.4 km²]),
20 up to 59,690 25-kW dish engines could be employed. For a large dish engine facility, about a
21 thousand step-up transformers would be embedded in the dish engine solar field, along with a
22 substation; however, the noise from these sources would be masked by dish engine noise.
23

24 The composite noise level of a single dish engine would be about 88 dBA at a distance of
25 3 ft (0.9 m) (SES Solar Two, LLC 2008). This noise level would be attenuated to about 40 dBA
26 (typical of the mean rural daytime environment) within 330 ft (100 m). However, the combined
27 noise level from tens of thousands of dish engines operating simultaneously would be high in the
28 immediate vicinity of the facility, for example, about 50 dBA at 1.0 mi (1.6 km) and 47 dBA at
29 2 mi (3 km) from the boundary of the square-shaped dish engine solar field. Both of these
30 values are higher than the typical daytime mean rural background level of 40 dBA. However,
31 because of noise attenuation by atmospheric absorption and temperature lapse during daytime
32 hours, these levels would actually occur at somewhat shorter distance than cited above.
33

34 To estimate noise levels at the nearest residences, it was assumed that dish engines were
35 placed all over the Millers SEZ at intervals of 98 ft (30 m). Under these assumptions, the
36 estimated noise level at the nearest residences, about 11 mi (18 km) from the SEZ boundary,
37 would be about 33 dBA, which is below the typical daytime mean rural background level of
38 40 dBA. Assuming 12-hour daytime operation only, the estimated 40 dBA L_{dn} at these
39 residences is well below the EPA guideline of 55 dBA L_{dn} for residential areas. Considering
40 other noise attenuation mechanisms, noise levels at the nearest residences would be lower than
41 values estimated above, and thus potential impacts on nearby residences would be expected to be
42 minimal.
43

44 During operations, no major ground-vibrating equipment would be used. In addition, no
45 sensitive structures are located close enough to the proposed Millers SEZ to experience physical

1 damage. Therefore, during operation of any solar facility, potential vibration impacts on
2 surrounding communities and vibration-sensitive structures would be negligible.

3
4 Transformer-generated humming noise and switchyard impulsive noises would be
5 generated during the operation of solar facilities. These noise sources would be located near the
6 power block area, typically near the center of a solar facility. Noise from these sources would
7 generally be limited to within the facility boundary and not be heard at the nearest residence,
8 assuming a 11.5-mi (18.5-km) distance (at least 0.5 mi [0.8 km] to the facility boundary and
9 11 mi [18 km] to the nearest residences). Accordingly, potential impacts of these noise sources
10 on the nearest residences would be negligible.

11
12 For impacts from transmission line corona discharge noise during rainfall events
13 (discussed in Section 5.13.1.5), the noise level at 50 ft (15 m) and 300 ft (91 m) from the center
14 of 230-kV transmission line towers would be about 39 and 31 dBA (Lee et al. 1996),
15 respectively, typical of daytime and nighttime mean background noise levels in rural
16 environments. Corona noise includes high-frequency components, considered to be more
17 annoying than low-frequency environmental noise. However, corona noise would not likely
18 cause impacts unless a residence was located close by (e.g., within 500 ft [152 m] of a 230-kV
19 transmission line). The proposed Millers SEZ is located in an arid desert environment, and
20 incidents of corona discharge are infrequent. Therefore, potential impacts on nearby residences
21 from corona noise along transmission lines within the SEZ would be negligible.

22 23 24 **11.7.15.2.3 Decommissioning/Reclamation**

25
26 Decommissioning/reclamation requires many of the same procedures and items of
27 equipment used in traditional construction. Decommissioning/reclamation would include
28 dismantling of solar facilities and support facilities, such as buildings/structures and
29 mechanical/electrical installations; disposal of debris; grading; and revegetation as needed.
30 Activities for decommissioning would be similar to those for construction but more limited.
31 Potential noise impacts on surrounding communities would be correspondingly lower than those
32 for construction activities. Decommissioning activities would be of short duration, and their
33 potential impacts would be minimal and temporary in nature. The same mitigation measures
34 adopted during the construction phase could also be implemented during the decommissioning
35 phase.

36
37 Similarly, potential vibration impacts on surrounding communities and vibration-
38 sensitive structures during decommissioning of any solar facility would be lower than those
39 during construction and thus negligible.

40 41 42 **11.7.15.3 SEZ-Specific Design Features and Design Feature Effectiveness**

43
44 The implementation of required programmatic design features described in Appendix A,
45 Section A.2.2, would greatly reduce or eliminate the potential for noise impacts from
46 development and operation of solar energy facilities. Because of the considerable separation

1 distances, activities within the proposed Millers SEZ during construction and operation would be
2 anticipated to cause only minimal increases in noise levels at the nearest residences and no
3 increases in noise levels at the specially designated areas. Accordingly, SEZ-specific design
4 features are not required.

11.7.16 Paleontological Resources

11.7.16.1 Affected Environment

The surface geology of the proposed Millers SEZ is predominantly lacustrine sediments (less than 100 ft [30 m] thick) and thick alluvial deposits (more than 100 ft [30 m] thick), ranging in age from the Pliocene to Holocene, with minimal playa deposits (approximately 0.1 acre [0.0004 km²]) of similar age in the southern tip of the SEZ. The total acreage of the lacustrine sediments within the SEZ is 15,819 acres (64 km²), and the alluvial deposits include 968 acres (3.9 km²), or 94% and 6% of the SEZ, respectively. In the absence of a PFYC map for Nevada, a preliminary classification of PFYC Class 3b is assumed for the lacustrine and playa deposits. Class 3b indicates that the potential for the occurrence of significant fossil materials is unknown and needs to be investigated further (see Section 4.14 for a discussion of the PFYC system). Pleistocene lake beds could have a high potential for subsurface fossil resources and could alternatively be classified as PFYC Class 4/5. A preliminary classification of PFYC Class 2 is assumed for the young Quaternary alluvial deposits, similar to that assumed for the Amargosa Valley SEZ (Section 11.1.16). Class 2 indicates a low potential for the occurrence of significant fossil material.

11.7.16.2 Impacts

The potential for impacts on significant paleontological resources in 94% of the proposed Millers SEZ is unknown but potentially high. A more detailed investigation of the lacustrine and playa deposits is needed prior to project approval. A paleontological survey will likely be needed following consultation with the BLM. The appropriate course of action would be determined as established in BLM IM2008-009 (BLM 2007) and IM2009-011 (BLM 2008a). Few, if any, impacts on significant paleontological resources are likely to occur in the remaining 6% of the proposed SEZ. However, a more detailed look at the geological deposits of the SEZ is needed to determine whether a paleontological survey is warranted. If the geological deposits are determined to be as described above and are classified as PFYC Class 2, further assessment of paleontological resources in this portion of the SEZ is not likely to be necessary. Important resources could exist; if identified, they would need to be managed on a case-by-case basis. Section 5.14 discusses the types of impacts that could occur on any significant paleontological resources found to be present within the Millers SEZ. Impacts would be minimized through the implementation of required programmatic design features described in Appendix A, Section A.2.2.

Indirect impacts on paleontological resources outside of the SEZ, such as through looting or vandalism, are unknown but unlikely, because any such resources would be below the surface and not readily accessed. Programmatic design features for controlling water runoff and sedimentation would prevent erosion-related impacts on buried deposits outside of the SEZ.

No new roads or transmission lines are currently assessed for the proposed Millers SEZ, assuming existing corridors would be used; therefore, no impacts on paleontological resources

1 are anticipated from new access pathways. Impacts on paleontological resources related to the
2 creation of new corridors not assessed in this PEIS would be evaluated at the project-specific
3 level if new road or transmission construction or line upgrades are to occur.
4

5 A programmatic design feature requiring a stop work order in the event of an inadvertent
6 discovery of paleontological resources would reduce impacts by preserving some information
7 and allowing excavation of the resource, if warranted. Depending on the significance of the find,
8 it could also result in some modification to the project footprint. Since the SEZ is predominantly
9 located in an area classified as PFYC Class 3b or greater, a stipulation would be included in
10 permitting documents to alert solar energy developers of the possibility of a delay if
11 paleontological resources were uncovered during surface-disturbing activities.
12
13

14 **11.7.16.3 SEZ-Specific Design Features and Design Feature Effectiveness**

15

16 Impacts would be minimized through the implementation of required programmatic
17 design features, including a stop-work stipulation in the event that paleontological resources are
18 encountered during construction, as described in Appendix A, Section A.2.2.
19

20 The need for and nature of SEZ-specific design features for 94% of the proposed Millers
21 SEZ would depend on the results of future paleontological investigations. If the geological
22 deposits for the remaining 6% of the SEZ are determined to be as described above and are
23 classified as PFYC Class 2, mitigation of paleontological resources in the alluvial deposits would
24 not likely be necessary.
25

11.7.17 Cultural Resources

11.7.17.1 Affected Environment

11.7.17.1.1 Prehistory

The proposed Millers SEZ is located in Big Smoky Valley in the Great Basin region of Nevada. It is situated in an area that was once a Late Pleistocene pluvial lake, Lake Tonopah. The earliest known use of the area was during the Paleoindian Period, starting sometime between 12,000 and 10,000 years before present (B.P.). Surface finds of Paleoindian projectile points, the hallmark of the Clovis culture, have been found in the Big Smoky Valley and around the former lakeshores of Pleistocene Lake Tonopah, but no sites with any stratigraphic context have been excavated. The Clovis culture is characterized by fluted projectile points and a hunting and gathering subsistence economy that followed migrating herds of Pleistocene mega fauna. Within the proposed Millers SEZ, a probable Clovis site was documented associated with Lake Tonopah. Sites established during this time period may be difficult to find if they have been buried by the ebb and flow of the pluvial lakes.

The cultural material associated with slightly later pluvial lake habitations is referred to as the Western Pluvial Lakes Tradition; at least eight sites affiliated with this cultural tradition have been well documented in the Big Smoky Valley, and in the proposed Millers SEZ. It is likely that people during this time did not rely entirely on the marshland habitats, but were nomadic hunters and gatherers who relied on both the wetland resources and those resources located away from the pluvial lakes. The archaeological assemblage associated with this cultural tradition is characterized by Lake Mohave and Silver Lake stemmed projectile points, leaf-shaped bifaces, scrapers, crescents, and in some cases ground stone tools for milling plant material. Often, projectile points and tools were made from locally procured obsidian, sources of which are not far from the proposed Millers SEZ. Exploiting these sources of obsidian and collecting raw materials for tool manufacture were a part of a larger resource exploitation system, in which groups moved in seasonal rounds to take advantage of resources in different localities (Haarklau et al. 2005; Fowler and Madsen 1986; Hockett et al. 2008; Eerkins and Glascock 2000; McGonagle and Waski 1978; NROSL 2009).

The Early Archaic Period in the region began with the recession of most of the pluvial lakes in the area, around 8,000 to 6,000 B.P., and extended until about 4,000 B.P. Archaic Period groups likely congregated around marsh areas, where they still existed, but also used the vast caves that can be found in the mountains of the Great Basin. The settlement system in some areas was most likely based around a central base camp, with temporary camps located at the margins of their territory to exploit resources that were not in the immediate vicinity of the base camp. Archaic groups would sometimes perform communal hunts, notably antelope drives, in which antelope were herded into a corral and then shot, and rabbit drives, in which large nets were used. Some of the key Archaic Period sites in the area near the proposed Millers SEZ are Gatecliff Shelter and Toquima Cave, to the northeast of the SEZ, and Lovelock Cave, Humbolt Cave, and Hidden Cave, to the north of the SEZ. Many of these sites are located near Pleistocene

1 lakes, such as Lake Lahontan to the north of the proposed Millers SEZ, Mud Lake to the east,
2 and Lake Tonopah. The archaeological assemblage from the Early Archaic Period maintains
3 some cultural continuity with the previous period, consisting of large notched Elko and Gatecliff
4 points, leaf-shaped bifaces, scrapers, drills, graters, and manos and metates (Fowler and
5 Madsen 1986; Neusius and Gross 2007; McGonagle and Waski 1978).

6
7 The Middle Archaic Period, 4,000 to 1,500 B.P., saw the climatic shift known as the
8 Little Pluvial, a wetter and cooler climate that caused some of the pluvial lakes to fill back up.
9 The cultural material of this time period is similar to the Early Archaic, with an increased
10 concentration of milling stones, mortars and pestles, and the appearance of normally perishable
11 items that become well preserved in the arid Great Basin climate, such as wicker baskets, split-
12 twig figurines, duck decoys, and woven sandals (Beck and Jones 2008).

13
14 In the vicinity of the proposed Millers SEZ, the Late Archaic Period began around
15 1,500 B.P. and extended until about 800 B.P. This period saw major technological shifts,
16 evidenced by smaller projectile points that were more useful because groups began using bow-
17 and-arrow technology instead of the atlatl and dart technology and changes in subsistence
18 techniques, particularly in the use of horticulture. Around A.D. 1000, Numic-speaking groups
19 migrated into the region; however, the exact timing of these events is unclear and is a subject
20 for further research in the region. These Numic-speaking people were the antecedents of the
21 Northern Paiute and Western Shoshone, and the archaeological assemblage associated with this
22 time period consists of Desert Series projectile points, brown-ware ceramic, unshaped manos
23 and milling stones, incised stones, mortars, pestles, and shell beads. Contemporary Native
24 Americans dispute the separation of periods between the Late Archaic and the Numic periods,
25 because they believe that they have been in the area since time immemorial, and see themselves
26 as descendants of all prehistoric people, and not just of Numic derivation. The following section
27 describes the cultural history of the time period in greater detail.

28 29 30 **11.7.17.1.2 Ethnohistory**

31
32 The proposed Millers SEZ is located in territory most often ascribed to the Western
33 Shoshone (Thomas et al. 1986). The Western Shoshone allowed their neighbors, the Northern
34 Paiute, with whom they were on good terms, access to its resources (McGonagle and Waski
35 1978), but they were far from the main centers of Northern Paiute population. Traditionally, the
36 closest Northern Paiute base camps were around Mono Lake in California; however, some
37 Northern Paiute travelled widely (Fowler and Liljeblad 1986). The Northern Paiute's southern
38 neighbors, the Owens Valley Paiute, may also have interacted with the Western Shoshone.

39 40 41 **Western Shoshone**

42
43 The Western Shoshone are a group of ethnically similar Central Numic speakers
44 who traditionally occupied a swath of the central Great Basin stretching from Death Valley
45 in California through central Nevada and northwestern Utah to southeastern Idaho
46 (Thomas et al. 1986). Their territory lies primarily within the basin and range province of the

1 Great Basin. They lived in small groups with rather fluid membership, usually identified with
2 the land on which they were centered. Their subsistence base and lifestyle varied with the
3 resources within their territory. Groups often established stable base camps near reliable water
4 sources where they could grow crops. From these base camps, they would move seasonally in a
5 flexible round to exploit resources as they became available in the surrounding mountains and
6 other areas. They gathered a wide variety of plant resources (Stoffle et al. 1990; Crum 1994;
7 Fowler 1986), which they supplemented by hunting and fishing. Pine nuts, available in the
8 mountains, were a storable staple. Pronghorn antelope, bighorn sheep, and mule deer were
9 among the large game animals they hunted, but smaller game, including rodents, birds, and,
10 where available, fish, provided more protein to their diet. Groups varied in size and composition
11 with the season. The largest groups gathered for the pine nut harvest, which could include a
12 rabbit or antelope drive as well. Winter villages were usually close to stores of pine nuts.
13 Additional information on the Western Shoshone can be found in Section 11.1.17.1.2.

14 15 16 **Northern Paiute** 17

18 At the time of Euro-American contact, the Northern Paiute consisted of a collection of
19 politically distinct, but linguistically homogenous, family-centered groups occupying much of
20 northwestern Nevada and southeastern Oregon extending into southwestern Idaho. Probably
21 arriving in the Great Basin sometime between A.D. 500 and A.D. 1000 (Quinian and
22 Woody 2003), their traditional lifeway was similar to that of other indigenous Great Basin
23 populations. Living in small, family-based groups, they pursued a hunting and gathering
24 subsistence base. They congregated in winter base camps located near relatively abundant
25 resources where many family groups could gather. From these base locations, smaller groups
26 followed a seasonal round taking advantage of plant and animal resources as they became
27 available. Although their seasonal movements were patterned, and individual hunting and
28 gathering territories were considered the property of one group or another, there was
29 considerable flexibility and sharing of resources between groups and with their Shoshone
30 neighbors, who spoke related languages (Fowler and Liljeblad 1986).

31
32 The game and plants that they exploited varied with local conditions. The more southerly
33 groups, based in the piedmont of the Sierra Nevada, relied on piñon nuts, mule deer, bighorn
34 sheep, quail, marmots, and the larvae of the Pandora moth. Large game animals were hunted
35 individually or in cooperative drives. Smaller game, including rabbits, marmots, porcupines,
36 grouse, and quail, was hunted individually or taken in traps or nets. Rabbits were also taken in
37 cooperative drives. Seeds and other plant products were gathered from over 150 plant species
38 (Fowler and Liljeblad 1986; Fowler and Leland 1967; Fowler 1986). Seeds were often gathered
39 using a variety of twined tools including beaters, trays, and gathering baskets, but some were cut
40 from the plant with knives and flash burned to harden. Seeds and nuts were ground with manos
41 and metates, or with wooden or stone mortars and pestles. Seed meal mushes were stone boiled
42 in twined cooking baskets. Winter houses were dome-shaped and mat-covered structures varying
43 in size with the size of the family, or conical semi-subterranean structures. Summer housing was
44 in open-sided ramada-like structures. Clothing was made of skins, including woven rabbit skins,
45 or plant materials, including tules and sagebrush bark. The family was the basic social and
46 political unit, but non-hereditary headmen emerged in local camp groups and chiefs emerged in

1 response to Euro-American contact. Supernatural power was believed to reside in natural objects,
2 including animals, plants, stones, water, and geographic features (Fowler and Liljeblad 1986).

3
4 As with other Great Basin groups, the Northern Paiute were affected by the introduction
5 of the horse by the Spanish, and the “opening of the west” by Euro-American trappers,
6 prospectors and miners, and eventually farmers and ranchers. Immigrant trains and settlements,
7 along with their associated livestock, consumed or destroyed many of the plant, animal, and
8 water resources upon which the Northern Paiute relied. Northern Paiute response varied. Some
9 groups retreated from major trails; others associated themselves with settlements and ranches,
10 forming colonies; and others formed mounted bands that preyed upon immigrants and their
11 settlements. The Northern Paiute were pacified by 1868. Three reservations, Pyramid Lake
12 and Walker River in Nevada, and Malheur in Oregon, were set aside in 1859 and formally
13 established in 1874. The intent was for all Northern Paiutes to subsist on these parcels of land,
14 and for the hunting and gathering Paiute to learn to farm. However, these reservations were not
15 well suited for agriculture and generally lacked sufficient water. Many Paiutes refused to leave
16 their home ranges, where they adapted to the new situation by engaging in wage labor. The
17 establishment of additional colonies and reservations continued well into the twentieth century.
18 The closest of these to the SEZ are Bridgeport Rancheria and Benton Reservation in California.
19 Most groups have organized under the Indian Reorganization Act of 1934 and reservations are
20 managed by Tribal councils. A free-ranging people, individual descendants of the Northern
21 Paiute may be found on reservations as far away as Oregon and Washington. Knowledge of their
22 former subsistence pursuits has been reduced, but has continued on a more limited scale (Fowler
23 and Liljeblad 1986).

24 25 26 **Owens Valley Paiute**

27
28 The Owens Valley Paiute inhabit the valley of the Owens River that parallels the eastern
29 slope of the Sierra Nevada. They speak Mono, a Western Numic language, and are linguistically
30 closely tied to the Northern Paiute (Liljeblad and Fowler 1986). A brief description of the Owens
31 Valley Paiute can be found in Section 11.1.17.1.2.

32 33 34 **11.7.17.1.3 History**

35
36 The Great Basin was one of the last areas of the continental United States to be fully
37 explored. The harsh and rugged landscape deterred most European and American explorers until
38 the late eighteenth century. Several early explorers made their way into the southern portion of
39 the state by the late eighteenth century, but the area around the proposed Millers SEZ was not
40 explored by Euro-Americans until about 1826. Fur trapping was a popular enterprise during this
41 time, and overzealous trappers were quickly depleting their supplies of furs as they moved west
42 in search of additional materials. Peter Ogden of the Hudson Bay Company and Jedidiah Smith
43 of the Rocky Mountain Fur Company were parts of two different expeditions that entered
44 Nevada in 1827 and 1826, respectively, seeking new beaver fields. Ogden took a more northerly
45 route through Elko, Pershing, and Humbolt Counties, and Smith entered Nevada near Mesquite
46 and traveled across the southern tip of Nevada into California. When he entered California,

1 Smith was detained by Mexican authorities, as he had entered Mexican territory, and was
2 ordered to go back the way from which he had come. However, he decided to travel farther north
3 in California; he was the first white man to cross the Sierra Nevada Mountains, and entered
4 Nevada just south of Lake Tahoe. From there he crossed the state of Nevada and passed very
5 close to (if not actually through) the proposed Millers SEZ; it is assumed that he likely followed
6 a path that would eventually be U.S. 6. Another fur-trapping party, the Walker-Bonneville party,
7 explored the region between 1833 and 1834. This group also likely explored the lands near the
8 proposed Millers SEZ on its way to exploring large portions of the Yosemite Valley in California
9 and the Great Basin. Fur trapping never became a lucrative enterprise in Nevada; however, these
10 trailblazers paved the way for later explorers and mappers, such as John C. Frémont. Frémont
11 was a member of the Topographical Engineers, and was commissioned to map and report on the
12 Great Basin area in 1843 and 1844. The results of his work gained wide circulation and were of
13 great importance in understanding the topography of the Great Basin, both for official use and
14 for those moving westward to seek new homes and fortunes. Frémont passed through the vicinity
15 of the proposed Millers SEZ, probably about 25 mi (40 km) to the north, at the northernmost
16 point of Esmeralda County, where it meets Mineral and Nye Counties (Elliott 1973).

17
18 Nevada and the Great Basin region have provided a corridor of travel for those seeking
19 to emigrate west. Several heavily traveled trails crossed the region, although other than those
20 initially traversed by Smith and the Walker-Bonneville party, none of the trails passes
21 particularly close to the proposed Millers SEZ. The Old Spanish Trail was an evolving trail
22 system generally established in the early nineteenth century that tended to follow established
23 paths used by earlier explorers and Native Americans. The 2,700-mi (4,345-km) network of trails
24 passes through six states, beginning in Santa Fe, New Mexico, and ending in Los Angeles,
25 California. The closest portion of the congressionally designated Old Spanish National Historic
26 Trail is about 200 mi (322 km) to the southeast of the proposed Millers SEZ as it passes near
27 Las Vegas, Nevada. Mormons also frequently used the Old Spanish Trail in emigrating farther
28 west to Nevada, Arizona, and California, and often the trail is referred to as the Old Spanish
29 Trail/ Mormon Road. Other notable trails that crossed Nevada included the California Trail,
30 which followed portions of the Oregon Trail farther east of Nevada, then broke off from that trail
31 and continued through the northern portion of Nevada along the Humbolt River, about 120 mi
32 (120 km) north of the proposed SEZ, until it reached California. The Pony Express Trail, a mail
33 route that connected Saint Joseph, Missouri, to Sacramento, California, entered Nevada northeast
34 of Ely and exited just south of Lake Tahoe, the closest portion being about 70 mi (113 km)
35 northwest of the proposed SEZ (von Till Warren 1980).

36
37 With the ratification of the Treaty of Guadalupe Hidalgo in 1848 closing out the
38 Mexican-American War, the area came under American control. In 1847, the first American
39 settlers arrived in the Great Basin, among them Mormon immigrants under the leadership of
40 Brigham Young, who settled in the Valley of the Great Salt Lake in Utah. They sought to bring
41 the entire Great Basin under their control, establishing an independent State of Deseret. From its
42 center in Salt Lake City, the church sent out colonizers to establish agricultural communities in
43 surrounding valleys and missions to acquire natural resources such as minerals and timber.
44 Relying on irrigation to support their farms, the Mormons often settled in the same places as
45 the Native Americans had centuries before. The result was a scattering of planned agricultural
46 communities from northern Arizona to southern Idaho and parts of Wyoming, Nevada, and

1 southern California. One of the first Mormon settlements in Nevada was a trading post, located
2 just north of Genoa, over 100 mi (160 km) northwest of the SEZ. Established in 1850, this
3 trading post provided supplies for those traversing the California Trail.
4

5 Nevada's nickname is the "Silver State;" it is so named for the Comstock Lode strike
6 in Virginia City, about 145 mi (233 km) north of the proposed Millers SEZ, in 1859. This was
7 the first major silver discovery in the United States, and with the news of the strike hopeful
8 prospectors flocked to the area in an effort to capitalize on the possible wealth under the surface
9 of the earth. The discovery of the Comstock Lode led to the creation of Virginia City and other
10 nearby towns that served the population influx. The population increase was so dramatic that in
11 1850 there were less than a dozen non-native people in the state of Nevada; by 1860, there were
12 6,857, and by 1875 an estimated 75,000 people had migrated to the state. The Comstock Lode
13 strike is important to the history of Nevada not just because of the population growth and
14 significant amount of money that was consequently brought to the area, but also because of
15 several technological innovations that were created and employed in the mines, including the
16 use of square-set timbering. This technique kept loose soil from collapsing on miners, a concept
17 that eventually was employed around the world in other mines (Paher 1970).
18

19 Mining for valuable deposits occurred in all regions of the state of Nevada, including in
20 the vicinity of the proposed Millers SEZ. Esmeralda County did not experience much of the early
21 mining boom that was associated with the Comstock Lode strike, other than a small silver strike
22 at Silverpeak, about 20 mi (32 km) south of the proposed Millers SEZ. Major mining operations
23 did not come into the area until the major silver strike at Tonopah, just 13 mi (22 km) to the
24 southeast of the proposed Millers SEZ. The strike at Tonopah was made in 1900, and miners
25 there soon began exporting large amounts of silver. Tonopah's location made it difficult to
26 obtain some of the raw materials and supplies necessary for large-scale mining operations, and
27 the Tonopah-Goldfield Railroad was constructed to alleviate some of these issues. The town of
28 Millers, just 1 mi (1.6 km) south of the proposed SEZ, was originally created as a watering and
29 resting place for stage coaches and freight wagons travelling between Silverpeak Mine and San
30 Antonio Mines to the northeast. After the Tonopah-Goldfield Railroad was constructed in 1904,
31 repair shops for the railroad were built here. In addition, a 100-stamp mill was constructed at
32 Millers in 1906 for crushing the Tonopah ore, and another 50-stamp mill was built the next year.
33 A turquoise mine at Royston, 14 mi (23 km) northeast of the proposed SEZ, was mined by
34 Native Americans in the region for several years, until Tiffany and Co. took control of the mine
35 to obtain the turquoise. Crow Spring, just 5 mi (8 km) north of the proposed Millers SEZ, was
36 an overnight stopping place for teamsters and stages between Sodaville and Tonopah, and
37 supported a short-lived turquoise mine. Goldfield, 25 mi (40 km) south of Tonopah, was initially
38 discovered in 1902 and was one of the single most prosperous gold strikes in the West. The
39 mining stampede to the area began in 1904, with the most lucrative years, 1906 and 1907,
40 producing about \$15 million in gold ore. Other mines in the vicinity of the proposed Millers
41 SEZ were mined for borax, notably at Columbus and Fish Lake, located 25 mi (40 km) and
42 30 mi (48 km) east of the proposed Millers SEZ, respectively, and minor turquoise mining
43 occurred at Gilbert, approximately 6 mi (10 km) from the proposed SEZ.
44

45 Nevada's desert-mountain landscape has made it a prime region for use by the
46 U.S. military for several decades. Beginning in October 1940, President Franklin D. Roosevelt

1 established the Las Vegas Bombing and Gunnery Range, a 3.5- million-acre (14,000-km²)
2 parcel of land northwest of Las Vegas, near Indian Springs, Nevada, 150 mi (241 km) southeast
3 of the SEZ. At the start of the Cold War in 1948, the range was renamed the Nellis Air Force
4 Base; three years later, the Nevada Test Site (NTS) was established within Nellis Air Force Base.
5 For the next 41 years, testing of nuclear weapons occurred throughout regions of the NTS, in
6 addition to regular Air Force training missions. Although the proposed Millers SEZ does not fall
7 within the specific boundaries of Nevada Test Site and Range, the closest portion of the military
8 installation is about 45 mi (72 km) to the southeast, and the Air Force Base and associated ranges
9 have impacted the overall history and context of the region.

11.7.17.1.4 *Traditional Cultural Properties—Landscape*

14 The Native Americans whose historical homelands lie within the Great Basin have
15 traditionally taken a holistic view of the world. In this view, the sacred and profane are
16 inextricably intertwined. Landscapes as a whole are often culturally important. Adverse effects
17 on one part damage the whole (Stoffle 2001). From their perspective, landscapes include places
18 of power. Among the most important such places are sources of water; peaks, mountains, and
19 elevated features; caves; distinctive rock formations; and panels of rock art. Places of power are
20 important to the religious beliefs of the Western Shoshone and Northern Paiute, and may be
21 sought out for individual vision quests or healing. The view from such a point of power or the
22 ability to see from one important place to another can be an important element of its integrity
23 (Stoffle and Zedeño 2001b). Landscapes as a whole are often tied together by a network of
24 culturally important trails (Stoffle and Zedeño 2001a).

26 The proposed Millers SEZ is located in Big Smoky Valley between the Monte Cristo
27 Range and Lone Mountain. As stated above, mountain prominences are often culturally
28 important landscape features and may be places of power. Project-specific investigations would
29 need to establish the cultural importance of these mountains through consultation with the
30 relevant Native American Tribe(s). Mt. Grant, where the Northern Paiute believe their ancestors
31 emerged (Fowler et al. 1970), is 72 mi (116 km) to the northwest and is not likely to be visible
32 from the SEZ. Known important rock art panels are located primarily well south and southwest
33 of the SEZ and should not be affected by development within the SEZ. Archaeological sites
34 within the proposed SEZ, including those associated with pluvial lakeshores, are considered by
35 the Tribes to be the work of their ancestors and form an important part of the Native American
36 cultural landscape. Native Americans commenting on a proposed site for the construction of a
37 solar energy facility directly east of the proposed Millers SEZ indicated that this part of the
38 Big Smoky Valley appeared to have been a travel corridor, not a living area (Rigby 2010).

11.7.17.1.5 *Cultural Surveys and Known Archaeological and Historical Resources*

43 In the proposed Millers SEZ, four surveys covering about 4% of the proposed SEZ have
44 been conducted within the boundaries of the SEZ; three were linear surveys and one was a block
45 survey. These surveys have documented 30 sites within the boundaries of the SEZ, all of which
46 are prehistoric in nature. An additional 49 surveys have been performed within 5 mi (8 km) of

1 the proposed SEZ, recording a total of 100 sites (86 prehistoric, 12 historic, and 2 multi-
2 component sites; de Dufour 2009).

3
4 Most of the sites that have been documented within the boundaries of the proposed
5 Millers SEZ are prehistoric lithic scatters, some of which contain diagnostic projectile points,
6 as mentioned in Section 11.5.17.1. There is one documented temporary camp site. The potential
7 eligibility of these sites for inclusion on the NRHP has not been evaluated.

8
9 The proposed SEZ has the potential to yield further significant cultural resources,
10 especially in the dune area along the edge of the former Lake Tonopah. Because of the fact that
11 the proposed Millers SEZ is located in the immediate vicinity of the Pleistocene lake, more
12 prehistoric cultural resources are likely to be encountered around the margins of this area.
13 Historic period artifacts, likely associated with the town site of Millers, as well as obsidian
14 debitage, were also noted during an initial site visit of the proposed SEZ.

15
16 The BLM has also designated several locations within 25 mi (40 km) of the proposed
17 Millers SEZ as cultural resources that should be managed for conservation (BLM 1997); these
18 areas include significant petroglyph sites.

19 20 21 ***National Register of Historic Places***

22
23 There are no historic properties listed in the NRHP in the SEZ or within 5 mi (8 km)
24 of the SEZ. However, there are 16 sites that have been documented within 5 mi (8 km) of the
25 proposed Millers SEZ that are potentially eligible for NRHP inclusion. The Millers town site has
26 been determined to be potentially eligible, and five additional sites have been documented that
27 are associated with the Millers town site. One site is the remains of three house basements,
28 associated residential trash, and a mine shaft. Residential activity has also been documented at
29 two sites. Another site is the remains of locomotive maintenance pits, a concrete foundation, and
30 associated trash. Historic corrals and feed lots that were associated with the Millers town site and
31 the Tonopah-Goldfield Railroad were also documented near the proposed Millers SEZ. The
32 Sodaville-Tonopah freight road, a 60-mi (97-km) road that connected these mining towns, has
33 been documented within 5 mi (8 km) of the SEZ. There are nine prehistoric sites within 5 mi
34 (8 km) of the proposed SEZ that are potentially eligible for NRHP inclusion. One site is an
35 Archaic campsite associated with Pleistocene Lake Tonopah. Six sites are campsites and lithic
36 scatters. Another site is a possible proto-historic site, consisting of Shoshone brown-ware pottery
37 and projectile points. A multi-component site, consisting of a prehistoric lithic scatter and an
38 historic wall/lean-to and associated trash, is also eligible for inclusion in the NRHP
39 (de Dufour 2009).

40
41 In Esmeralda County, only one property, the Goldfield Historic District, which is located
42 about 32 mi (52 km) south of the proposed Millers SEZ, is listed in the NRHP. In neighboring
43 Nye County, there are 53 properties listed in the NRHP, 48 of which are associated with the
44 Tonopah Multiple Resource Area 13 mi (21 km) southeast of the proposed Millers SEZ. The
45 other five NRHP properties in Nye County are located far enough away (Gatecliff Rockshelter
46 near Austin, 97 mi [157 km] northeast; James Wild Horse Trap near Fish Springs, 80 mi

1 [129 km] northeast; Tybo Charcoal Kilns, near Tybo, 65 mi [105 km] east; Manhattan School,
2 Manhattan, 42 mi [68 km] northeast; Sedan Crater, near Mercury, 132 mi [212 km] southeast)
3 from the SEZ not to be affected by solar development.
4
5

6 **11.7.17.2 Impacts**

7

8 Direct impacts on significant cultural resources could occur in the proposed Millers SEZ;
9 however, further investigation is needed. At least 30 sites have been recorded within the SEZ,
10 although none of them have been evaluated for inclusion in the NRHP. Consistent with findings
11 at other SEZs, dune areas continue to be areas with considerable potential for containing
12 significant sites on the valley floors suitable for solar development. The area within the proposed
13 Millers SEZ associated with Lake Tonopah also has the potential to provide significant sites
14 related to exploitation of lacustrine resources. A cultural resource survey of the entire area of
15 potential effect, including consultation with affected Native American Tribes, would first need to
16 be conducted to identify archaeological sites, historic structures and features, and traditional
17 cultural properties, and an evaluation would need to follow to determine whether any are eligible
18 for listing in the NRHP as historic properties. It is further recommended that subsurface testing
19 be conducted, because there is potential for significant buried cultural deposits associated with
20 prehistoric use of Lake Tonopah. Section 5.15 discusses the types of effects that could occur on
21 any significant cultural resources found to be present within the proposed Millers SEZ. Impacts
22 would be minimized through the implementation of required programmatic design features
23 described in Appendix A, Section A.2.2. Programmatic design features assume that the necessary
24 surveys, evaluations, and consultations will occur. No traditional cultural properties have been
25 identified to date within the vicinity of the SEZ.
26

27 Indirect impacts on cultural resources that result from erosion outside of the SEZ
28 boundary (including along ROWs) are unlikely, assuming programmatic design features to
29 reduce water runoff and sedimentation are implemented (as described in Appendix A,
30 Section A.2.2).
31

32 No needs for new transmission or access corridors have currently been identified,
33 assuming existing infrastructure would be used. Therefore, no new areas of cultural concern
34 would be made accessible as a result of development within the proposed Millers SEZ, so
35 indirect impacts resulting from vandalism or theft of cultural resources is not anticipated.
36 However, impacts on cultural resources related to the creation of new corridors not assessed in
37 this PEIS would be evaluated at the project-specific level if new road or transmission
38 construction or line upgrades were to occur.
39
40

41 **11.7.17.3 SEZ-Specific Design Features and Design Feature Effectiveness**

42

43 Programmatic design features to mitigate adverse effects on significant cultural
44 resources, such as avoidance of significant sites and features, cultural awareness training for the
45 workforce, and measures for addressing possible looting/vandalism issues through formalized
46 agreement documents, are provided in Appendix A, Section A.2.2.

1 SEZ-specific design features would be determined in consultation with the Nevada SHPO
2 and affected Tribes and would depend on the results of future investigations.
3

- 4 • Avoidance of high-potential, high-density areas is recommended. Because of
5 the high sensitivity of the area for containing prehistoric sites associated with
6 Lake Tonopah and the presence of historic period sites related to the
7 development of Millers town site, complete avoidance of NRHP-eligible sites
8 may not be possible, and it may not be possible to fully mitigate the loss of
9 such a large number of sites associated with one lake system; therefore
10 avoidance of these general areas is recommended.
11

11.7.18 Native American Concerns

Native Americans share many environmental and socioeconomic concerns with other ethnic groups. This section focuses on concerns specific to Native Americans and to which Native Americans bring a distinct perspective. For a discussion of issues of possible Native American concern shared with the population as a whole, several sections in this PEIS should be consulted. General topics of concern are addressed in Section 4.16. Specifically for the proposed Millers SEZ, Section 11.7.17 discusses archaeological sites, structures, landscapes, trails, and traditional cultural properties; Section 11.7.8 discusses mineral resources; Section 11.7.9.1.3 discusses water rights and water use; Section 11.7.10 discusses plant species; Section 11.7.11 discusses wildlife species, including wildlife migration patterns; Section 11.7.13 discusses air quality; Section 11.7.14 discusses visual resources; Sections 11.7.19 and 11.7.20 discuss socioeconomics and environmental justice, respectively; and issues of human health and safety are discussed in Section 5.21.

11.7.18.1 Affected Environment

The proposed Millers SEZ falls within the Tribal traditional use area generally attributed to the Western Shoshone (Liljeblad and Fowler 1986) and is within the area recognized as traditionally belonging to the Western Shoshone by the Indian Claims Commission (Royster 2008). Lying near the western edge of Western Shoshone territory, the SEZ was accessible by the Northern Paiutes, who were on friendly terms with the Western Shoshone (McGonagle and Waski 1978). All federally recognized Tribes with Western Shoshone, Northern Paiute, or Owens Valley Paiute roots have been contacted and provided an opportunity to comment or consult regarding this PEIS. They are listed in Table 11.7.18.1-1. Details of government-to-government consultation efforts are presented in Chapter 14; a listing of all federally recognized tribes contacted for this PEIS is given in Appendix K.

11.7.18.1.1 Territorial Boundaries

Western Shoshone

The Western Shoshone traditionally occupied a swath of the central Great Basin stretching from Death Valley in California through central Nevada and northwestern Utah to southeastern Idaho (Thomas et al. 1986). The proposed Millers SEZ lies near the northwestern periphery of their traditional range where Shoshone territory blends into Northern and Owens Valley Paiute territory.

Northern Paiutes

The traditional territory of the Northern Paiute lies mainly along the eastern front of the Sierra Nevada and the divide separating the Pit and Klamath Rivers from the Great Basin,

TABLE 11.7.18.1-1 Federally Recognized Tribes with Traditional Ties to the Proposed Millers SEZ

Tribe	Location	State
Benton Paiute-Shoshone Tribe	Benton	California
Big Pine Paiute Tribe	Big Pine	California
Bishop Paiute Tribe	Bishop	California
Bridgeport Indian Colony	Bridgeport	California
Duck Valley Shoshone-Paiute Tribes	Owyhee	Nevada
Duckwater Shoshone Tribe	Duckwater	Nevada
Ely Shoshone Tribe	Ely	Nevada
Las Vegas Paiute Tribe	Las Vegas	Nevada
Lone Pine Paiute-Shoshone Tribe	Lone Pine	California
Lovelock Paiute Tribe	Lovelock	Nevada
Reno-Sparks Indian Colony	Reno	Nevada
Summit Lake Paiute Tribe	Sparks	Nevada
Te-Moak Tribe of Western Shoshone	Elko	Nevada
Timbisha Shoshone Tribe	Death Valley	California
Washoe Tribe	Gardnerville	Nevada
Wells Indian Colony	Wells	Nevada
Yerington Paiute Tribe	Yerington	Nevada
Yomba Shoshone Tribe	Austin	Nevada

extending from Mono Lake (California) in the south as far as southeastern Oregon. They occupied a wedge-shaped territory extending as far as western Idaho in the north and as far as Nevada's Reese River in the south (Fowler and Liljeblad 1986).

Owens Valley Paiutes

The Owens Valley Paiutes occupy five relatively small reservations within Owens Valley in Inyo and Mono Counties, California, west of the SEZ. Their traditional use area ranged from the headwaters of the Owens River near Benton, California, southward to Owens Lake. They shared the shores of Owens Lake with Western Shoshone groups. The Indian Claims Commission placed Owens Valley within the traditional territory of the Northern Paiutes, with whom the Owens Valley Tribes are linked linguistically (Liljeblad and Fowler 1986; Royster 2008).

11.7.18.1.2 Plant Resources

Native Americans continue to make use of a wide range of indigenous plants for food, medicine, construction materials, and other uses. Although the proposed SEZ is sparsely vegetated, some species traditionally used by Native Americans have been observed or are possible in the SEZ. The vegetation present at the proposed Millers SEZ is described in Section 11.7.10. The cover types present at the SEZ are part of the Inter-mountain Basin series.

Mixed Salt Desert Scrub dominates, but there are substantial areas of Greasewood Flat, smaller amounts of Playa, and a sprinkling of Semi-desert Shrub Steppe (USGS 2005a). As shown in Table 11.7.18.1-2, there are some plants found in the SEZ that have been traditionally used by Native Americans for food and medicine (Stoffle and Dobyns 1983; Stoffle et al. 1999; Fowler 1986). The most common is black greasewood. Other seed-bearing plants appear to be scarce. However, project-specific analyses will be needed to determine their presence at any proposed development site. The importance of any stand to Native Americans must be determined in consultation with the affected Tribe(s).

11.7.18.1.3 Other Resources

Water is an essential prerequisite for life in the arid areas of the Great Basin. As a result, it is a keystone of desert cultures' religion. Most desert cultures consider all water sacred and a purifying agent. Water sources are often associated with rock art. Springs are often associated with powerful beings, and hot springs in particular figure prominently in Owens Valley Paiute creation stories. Water sources are seen as connected—damage to one source damages all (Stoffle and Zedeño 2001a). Tribes are also sensitive about the use of scarce local water supplies for the benefit of distant communities and recommend that determination of adequate water supplies be a primary consideration for whether a site is suitable for the development of a utility-scale solar energy facility (Moose 2009).

Wildlife likely to be found in the proposed Millers Valley SEZ is described in Section 11.7.11. Native American game species whose range includes the SEZ are listed in Table 11.7.18.1-3. Most of these are small animals and birds common throughout much of the

Great Basin. Traditionally, the most important was the black-tailed jackrabbit (*Lepus californicus*), which provided both meat and pelts. Rabbit skin blankets and clothing were common throughout the Great Basin. Important large game animals, mule deer (*Odocoileus hemionus*) and bighorn sheep (*Ovis canadensis*), occur in the nearby Monte Cristo Range and on Lone Mountain (BLM 1994), and occasionally cross through the SEZ when passing between mountain habitats. Bighorn sheep have been observed near the SEZ. The golden eagle (*Aquila chrysaetos*), which is important culturally, has also been observed at the SEZ.

Other natural resources traditionally important to Native Americans include clay for pottery, salt, and naturally occurring mineral pigments for the decoration and protection of the skin (Stoffle and Dobyns 1983). None of these has been reported in the SEZ (see Section 11.7.7).

11.7.18.2 Impacts

In the past, the Western Shoshone and Owens Valley Paiutes have expressed concern over project impacts on a variety of resources. They tend to take a holistic view of their traditional homelands. Effects on one part have ripple effects on the whole. For them, cultural and natural features are inextricably bound together. Western distinctions between the sacred and the secular have no meaning in their traditional worldview (Stoffle and Dobyns 1983). While no comments specific to the proposed Millers SEZ have been received from Native American Tribes to date, the Big Pine Paiute Tribe of the Owens Valley has commented on the scope of this PEIS. The Tribe recommends that the BLM preserve undisturbed lands intact and that recently disturbed lands, such as abandoned farm fields, rail yards, mines, and airfields, be given primary consideration for solar energy development. Potential impacts on existing water supplies are also a primary concern (Moose 2009). During energy development projects in adjacent areas, other Great Basin Tribes have expressed concern over adverse effects on a wide range of resources. Among these are geophysical features and physical cultural remains. Known resources of this type in the Millers area are discussed in Section 11.7.17.1.4. Such places are often seen as important because they are thought to be places of power. They are often the location of or have ready access to a variety of plant, animal, and mineral resources (Stoffle et al. 1997). Resources that Native Americans have identified as important include food plants, medicinal plants, plants used in basketry, and plants used in construction; game animals and birds; and sources of clay, salt, and pigments (Stoffle and Dobyns 1983). Those likely to be found within the proposed Millers SEZ are discussed in Section 11.7.18.1.

The construction of utility-scale solar energy facilities within the proposed SEZ would almost certainly result in the destruction of some plants important to Native Americans and the habitat of some traditionally important animals. The Big Smoky Valley is reported to have been a joint use area shared by the surrounding Native American groups (McGonagle and Waski 1978), and to have been a travel corridor, not a habitation area (Rigby 2010). Although it includes some plant species traditionally important to Native Americans, they appear to be relatively scant. While it is within the range of a number of traditional Native American game species, these species for the most part are common throughout the valleys in the area, and may be more abundant elsewhere (See Sections 11.7.10 and 11.7.11). The most important traditional resource likely to be present in the valley is the black-tailed jackrabbit (*Lepus californicus*). Project-specific consultation with Western Shoshone and Northern Paiute Tribes will be required to determine whether the resources present at the SEZ are significant.

As consultation with the Tribes continues and project-specific analyses are undertaken, it is possible that Native Americans will express concern over potential visual, acoustic and other effects of solar energy development within the SEZ on specific resources including culturally important landscapes.

Implementation of required programmatic design features, as discussed in Appendix A, Section A.2.2, should eliminate impacts on Tribes' reserved water rights and the potential for groundwater contamination issues.

1 **11.7.18.3 SEZ-Specific Design Features and Design Feature Effectiveness**
2

3 Programmatic design features to mitigate impacts of potential concern to Native
4 Americans, such as avoidance of sacred sites, water resources, and tribally important plant and
5 animal species are provided in Appendix A, Section A.2.2.
6

7 The need for and nature of SEZ-specific design features addressing issues of potential
8 concern would be determined during government-to-government consultation with the affected
9 Tribes listed in Table 11.7.18.1-1.
10

11 Mitigation of impacts on archaeological sites and traditional cultural properties is
12 discussed in Section 11.7.17.3, in addition to programmatic design features for historic properties
13 also discussed in Section A.2.2.
14

11.7.19 Socioeconomics

11.7.19.1 Affected Environment

This section describes current socioeconomic conditions and local community services within the ROI surrounding the proposed Millers SEZ. The ROI is a three-county area comprising Esmeralda, Mineral, and Nye Counties in Nevada. It encompasses the area in which workers are expected to spend most of their salaries and in which a portion of site purchases and nonpayroll expenditures from the construction, operation, and decommissioning phases of the proposed SEZ facility are expected to take place.

11.7.19.1.1 ROI Employment

In 2008, employment in the ROI stood at 18,672 (Table 11.7.19.1-1). Over the period 1999 to 2008, the annual average employment growth rate was low in each county in the ROI, with lower rates in Nye County (0.5%) and in Esmeralda County (–2.7%). At 0.4%, growth rates in the ROI as a whole were lower than the average rate for Nevada (2.7%).

In the ROI in 2006, the services sector provided the highest percentage of employment at 46.5%, followed by wholesale and retail trade at 17.9%, with a smaller employment share held by construction (8.7%) and mining (7.0%) (Table 11.7.19.1-2).

TABLE 11.7.19.1-1 ROI Employment in the Proposed Millers SEZ

^a Agricultural employment includes 2007 data for hired farmworkers.

Sources: U.S. Bureau of the Census (2009a); USDA (2009).

11.7.19.1.2 ROI Unemployment

The average unemployment rate in Nye County over the period 1999 to 2008 was 6.9%, slightly higher than the rate in Mineral County (6.7%) and higher than the rate for Esmeralda County (Table 11.7.19.1-3). The average rate in the ROI over this period was 6.9%, higher than the average rate for Nevada. Unemployment rates for the first 11 months of 2009 contrast with rates for 2008 as a whole; in Nye County, the unemployment rate increased to 14.3%, in Mineral County to 9.1%, and in Esmeralda County to 8.4%. The average rates for the ROI (13.6%) and for Nevada as a whole (11.0%) were also higher during this period than the corresponding average rates for 2008.

11.7.19.1.3 ROI Urban Population and Income

There are no incorporated places in the ROI, and consequently, no urban population or income.

11.7.19.1.4 ROI Total Population

Table 11.7.19.1-4 presents recent and projected populations in the ROI and for the state as a whole. Population in the ROI stood at 49,487 in 2008, having grown at an average annual rate of 3.2% since 2000. Growth rates for ROI were higher than those in Nevada (3.4%) over the same period.

Only one of the three counties in the ROI experienced growth in population between 2000 and 2008; population in Nye County grew at an annual rate of 3.9%, while in Mineral

County, population fell by –1.1%, and by –4.6% in Esmeralda County. The ROI population is expected to increase to 82,282 by 2021 and to 85,021 by 2023.

11.7.19.1.5 ROI Total Income

Total personal income in the ROI stood at \$1.6 billion in 2007 and has grown at an annual average rate of 3.9% over the period 1998 to 2007 (Table 11.7.19.1-5). Per-capita income also rose over the same period at a rate of 1.5%, increasing from \$29,208 to \$31,882. Per-capita incomes were higher in Esmeralda County (\$41,370) than in Nye County (\$31,836) and Mineral County (\$30,935) in 2007. Growth rates in total personal income have been higher in Nye County than in Mineral County and Esmeralda County. Personal income growth rates in Nevada (4.3%) were higher than the rate for the ROI (3.9%), while per-capita income growth rates in Esmeralda County were higher than those for Nevada as a whole (1.0%), the same as the state rate in Nye County and lower in Mineral County.

Median household income in 2006 to 2008 varied from \$42,275 in Nye County, to \$42,348 in Mineral County to \$42,749 in Esmeralda County (U.S. Bureau of the Census 2009c).

11.7.19.1.6 ROI Housing

In 2007, more than 20,300 housing units were located in the three ROI counties, with about 82% of these located in Nye County (Table 11.7.19.1-6). Owner-occupied units account for approximately 72% of the occupied units in the three counties, with rental housing making up 28% of the total. Vacancy rates in 2007 were 45.4% in Esmeralda County, 23.3% in Mineral County, and 19.3% in Nye County; with an overall vacancy rate of 21% in the ROI, there were

4,258 vacant housing units in the ROI in 2007, of which 1,198 are estimated to be rental units that would be available to construction workers. There were 734 units in seasonal, recreational, or occasional use in the ROI at the time of the 2000 Census, with 9.5% of housing units in Esmeralda County, 3.5% in Nye County and 3.2% in Mineral County used for seasonal or recreational purposes.

Housing stock in the ROI as a whole grew at an annual rate of 0.5% over the period 2000 to 2007, with 675 new units added to the existing housing stock (Table 11.7.19.1-6).

The median value of owner-occupied housing in 2006 to 2008 varied between \$59,500 in Mineral County, \$75,600 in Esmeralda County and \$122,100 in Nye County (U.S. Bureau of the Census 2009f).

11.7.19.1.7 ROI Local Government Organizations

The various local and county government organizations in the ROI are listed in Table 11.7.19.1-7. In addition, one Tribal governments is located in the ROI, with members of other Tribal groups located in the county, but whose Tribal governments are located in adjacent counties or states.

11.7.19.1.8 ROI Community and Social Services

This section describes educational, health care, law enforcement, and firefighting resources in the ROI.

Schools

In 2007, the three-county ROI had a total of 32 public and private elementary, middle, and high schools (NCES 2009). Table 11.7.19.1-8 provides summary statistics for enrollment and educational staffing and two indices of educational quality—student-teacher ratios and levels of service (number of teachers per 1,000 population). The student-teacher ratio in Nye County schools (16.2) is higher than that in Mineral County (11.5) and Esmeralda County schools (9.6), while the level of service is higher in Esmeralda County (11.6) than elsewhere in the ROI, where there are fewer teachers per 1,000 population (Mineral County, 11.2; Nye County, 9.0).

Health Care

The total number of physicians (41) is much higher in Nye County than Mineral County (4), while the number of physicians per 1,000 population in both counties is similar. No data are available for Esmeralda County (Table 11.7.19.1-9).

Public Safety

Several state, county, and local police departments provide law enforcement in the ROI (Table 11.7.19.1-10). Esmeralda County has 10 officers and would provide law enforcement services to the SEZ; there are 104 officers in Nye County and 18 officers in Mineral County. Levels of service of police protection are 14.5 per 1,000 population in Esmeralda County, 3.8 in Mineral County, and 2.4 in Nye County. Currently, there are 110 professional firefighters in the ROI (Table 11.7.19.1-10).

11.7.19.1.9 ROI Social Structure and Social Change

Community social structures and other forms of social organization within the ROI are related to various factors, including historical development, major economic activities and

sources of employment, income levels, race and ethnicity, and forms of local political organization. Although an analysis of the character of community social structures is beyond the scope of the current programmatic analysis, project-level NEPA analyses would include a description of ROI social structures, contributing factors, their uniqueness, and, consequently, the susceptibility of local communities to various forms of social disruption and social change.

Various energy development studies have suggested that once the annual growth in population is between 5 and 15% in smaller rural communities, alcoholism, depression, suicide, social conflict, divorce, and delinquency would increase and levels of community satisfaction would deteriorate (BLM 1980, 1983, 1996). Data on violent crime and property crime rates and on alcoholism and illicit drug use, mental health, and divorce, which might be used as indicators of social change, are presented in Tables 11.7.19.1-11 and 11.7.19.1-12, respectively.

There is some variation in the level of crime across the ROI, with higher rates of violent crime in Esmeralda County (4.5 per 1,000 population) than in Mineral County (3.2) and Nye County (2.9) (Table 11.7.19.1-11). Property-related crime rates are higher in Nye County (20.8) than in Esmeralda County (15.1) and Mineral County (5.2); overall crime rates in Nye County (23.0) were higher than in Esmeralda County (19.6) and Mineral County (8.4).

Data on other measures of social change—alcoholism, illicit drug use, and mental health—are not available at the county level and thus are presented for the SAMHSA region in which the ROI is located (Table 11.7.19.1-12).

11.7.19.1.10 ROI Recreation

Various areas in the vicinity of the proposed Millers SEZ are used for recreational purposes, with natural, ecological, and cultural resources in the ROI attracting visitors for a range of activities, including backcountry driving, OHV use and hunting. These activities are discussed in Section 11.7.5.

Because the number of visitors using state and federal lands for recreational activities is not available from the various administering agencies, the value of recreational resources in these areas, based solely on the number of recorded visitors, is likely to be an underestimation. In addition to visitation rates, the economic valuation of certain natural resources can also be assessed in terms of the potential recreational destination for current and future users, that is, their nonmarket value (see Section 5.17.1.1.1).

Another method is to estimate the economic impact of the various recreational activities supported by natural resources on public land in the vicinity of the proposed solar development, by identifying sectors in the economy in which expenditures on recreational activities occur. Not all activities in these sectors are directly related to recreation on state and federal lands, with some activity occurring on private land (e.g., dude ranches, golf courses, bowling alleys, and movie theaters). Expenditures associated with recreational activities form an important part of the economy of the ROI. In 2007, 1,859 people were employed in the ROI in the various sectors identified as recreation, constituting 9.8 % of total ROI employment (Table 11.7.19.1-13). Recreation spending also produced almost \$41.5 million in income in the ROI in 2007. The primary sources of recreation-related employment were hotels and lodging places and eating and drinking places.

11.7.19.2 Impacts

The following analysis begins with a description of the common impacts of solar development, including common impacts on recreation, social change, and livestock grazing. These impacts would occur regardless of the solar technology developed in the SEZ. The impacts of facilities employing various solar energy technologies are analyzed in detail in subsequent sections.

TABLE 11.7.19.1-13 Recreation Sector Activity in the Proposed Millers SEZ ROI, 2007

ROI	Employment	Income (\$ million)
Amusement and recreation services	105	3.8
Automotive rental	13	0.4
Eating and drinking places	923	16.5
Hotels and lodging places	691	17.8
Museums and historic sites,	1	0.2
Recreational vehicle parks and campsites	56	1.5
Scenic tours	39	1.0
Sporting goods retailers	31	0.4
Total ROI	1,859	41.5

11.7.19.2.1 Common Impacts

Construction and operation of a solar energy facility at the proposed Millers SEZ would produce direct and indirect economic impacts. Direct impacts would occur as a result of expenditures on wages and salaries and on procurement of goods and services required for project construction and operation, and the collection of state sales and income taxes. Indirect impacts would occur as project wages and salaries, procurement expenditures, and tax revenues subsequently circulate through the economy of each state, thereby creating additional employment, income, and tax revenues. Facility construction and operation would also require in-migration of workers and their families into the ROI surrounding the site, which would affect population, rental housing, health service employment, and public safety employment. Socioeconomic impacts common to all utility-scale solar energy facilities are discussed in detail in Section 5.17. These impacts will be minimized through the implementation of programmatic design features described in Appendix A, Section A.2.2.

Recreation Impacts

Estimating the impact of solar facilities on recreation is problematic, because it is not clear how solar development in the SEZ would affect recreational visitation and nonmarket values (i.e., the value of recreational resources for potential or future visits; see Section 5.17.1.2.3). While it is clear that some land in the ROI would no longer be accessible for recreation, the majority of popular recreational locations would be precluded from solar development. It is also possible that solar development in the ROI would be visible from popular recreation locations, and that construction workers residing temporarily in the ROI would occupy accommodations otherwise used for recreational visits, thus reducing visitation and consequently affecting the economy of the ROI.

Social Change

Although an extensive literature in sociology documents the most significant components of social change in energy boomtowns, the nature and magnitude of the social impact of energy development in small rural communities are still unclear (see Section 5.17.1.1.4). While some degree of social disruption is likely to accompany large-scale in-migration during the boom phase, there is insufficient evidence to predict the extent to which specific communities are likely to be affected, which population groups within each community are likely to be most affected, and the extent to which social disruption is likely to persist beyond the end of the boom period (Smith et al. 2001). Accordingly, because of the lack of adequate social baseline data, it has been suggested that social disruption is likely to occur once an arbitrary population growth rate associated with solar energy projects has been reached, with an annual rate of between 5 and 10% growth in population assumed to result in a breakdown in social structures, with a consequent increase in alcoholism, depression, suicide, social conflict, divorce, and delinquency and deterioration in levels of community satisfaction (BLM 1980, 1983, 1996).

1 In overall terms, the in-migration of workers and their families into the ROI would
2 represent an increase of 4.4% in regional population during construction of the trough
3 technology, with smaller increases for the power tower, dish engine, and PV technologies, and
4 during the operation of each technology. While it is possible that some construction and
5 operations workers will choose to locate in communities closer to the SEZ, the lack of available
6 housing in smaller rural communities in the ROI to accommodate all in-migrating workers and
7 families and insufficient range of housing choices to suit all solar occupations, many workers are
8 likely to commute to the SEZ from larger communities elsewhere in the ROI, thereby reducing
9 the potential impact of solar development on social change. Regardless of the pace of population
10 growth associated with the commercial development of solar resources and the likely residential
11 location of in-migrating workers and families in communities some distance from the SEZ itself,
12 the number of new residents from outside the ROI is likely to lead to some demographic and
13 social change in small rural communities in the ROI. Communities hosting solar development
14 are likely to be required to adapt to a different quality of life, with a transition away from a more
15 traditional lifestyle involving ranching and taking place in small, isolated, close-knit,
16 homogenous communities with a strong orientation toward personal and family relationships,
17 toward a more urban lifestyle, with increasing cultural and ethnic diversity and increasing
18 dependence on formal social relationships within the community.

21 **Livestock Grazing Impacts**

23 Cattle ranching and farming supported 82 jobs, and \$1.8 million in income in the ROI in
24 2007,(MIG, Inc. 2010). The construction and operation of solar facilities in the Millers SEZ
25 could result in a decline in the amount of land available for livestock grazing. However, because
26 the amount of acreage that would be used in the proposed SEZ would be small compared to the
27 overall size of locally affected land allotments, acreage loss would not have a significant impact
28 on overall grazing operations, with livestock management changes, or the provision of additional
29 livestock management facilities, meaning that no loss of AUMs is anticipated.

32 **11.7.19.2.2 Technology-Specific Impacts**

34 The economic impacts of solar energy development in the proposed SEZ were measured
35 in terms of employment, income, state tax revenues (sales and income), population in-migration,
36 housing, and community service employment (education, health, and public safety). More
37 information on the data and methods used in the analysis is presented in Appendix M.

39 The assessment of the impact of the construction and operation of each technology was
40 based on SEZ acreage, assuming 80% of the area could be developed. To capture a range of
41 possible impacts, solar facility size was estimated on the basis of the land requirements of
42 various solar technologies, assuming that 9 acres/MW (0.04 km²/MW) would be required for
43 power tower, dish engine, and PV technologies and 5 acres/MW (0.02 km²/MW) for solar trough
44 technologies. Impacts of multiple facilities employing a given technology at each SEZ were
45 assumed to be the same as impacts for a single facility with the same total capacity. Construction
46 impacts were assessed for a representative peak year of construction, assumed to be 2021 for

each technology. Construction impacts assumed that a maximum of two projects could be constructed within a given year, with a corresponding maximum land disturbance of up to 6,000 acres (24 km²). For operations impacts, a representative first year of operations was assumed to be 2023 for trough and power tower, 2022 for the minimum facility size for dish engine and PV, and 2023 for the maximum facility size for these technologies. The years of construction and operations were selected as representative of the entire 20-year study period, because they are the approximate midpoint; construction and operations could begin earlier.

Solar Trough

Construction. Total construction employment impacts in the ROI (including direct and indirect impacts) from the use of solar trough technologies would be up to 4,578 jobs (Table 11.7.1.19.2-1). Construction activities would constitute 14.7% of total ROI employment. A solar facility would also produce \$278.3 million in income and \$0.2 million in direct sales taxes.

Based on the scale of construction activities and the likelihood of local worker availability in the required occupational categories, construction of a solar facility would mean that some in-migration of workers and their families from outside the ROI would be required, with 3,654 persons in-migrating into the ROI. Although in-migration may potentially affect local housing markets, the relatively small number of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility construction on the number of vacant rental housing units would be expected to be large, with 1,827 rental units expected to be occupied in the ROI. This occupancy rate would represent 91.7% of the vacant rental units expected to be available in the ROI.

In addition to the potential impact on housing markets, in-migration would affect community service employment (education, health, and public safety). An increase in such employment would be required to meet existing levels of service in the ROI. Accordingly, 34 new teachers, 3 physicians, and 17 public safety employees (career firefighters and uniformed police officers) would be required in the ROI. These increases would represent 4.4% of total ROI employment expected in these occupations.

Operations. Total operations employment impacts in the ROI (including direct and indirect impacts) of a build-out using solar trough technologies would be 785 jobs (Table 11.7.19.2-1). Such a solar facility would also produce \$26.3 million in income and \$0.2 million in direct sales taxes. Based on fees established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010d), acreage-related fees would be \$1.1 million, and solar generating capacity fees would total at least \$17.6 million.

Based on the likelihood of local worker availability in the required occupational categories, operation of a solar facility would mean that some in-migration of workers and their families from outside the ROI would be required, with 373 persons in-migrating into the ROI.

TABLE 11.7.19.2-1 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Millers SEZ with Trough Facilities^a

Parameter	Maximum Annual Construction Impacts	Operations Impacts
Employment (no.)		
Direct	3,283	585
Total	4,578	785
Income ^b		
Total	278.3	26.3
Direct state taxes ^b		
Sales	0.2	0.2
BLM payments		
Acreage-related fee	NA	1.1
Capacity fee ^d	NA	17.6
In-migrants (no.)	3,654	373
Vacant housing ^c (no.)	1,827	336
Local community service employment		
Teachers (no.)	34	3
Physicians (no.)	3	0
Public safety (no.)	17	2

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 1,200 MW (corresponding to 6,000 acres [24 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 2,686 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010d), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 Although in-migration may potentially affect local housing markets, the relatively small number
2 of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile
3 home parks) mean that the impact of solar facility operation on the number of vacant owner-
4 occupied housing units would not be expected to be large, with 336 owner-occupied units
5 expected to be occupied in the ROI.
6

7 In addition to the potential impact on housing markets, in-migration would affect
8 community service (health, education, and public safety) employment. An increase in such
9 employment would be required to meet existing levels of service in the provision of these
10 services in the ROI. Accordingly, 3 new teachers and 2 public safety employees (career
11 firefighters and uniformed police officers) would be required in the ROI.
12

13 14 **Power Tower**

15
16
17 **Construction.** Total construction employment impacts in the ROI (including direct
18 and indirect impacts) from the use of power tower technologies would be up to 1,823 jobs
19 (Table 11.7.19.2-2). Construction activities would constitute 5.9% of total ROI employment.
20 Such a solar facility would also produce \$110.8 million in income and \$0.1 million in direct sales
21 taxes.
22

23 Based on the scale of construction activities and the likelihood of local worker
24 availability in the required occupational categories, construction of a solar facility would mean
25 that some in-migration of workers and their families from outside the ROI would be required,
26 with 1,456 persons in-migrating into the ROI. Although in-migration may potentially affect local
27 housing markets, the relatively small number of in-migrants and the availability of temporary
28 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
29 construction on the number of vacant rental housing units would not be expected to be large,
30 with 728 rental units expected to be occupied in the ROI. This occupancy rate would represent
31 36.5% of the vacant rental units expected to be available in the ROI.
32

33 In addition to the potential impact on housing markets, in-migration would affect
34 community service (education, health, and public safety) employment. An increase in such
35 employment would be required to meet existing levels of service in the ROI. Accordingly,
36 13 new teachers, 1 physician, and 7 public safety employees would be required in the ROI.
37 These increases would represent 1.8% of total ROI employment expected in these occupations.
38

39
40 **Operations.** Total operations employment impacts in the ROI (including direct
41 and indirect impacts) of a build-out using power tower technologies would be 370 jobs
42 (Table 11.7.19.2-3). Such a solar facility would also produce \$12.0 million in income.
43 Direct sales taxes would be less than \$0.1 million. Based on fees established by the BLM in its
44 Solar Energy Interim Rental Policy (BLM 2010d), acreage-related fees would be \$1.1 million,
45 and solar generating capacity fees would total at least \$9.8 million.
46

TABLE 11.7.19.2-2 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Millers SEZ with Power Tower Facilities^a

Parameter	Maximum Annual Construction Impacts	Operations Impacts
Employment (no.)		
Direct	1,308	302
Total	1,823	370
Income ^b

Local community service employment		
Teachers (no.)	13	2
Physicians (no.)	1	0
Public safety (no.)	7	1

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 667 MW (corresponding to 6,000 acres [24 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 1,492 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010d), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 Based on the likelihood of local worker availability in the required occupational
2 categories, operation of a solar facility means that some in-migration of workers and their
3 families from outside the ROI would be required, with 193 persons in-migrating into the ROI.
4 Although in-migration may potentially affect local housing markets, the relatively small number
5 of in-migrants and the availability of temporary accommodations (hotels, motels, and mobile
6 home parks) mean that the impact of solar facility operation on the number of vacant
7 owner-occupied housing units would not be expected to be large, with 173 owner-occupied
8 units expected to be required in the ROI.

9
10 In addition to the potential impact on housing markets, in-migration would affect
11 community service (education, health, and public safety) employment. An increase in such
12 employment would be required to meet existing levels of service in the ROI. Accordingly,
13 2 new teachers and 1 public safety employee would be required in the ROI.

14 15 16 **Dish Engine**

17
18
19 **Construction.** Total construction employment impacts in the ROI (including direct
20 and indirect impacts) from the use of dish engine technologies would be up to 741 jobs
21 (Table 11.7.19.2-3). Construction activities would constitute 2.4% of total ROI employment.
22 Such a solar facility would also produce \$45.1 million in income and less than \$0.1 million in
23 direct sales taxes.

24
25 Based on the scale of construction activities and the likelihood of local worker
26 availability in the required occupational categories, construction of a solar facility would mean
27 that some in-migration of workers and their families from outside the ROI would be required,
28 with 592 persons in-migrating into the ROI. Although in-migration may potentially affect local
29 housing markets, the relatively small number of in-migrants and the availability of temporary
30 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
31 construction on the number of vacant rental housing units would not be expected to be large,
32 with 296 rental units expected to be occupied in the ROI. This occupancy rate would represent
33 14.9% of the vacant rental units expected to be available in the ROI.

34
35 In addition to the potential impact on housing markets, in-migration would affect
36 community service (education, health, and public safety) employment. An increase in such
37 employment would be required to meet existing levels of service in the ROI. Accordingly,
38 5 new teachers, 1 physician, and 3 public safety employees would be required in the ROI.
39 These increases would represent less than 0.7% of total ROI employment expected in these
40 occupations.

41
42
43 **Operations.** Total operations employment impacts in the ROI (including direct
44 and indirect impacts) of a build-out using dish engine technologies would be 360 jobs
45 (Table 11.7.19.2-3). Such a solar facility would also produce \$11.7 million in income and
46 less than \$0.1 million in direct sales taxes. Based on fees established by the BLM in its Solar

TABLE 11.7.19.2-3 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Millers SEZ with Dish Engine Facilities^a

Parameter	Maximum Annual Construction Impacts	Operations Impacts

^a Construction impacts are based on the development at the site in a single year; it was assumed that several facilities with a combined capacity of up to 667 MW (corresponding to 6,000 acres [24 km²] of land disturbance) could be built. Operations impacts were based on full build-out of the site, producing a total output of 1,492 MW.

^b Unless indicated otherwise, values are reported in \$ million 2008. There is currently no individual income tax in Nevada.

^c Construction activities would affect vacant rental housing; operations activities would affect vacant owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$6,570 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010d), assuming a solar facility with no storage capability, and full build-out of the site. Projects with three or more hours of storage would generate higher payments, based on a fee of \$7,884 per MW.

1 Energy Interim Rental Policy (BLM 2010d), acreage-related fees would be \$1.1 million, and
2 solar generating capacity fees would total at least \$9.8 million.

3
4 Based on the likelihood of local worker availability in the required occupational
5 categories, operation of a dish engine solar facility means that some in-migration of workers and
6 their families from outside the ROI would be required, with 187 persons in-migrating into the
7 ROI. Although in-migration may potentially affect local housing markets, the relatively small
8 number of in-migrants and the availability of temporary accommodations (hotels, motels, and
9 mobile home parks) mean that the impact of solar facility operation on the number of vacant
10 owner-occupied housing units would not be expected to be large, with 168 owner-occupied units
11 expected to be required in the ROI.

12
13 In addition to the potential impact on housing markets, in-migration would affect
14 community service employment (education, health, and public safety). An increase in such
15 employment would be required to meet existing levels of service in the ROI. Accordingly,
16 2 new teachers and 1 public safety employee would be required in the ROI.

17 18 19 **Photovoltaic**

20
21
22 **Construction.** Total construction employment impacts in the ROI (including direct and
23 indirect impacts) from the use of PV technologies would be up to 346 jobs (Table 11.7.19.2-4).
24 Construction activities would constitute 1.1% of total ROI employment. Such a solar
25 development would also produce \$21.0 million in income and less than \$0.1 million in direct
26 sales taxes.

27
28 Based on the scale of construction activities and the likelihood of local worker
29 availability in the required occupational categories, construction of a solar facility would mean
30 that some in-migration of workers and their families from outside the ROI would be required,
31 with 276 persons in-migrating into the ROI. Although in-migration may potentially affect local
32 housing markets, the relatively small number of in-migrants and the availability of temporary
33 accommodations (hotels, motels, and mobile home parks) mean that the impact of solar facility
34 construction on the number of vacant rental housing units would not be expected to be large,
35 with 138 rental units expected to be occupied in the ROI. This occupancy rate would
36 represent 6.9% of the vacant rental units expected to be available in the ROI.

37
38 In addition to the potential impact on housing markets, in-migration would affect
39 community service (education, health, and public safety) employment. An increase in such
40 employment would be required to meet existing levels of service in the ROI. Accordingly, 3 new
41 teachers and 1 public safety employee would be required in the ROI. This increase
42 would represent less than 0.3% of total ROI employment expected in this occupation.
43

TABLE 11.7.19.2-4 ROI Socioeconomic Impacts Assuming Full Build-out of the Proposed Millers SEZ with PV Facilities^a

^c Construction activities would affect vacant rental housing; operations activities would affect owner-occupied housing.

^d The BLM annual capacity payment was based on a fee of \$5,256 per MW, established by the BLM in its Solar Energy Interim Rental Policy (BLM 2010d) , assuming full build-out of the site.

1
2
3
4

1 **Operations.** Total operations employment impacts in the ROI (including direct and
2 indirect impacts) of a build-out using PV technologies would be 36 jobs (Table 11.7.19.2-4).
3 Such a solar facility would also produce \$1.2 million in income and less than \$0.1 million in
4 direct sales taxes. Based on fees established by the BLM in its Solar Energy Interim Rental
5 Policy (BLM 2010d), acreage-related fees would be \$1.1 million, and solar generating capacity
6 fees would total at least \$7.8 million.
7

8 Given the likelihood of local worker availability in the required occupational categories,
9 operation of a solar facility would mean that some in-migration of workers and their families
10 from outside the ROI would be required, with 19 persons in-migrating into the ROI. Although
11 in-migration may potentially affect local housing markets, the relatively small number of
12 in-migrants and the availability of temporary accommodations (hotels, motels, and mobile home
13 parks) mean that the impact of solar facility operation on the number of vacant owner-occupied
14 housing units would not be expected to be large, with 17 owner-occupied units expected to be
15 required in the ROI.
16

17 No new community service employment would be required to meet existing levels of
18 service in the ROI.
19
20

21 **11.7.19.3 SEZ-Specific Design Features and Design Feature Effectiveness** 22

23 No SEZ-specific design features addressing socioeconomic impacts have been identified
24 for the proposed Millers SEZ. Implementing the programmatic design features described in
25 Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would reduce the
26 potential for socioeconomic impacts during all project phases.
27
28
29

11.7.20 Environmental Justice

11.7.20.1 Affected Environment

Executive Order 12898, “Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations,” formally requires federal agencies to incorporate environmental justice as part of their missions (*Federal Register*, Volume 59, page 7629, Feb. 11, 1994). Specifically, it directs them to address, as appropriate, any disproportionately high and adverse human health or environmental effects of their actions, programs, or policies on minority and low-income populations.

The analysis of the impacts of solar energy projects on environmental justice issues follows guidelines described in the CEQ’s *Environmental Justice Guidance under the National Environmental Policy Act* (CEQ 1997). The analysis method has three parts: (1) a description of the geographic distribution of low-income and minority populations in the affected area is undertaken; (2) an assessment is conducted to determine whether construction and operation would produce impacts that are high and adverse; and (3) if impacts are high and adverse, a determination is made as to whether these impacts disproportionately affect minority and low-income populations.

Construction and operation of solar energy projects in the proposed Millers SEZ could affect environmental justice if any adverse health and environmental impacts resulting from either phase of development are significantly high and if these impacts disproportionately affect minority and low-income populations. If the analysis determines that health and environmental impacts are not significant, there can be no disproportionate impacts on minority and low-income populations. In the event impacts are significant, disproportionality would be determined by comparing the proximity of any high and adverse impacts with the location of low-income and minority populations.

The analysis of environmental justice issues associated with the development of solar facilities considered impacts within the SEZ and an associated 50-mi (80-km) radius around the boundary of the SEZ. A description of the geographic distribution of minority and low-income groups in the affected area was based on demographic data from the 2000 Census (U.S. Bureau of the Census 2009j,k). The following definitions were used to define minority and low-income population groups:

- **Minority.** Persons who identify themselves as belonging to any of the following racial groups: (1) Hispanic, (2) Black (not of Hispanic origin) or African American, (3) American Indian or Alaska Native, (4) Asian, or (5) Native Hawaiian or Other Pacific Islander.

Beginning with the 2000 Census, where appropriate, the census form allows individuals to designate multiple population group categories to reflect their ethnic or racial origin. In addition, persons who classify themselves as being of multiple racial origin may choose up to six racial groups as the basis of

1 their racial origins. The term minority includes all persons, including those
2 classifying themselves in multiple racial categories, except those who classify
3 themselves as not of Hispanic origin and as White or "Other Race"
4 (U.S. Bureau of the Census 2009j).

5
6 The CEQ guidance proposed that minority populations should be identified
7 where either (1) the minority population of the affected area exceeds 50% or
8 (2) the minority population percentage of the affected area is meaningfully
9 greater than the minority population percentage in the general population or
10 other appropriate unit of geographic analysis.

11
12 This PEIS applies both criteria in using the Census data for census block
13 groups, wherein consideration is given to the minority population that is both
14 greater than 50% and 20 percentage points higher than in the state (the
15 reference geographic unit).

- 16
17 • **Low-Income.** Individuals who fall below the poverty line. The poverty line
18 takes into account family size and age of individuals in the family. In 1999,
19 for example, the poverty line for a family of five with three children below
20 the age of 18 was \$19,882. For any given family below the poverty line, all
21 family members are considered as being below the poverty line for the
22 purposes of analysis (U.S. Bureau of the Census 2009k).

23
24 The data in Table 11.7.20.1-1 show the minority and low-income composition of the
25 total population located in the proposed SEZ based on 2000 Census data and CEQ guidelines.
26 Individuals identifying themselves as Hispanic or Latino are included in the table as a separate
27 entry. However, because Hispanics can be of any race, this number also includes individuals
28 identifying themselves as being part of one or more of the population groups listed in the table.

29
30 Minority and low-income individuals are located in the 50-mi (80-km) area around the
31 boundary of the SEZ. Within the 50-mi (80-km) radius in California, 18.2% of the population is
32 classified as minority, while 9.3% is classified as low-income. However, the number of minority
33 individuals does not exceed 50% of the total population in the area, and the number of minority
34 individuals does not exceed the state average by 20 percentage points or more; thus, in
35 aggregate, there is no minority population in the SEZ area based on 2000 Census data and CEQ
36 guidelines. The number of low-income individuals does not exceed the state average by
37 20 percentage points or more and does not exceed 50% of the total population in the area; thus,
38 in aggregate, there are no low-income populations in the SEZ area.

39
40 In the Nevada portion of the 50-mi (80-km) radius, 16.2% of the population is classified
41 as minority, while 11.6% is classified as low-income. The number of minority individuals does
42 not exceed 50% of the total population in the area and the number of minority individuals does
43 not exceed the state average by 20 percentage points or more; thus, in aggregate, there is no
44 minority population in the SEZ area based on 2000 Census data and CEQ guidelines. The
45 number of low-income individuals does not exceed the state average by 20 percentage points or

TABLE 11.7.20.1-1 Minority and Low-Income Populations within the 50-mi (80-km) Radius Surrounding the Proposed Millers SEZ

Parameter	California	Nevada
Total population	3,162	7,713
White, non-Hispanic	2,586	6,464
Hispanic or Latino	348	535
Non-Hispanic or Latino minorities	228	714
One race	170	460
Black or African American	3	66
American Indian or Alaskan Native	144	337
Asian	13	24
Native Hawaiian or Other Pacific Islander	5	12
Some other race	5	21
Two or more races	58	254
Total minority	576	1,249
Low-income	293	893
Percentage minority	18.2	16.2
State percentage minority	53.3	34.8
Percentage low-income	9.3	11.6
State percentage low-income	14.2	10.5

Source: U.S. Bureau of the Census (2009j,k).

more and does not exceed 50% of the total population in the area; thus, in aggregate, there are no low-income populations in the SEZ area.

11.7.20.2 Impacts

Environmental justice concerns common to all utility-scale solar energy facilities are described in detail in Section 5.18. These impacts will be minimized through the implementation of the programmatic design features described in Appendix A, Section A.2.2, which address the underlying environmental impacts contributing to the concerns. The potentially relevant environmental impacts associated with solar facilities within the proposed Millers SEZ include noise and dust during the construction; noise and electromagnetic field (EMF) effects associated with operations; visual impacts of solar generation and auxiliary facilities, including transmission lines; access to land used for economic, cultural, or religious purposes; and effects on property values as areas of concern that might potentially affect minority and low-income populations.

1 Potential impacts on low-income and minority populations could be incurred as a result
2 of the construction and operation of solar facilities involving each of the four technologies.
3 Impacts are likely to be small, however, and there are no minority populations defined by CEQ
4 guidelines (Section 11.7.20.1) within the 50-mi (80-km) radius around the boundary of the SEZ;
5 this means that any adverse impacts of solar projects could not disproportionately affect minority
6 populations. Because there are no low-income populations within the 50-mi (80-km) radius,
7 there could be no impacts on low-income populations.
8
9

10 **11.7.20.3 SEZ-Specific Design Features and Design Feature Effectiveness**

11

12 No SEZ-specific design features addressing environmental justice impacts have been
13 identified for the proposed Millers SEZ. Implementing the programmatic design features
14 described in Appendix A, Section A.2.2, as required under BLM's Solar Energy Program, would
15 reduce the potential for environmental justice impacts during all project phases.
16
17
18

11.7.21 Transportation

The proposed Millers SEZ is accessible by road. One U.S. highway serves the immediate area. The nearest railroad access is approximately 90 mi (145 km) away. Five small airports serve the area within a drive of approximately 90 mi (145 km). General transportation considerations and impacts are discussed in Sections 3.4 and 5.19, respectively.

11.7.21.1 Affected Environment

U.S. 95/U.S. 6 runs east–west along the southern border of the Millers SEZ, as shown in Figure 11.7.21.1-1. The small town of Tonopah is approximately 15 mi (24 km) to the east of the SEZ along U.S. 95. To the southeast of the SEZ, U.S. 95 intersects Interstate 15 (I-15) in the center of the Las Vegas metropolitan area, about 230 mi (370 km) away. The town of Fernley to the northwest, at about the closest approach of I-80 to the SEZ, is approximately a 185-mi (298-km) drive. From the east, U.S. 6 merges with U.S. 95 at Tonopah before they pass along the southern edge of the SEZ. Approximately 20 mi (32 km) to the west of the SEZ, U.S. 95 and U.S. 6 again become separate highways. Several local unimproved dirt roads cross the SEZ as shown in Figure 11.7.21.1-1. Data identifying open OHV routes within the proposed SEZ were not available. As listed in Table 11.7.21.1-1, U.S. 95 carries an average traffic volume of about 2,000 vehicles per day in the vicinity of the Millers SEZ (NV DOT 2010).

The UP Railroad serves the region. A spur from the main line that crosses northern Nevada ends at Thorne (UP Railroad 2009), 90 mi (145 km) northwest of the SEZ along U.S. 95, immediately north of Hawthorne.

The nearest public airport is the Tonopah Airport, a small county airport about a 23-mi (37-km) drive to the east of the SEZ on U.S. 6. The airport has two asphalt runways in good condition, as listed in Table 11.7.21.1-2. Three small airports with single dirt runways managed by the BLM—Dyer, Lida Junction, and Mina—are within a 64-mi (103-km) drive of the Millers SEZ. Hawthorne Industrial Airport, in Hawthorne, has one asphalt and one dirt runway. None of the airports has scheduled commercial passenger service or regular freight service.

Nellis Air Force Base, available only to military aircraft, lies on the northeastern edge of the Las Vegas metropolitan area. Nellis Air Force Base is one of the largest fighter bases in the world and is involved in conducting advanced fighter training. Operations occur over the NTTR, which offers 4,700 mi² (12,173 km²) of restricted land (U.S. Air Force 2010). The northwestern corner of the NTTR is approximately 26 mi (42 km) to the southeast of the Millers SEZ.

11.7.21.2 Impacts

As discussed in Section 5.19, the primary transportation impacts are anticipated to be from commuting worker traffic. Single projects could involve up to 1,000 workers each day, with an additional 2,000 vehicle trips per day (maximum) or possibly 4,000 vehicle trips per day if two larger projects were to be developed at the same time. The volume of traffic on U.S. 95

FIGURE 11.7.21.1-1 Local Transportation Network Serving the Proposed Millers SEZ

TABLE 11.7.21-1 AADT on Major Roads near the Proposed Millers SEZ for 2009

Road	General Direction	Location	AADT (Vehicles)
U.S. 6	East–West	<i>East of merge with U.S. 95</i>	
		East of State Route 376	580
		East of Tonopah (west of State Route 376)	1,100
		<i>West of merge with U.S. 95</i>	
		West of Coaldale junction	280
U.S. 95	Northwest–Southeast	North of Coaldale junction	1,700
		West of junction with State Route 265 (west of SEZ)	2,000
		North of Tonopah, 13 mi (21 km) past the Nye/ Esmeralda County line (east of the SEZ)	1,900
		South of Tonopah	2,100
		South of Goldfield	2,000
		North of junction with State Route 266	1,900
		South of junction with State Route 266	2,000
State Route 265	North–South	South of junction with U.S. 95	110
State Route 376	North–South	North of U.S. 6	490
State Route 773	Southwest–Northeast	South of junction with U.S. 6	70

Source: NV DOT (2010).

along the southern edge of the Millers SEZ would represent an increase in traffic of about 100 or 200% for one or two projects, respectively, should all traffic access the SEZ in that area.

Because higher traffic volumes would be experienced during shift changes, traffic on U.S. 95 would experience slowdowns during these time periods in the vicinity of access roads for projects in the SEZ. Local road improvements would be necessary on any portion of U.S. 95 that might be developed so as not to overwhelm the local access roads near any site access point(s).

Solar development within the SEZ would affect public access along OHV routes designated open and available for public use. If there are any designated as open within the proposed SEZ, open routes crossing areas issued ROWs for solar facilities would be re-designated as closed (see Section 5.5.1 for more details on how routes coinciding with proposed solar facilities would be treated).

11.7.21.3 Specific Design Features and Design Feature Effectiveness

No SEZ-specific design features have been identified related to impacts on transportation systems around the proposed Millers SEZ. The programmatic design features described in Appendix A, Section A.2.2, including local road improvements, multiple site access locations, staggered work schedules, and ride-sharing, would all provide some relief to traffic congestion on local roads leading to the site. Depending on the location of solar facilities within the SEZ, more specific access locations and local road improvements could be implemented.

TABLE 11.7.21-2 Airports Open to the Public in the Vicinity of the Proposed Millers SEZ

Airport	Location	Owner/Operator	Runway 1 ^a			Runway 2 ^a		
			Length (ft [m])	Type	Condition	Length (ft [m])	Type	Condition

11.7.22 Cumulative Impacts

The analysis presented in this section addresses the potential cumulative impacts in the vicinity of the proposed Millers SEZ in Esmeralda County, Nevada. The CEQ guidelines for implementing NEPA define cumulative impacts as environmental impacts resulting from the incremental impacts of an action when added to other past, present, and reasonably foreseeable future actions (40 CFR 1508.7). The impacts of other actions are considered without regard to the agency (federal or nonfederal), organization, or person that undertakes them. The time frame of this cumulative impacts assessment could appropriately include activities that would occur up to 20 years in the future (the general time frame for PEIS analyses), but little or no information is available for projects that could occur further than 5 to 10 years in the future.

The Millers SEZ is located 15 mi (24 km) northwest of Tonopah, Nevada. The land surrounding the Millers SEZ is undeveloped with few permanent residents living in the area. The nearest population center is the small community of Tonopah, population approximately 1,500. The NTTR is 30 mi (48 km) northeast of the SEZ. Several WAs in California are within 50 mi (80 km) of the SEZ. The BLM administers approximately 68% of the land in the Southern Nevada District, which contains the Millers SEZ, and about 56% of the land in Nye County.

The geographic extent of the cumulative impacts analysis for potentially affected resources near the Millers SEZ is identified in Section 11.7.22.1. An overview of ongoing and reasonably foreseeable future actions is presented in Section 11.7.22.2. General trends in population growth, energy demand, water availability, and climate change are discussed in Section 11.7.22.3. Cumulative impacts for each resource area are discussed in Section 11.7.22.4.

11.7.22.1 Geographic Extent of the Cumulative Impacts Analysis

The geographic extent of the cumulative impacts analysis for potentially affected resources evaluated near the Millers SEZ is provided in Table 11.7.22.1-1. These geographic areas define the boundaries encompassing potentially affected resources. Their extent may vary based on the nature of the resource being evaluated and the distance at which an impact may occur (thus, for example, the evaluation of air quality may have a greater regional extent of impact than visual resources). The BLM, USFS, and DoD administer most of the land around the SEZ; there are also some Tribal lands nearby at the Yomba Reservation 48 mi (77 km) to the north of the SEZ. The BLM administers approximately 76.6% of the lands within a 50-mi (80-km) radius of the SEZ.

11.7.22.2 Overview of Ongoing and Reasonably Foreseeable Future Actions

The future actions described below are those that are “reasonably foreseeable”; that is, they have already occurred, are ongoing, are funded for future implementation, or are included in firm near-term plans. Types of proposals with firm near-term plans are as follows:

- Proposals for which NEPA documents are in preparation or finalized;

TABLE 11.7.22.1-1 Geographic Extent of the Cumulative Impacts Analysis by Resource Area: Proposed Millers SEZ

Resource Area	Geographic Extent
Land Use	Esmeralda County
Specially Designated Areas and Lands with Wilderness Characteristics	Esmeralda County
Rangeland Resources	
Grazing	Esmeralda County
Wild Horses and Burros	A 50 mi (80 km) radius from the center of the Millers SEZ
Recreation	Esmeralda County
Military and Civilian Aviation	Esmeralda and Nye Counties
Soil Resources	Areas within and adjacent to the Millers SEZ
Minerals	Esmeralda County
Water Resources	
Surface Water	Ione Wash, Peavine Creek, unnamed wash, Slime Wash, unnamed dry lake
Groundwater	Tonopah Flat Groundwater Basin
Air Quality and Climate	A 31-mi (50-m) radius from the center of the Millers SEZ
Vegetation, Wildlife and Aquatic Biota, Special Status Species	A 50-mi (80-km) radius from the center of the Millers SEZ, including portions of Esmeralda, Nye, and Mineral Counties in Nevada, and Inyo County in California
Visual Resources	Viewshed within a 25-mi (40-km) radius of the Millers SEZ
Acoustic Environment (noise)	Areas adjacent to the Millers SEZ
Paleontological Resources	Areas within and adjacent to the Millers SEZ
Cultural Resources	Areas within and adjacent to the Millers SEZ for archaeological sites; viewshed within a 25-mi (40-km) radius of the Millers SEZ for other properties, such as traditional cultural properties.
Native American Concerns	Areas within and adjacent to the Millers SEZ in the Big Smoky Valley viewshed within a 25-mi (40-km) radius of the Millers SEZ
Socioeconomics	Esmeralda and Nye Counties
Environmental Justice	Esmeralda and Nye Counties
Transportation	U.S. 95, U.S. 6

- Proposals in a detailed design phase;
- Proposals listed in formal NOIs published in the *Federal Register* or state publications;
- Proposals for which enabling legislations has been passed; and
- Proposals that have been submitted to federal, state, or county regulators to begin a permitting process.

Projects in the bidding or research phase or that have been put on hold were not included in the cumulative impact analysis.

The ongoing and reasonably foreseeable future actions described below are grouped into two categories: (1) actions that relate to energy production and distribution, including potential solar energy projects under the proposed action (Section 11.7.22.2.1); and (2) other ongoing and reasonably foreseeable actions, including those related to mining and mineral processing, grazing management, transportation, recreation, water management, and conservation (Section 11.7.22.2.2). Together, these actions have the potential to affect human and environmental receptors within the geographic range of potential impacts over the next 20 years.

11.7.22.2.1 Energy Production and Distribution

On February 16, 2007, Governor Gibbons signed an Executive Order to encourage the development of renewable energy resources in Nevada (Gibbons 2007a). The Executive Order requires all relevant state agencies to review their permitting processes to ensure the timely and expeditious permitting of renewable energy projects. On May 9, 2007, and June 12, 2008, the Governor signed Executive Orders creating the Nevada Renewable Energy Transmission Access Advisory Committee Phase I and Phase II, which will propose recommendations for improved access to the grid system for renewable energy industries (Gibbons 2007b, 2008). In May 28, 2009, the Nevada Legislature passed a bill modifying the Renewable Energy Portfolio Standards (Nevada Senate 2009). The bill requires that 25% of the electricity sold to be produced by renewable energy sources by 2025.

Reasonably foreseeable future actions related to energy production and distribution are identified in Table 11.7.22.2-1 and described in the following sections.

TABLE 11.7.22.2-1 Reasonably Foreseeable Future Actions Related to Energy Development and Distribution near the Proposed Millers SEZ^a

Description	Status	Resources Affected	Primary Impact Location
<i>Fast-Track Solar Energy Projects on BLM-Administered Land</i>			
Crescent Dunes Solar Energy Project (NVN-86292); 180 MW, solar tower, 1,600 acres	NOI, Nov. 24, 2009	Terrestrial habitats, wildlife, vegetation, water, soils, cultural, visual, aviation, and land use	3 mi (5 km) east of the SEZ
<i>Renewable Energy Development</i>

<i>Transmission and Distribution Systems</i>			
None			

^a Projects in later stages of agency environmental review and project development.

Renewable Energy Development

Renewable energy ROW applications are considered as either foreseeable or potential projects. Fast-track applications are considered to represent foreseeable projects, since the environmental review and public participation process is completed or under way and the applications could be approved by December 2010. There is one fast-track solar project and one other foreseeable geothermal project within 50 mi (80 km) of the proposed Millers SEZ, the Crescent Dunes Solar Energy Project, and Darrough Hot Springs Geothermal Leasing Project, respectively. Regular-track applications are considered potential future projects, but not necessarily foreseeable projects, since not all applications would be expected to result in completed projects. These proposals are considered together as a general level of interest in development of renewable energy in the region. Identified foreseeable and potential (pending) renewable energy projects are discussed in the following sections.

Foreseeable Renewable Energy Projects

Crescent Dunes Solar Energy Project (NVN 86292). This proposed fast-track project would be a CSP/tower facility with an output of 180 MW. Tonopah Solar Energy proposed to construct and operate the facility. The project would be located about 3 mi (5 km) east of the SEZ on 1,600 acres (6.5 km²) of the 7,680-acre (31-km²) site on BLM-administered land 13 mi

(21 km) northwest of Tonopah, Nevada. The facility would include a circular array of 17,350 heliostats that reflect the sunlight onto a central 633-ft (193-m) tall receiver tower. A liquid salt circulating through the tubes of the receiver is heated to more than 1,000°F (538°C) and routed to a thermal storage tank. When electricity is to be generated, the hot salt passes through a heat exchanger to produce steam for use in a steam turbine/generator. A hybrid cooling system would consist of an air-cooled condenser augmented with a wet-cooling system. The facility would also include associated equipment, an 8-mi (13-km) transmission line, an operation and maintenance building, and access roads (Tonopah Solar Energy 2009; BLM 2009a).

Darrouh Hot Springs Geothermal Leasing Project. Great America Energy is proposing to construct and operate a 27-MW geothermal plant on 160 acres (0.65 km²) of Humboldt-Toiyabe National Forest land, 45 mi (72 km) north of the SEZ. The physical facilities comprise production and injection wells, a gathering and injection system, and a power generation plant on site, with a transmission line connecting it to the grid (Great American Energy 2010).

Pending Solar, Wind, and Geothermal ROW Applications on BLM-Administered Lands. Applications for ROWs that have been submitted to the BLM include one fast-track solar application, one pending solar project, one pending wind site testing application, four authorized wind site testing projects, and two authorized geothermal projects that would be located within 50 mi (80 km) of the Millers SEZ. Table 11.7.22.2-2 lists these applications and Figure 11.7.22.2-1 shows their locations.

There is a pending solar project that would be on private land adjacent to the Millers SEZ. In 2010, Altella Energy Corporation proposed to Esmeralda County the development of a 100-MW solar energy facility on private land. The proposed site is located within one mile south of the Millers SEZ, near Highways 6 and 95. The site is known as the Miller's Well site. The project's estimated cost is \$500 million (Esmeralda County 2010a,b).

The likelihood of any of the regular-track application projects actually being developed is uncertain, but it is generally assumed to be less than that for fast-track applications. The number and types of applications listed in Table 11.7.22.2-2 are an indication of the level of interest in the development of renewable energy in the region. Some number of these applications would be expected to result in actual projects. Thus, the cumulative impacts of these potential projects are analyzed in their aggregate effects.

Wind testing would involve some relatively minor activities that could have some environmental effects, mainly the erection of meteorological towers and monitoring of wind conditions. These towers may or may not employ guy wires and may be 200 ft (60 m) high.

FIGURE 11.7.22.2-1 Locations of Renewable Energy Project ROW Applications on Public Land within a 50-mi (80-km) Radius of the Proposed Millers SEZ

11.7.22.2.2 Other Actions

Other major ongoing and foreseeable actions identified within 50 mi (80 km) of the proposed Millers SEZ are listed in Table 11.7.22.2-3 and are described in the following subsections. Producing geothermal leases are covered in the previous section.

Round Mountain Mine Expansion. The Round Mountain Gold Corporation proposes to expand its existing Round Mountain Mine, located east and southeast of the town of Carver and 45 mi (72 km) north of the SEZ, including expansion of the Round Mountain open pit, North Waste Rock Dump, mill facility, tailings impoundment, growth media and ore stockpiles, stormwater control and diversion structures, dewatering operations for the open pit, west and south dedicated leach pads, reusable pad, and process facilities. The proposed action would include the expansion and development of facilities and construction of new facilities in the Gold Hill area, 1.6 mi (2.4 km) north, and would include the construction of a 1.1-mi (1.8-km) long

TABLE 11.7.22.2-3 Other Major Actions near the Proposed Millers SEZ^a

Description	Status	Resources Affected	Primary Impact Location
Round Mountain Mine Expansion	FEIS issued April 2010	Terrestrial habitats, wildlife, cultural resources	45 mi (72 km) north of the SEZ
Chemetall Foote Lithium Carbonate Facility Expansion	EA issued Sept 2010	Terrestrial habitats, wildlife, air quality	30 mi (48 km) south of the SEZ
Mineral Ridge Project	Restarting in 2011	Terrestrial habitats, groundwater, air quality	28 mi (45 km) south of the SEZ
Caliente Rail Realignment	FEIS June 2008	Terrestrial habitats, wildlife cultural resources	24 mi (38 km) southeast of the SEZ
Montezuma Peak Herd Management Area (HMA) and Paymaster HMA Wild Horse and Burro Gather	EA issued June 2010	Terrestrial habitats, wildlife	32 mi (51 km) and 8 mi (13 km) southeast of the SEZ
Five Producing Geothermal Leases: NVN 8421, 8428, 9647, 31991, and 31993	Operating	Terrestrial habitats, wildlife	32 mi (51 km) southwest of the SEZ

^a Projects in latter stages of agency environmental review and project development.

1 Transportation/Utility Corridor between the Round Mountain and Gold Hill areas, which would
2 include a haul road, electric transmission line, water pipeline, and communication lines. The total
3 disturbed area would be 4,698 acres (19.0 km²) The existing total employment level of
4 approximately 730 workers would grow to a maximum of 1,140 during construction and would
5 range between 760 and 940 through completion of surface mining in 2016 (BLM 2010a).
6
7

8 ***Chemetall Foote Lithium Carbonate Facility Expansion.*** The DOE is proposing to
9 upgrade an existing brine field production system, brine evaporation pond system, and lithium
10 carbonate plant at the Chemetall Foote facility adjacent to the unincorporated town of Silver
11 Peak, Nevada and 30 mi (48 km) south of the SEZ. The site is about 15,000 acres (61 km²),
12 mostly occupied by large evaporation ponds. The plant and administrative offices occupy
13 approximately 20 acres (0.08 km²). Existing lithium brine ponds would be expanded through
14 recovering old ponds and rebuilding the dikes. Construction of new brine production wells would
15 require soil placement for drill pads (DOE 2010).
16
17

18 ***Mineral Ridge Project.*** Mineral Ridge, a formerly producing gold and silver mine, has
19 both underground workings and open pits, with a six-acre (0.024-km²) deep leach operation and
20 a high volume crusher plant. It is currently not operational but engineering work is being
21 performed for future operations. It is anticipated that active mining will commence in 2011. The
22 site is 3 mi (3 km) northwest of the unincorporated town of Silver Peak and approximately 28 mi
23 (45 km) south of the SEZ (Top Stock Picks 2010).
24
25

26 ***Caliente Rail Alignment.*** The DOE proposes to construct and operate a railroad for the
27 shipment of spent nuclear fuel and high-level radioactive waste to the geologic repository at
28 Yucca Mountain, Nevada. The rail line would begin near Caliente, Nevada and extend north,
29 then turn in a westerly direction, passing about 24 mi (38 km) southeast of the SEZ, to a location
30 near the northwest corner of the Nevada Test and Training Range (labeled Nellis Air Force
31 Range in Figure 11.7.22.2-1), and then continue south-southwest to Yucca Mountain. The rail
32 line would range in length from approximately 328 mi (528 km) to 336 mi (541 km), depending
33 upon the exact location of the alignment, and would be restricted to DOE shipments. Over a
34 50-year period, 9,500 casks containing spent nuclear fuel and high-level radioactive waste, and
35 approximately 29,000 rail cars of other materials, including construction materials, would be
36 shipped to the repository. An average of 17 one-way trains per week would travel along the rail
37 line. Construction of support facilities - interchange yard, staging yard, maintenance-of-way
38 facility, rail equipment maintenance yard, cask maintenance facility, and Nevada Rail Control
39 Center and National Transportation Operation Center would also be required. Construction
40 would take 4 to 10 years and cost \$2.57 billion. Construction activities would occur inside a
41 1000 ft (300 m) wide ROW for a total footprint of 40,600 acres (164 km²) (DOE 2008).
42
43

44 ***Montezuma Peak HMA and Paymaster HMA Wild Horse and Burro Gather.*** The BLM
45 Tonopah Field Office is proposing to conduct a wild horse and burro gather to remove
46 approximately 182 wild horses and burros residing primarily outside the boundaries of the

1 HMAs. The Montezuma Peak HMA is located west of the town of Goldfield, 32 mi (51 km)
2 southeast of the SEZ and encompasses approximately 77,931 acres (315 km²). The Paymaster
3 HMA is 7 mi (11 km) west of Tonopah, 8 mi (13 km) southeast of the SEZ and encompasses
4 100,500 acres (425 km²) (BLM 2010b).

5
6
7 **Existing Geothermal Leases.** There is a small, contiguous cluster of five producing
8 geothermal leases located about 32 mi (51 km) southwest of the proposed SEZ, shown in
9 Figure 11.7.22.2-1.

10 11 12 **Grazing**

13
14 The Monte Cristo grazing allotment is in the immediate vicinity of the SEZ.

15 16 17 **Mining**

18
19 The existing Round Mountain gold mine and proposed expansion is discussed above in
20 this section.

21 22 23 **11.7.22.3 General Trends**

24
25 General trends of population growth, energy demand, water availability, and climate
26 change for the proposed Millers SEZ are presented in this section. Table 11.7.22.2-4 lists the
27 relevant impacting factors for the trends.

28 29 30 **11.7.22.3.1 Population Growth**

31
32 Over the period 2000 to 2008, the population grew annually by 3.9% in Nye County but
33 the population fell by –4.6% annually in Esmeralda County and by –1.1 in Mineral County, the
34 ROI for the Millers SEZ (see Section 11.7.19.1.5). The population of the ROI in 2008 was
35 49,487, having grown at an average annual rate of 3.2% since 2000. The annual growth rate for
36 the state of Nevada as a whole was 3.4%.

37 38 39 **11.7.22.3.2 Energy Demand**

40
41 The growth in energy demand is related to population growth through increases in
42 housing, commercial floorspace, transportation, manufacturing, and services. Given that
43 population growth is expected in seven-SEZ areas in Nevada between 2006 and 2016, an
44 increase in energy demand is also expected. However, the EIA projects a decline in per-capita
45 energy use through 2030, mainly because of improvements in energy efficiency and the high
46 cost of oil throughout the projection period. Primary energy consumption in the United States

TABLE 11.7.22.2-4 General Trends Relevant to the Proposed SEZs in Nevada

General Trend	Impacting Factors
Population growth	Urbanization Increased use of roads and traffic Land use modification Employment Education and training Increased resource use (e.g., water and energy) Tax revenue
Energy demand	Increased resource use Energy development (including alternative energy sources) Energy transmission and distribution
Water availability	Drought conditions and water loss Conservation practices Changes in water distribution
Climate change	Water cycle changes Increased wildland fires Habitat changes Changes in farming production and costs

between 2007 and 2030 is expected to grow by about 0.5% each year, with the fastest growth projected for the commercial sector (at 1.1% each year). Transportation, residential, and industrial energy consumption are expected to grow by about 0.5, 0.4, and 0.1% each year, respectively (EIA 2009).

11.7.22.3.3 Water Availability

As described in Section 11.7.9.1.3, the perennial yield of the Tonopah Flat groundwater basin is set at 6,000 ac-ft/yr (7.4 million m³/yr), and water rights in the basin are over-appropriated with a total of 19,588 ac-ft/yr (24.2 million m³/yr) being allotted for irrigation, mining, municipal, and stockwater uses (95% of allotments used for irrigation and mining [NDWR 2010a]).

The general groundwater flow pattern in the Tonopah Flat basin is from northeast to southwest along the axis of the valley. The depth to groundwater ranges from 8 to 78 ft (2 to 24 m) below the land surface within a 5-mi (8-km) radius of the proposed SEZ (USGS 2010b). In general, depth to groundwater is greater in the northern portion of the Tonopah Flat basin and is near surface levels in the vicinity of the dry lake playas in the south portion of the basin (Meinzer 1917; Rush and Schroer 1971).

1 In 2005, water withdrawals from surface waters and groundwater in Esmeralda County
2 were 46,786 million ac-ft/yr (57.7 million m³/yr), of which 9% came from surface waters and
3 91% came from groundwater. The largest water use categories for groundwater were irrigation
4 and mining at 28,235 and 14,202 ac-ft/yr (34.8 million and 17.5 million m³/yr), respectively. The
5 remaining groundwater withdrawals were used for domestic and livestock (Kenny et al. 2009). In
6 the Tonopah Flat basin, groundwater extractions totaled 260 ac-ft/yr (320,700 m³/yr) in 1968,
7 which was primarily used for irrigation purposes (Rush and Schroer 1971).
8
9

10 **11.7.22.3.4 Climate Change**

11
12 Governor Jim Gibbons' Nevada Climate Change Advisory committee (NCCAC)
13 conducted a study of climate change and its effects on Nevada (NCCAC 2008). The report
14 summarized the present scientific understanding of climate change and its potential impacts
15 on Nevada. A report on global climate change in the United States prepared by the U.S. Global
16 Research Change Program (GCRP 2009) documents current temperature and precipitation
17 conditions and historic trends. Excerpts of the conclusions from these reports indicate:
18

- 19 • Decreased precipitation, with a greater percentage of that precipitation coming
20 from rain, will result in a greater likelihood of winter and spring flooding and
21 decreased stream flow in the summer.
22
- 23 • The average temperature in the Southwest has already increased by about
24 1.5°F (0.08°C) compared to a 1960 to 1979 baseline, and by the end of the
25 century, the average annual temperature is projected to rise 4°F to 10°F (2.2 to
26 5.5°C).
27
- 28 • Warming climate and the related reduction in spring snowpack and soil
29 moisture have increased the length of the wildfire season and intensity of
30 forest fires.
31
- 32 • Later snow and less snow coverage in ski resort areas could force ski areas to
33 shut down before the season would otherwise end.
34
- 35 • Much of the Southwest has experienced drought conditions since 1999. This
36 represents the most severe drought in the last 110 years. Projections indicate
37 an increasing probability of drought in the region.
38
- 39 • As temperatures rise, landscape will be altered as species shift their ranges
40 northward and upward to cooler climates.
41
- 42 • Temperature increases, when combined with urban heat island effects for
43 major cities such as Las Vegas, present significant stress to health, electricity,
44 and water supply.
45

- Increased minimum temperatures and warmer springs extend the range and lifetime of many pests that stress trees and crops, and lead to northward migration of weed species.

11.7.22.4 Cumulative Impacts on Resources

This section addresses potential cumulative impacts in the proposed Millers SEZ on the basis of the following assumptions: (1) because of the moderate size of the proposed SEZ (10,000 to 30,000 acres [40.5 to 121 km²]), up to two projects could be constructed at a time, and (2) maximum total disturbance over 20 years would be about 13,430 acres (54.4 km²) (80% of the entire proposed SEZ). For purposes of analysis, it is also assumed that no more than 3,000 acres (12.1 km²) would be disturbed per project annually and 250 acres (1.01 km²) monthly on the basis of construction schedules planned in current applications. Since an existing 120-kV transmission line runs through the SEZ, no analysis of impacts has been conducted for the construction of a new transmission line outside of the SEZ that might be needed to connect solar facilities to the regional grid (see Section 11.7.1.2). Regarding site access, because U.S. 95/U.S. 6 runs from east to west along the southern border of the SEZ, no major road construction activities outside of the SEZ would be needed to support solar development in the SEZ.

Cumulative impacts that would result from the construction, operation, and decommissioning of solar energy development projects within the proposed SEZ when added to other past, present, and reasonably foreseeable future actions described in the previous section in each resource area are discussed below. At this stage of development, because of the uncertain nature of the future projects in terms of size, number, location within the proposed SEZ, and the types of technology that would be employed, the impacts are discussed qualitatively or semi-quantitatively, with ranges given as appropriate. More detailed analyses of cumulative impacts would be performed in the environmental reviews for the specific projects in relation to all other existing and proposed projects in the geographic areas.

11.7.22.4.1 Lands and Realty

The area covered by the proposed Millers SEZ is largely isolated and undeveloped. In general, the areas surrounding the SEZ are rural in nature. Existing dirt roads from separate access points on U.S. 95/U.S. 6 provide access to the southern portion of the SEZ. Numerous dirt/ranch roads provide access throughout the SEZ (Section 11.7.2.1).

Development of the SEZ for utility-scale solar energy production would establish a large industrial area that would exclude many existing and potential uses of the land, perhaps in perpetuity. Access to such areas by both the general public and much wildlife would be eliminated. Traditional uses of public lands would no longer be allowed. Utility-scale solar energy development would be a new and discordant land use in the area.

1 As shown in Table 11.7.22.2-2 and Figure 11.7.22.2-1, there is one fast-track solar
2 application, one pending solar application, one pending wind site testing application, four
3 authorized wind site testing projects, two authorized geothermal projects, and five producing
4 geothermal lease agreements within a 50-mi (80-km) radius of the proposed Millers SEZ. There
5 are currently no solar applications within the SEZ. The Crescent Dunes Solar Energy Project
6 fast-track solar application lies about 3 mi (5 km) northeast of the SEZ. The mix of renewable
7 energy applications indicates modest interest in renewable energy development of all three major
8 types within 50 mi (80 km) of the proposed SEZ, but only the fast-track solar application and the
9 Darrough Hot Springs geothermal project are considered firmly foreseeable projects
10 (Section 11.7.22.2.1).

11
12 The Round Mountain Mine Expansion project is the only other major foreseeable action
13 identified within this distance. The mine is located 45 mi (72 km) north of the proposed SEZ
14 (Section 11.7.22.2.2), and the expansion would have minimal impacts on land use near the SEZ.

15
16 The development of utility-scale solar projects in the proposed Millers SEZ in
17 combination with other ongoing, foreseeable, and potential actions within the geographic extent
18 of effects, nominally 50 mi (80 km), could have cumulative effects on land use in the vicinity of
19 the proposed SEZ. Ongoing and foreseeable actions on or near the SEZ could result in small
20 cumulative impacts on land use through impacts on land access, groundwater availability, and on
21 visual resources, especially if the SEZ is fully developed with solar projects.

22 23 24 **11.7.22.4.2 Specially Designated Areas and Lands with Wilderness Characteristics**

25
26 There are no specially designated areas within 25 mi (40 km) of the proposed Millers
27 SEZ in Nevada (Section 11.7.3.1). Thus, no potential exists for cumulative visual impacts on
28 such areas from the construction of utility-scale solar energy facilities within the SEZ.

29 30 31 **11.7.22.4.3 Rangeland Resources**

32
33 The proposed Millers SEZ contains a small portion of one perennial grazing allotment
34 (Section 11.7.4.1.1). If utility-scale solar facilities were constructed on the SEZ, those areas
35 occupied by the solar projects would be excluded from grazing. The effects of other renewable
36 energy projects within the geographic extent of effects, including pending solar, wind, and
37 geothermal applications within 50 mi (80 km) of the SEZ that are ultimately developed, would
38 not likely result in cumulative impacts on grazing due to the small number and distance of the
39 proposed facilities from the proposed SEZ. Other foreseeable projects would likewise have
40 minimal effects on grazing. However, any closure of county roads or interconnected roads on the
41 SEZ could affect access to grazing areas outside the SEZ unless rerouted. Mitigations would
42 minimize such effects.

43
44 A number of BLM HMAs and HAs occur within the 50-mi (80-km) SEZ region for the
45 proposed Millers SEZ (Section 11.7.4.2.1), including two within the 5-mi (8-km) area of indirect
46 effects. While such areas near the proposed SEZ contain wild horses, potential indirect impacts

1 from development within the SEZ would be mitigated. Since foreseeable projects within this
2 distance would have minimal effects on wild horses and burros, cumulative impacts are unlikely
3 to occur.

6 **11.7.22.4.4 Recreation**

7
8 Limited outdoor recreation (e.g., backcountry driving, OHV use, and some camping and
9 hunting) occurs on or in the immediate vicinity of the SEZ. While there are no current solar
10 applications within the proposed SEZ, construction of utility-scale solar projects on the SEZ
11 would preclude recreational use of the affected lands for the duration of the projects. Road
12 closures and access restrictions within the proposed SEZ would affect access to recreation both
13 inside and outside the SEZ. OHV use in particular could be affected. Foreseeable and potential
14 actions would also affect areas of low recreational use and would have minimal effects on
15 current recreational activities. Thus, cumulative impacts on recreation within the geographic
16 extent of effects are not expected.

19 **11.7.22.4.5 Military and Civilian Aviation**

20
21 The eastern two-thirds of the proposed SEZ is covered by MTRs with 50- and 100-ft
22 (15- and 30-m) AGL operating limits. The area is located about 30 mi (48 km) northwest of the
23 boundary of the NTTR. The closest civilian municipal aviation facility is the Tonopah Municipal
24 Airport, which is located about 20 mi (32 km) southeast of the SEZ. The military has expressed
25 serious concern over possible solar energy facilities within the SEZ and at the fast-track solar
26 energy site east of the SEZ. Nellis Air Force Base has indicated that any facilities higher than
27 50 ft (15 m) AGL may present unacceptable electromagnetic compatibility concerns for their test
28 mission (Section 11.7.6.2). Potential new solar, wind, and geothermal facilities and associated
29 new transmission lines outside the SEZ could present additional concerns for military aviation,
30 depending on the eventual location of such facilities with respect to training routes, and thus,
31 could result in cumulative impacts on military aviation. The Tonopah Airport is located at a
32 distance where there would be no effect on airport operations by facilities in the SEZ.

35 **11.7.22.4.6 Soil Resources**

36
37 Ground-disturbing activities (e.g., grading, excavating, and drilling) during the
38 construction phase of a solar project, including the construction of any associated transmission
39 line connections and new roads, would contribute to soil loss due to wind erosion. Road use
40 during construction, operations, and decommissioning of the solar facilities would further
41 contribute to soil loss. Programmatic design features would be employed to minimize erosion
42 and loss. Residual soil losses with mitigations in place would be in addition to losses from
43 construction of other potential renewable energy facilities, proposed transmission lines, proposed
44 water line, and recreational uses. Cumulative impacts on soil resources from other foreseeable
45 projects within the geographic extent of effects are possible. The proposed 1,600-acre (6.5-km²)
46 fast-track Crescent Dunes Solar Energy Project would be located 3 mi (5 km) east of the SEZ

1 and would contribute incremental impacts on soils, as could some number of the pending
2 geothermal projects located to the southwest. Such future impacts from renewable energy
3 projects could produce small cumulative increases over those from any development in the SEZ.
4

5 Landscaping of solar energy facility areas in the SEZ could alter drainage patterns and
6 lead to increased siltation of surface water streambeds, in addition to that from other foreseeable
7 projects and other activities (e.g., OHV use, outside the SEZ). However, with the required
8 programmatic design features in place, cumulative impacts would be small.
9

10 11 **11.7.22.4.7 Minerals (Fluids, Solids, and Geothermal Resources)** 12

13 As discussed in Section 11.7.8, about two-thirds of the proposed Millers SEZ is covered
14 by placer mining claims, which would represent prior existing rights, as well as potential
15 limitations on solar development. Conversely, additional mining claims could be foreclosed if
16 the SEZ was identified for solar development. In addition, any road closures on the SEZ could
17 affect access to mining areas outside the SEZ. There are currently no active oil and gas leases
18 within the proposed SEZ, while there are proposals for geothermal energy development pending.
19 Because of the expected low impact on mineral accessibility of other foreseeable actions within
20 the geographic extent of effects, and minimization and mitigation of road access closures,
21 cumulative impacts on mineral resources are not expected.
22

23 24 **11.7.22.4.8 Water Resources** 25

26 Section 11.7.9.2 describes the water requirements for various technologies if they were to
27 be employed on the proposed SEZ to develop utility-scale solar energy facilities. The amount of
28 water needed during the peak construction year for all evaluated solar technologies would be
29 2,288 to 3,300 ac-ft (2.8 million to 4.1 million m³). During operations, with full development of
30 the SEZ over 80% of its available land area, the amount of water needed for all evaluated solar
31 technologies would range from 77 to 40,327 ac-ft/yr (95 thousand to 50 million m³). The amount
32 of water needed during decommissioning would be similar to or less than the amount used
33 during construction. As discussed in Section 11.7.22.3.3, water withdrawals in 2005 from surface
34 waters and groundwater in Esmeralda County were 46,786 ac-ft/yr (57.7 million m³/yr), of
35 which 9% came from surface waters and 91% came from groundwater. The largest water
36 use categories for groundwater were irrigation and mining at 28,235 and 14,202 ac-ft/yr
37 (34.8 million and 17.5 million m³/yr), respectively. Therefore, cumulatively the additional
38 water resources needed for solar facilities in the SEZ during operations would constitute from a
39 relatively small (0.2%) to a very large (86%) increment (the ratio of the annual operations water
40 requirement to the annual amount withdrawn in Esmeralda County), depending on the solar
41 technology used (PV technology at the low end and the wet-cooled parabolic trough technology
42 at the high end). However, as discussed in Section 11.7.9.1.3, very little water has been
43 historically withdrawn from the Tonopah Flat basin, roughly 260 ac-ft/yr (320,700 m³/yr). The
44 perennial yield of the basin is set at 6,000 ac-ft/yr (7.4 million m³/yr), and water rights in the
45 basin are over-appropriated. Thus, even if water rights were available, solar facilities on the SEZ
46 would have the capacity to far exceed the physically available groundwater in the basin using

1 wet cooling, while full development with dry-cooled solar trough technologies could require
2 two-thirds of estimated basin yields (Section 11.7.9.2.2).

3
4 While solar development of the proposed SEZ with water-intensive technologies would
5 likely be infeasible due to impacts on groundwater supplies and restrictions on water rights,
6 excessive groundwater withdrawals could affect groundwater and surface water flows, cause
7 drawdown of groundwater, modify natural drainage pathways, obstruct natural recharge zones,
8 and alter surface water-wetland-groundwater connectivity in the Tonopah Flat basin
9 (Section 11.7.9.2). Therefore the use of groundwater monitoring wells is encouraged in order to
10 determine the actual impact of development within the SEZ on the water table. Small cumulative
11 impacts could occur when combined with other future projects in the region. The proposed fast-
12 track Crescent Dunes Solar Energy Project, which would be located 3 mi (5 km) east of the SEZ,
13 would use hybrid cooling, which would minimize water use, while the authorized geothermal
14 leases to the southwest would not likely contribute to groundwater impacts in the Tonopah Flats
15 basin.

16
17 Small quantities of sanitary wastewater would be generated during the construction and
18 operation of the potential utility-scale solar energy facilities. The amount generated from solar
19 facilities would be in the range of 19 to 148 ac-ft (23 to 183 thousand m³) during the peak
20 construction year and would range from 2 to 38 ac-ft/yr (up to 47,000 m³/yr) during operations.
21 Because of the small quantity, the sanitary wastewater generated by the solar energy facilities
22 would not be expected to put undue strain on available sanitary wastewater treatment facilities
23 in the general area of the SEZ. For technologies that rely on conventional wet-cooling systems,
24 there would also be from 424 to 763 ac-ft/yr (0.52 to 0.94 million m³) of blowdown water from
25 cooling towers. Blowdown water would need to be either treated on-site or sent to an off-site
26 facility. Any on-site treatment of wastewater would have to ensure that treatment ponds are
27 effectively lined in order to prevent any groundwater contamination. Thus, blowdown water
28 would not contribute to cumulative effects on treatment systems or on groundwater.

30 31 **11.7.22.4.9 Vegetation**

32
33 The proposed Millers SEZ is located within the Tonopah Basin ecoregion, which
34 primarily supports sparse shadscale communities. Lands within the SEZ are classified primarily
35 as Inter-Mountain Basins Mixed Salt Desert Scrub. Much of the SEZ consists of north to south
36 trending broad, barren, gravel-covered washes, with small scattered playa areas, with shadscale
37 and fourwing saltbush along the margins or in isolated stands. In the 5-mi (8-km) area of indirect
38 effects, the predominant cover type is Inter-Mountain Basins Mixed Salt Desert Scrub. If utility-
39 scale solar energy projects were to be constructed within the SEZ, all vegetation within the
40 footprints of the facilities would likely be removed during land-clearing and land-grading
41 operations. Full development of the SEZ over 80% of its area would result in up to moderate
42 impacts on certain cover types (Section 11.7.10.2.1). Wetlands and associated playa habitats
43 could be affected by project development, while intermittently flooded areas downgradient
44 from solar projects or access road could be affected by ground-disturbing activities. Alteration
45 of surface drainage patterns or hydrology could adversely affect downstream dry wash

1 communities. Wetland and riparian habitats outside of the SEZ that are supported by
2 groundwater discharge could be affected by hydrologic changes resulting from project activities.
3

4 The fugitive dust generated during the construction of the solar facilities could increase
5 the dust loading in habitats outside a solar project area, in combination with that from other
6 construction, mining, agriculture, recreation, and transportation. The cumulative dust loading
7 could result in reduced productivity or changes in plant community composition. Similarly,
8 surface runoff from project areas after heavy rains could increase sedimentation and siltation in
9 areas downstream. Programmatic design features would be used to reduce the impacts from solar
10 energy projects and thus reduce the overall cumulative impacts on plant communities and
11 habitats. While most of the cover types within the SEZ are relatively common in the greater SEZ
12 region, at least one cover type, Mojave Mid-Elevation Mixed Desert Scrub, is relatively
13 uncommon, representing 1% or less of the land area within the region. Thus, other ongoing and
14 reasonably foreseeable future actions would have a cumulative effect on this and other rare cover
15 types as well as on more abundant species. Such effects could be moderate with full build-out of
16 the SEZ, but would likely fall to small for foreseeable development due to the abundance of the
17 primary species and the relatively small number of foreseeable actions within the geographic
18 extent of effects. However, the proposed fast-track Crescent Dunes Solar Energy Project
19 covering 1,600 acres (174 km²) and located about 3 mi (5 km) east of the proposed SEZ
20 (Section 11.7.22.2.2), could contribute to cumulative effects on some rare cover types if they are
21 present in the development area. In addition, cumulative effects on wetland species could occur
22 from water use, drainage modifications, and stream sedimentation from this and any other future
23 projects in the region. The magnitude of such effects is difficult to predict at the current time.
24
25

26 **11.7.22.4.10 Wildlife and Aquatic Biota** 27

28 Wildlife species that could potentially be affected by the development of utility-scale
29 solar energy facilities in the proposed Millers SEZ include amphibians, reptiles, birds, and
30 mammals. The construction of utility-scale solar energy projects in the SEZ and any associated
31 transmission lines and roads in or near the SEZ would have an impact on wildlife through habitat
32 disturbance (i.e., habitat reduction, fragmentation, and alteration), wildlife disturbance, and
33 wildlife injury or mortality. In general, impacted species with broad distributions and a variety of
34 habitats would be less affected than species with a narrowly defined habitat within a restricted
35 area. The use of programmatic design features would reduce the severity of impacts on wildlife.
36 These design features may include pre-disturbance biological surveys to identify key habitat
37 areas used by wildlife, followed by avoidance or minimization of disturbance to those habitats.
38

39 As noted in Section 11.7.22.2, other ongoing, reasonably foreseeable and potential future
40 actions within 50 mi (80 km) of the proposed SEZ include one fast-track solar application, one
41 pending solar development application, one pending wind site testing application, four
42 authorized wind site testing applications, two authorized geothermal lease agreements, and five
43 producing geothermal lease agreements (Figure 11.7.22.2-1). While impacts from full build-out
44 over 80% of the proposed SEZ would result in small to moderate impacts on some amphibian,
45 reptile, and bird species and small impacts on mammal species (Section 11.7.11), impacts from
46 foreseeable development within the 50-mi (80-km) geographic extent of effects would be small.

1 Many of the wildlife species present within the proposed SEZ that could be affected by other
2 actions have extensive available habitat within the region, while only one foreseeable solar and
3 no foreseeable wind projects have been firmly identified within the geographic extent of effects.
4 The pending solar, wind, and geothermal applications in the region could contribute to small
5 cumulative effects, however, as would one foreseeable fast-track solar project. The proposed
6 Crescent Dunes Solar Energy Project covering 1,600 acres (174 km²) would be located about
7 3 mi (5 km) east of the proposed SEZ and could contribute to cumulative effects on some species
8 from habitat disturbance.
9

10 There are no surface water bodies or perennial streams within the proposed Millers SEZ
11 or within the 5-mi (8-km) area of indirect effects. One named intermittent/ephemeral wash
12 (Ione Wash) runs for approximately 3 mi (5 km) through the center of the SEZ. This and other
13 ephemeral washes in the SEZ are typically dry and flow only after precipitation, while identified
14 wetlands present in the SEZ rarely contain water. Thus, no standing aquatic communities are
15 likely to be present in the proposed SEZ. Aquatic communities do exist within the 50-mi (80-km)
16 geographic extent of effects, but the nearest perennial surface water feature is more than 35 mi
17 (56 km) from the SEZ (Section 11.7.11.2). Thus, potential contributions to cumulative impacts
18 on aquatic biota and habitats resulting from water or airborne soil transport to surface streams
19 from solar facilities within the SEZ and within the geographic extent of effects are unlikely.
20 There is little foreseeable development within the geographic extent of effects that would affect
21 the same aquatic habitats potentially affected by the proposed SEZ. Adverse impacts on aquatic
22 habitats from groundwater drawdown are unlikely because groundwater is already fully
23 appropriated, and solar energy developers would have to purchase and transfer existing water
24 rights.
25
26

27 ***11.7.22.4.11 Special Status Species (Threatened, Endangered, Sensitive,*** 28 ***and Rare Species)*** 29

30 On the basis of recorded occurrences or suitable habitat, as many as 19 special status
31 species could occur within the Millers SEZ. Of these species, two are known to occur within the
32 affected area of the SEZ: Tonopah milkvetch and western small-footed bat. No groundwater-
33 dependent species and no potentially suitable habitat for the desert tortoise, a species listed as
34 threatened under the ESA, occurs within the affected area of the SEZ. Numerous additional
35 species that occur on or in the vicinity of the SEZ are listed as threatened or endangered by the
36 states of Nevada or California or listed as a sensitive species by the BLM (Section 11.7.12.1).
37 Programmatic design features to be used to reduce or eliminate the potential for effects on these
38 species from the construction and operation of utility-scale solar energy projects in the SEZs and
39 related projects (e.g., access roads and transmission line connections) outside the SEZ include
40 avoidance of habitat and minimization of erosion, sedimentation, and dust deposition. Ongoing
41 effects on special status species include those from roads, transmission lines, and recreational
42 activities in the area. However, the amount of foreseeable development within the geographic
43 extent of effects is low, including mainly one foreseeable fast-track solar and several potential
44 solar, wind and geothermal projects. Cumulative impacts on protected species are possible but
45 are expected to be relatively low. Actual impacts would depend on the number, location, and

1 cooling technologies of projects that are actually built. Projects would employ mitigation
2 measures to limit effects.

3 4 5 **11.7.22.4.12 Air Quality and Climate** 6

7 While solar energy generates minimal emissions compared with fossil fuels, the site
8 preparation and construction activities associated with solar energy facilities would be
9 responsible for some amount of air pollutants. Most of the emissions would be particulate matter
10 (fugitive dust) and emissions from vehicles and construction equipment. When these emissions
11 are combined with those from other nearby projects outside the proposed Millers SEZ or when
12 they are added to natural dust generation from winds and windstorms, the air quality in the
13 general vicinity of the projects could be temporarily degraded. For example, the maximum
14 24-hour PM₁₀ concentration at or near the SEZ boundaries could at times exceed the applicable
15 standard of 150 µg/m³. The dust generation from the construction activities can be controlled by
16 implementing aggressive dust control measures, such as increased watering frequency or road
17 paving or treatment.

18
19 Because the area proposed for the SEZ is rural and undeveloped land, there are no
20 significant industrial sources of air emissions in the area. The only type of air pollutant of
21 concern is dust generated by winds. Because the number of other foreseeable and potential
22 actions that could produce fugitive dust emissions is small, while such projects are unlikely to
23 overlap in both time and affected area, cumulative air quality effects due to dust emissions
24 during any overlapping construction periods would be small.

25
26 Over the long term and across the region, the development of solar energy may have
27 beneficial cumulative impacts on the air quality and atmospheric values by offsetting the need
28 for energy production that results in higher levels of emissions, such as coal, oil, and natural gas.
29 As discussed in Section 11.7.13.2.2, air emissions from operating solar energy facilities are
30 relatively minor, while the displacement of criteria air pollutants, VOCs, TAPs, and GHG
31 emissions currently produced from fossil fuels could be significant. For example, if the Millers
32 SEZ were fully developed (80% of its acreage) with solar facilities, the quantity of pollutants
33 avoided could be as large as 12% of all emissions from the current electric power systems in
34 Nevada.

35 36 37 **11.7.22.4.13 Visual Resources** 38

39 The proposed Millers SEZ is located in a flat treeless plain in the Big Smoky Valley. The
40 SEZ is bounded by mountain ranges on the east, south and west, with open views to the northeast
41 and southwest (Section 11.7.14.1). The area is sparsely inhabited, remote, and rural in character.
42 Currently, there is a low level of cultural disturbance, including from existing transmission lines,
43 fences and roads. Construction of utility-scale solar facilities on the SEZ and associated
44 transmission lines outside the SEZ would significantly alter the natural scenic quality of the area.
45 Other potential solar, wind, and geothermal projects and related roads and transmission lines
46 outside the proposed SEZ would cumulatively affect the visual resources in the area. Because of

1 the large size of utility-scale solar energy facilities and the generally flat, open nature of the
2 proposed SEZ, some lands outside the SEZ would also be subjected to visual impacts related to
3 the construction, operation, and decommissioning of utility-scale solar energy facilities. Potential
4 impacts would include night sky pollution, including increased skyglow, light spillage, and glare.

5
6 Visual impacts resulting from solar energy development within the SEZ would be in
7 addition to impacts caused by other potential projects in the area. There is currently only one
8 foreseeable fast-track solar facility application, about 3 mi (5 km) east of the SEZ, and several
9 pending solar, wind and geothermal applications within 50 mi (80 km) of the SEZ
10 (Figure 11.7.22.2-1). While the contribution to cumulative impacts in the area of foreseeable and
11 potential projects would depend on the location of facilities that are actually built, it may be
12 concluded that the general visual character of the landscape within this distance could be
13 significantly altered by the presence of solar facilities, transmission lines, and other new
14 infrastructure. Because of the topography of the region, such projects, located in basin flats,
15 would be visible at great distances from surrounding mountains, which include sensitive
16 viewsheds. Given the proximity of the foreseeable fast-track solar project 3 mi (5 km) east of the
17 proposed SEZ, it is possible that two or more facilities would be viewable from a single location.
18 In addition, facilities would be located near major roads and thus would be viewable by
19 motorists, who would also be viewing transmission lines, towns, and other infrastructure, as well
20 as the road system itself.

21
22 As additional facilities are added, several projects might become visible from one
23 location, or in succession, as viewers move through the landscape, as by driving on local roads.
24 In general, the new projects would not be expected to be consistent in terms of their appearance
25 and, depending on the number and type of facilities, the resulting visual disharmony could
26 exceed the visual absorption capability of the landscape and add significantly to the cumulative
27 visual impact. Considering the above in light of the fact that relatively few foreseeable and
28 potential solar, wind, and geothermal projects have been identified, small cumulative visual
29 impacts could occur within the geographic extent of effects from future solar, wind, geothermal,
30 and other existing and future projects.

31 32 33 **11.7.22.4.14 Acoustic Environment**

34
35 The areas around the proposed Millers SEZ are relatively quiet. The existing noise
36 sources around the SEZ include road traffic, aircraft flyover, and cattle grazing. Other noise
37 sources are associated with current land use around the SEZ, including OHV use.
38 The construction of solar energy facilities could increase the noise levels periodically for up to
39 3 years per facility, but there would be little or no noise during the operation of solar facilities,
40 except from solar dish engine facilities and from parabolic trough or power tower facilities using
41 TES, which could also minimally affect nearby residences due to considerable separation
42 distances.

43
44 Other ongoing and reasonably foreseeable and potential future activities in the general
45 vicinity of the SEZs are described in Section 11.7.22.2. Because proposed projects and the
46 nearest residents are relatively far from the SEZ with respect to noise impacts and the area is

1 sparsely populated, cumulative noise effects during the construction or operation of solar
2 facilities are unlikely.

3 4 5 **11.7.22.4.15 Paleontological Resources** 6

7 The proposed Millers SEZ has unknown, but potentially high, potential for the
8 occurrence of significant fossil material in 94% of its area, mainly lacustrine deposits, and
9 low potential in about 6% of its area, mainly alluvial deposits (Section 11.7.16.1). Surveys of
10 the lacustrine and playa deposits would likely be needed prior to project approval. Any
11 paleontological resources encountered would be mitigated to the extent possible. No significant
12 cumulative impacts on paleontological resources are expected, but such a determination would
13 depend on the results of future paleontological investigations.
14

15 16 **11.7.22.4.16 Cultural Resources** 17

18 The proposed Millers SEZ is rich in cultural history, with settlements dating as far back
19 as 12,000 years. The area covered by the SEZ has the potential to contain significant cultural
20 resources. At least 4 surveys have been conducted within the boundaries of the SEZ, and
21 49 additional surveys have been conducted within 5 mi (8 km) of the SEZ, resulting in the
22 recording of 30 sites within SEZ and at least 100 sites located within 5 mi (8 km) of the SEZ
23 (Section 11.7.17.1). Areas with potential for significant sites within the proposed SEZ include
24 dune areas near the former Lake Tonopah, related to exploitation of lacustrine resources, and
25 historic resources associated with the Millers town site. It is possible that the development of
26 utility-scale solar energy projects in the SEZ, when added to other potential projects likely to
27 occur in the area, could contribute cumulatively to cultural resource impacts occurring in the
28 region. However, the amount of potential and foreseeable development is low, including one
29 fast-track solar project and four authorized geothermal leases within the 25-mi (40-km)
30 geographic extent of effects (Section 11.7.22.2). While any future solar projects would disturb
31 large areas, the specific sites selected for future projects would be surveyed; historic properties
32 encountered would be avoided or mitigated to the extent possible. Through ongoing consultation
33 with the Nevada SHPO and appropriate Native American Tribes, it is likely that many adverse
34 effects on significant resources in the region could be mitigated to some degree. Because the
35 proposed Millers SEZ occupies the area of a Late Pleistocene lakebed, it is possible that
36 development of this SEZ could cumulatively cause an irretrievable loss of information on
37 significant sites pertaining to this prehistoric lake system. Pre-disturbance surveys for cultural
38 sites would identify areas for potential use or avoidance.
39
40

41 **11.7.22.4.17 Native American Concerns** 42

43 Major Native American concerns in arid portions of the Great Basin include water,
44 culturally important plant and animal resources, and culturally important landscapes. The
45 development of utility-scale solar energy facilities within the proposed Millers SEZ in
46 combination with the foreseeable development in the surrounding area could cumulatively

1 contribute to effects on these resources. Development of the SEZ would result in the removal of
2 plant species from the footprint of the facility during construction. This would include some
3 plants of cultural importance. However, the primary species that would be affected are abundant
4 in the region; thus the cumulative effect would likely be small. Likewise, habitat for important
5 species, such as the black-tailed jack rabbit, would be reduced; however, extensive habitat is
6 available in the area, reducing the cumulative effect. The cultural importance of the mountains
7 surrounding the SEZ is as yet undetermined. If culturally important, the view from these features
8 can be an important part of their cultural integrity. The degree of impact on these resources of
9 development at specific locations must be determined in consultation with the Native American
10 Tribes whose traditional use area includes the proposed SEZ. In general, Tribes prefer that
11 development occur on previously disturbed land, and this SEZ is largely undeveloped.
12 Government-to-government consultation is under way with federally recognized Native
13 American Tribes with possible traditional ties to the Millers area. All federally recognized
14 Tribes with Western Shoshone, Northern Paiute, or Owens Valley Paiute roots have been
15 contacted and provided an opportunity to comment or consult regarding this PEIS. To date, no
16 specific concerns have been raised to the BLM regarding the proposed Millers SEZ. However,
17 the Big Pine Paiute Tribe of the Owens Valley has commented on the scope of this PEIS,
18 recommending that already disturbed lands be preferred for solar development while preserving
19 undisturbed lands. Potential impacts on existing water supplies are also of concern to tribes
20 (Section 11.7.18.2). Continued discussions with the area Tribes through government-to-
21 government consultation is necessary to effectively consider and address the Tribes' concern tied
22 to solar energy development in the proposed Millers SEZ.

23 24 25 **11.7.22.4.18 Socioeconomics** 26

27 Solar energy development projects in the proposed Millers SEZ could cumulatively
28 contribute to socioeconomic effects in the immediate vicinity of the SEZs and in the surrounding
29 multicounty ROI. The effects could be positive (e.g., creation of jobs and generation of extra
30 income, increased revenues to local governmental organizations through additional taxes paid by
31 the developers and workers) or negative (e.g., added strain on social institutions such as schools,
32 police protection, and health care facilities). Impacts from solar development would be most
33 intense during facility construction, but of greatest duration during operations. Construction
34 would temporarily increase the number of workers in the area needing housing and services in
35 combination with temporary workers involved in other new projects in the area, including other
36 renewable energy development. Local, county, and state roads could be affected by traffic loads.
37 The number of workers involved in the construction of solar projects in the peak construction
38 year (including the transmission lines) could range from about 250 to 3,300 depending on the
39 technology being employed, with solar PV facilities at the low end and solar trough facilities at
40 the high end. The total number of jobs created in the area could range from approximately
41 350 (solar PV) to as high as 4,600 (solar trough). Cumulative socioeconomic effects in the ROI
42 from construction of solar facilities would occur to the extent that multiple construction projects
43 of any type were ongoing at the same time. It is a reasonable expectation that this condition
44 would occur within a 50-mi (80-km) radius of the SEZ occasionally over the 20-year or more
45 solar development period.
46

1 Annual impacts during the operation of solar facilities would be less, but of 20- to
2 30-year duration, and could combine with those from other new projects in the area, including
3 from the fast-track Crescent Dunes Solar Energy Project, which would be located 3 mi (5km)
4 east of the proposed SEZ. The number of workers needed at the solar facilities in the SEZ would
5 be in the range of 30 to 600 with approximately 40 to 800 total jobs created in the region,
6 assuming full build-out of the SEZ (Section 11.7.19.2.2). Population increases would contribute
7 to general upward trends in the region in recent years. The socioeconomic impacts overall would
8 be positive, through the creation of additional jobs and income. The negative impacts, including
9 some short-term disruption of rural community quality of life, would not likely be considered
10 large enough to require specific mitigation measures.

11.7.22.4.19 *Environmental Justice*

11
12
13
14
15 Any impacts from solar development could have cumulative impacts on minority and
16 low-income populations within 50 mi (80 km) of the proposed SEZ in combination with other
17 development in the area. Such impacts could be both positive, such as from increased economic
18 activity, and negative, such as from visual impacts, noise, and exposure to fugitive dust. Actual
19 impacts would depend on where low-income populations are located relative to solar and other
20 proposed facilities and on the geographic range of effects. Overall, effects from facilities within
21 the SEZ are expected to be small, while other foreseeable and potential actions would not likely
22 combine with effects from the SEZ on minority and low-income populations. However, no
23 minority or low-income populations have been identified within the 50-mi (80-km) region of
24 interest around the SEZ (Section 11.7.20.2). Thus, it is not expected that the proposed Millers
25 SEZ would contribute to cumulative impacts on minority and low-income populations.

11.7.22.4.20 *Transportation*

26
27
28
29
30 U.S. 95/U.S. 6 runs along the southern border of the proposed Millers SEZ. The nearest
31 public airport is the Tonopah Airport, about 23 mi (37 km) east of the SEZ, and the closest
32 railroad access is the UP Railroad stop at Thorne, 90 mi (145 km) northwest of the SEZ.
33 During construction of utility-scale solar energy facilities, there could be up to 1,000 workers
34 commuting to the construction site at the SEZ, which could increase the AADT on these roads
35 by 2,000 vehicle trips for each facility under construction. With as many as two facilities
36 assumed under construction at the same time, traffic on U.S. 95/U.S. 6 could experience
37 slowdowns in the area of the SEZ (Section 11.7.21.2). This increase in highway traffic from
38 construction workers could likewise have moderate cumulative impacts in combination with
39 existing traffic levels and increases from additional future projects in the area, including from
40 construction of the fast-track Crescent Dunes Solar Energy 3 mi (5 km) east of the SEZ, should
41 construction schedules overlap. Local road improvements may be necessary on portions of
42 U.S. 95/U.S. 6 near the SEZ. Any impacts during construction activities would be temporary.
43 The impacts can also be mitigated to some degree by staggered work schedules and ride-sharing
44 programs. Traffic increases during operation would be relatively small because of the low
45 number of workers needed to operate the solar facilities and would have little contribution to
46 cumulative impacts.
