

**Final**

## **Record of Decision for Parcel E**

**Hunters Point Naval Shipyard  
San Francisco, California**

**December 2013**

Prepared by:

**Department of the Navy  
Base Realignment and Closure  
Program Management Office West  
1455 Frazee Road, Suite 900  
San Diego, California 92108**

Prepared under:

**Naval Facilities Engineering Command  
Contract Number N68711-05-C-6011**

| 1.1. Selected Remedy .....                                              | 1-2        |
| 1.2. Statutory Determinations.....                                      | 1-4        |
| 1.3. Data Certification Checklist .....                                 | 1-5        |
| 1.4. Authorizing Signatures.....                                        | 1-6        |
| <b>SECTION 2. DECISION SUMMARY .....</b>                                | <b>2-1</b> |
| 2.1. Site Description and History .....                                 | 2-1        |
| 2.2. Site Characteristics .....                                         | 2-5        |
| 2.3. Previous Investigations and Removal Actions .....                  | 2-7        |
| 2.3.1. Nonradioactive Chemicals in Soil and Shoreline Sediment.....     | 2-14       |
| 2.3.2. Nonradioactive Chemicals in Groundwater .....                    | 2-15       |
| 2.3.3. NAPLs at IR-03.....                                              | 2-16       |
| 2.3.4. Radionuclides in Soil, Shoreline Sediment, and Groundwater ..... | 2-16       |
| 2.4. Current and Potential Future Site Uses .....                       | 2-17       |
| 2.5. Summary of Site Risks .....                                        | 2-18       |
| 2.5.1. Human Health Risk Assessment .....                               | 2-19       |
| 2.5.2. Ecological Risk Assessment.....                                  | 2-22       |
| 2.5.3. Basis for Response Action .....                                  | 2-23       |
| 2.6. Principal Threat Waste .....                                       | 2-27       |
| 2.7. Remedial Action Objectives.....                                    | 2-27       |
| 2.8. Description and Evaluation of Remedial Alternatives .....          | 2-35       |
| 2.8.1. Description of Remedial Alternatives .....                       | 2-35       |
| 2.8.2. Comparative Analysis of Alternatives .....                       | 2-40       |
| 2.9. Selected Remedy .....                                              | 2-45       |
| 2.9.1. Rationale for Selected Remedies.....                             | 2-45       |
| 2.9.2. Description of Selected Remedy .....                             | 2-46       |
| 2.9.3. Expected Outcomes of the Selected Remedy .....                   | 2-59       |
| 2.9.4. Statutory Determinations.....                                    | 2-59       |
| 2.9.5. Documentation of Significant Changes.....                        | 2-61       |
| 2.10. Community Participation .....                                     | 2-61       |
| <b>SECTION 3. RESPONSIVENESS SUMMARY.....</b>                           | <b>3-1</b> |

## Section 1. Declaration

---

This Record of Decision (ROD) presents the selected remedy for Parcel E at Hunters Point Naval Shipyard (HPNS) in San Francisco, California. HPNS was placed on the National Priorities List (NPL) in 1989 (U.S. Environmental Protection Agency [EPA] ID: CA71170090087). The remedy was selected in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980, as amended by the Superfund Amendments and Reauthorization Act (SARA) of 1986 (Title 42 United States Code Section [§] 9601, et seq.); and, to the extent practicable, the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) (Title 40 Code of Federal Regulations Part 300). This decision is based on the Administrative Record Index for this site<sup>1</sup>. The Administrative Record Index is included in the electronic version of the ROD as [Attachment 1](#). The Department of the Navy (Navy) and EPA jointly selected the remedy for Parcel E. The California Department of Toxic Substances Control (DTSC) and the San Francisco Bay Regional Water Quality Control Board (Water Board) concur on the remedy for Parcel E. The Navy provides funding for site cleanups at HPNS. The Federal Facility Agreement (FFA) for HPNS documents how the Navy intends to meet and implement CERCLA in partnership with EPA, DTSC, and the Water Board.

Parcel E is one of six parcels (Parcels A through F) originally designated for environmental restoration. In September 2004, the Navy divided Parcel E into two parcels (Parcels E and E-2) to facilitate CERCLA administrative closure of the Parcel E-2 Landfill and its adjacent areas<sup>2</sup>. In February 2013, the Navy further divided Parcel E into two parcels (Parcels E and UC-3) to facilitate CERCLA administrative closure of Crisp Road, which will serve as a future utility corridor, and the adjoining railroad right-of-way<sup>3</sup>. This ROD addresses only Parcel E.

Parcel E includes two future land use districts: the Shipyard South Multi-Use District and Shipyard Shoreline Open Space. The Shipyard South Multi-Use District will include athletic and recreational facilities, office and industrial spaces, mixed commercial areas, institutional use, and residential areas. The Shipyard Shoreline Open Space will include recreational areas and ancillary commercial use.

---

<sup>1</sup> **Blue text** identifies detailed site information available in the Administrative Record and listed in the References Table ([Attachment 2](#)). This ROD is also available on CD, whereby blue text serves as a hyperlink to reference information. The excerpts referenced by the hyperlinks are part of the ROD. The hyperlink will open a text box at the top of the screen. A blue box surrounds applicable information in the hyperlink. To the extent inconsistencies may exist between the referenced information attached to the ROD via hyperlinks and the information in the basic ROD itself, the language in the basic ROD controls.

<sup>2</sup> Discussions within this ROD (as well as the Revised RI Report, FS Report, and the radiological addendum to the FS Report) that reference documents published prior to September 2004 refer to the portion of Parcel E that excludes Parcel E-2.

<sup>3</sup> The division of Parcel E into Parcels E and UC-3 was documented in the Proposed Plan in February 2013. Discussions within this ROD that reference documents published prior to February 2013 refer to the portion of Parcel E that excludes Parcel UC-3.

Environmental investigations began at Parcel E in 1984. A Draft Final Remedial Investigation (RI) Report for Parcel E was completed in 1997. The Final Revised RI Report for Parcel E was completed in 2008. The Final Feasibility Study (FS) Report was completed in 2012. This ROD documents the final remedial action for Parcel E and does not include or affect any other sites at HPNS.

### 1.1. SELECTED REMEDY

The CERCLA remedial action selected in this ROD is necessary to protect the public health, welfare, or the environment from actual or potential releases of hazardous substances from Parcel E. The selected remedy for Parcel E addresses the following contaminated media:

- **Soil** – metals, pesticides, polychlorinated biphenyls (PCBs), dioxins/furans, semivolatile organic compounds (SVOCs), total petroleum hydrocarbons (TPH), and volatile organic compounds (VOCs)
- **Soil Gas** – VOC contamination in soil and groundwater has also resulted in contamination of soil gas at several locations in Parcel E, including Building 406, where the most laterally extensive soil gas contamination is located
- **Shoreline sediment** (i.e., shallow sediment subject to erosion or deposition within the intertidal shoreline zone) – metals, pesticides, and PCBs
- **Groundwater** – metals, PCBs, TPH, and VOCs
- **Nonaqueous-phase liquid (NAPL)** – NAPL at the Former Oily Waste Ponds (referred to as Installation Restoration [IR] Site 03 [IR-03]) contains metals, PCBs, SVOCs, TPH, and VOCs that are a source to soil and groundwater contamination (radionuclides, although not attributed to the NAPL source, are potentially present in soil at IR-03)
- **Radiologically Impacted Media** – soil, shoreline sediment, and structures at various Parcel E locations (referred to as radiologically impacted sites) may contain radiological contamination, including IR-02 and IR-03, where the most laterally extensive radiological contamination is present (radiological contamination in groundwater, although not identified during previous investigations, is potentially present at IR-02 and IR-03)

The selected remedy consists of the following actions to address risks posed by contaminated media:

#### *Soil, Soil Gas, and Shoreline Sediment*

- Remove and dispose of contaminated soil in selected areas (referred to as Tier 1, Tier 2, and TPH locations<sup>4</sup>) that contain nonradioactive chemicals (including metals, PCBs, SVOCs, and TPH<sup>5</sup>) at concentrations exceeding risk-based levels, as well as separate and dispose of materials and soil with radiological contamination found in these areas

---

<sup>4</sup> Soil removal is proposed in selected areas where nonradioactive chemicals are present at concentrations that exceeded the remediation goals. Tier 1 locations contain COCs at concentrations greater than 10 times the remediation goals. Tier 2 locations contain COCs at concentrations greater than 5 times the remediation goals. TPH locations contain TPH (commingled with CERCLA-regulated chemicals) at concentrations exceeding the petroleum source criterion (3,500 mg/kg). Please see [Section 2.5.3](#) of this ROD for further information.

<sup>5</sup> These chemical groups comprise the Tier 1, Tier 2, and TPH locations proposed for removal. Dioxins and furans are not included in this list because these chemicals are not found at concentrations greater than 5 times the remediation goals.

- Treat VOC contamination in soil and soil gas at Building 406 by using in-situ soil vapor extraction (SVE)
- Install durable covers (consisting of either asphalt or soil) throughout Parcel E to prevent exposure to remaining contaminants in soil (the soil cover at IR-03 and the northwest portion of IR-02 would also include a protective liner to minimize water seeping into contaminated soil)
- Remove and dispose of contaminated shoreline sediment and install shoreline protection consisting of natural materials (such as sand) and large rocks to prevent exposure to remaining contaminants in shoreline sediment (and to integrate with the durable covers at onshore areas)
- Monitor and maintain the different parts of the selected remedies to ensure they are working properly (also applies to actions for groundwater and NAPL at IR-03)
- Use institutional controls (ICs) to restrict specific land uses and activities on Parcel E (also applies to actions for groundwater and NAPL at IR-03)

### ***Groundwater***

- Treat VOC contamination in groundwater at inland plumes using injected biological nutrients (or potentially a mixture of biological nutrients and zero-valent iron) to accelerate the breakdown of VOCs to nontoxic compounds
- Install a below-ground barrier in the northwest portion of IR-02 to control discharge of contaminated groundwater (containing primarily metals and PCBs) into San Francisco Bay (below-ground barrier would work, in combination with protective liner installed under the soil cover in this area, to limit contaminant migration)
- Monitor groundwater concentrations and plumes to support the selected remedies, including documenting the beneficial impact to groundwater quality following implementation of the selected remedies (e.g., the ongoing degradation of VOC contamination by natural processes)

### ***NAPL at IR-03***

- Remove or treat contaminated materials at the Former Oily Waste Ponds (primarily NAPL, but also including associated soil and groundwater contamination)
- Install below-ground barrier to control discharge of NAPL and contaminated groundwater into San Francisco Bay (below-ground barrier would work, in combination with protective liner installed under the soil cover in this area, to limit contaminant migration)
- Treat VOC and TPH contamination in groundwater using injected biological nutrients to accelerate the breakdown of chemicals to nontoxic compounds

***Radionuclides (also referred to as radiologically impacted media)***

- Perform surveys in areas with potential radiological contamination (including structures, former building sites, and buried storm drain and sewer lines), and separate and dispose of materials and soil with radiological contamination found during the surveys (the final radiological cleanup has been initiated under a time-critical removal action in all of Parcel E areas, except IR-02 and IR-03, and is scheduled to be completed in 2015)
- Perform the following activities throughout IR-02 and IR-03: (1) scan the entire area for radioactivity to a depth of at least 1 foot; (2) separate and dispose of materials and soil with radiological contamination found during the surveys; (3) construct, inspect, and maintain a 2-foot-thick soil cover (as provided by the selected remedy for soil) to prevent exposure to remaining contaminants (the soil cover at IR-02 and IR-03 would also include a demarcation layer to mark the boundary between the existing surface and the soil cover); (4) use ICs (specific to radionuclides) to restrict specific land uses and activities (e.g., to ensure the integrity of the soil cover and demarcation layer); and (5) monitor groundwater to demonstrate, consistent with the findings of previous radiological investigations, that radionuclides are not present in groundwater at activity levels that are both statistically significant and pose an unacceptable risk to human health and the environment

**1.2. STATUTORY DETERMINATIONS**

The selected remedy is protective of human health and the environment, complies with federal and state statutes and regulations that are applicable or relevant and appropriate to the remedy, and is cost-effective. The selected remedy uses permanent solutions and alternative treatment (or resource recovery) technologies to the maximum extent practicable. It provides the best balance of tradeoffs relative to the five balancing criteria and properly considers the two modifying criteria<sup>6</sup>. The selected remedy satisfies the statutory preference for treatment<sup>7</sup> as a principal element through the treatment of VOC contamination in portions of Parcel E and the treatment of the NAPL source at the Former Oily Waste Ponds. Statutory five-year reviews pursuant to CERCLA § 121 and the NCP will be conducted because the remedy will leave contamination in place at Parcel E above concentrations that allow for unlimited use and unrestricted exposure.

---

<sup>6</sup> As defined in the NCP (Title 40 Code of Federal Regulations § 300.430[f][1][i]), the five primary balancing criteria are long-term effectiveness and permanence; reduction of toxicity, mobility, or volume through treatment; short-term effectiveness; implementability; and cost. State and community acceptance are modifying criteria that shall be considered in remedy selection.

<sup>7</sup> As defined in the NCP (Title 40 Code of Federal Regulations § 300.5), "treatment technology" means any unit operation or series of unit operations that alters the composition of a hazardous substance or pollutant or contaminant through chemical, biological, or physical means so as to reduce toxicity, mobility, or volume of the contaminated materials being treated. Treatment technologies are an alternative to land disposal of hazardous wastes without treatment.

### 1.3. DATA CERTIFICATION CHECKLIST

The following information is included in [Section 2](#) of this ROD. Additional information can be found in the Administrative Record file for this site:

- Chemicals of concern (COCs) and chemicals of ecological concern (COECs) and their concentrations ([Sections 2.3 and 2.5](#)).
- Baseline risk represented by COCs and COECs ([Section 2.5](#)).
- Remediation goals established for COCs and COECs and the basis for these goals ([Sections 2.5 and 2.7](#)).
- Principal threat wastes ([Section 2.6](#)).
- Current and reasonably anticipated future land use assumptions and current and potential future beneficial uses of groundwater ([Section 2.4](#)).
- Potential land and groundwater use that will be available at Parcel E as a result of the selected remedy ([Section 2.9.3](#)).
- Estimated capital costs, annual operation and maintenance, and total present-worth costs; discount rate; and the number of years over which the remedy cost estimate is projected ([Section 2.8](#)).
- Key factors that led to selecting the remedy (e.g., a description of how the selected remedy provides the best balance of tradeoffs with respect to the balancing and modifying criteria, highlighting criteria key to the decision; [Section 2.9.1](#)).

**1.4. AUTHORIZING SIGNATURES**

This signature sheet documents the Navy's and EPA's co-selection of the remedy in this ROD. This signature sheet also documents the State of California's (DTSC and Water Board) concurrence with this ROD.

## Section 2. Decision Summary

### 2.1. SITE DESCRIPTION AND HISTORY

HPNS is located in southeastern San Francisco on a peninsula that extends east into San Francisco Bay (see [Figure 1](#)). HPNS consists of 866 acres: 420 acres on land and 446 acres under water in the San Francisco Bay. In 1940, the Navy obtained ownership of HPNS for shipbuilding, repair, and maintenance activities. After World War II, activities at HPNS shifted to submarine maintenance and repair. HPNS was also the site of the Naval Radiological Defense Laboratory (NRDL).

**Figure 1. Facility and Parcel E Location Map**

HPNS was deactivated in 1974 and remained relatively unused until 1976. Between 1976 and 1986, the Navy leased most of HPNS to Triple A Machine Shop, Inc. (Triple A), a private ship repair company. In 1987, the Navy resumed occupancy of HPNS. Because past shipyard operations left hazardous substances on site, HPNS property was placed on the NPL in 1989 pursuant to CERCLA, as amended by SARA. In 1991, HPNS was designated for closure pursuant to the Defense Base Closure and Realignment Act of

1990. Closure activities at HPNS involve conducting environmental remediation and making the property available for nondefense use.

**Parcel E<sub>(1)</sub>**, which includes about 128 acres of shoreline and lowland coast along the southwestern portion of HPNS (see [Figure 1](#)), contains 17 existing buildings, 25 former buildings, and 1 ship berth. Historically, most of Parcel E was used as an industrial support area, including a warehouse (Building 406) where chlorinated solvents were spilled and Former Oily Waste Ponds (referred to as IR-03) where waste oil was stored from 1944 to 1974. Shoreline areas at Parcel E (referred to as IR-02) were used to store construction and industrial materials, as well as to dispose of industrial waste and construction debris. The NRDL used several Parcel E buildings during the 1950s and 1960s. During its occupancy of HPNS, Triple A allegedly disposed of hazardous wastes at various locations at HPNS, including possibly discharging waste oil within Parcel E using below-ground fuel and steam lines. Areas with historical activities that may have resulted in contamination were identified by reviewing historical records and categorized as **IR sites<sub>(2)</sub>**. The potential contamination at the IR sites was evaluated through a series of investigations, which are described in [Section 2.3](#). [Figure 2](#) identifies the IR sites within Parcel E, and [Figure 3](#) identifies the Parcel E areas with historical shipyard operations, including NRDL buildings and Triple A sites.

**Figure 2. IR Sites at Parcel E**

**Figure 3. Areas with Historical Shipyard Operations at Parcel E**

A history of radiological operations by the Navy at HPNS is presented in Volume II of the Historical Radiological Assessment (HRA). The review of previous radiological activities, cleanup actions, and release surveys identified no imminent threat or substantial risk to tenants or the environment of HPNS or the local community. The HRA identified **radiologically impacted areas**<sup>(3)</sup> at Parcel E (see Figure 4), which have the potential for radioactive contamination based on historical information or are known to contain or have contained radioactive materials.

**Figure 4. Radiologically Impacted Areas**

Two general sources of potential radioactive contamination exist at Parcel E: research activities at various buildings formerly occupied by NRDL and historical waste disposal activities that occurred along the shoreline (IR-02 and IR-03). The NRDL performed practical and applied research on radiation decontamination methods and on the effects of radiation on living organisms and natural and synthetic materials. NRDL primarily conducted research activities within the former 500 series buildings and within the Building 707 Triangle Area. NRDL activities at these buildings may have discharged small amounts of low-level radioactive liquids into sanitary sewer, storm drain, and septic sewer lines; as a result, sanitary sewer, storm drain, and septic sewer lines throughout Parcel E are radiologically impacted. Historical activities in IR-02 and IR-03 included the disposal of radioluminescent commodity items (such as dials, gauges, and deck markers) in conjunction with the disposal of other construction debris and industrial wastes.

The [2010 redevelopment plan for HPNS](#)<sup>(4)</sup> identifies two future land use districts located partially in Parcel E: the Shipyard South Multi-Use District and the Shipyard Shoreline Open Space District. For evaluation purposes in the FS Report, the portions of these two land use districts within Parcel E were subdivided into eight reuse areas (see [Figure 5](#)). The Shipyard South Multi-Use District encompasses the central and northern portion of Parcel E, and was divided into reuse areas MU-1, MU-2, and MU-3. The Shipyard Shoreline Open Space District encompasses the shoreline area and the southern portion of Parcel E

and was divided into reuse areas EOS-1 through EOS-5. EOS-5, which is contiguous with future open space areas within adjoining Parcel E-2, is shown on [Figure 5](#) as EOS-5A, EOS-5B, and EOS-5C). [Section 2.4](#) further describes the current and future land use of Parcel E.

**Figure 5. Reuse Areas**

## 2.2. SITE CHARACTERISTICS

Land at HPNS consists of relatively level lowlands constructed by excavating portions of surrounding hills and placing nonengineered fill materials<sup>8</sup> along the margin of San Francisco Bay. The remaining land is a moderate to steep sloping, northwest-trending ridge. Parcel E is located in the lowlands with surface elevations ranging from 0 to 12 feet above mean sea level (msl). Ground surface elevations across most of Parcel E range from 7 to 10 feet above msl; elevations within the narrow intertidal shoreline zone range from about 0 to 4 feet above msl.

The [hydrostratigraphy](#)<sup>(5)</sup> of Parcel E consists of four distinct units: the shallow A-aquifer, several aquitard zones, the deeper B-aquifer, and underlying bedrock water-bearing zone. An aquitard zone separates the A- and B-aquifer across most of Parcel E, except for a small area along the northern border of Parcel E

<sup>8</sup> The nonengineered fill materials that were derived from serpentinite bedrock contain minerals with relatively high concentrations of certain metals, including arsenic, iron, manganese, mercury, nickel, and vanadium.

(adjacent to Crisp Road within Parcel UC-3). The presence of additional aquitard zones within B-aquifer sediments isolates the uppermost portions of the B-aquifer from the lower portions of the B-aquifer. Groundwater is not currently used for any purpose at Parcel E. Groundwater in the A-aquifer is not suitable as a potential source of **drinking water**<sup>(6)</sup>. Based on an evaluation of site-specific conditions relative to pertinent regulatory criteria, groundwater in the B-aquifer has a moderate potential to be used as a future source of drinking water; however, the potential use of B-aquifer groundwater is subject to local regulatory controls.

The City and County of San Francisco (CCSF) regulates the installation and use of water wells within city boundaries under Article 12B of the CCSF Health Code. Under the Health Code, San Francisco Public Utilities Commission (SFPUC) administers the withdrawal and use of groundwater within the CCSF, including the South San Francisco Groundwater Basin in which Parcel E is located. The South San Francisco Basin is generally inadequate to supply a significant amount of groundwater for municipal supply (primarily due to low yield). As such, the SFPUC does not provide for the use of groundwater from the South San Francisco Basin. CCSF currently obtains its municipal water supply from the Hetch Hetchy watershed in the Sierra Nevada and plans to continue using the Hetch Hetchy watershed as a drinking water source in the future.

**Groundwater flow patterns**<sup>(7)</sup> within the A-aquifer (see [Figure 6](#)) at Parcel E are complex because they are potentially affected by a groundwater divide in the northwest portion of IR-02 and submerged utility lines throughout Parcel E (which, if leaking, may allow groundwater to infiltrate into them). The natural flow of groundwater toward San Francisco Bay from the topographically high area of the former Parcel A is disrupted by the groundwater divide along the northwest portion of IR-02. The effect of the submerged utility lines on A-aquifer groundwater flow patterns has been reduced because these lines are inactive and are in the process of being removed (to address potential radiological contamination).

**Figure 6. Parcel E Site Features**

**Parcel E ecology**<sup>(8)</sup> includes terrestrial habitat, aquatic environments, and transitional wetlands. All of these ecological areas have been disturbed by human activities such as excavation, filling, and development, and support relatively few plant species. Birds, mammals, and reptiles have been observed in this parcel. No threatened or endangered species are known to inhabit Parcel E or its immediate vicinity. The existing wetlands within the intertidal shoreline zone (see [Figure 6](#)) provide habitat for wintering and migrating wildlife; however, their value in terms of social significance, effectiveness, and opportunity is low because the wetlands are located on manmade land that has been disturbed by human activities and contains chemical contamination.

### 2.3. PREVIOUS INVESTIGATIONS AND REMOVAL ACTIONS

Parcel E contains several environmental investigation sites identified at HPNS during the Initial Assessment Study conducted by the Navy in 1984. Since that time, the Navy has performed multiple environmental investigations at Parcel E to further evaluate 21 IR sites associated with former shipyard operations. The Navy has also performed several treatability studies that involved testing of technologies to reduce VOCs in groundwater and soil. The Navy has collected extensive information during these investigations and studies, as well as during ongoing environmental monitoring programs for groundwater.

The Revised RI Report (May 2, 2008), FS Report (August 31, 2012), and radiological addendum to the FS Report (August 31, 2012) summarize the results of the environmental investigations at Parcel E and document the site conditions. The previous investigations provide sufficient information to evaluate site risks, develop remedial alternatives, and support the remedy decision made in this ROD.

The Navy has also performed several removal actions at Parcel E to minimize potential exposure to hazardous chemicals. The previous excavations successfully removed significant amounts of contamination from Parcel E but some contamination remains. [Table 1](#) summarizes the investigations, treatability studies, and removal actions performed at Parcel E.

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions**

| Date(s)      | Investigation/Study/Removal Action <sup>a</sup>            | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1984         | Initial Assessment Survey                                  | The Initial Assessment Study was based on reviews of records and interviews of previous workers at the site. Based on the findings of the study, five of the eight sites (IR-02, IR-03, IR-04, and IR-05) were recommended for further evaluation.                                                                                                                                                                                                             |
| 1987         | Confirmation Study and Verification Step                   | Activities included a geophysical survey; subsurface exploration using exploratory borings; and soil, groundwater, and air sampling. The study verified the presence of hazardous waste contamination at IR-02, IR-03, IR-04, IR-05, and IR-11.                                                                                                                                                                                                                |
| 1987         | Area Study                                                 | The study consisted of soil sampling to evaluate the potential presence of ACM. ACM was detected in subsurface soil at IR-11/14/15, IR-12, and IR-36 that was attributed to naturally occurring asbestos derived from the serpentinite bedrock.                                                                                                                                                                                                                |
| 1988         | Fence-to-Fence Survey                                      | Conducted to inventory suspected and known hazardous wastes and materials. The survey report concluded tenants generally managed hazardous wastes and materials in ways that did not pose an immediate environmental threat to HPNS.                                                                                                                                                                                                                           |
| 1988 to 1989 | Solid Waste Air Quality Assessment Test                    | Focused evaluation of meteorological conditions, ambient air quality, surface gas emissions, and subsurface gas migration at the Parcel E-2 Landfill, but also included limited investigation at Parcel E sites IR-02, IR-03, IR-12, and IR-14. Subsurface methane gas was detected in isolated pockets at IR-03 and in the southern portion of IR-12; however, no available information suggested that subsurface methane was migrating from these locations. |
| 1988         | RI Phase 1 Reconnaissance                                  | Evaluated hydrogeologic conditions and identified waste boundaries using GPR, electromagnetic survey, and test pits to delineate the extent of waste depositions in fill material. Results were used to identify data needs for subsequent RI activities.                                                                                                                                                                                                      |
| 1988         | Basewide Removal of PCB-Containing Electrical Transformers | Forty-eight transformers were removed from Parcel E and disposed of off site.                                                                                                                                                                                                                                                                                                                                                                                  |
| 1988         | Removal of Soil at IR-08 PCB Spill Area                    | About 1,255 cubic yards of soil with PCBs was excavated from a PCB spill area, which underlies the southeast portion of Building 606.                                                                                                                                                                                                                                                                                                                          |

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions** *(continued)*

| Date(s)              | Investigation/Study/<br>Removal Action <sup>a</sup> | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|-----------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1989 to 1990         | Preliminary Assessment                              | Additional areas where leaks or spills of chemicals were suspected or identified were evaluated and recommended for further action during the site inspection. The following Parcel E sites were evaluated as part of this assessment and recommended for further action: IR-12 through IR-15, IR-36 North, IR-36 South, IR-36 West, IR-38, IR-39, IR-40, IR-52, IR-54, IR-56, and portions of facilitywide utility systems. IR-12 and IR-15 were carried forward directly to the RI phase (IR-14/IR-15 were combined with IR-11), and the remaining sites were carried forward to the site inspection phase. |
| 1991                 | Removal of Floating Product at IR-03                | About 25 gallons of floating petroleum product on the water table and 70 gallons of subsurface waste oil were recovered by pumping and disposed of off site.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1991 to 1992         | Intertidal Sediment Study                           | Sediment samples were collected in the intertidal zone, and the resulting data were used to identify COPECs in the Phase 1A ERA.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 1991 to 1992         | Phase I Radiological Investigation                  | The surface confirmation radiation survey detected elevated gamma activity in a centralized area of IR-02 Northwest that extended across the IR-02 Central boundary; these results indicated the presence of radium-containing devices.                                                                                                                                                                                                                                                                                                                                                                       |
| 1991 to 1994         | Removal and Closure of ASTs and USTs                | Ten USTs were located in Parcel E: 2 were closed in place and 8 were removed. Parcel E also contained 32 ASTs, including Tank S-505, a 630,000-gallon tank at IR-02 Southeast. In total, 12 of 32 ASTs (including Tank S-505) were removed.                                                                                                                                                                                                                                                                                                                                                                   |
| 1991 to 1995         | Sandblast Waste Fixation                            | More than 4,900 tons of sandblast waste was collected from locations around HPNS, temporarily stockpiled at Parcel E, and sent to an asphalt plant for recycling.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1992 to 1996         | RI Report                                           | Based on the results from more than 4,700 soil and 1,200 groundwater samples, the RI Report recommended that all Parcel E sites be carried forward to an FS. Additionally, the report noted that additional soil and groundwater samples should be collected to better define the nature and extent of contamination at the parcel. The Parcel E RI also included a baseline ERA and HHRA.                                                                                                                                                                                                                    |
| 1992, 1994, and 1996 | Facilitywide Ambient Air Monitoring                 | Results indicated that concentrations of asbestos, metals, and VOCs were not present or present at very low concentrations that were similar to regional background concentrations. As a result, no further actions or studies for ambient air at HPNS were recommended.                                                                                                                                                                                                                                                                                                                                      |
| 1993                 | Phase II Radiological Investigation                 | Investigation delineated the subsurface distribution of radium-containing devices in the disposal area at IR-02 Northwest and IR-02 Central. A removal action was recommended to address radiological contamination in this area. The removal action at IR-02 Northwest and IR-02 Central was performed from 2005 to 2007.                                                                                                                                                                                                                                                                                    |
| 1993 to 1994         | Site Inspection                                     | Based on soil and groundwater sample results, the Site Inspection Report recommended further evaluation of IR-36, IR-38, IR-39, IR-40, IR-52, IR-54, and IR-56 as part of the RI phase. The report also recommended that the utility sites (IR-45, IR-47, and IR-50) be investigated further in the RI phase.                                                                                                                                                                                                                                                                                                 |

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions** *(continued)*

| Date(s)      | Investigation/Study/<br>Removal Action <sup>a</sup>                                              | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------|--------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1993 to 1994 | Site Assessment                                                                                  | Evaluated areas that had not been previously investigated under the IR Program because of lack of access or documentation. The assessment recommended further investigation at three areas in Parcel E (subsequently identified as IR-11, IR-72, and IR-73).                                                                                                                                                                                                                                                        |
| 1996         | Removal of Soil from IR-11/14/15                                                                 | About 36 cubic yards of arsenic- and mercury-contaminated soil was excavated from an area east of Building 521 at IR-11/14/15.                                                                                                                                                                                                                                                                                                                                                                                      |
| 1996 to 1997 | Phase III Radiological Investigation                                                             | The investigation included surveys and swipe sampling at former NRD buildings at Parcel E. Based on the investigation results, the report recommended (1) further investigation and potential excavation at former Buildings 509 and 517, where anomalous gamma activity was measured; (2) excavation of a potential buried point source behind Building 529; and (3) further investigation of Building 707 and its concrete pad.                                                                                   |
| 1996 to 1997 | Removal of Sediment from the Storm Drain System                                                  | More than 1,200 tons of sediment and debris was removed from storm drain lines across HPNS, including from storm drain lines in Parcel E, to reduce the potential for chemicals to be transported to San Francisco Bay.                                                                                                                                                                                                                                                                                             |
| 1996 to 1998 | Installation of Sheet Pile Wall and Low-Permeability Cap at the Former Oily Waste Ponds in IR-03 | A 900-foot-long sheet pile wall was installed to a maximum depth of 27 feet below ground surface to reduce the potential for oil to migrate from IR-03 to San Francisco Bay. A geosynthetic clay liner with a 1-foot topsoil layer was placed over the area to minimize rainfall infiltration.                                                                                                                                                                                                                      |
| 1997 to 1998 | Parcel E FS Report                                                                               | Based on the data presented in the RI Report, the FS Report identified and evaluated remedial alternatives for Parcel E. However, the FS Report was not finalized because the Department of the Navy and regulatory agencies identified additional tasks to better characterize the nature and extent of contamination at Parcel E. These tasks were performed as part of data gaps investigations from 2000 through 2003, and results of these investigations were used in Revised RI and FS Reports for Parcel E. |
| 1998 to 1999 | Phase IV Radiological Investigation                                                              | Investigation involved collecting and analyzing 38 concrete and 38 soil samples from the Building 707 concrete pad area. Based on results from the investigation, a removal action was recommended to address elevated radioactivity at the concrete pad. The removal action at Building 707 was performed as part of the basewide radiological removal action that was initiated in 2009.                                                                                                                          |
| 1999 to 2000 | Parcel E Validation Study and Protective Soil Concentrations Technical Memorandum                | Results of the study concluded cadmium, copper, lead, nickel, selenium, and zinc posed a potential unacceptable risk to wildlife at Parcel E. Protective soil concentrations were subsequently derived for these chemicals and used to evaluate risk to wildlife in the Revised Parcel E RI Report.                                                                                                                                                                                                                 |
| 2000 to 2002 | Groundwater Data Gaps Investigation                                                              | Water level measurements and results of a tidal study were used to refine the Parcel E hydrogeological conceptual model, and three rounds of groundwater monitoring data were used to develop a basewide groundwater monitoring program and to refine the nature and extent evaluation presented in the Revised RI Report.                                                                                                                                                                                          |

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions (continued)**

| Date(s)      | Investigation/Study/Removal Action <sup>a</sup>               | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000 to 2002 | SVE Treatability Study                                        | A SVE treatability study was performed inside and immediately northwest of Building 406. The SVE system, which consisted of 3 SVE wells and 15 vapor monitoring wells, removed about 7 pounds of VOCs, with over 90 percent of the VOC mass attributed to TCE.                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2001         | Removal of Soil with Non-VOCs at IR-08                        | About 1,550 cubic yards of PCB- and PAH-contaminated soil was excavated from four remediation areas at IR-08.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 2001         | Radiological Investigation of Parcel E Shoreline              | Several areas contained gamma activity at levels exceeding background, most notably in the Metal Reef Area in IR-02 Southeast. A removal action was recommended to address radioactive materials in this area. The removal action at the Metal Reef Area was performed from 2005 to 2007.                                                                                                                                                                                                                                                                                                                                                                                     |
| 2001 to 2002 | Wetland Delineation and Wetland Functions Assessment          | About 0.73 acres of tidal wetland areas were identified along the Parcel E shoreline. The functions and values assessment found that the value of these wetlands is low, and the most significant function of these wetlands to be seasonal wildlife use for wintering and migrating birds.                                                                                                                                                                                                                                                                                                                                                                                   |
| 2002         | Standard Data Gaps Investigation                              | Data from this investigation were used in the Revised Parcel E RI Report to identify potential source areas of contamination, evaluate the nature and extent of soil contamination in each reuse area, and evaluate risk to human health and the environment.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 2002 to 2004 | Waste Consolidation and Removal                               | Industrial process equipment was decontaminated and waste was consolidated throughout Parcel E, including removal of waste material stored in or near buildings and removal or encapsulation of ACM. Eight ASTs located at Building 521 were also removed.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2002 to 2005 | Parcels E and E-2 Shoreline Investigation and Risk Assessment | Shoreline investigation and associated ERA identified a potential risk to benthic invertebrates, birds, and mammals from exposure to metals and total PCBs in surface and subsurface sediments along the shoreline. Based on these results, source control measures were recommended for the Parcel E shoreline, particularly in IR-02 Northwest.                                                                                                                                                                                                                                                                                                                             |
| 2002 to 2003 | Phase V Radiological Investigation                            | At Parcel E, 21 buildings or former building locations were evaluated as part of Phase V. Investigation activities consisted of conducting surveys, collecting samples, and performing remedial activities. Several areas with elevated levels of radioactivity were reported. Future investigation and cleanup were recommended for several sites, including Building 406; the area around former Buildings 506, 520, and 529; the Building 707 concrete pad and drains; the Shack 80 site; and IR-04.                                                                                                                                                                       |
| 2003 to 2004 | HRA                                                           | The HRA identified 33 areas in Parcel E as radiologically impacted. These sites included small areas such as former building foundation footprints and fill areas that may contain dials, gauges, deck markers, or sandblast waste. The HRA also identified basewide utility systems as impacted sites, including the underground storm drain and sanitary sewer lines. The HRA reported that no radiological contamination was suspected in groundwater at Parcel E, except at IR-02 and areas where storm drains are present; these areas have a low potential for groundwater contamination. The HRA concluded that further evaluation of the impacted sites was required. |

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions (continued)**

| Date(s)         | Investigation/Study/Removal Action <sup>a</sup>                                           | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2003 to 2004    | Parcel E Shoreline Debris Removal                                                         | Bricks and other industrial debris along the Parcel E shoreline were collected for disposal. About 468 cubic yards of non-RCRA hazardous waste debris (poles with creosote), about 400 cubic yards of nonregulated nonhazardous debris, and about 81 tons of recyclable metals were removed.                                                                                                                                                                                                                                        |
| 2003 to 2004    | Removal of Soil Stockpiles                                                                | A field inventory of soil stockpiles at HPNS identified multiple stockpiles at IR-02 Southeast and IR-73. In total, about 3,000 cubic yards of soil, 150 cubic yards of gravel, and 22 cubic yards of other material were removed and disposed of off site.                                                                                                                                                                                                                                                                         |
| 2004            | Removal of TPH-Contaminated Soil from Various Locations                                   | Six areas at IR-05, IR-36 West, IR-39, and IR-73 were excavated to remove soil containing TPH at concentrations exceeding the screening criterion of 3,500 mg/kg. More than 13,000 cubic yards of soil was removed from these areas and disposed of off site.                                                                                                                                                                                                                                                                       |
| 2004 to Present | Basewide Groundwater Monitoring Program                                                   | Monitors groundwater on a quarterly basis at HPNS. Most locations included in the program exhibited chemical concentrations that pose potential risk to humans and wildlife.                                                                                                                                                                                                                                                                                                                                                        |
| 2005 to 2007    | Metal Debris Reef Removal Action                                                          | Approximately 11,200 cubic yards of soil, metal slag, and debris was removed from the Metal Debris Reef (in IR-02 Southeast). Low-level radioactive waste removed from the site included 131 devices and button sources and 31 cubic yards of metal debris.                                                                                                                                                                                                                                                                         |
| 2005 to 2007    | Removal of Soil at IR-02 Northwest and IR-02 Central Area                                 | Approximately 49,500 cubic yards of soil was excavated and tested for radioactive substances. Low-level radioactive waste removed from the site included 11,840 tons of soil, 2,342 devices and button sources, 420 tons of firebrick, 1,940 tons of metal debris, and 58 tons of miscellaneous debris (concrete, plastic, hoses, and rocks). After removing the radioactive waste, the soil was used to backfill the excavation.                                                                                                   |
| 2009 to 2012    | Groundwater Characterization and ZVI Treatability Study at Various VOC Groundwater Plumes | The study further characterized VOC groundwater plumes in Parcel E and evaluated the effectiveness of ZVI injection in reducing VOC concentrations at two plumes (IR-12 PCE plume and Building 406 TCE plume). The characterization refined the extent of the VOC groundwater plumes and identified elevated VOCs in soil gas at IR-04 and IR-36 (Building 406). The study determined that ZVI could effectively treat the VOC plumes but recommended additional monitoring to better assess post-injection groundwater conditions. |
| 2009 to Present | Basewide Radiological Removal Action                                                      | Activities in Parcel E are designed to identify and remove low-level radiological material with radioactivity levels exceeding the remediation goals at all radiologically impacted sites outside of IR-02 and IR-03, which includes the 500 series buildings, Building 707 triangle area, and storm drain and sewer lines. The fieldwork is scheduled for completion in 2015.                                                                                                                                                      |
| 2011 to Present | Characterization and Treatability Study at IR-03                                          | An initial study (from 2011 to 2012) further characterized the extent of NAPL at IR-03, and tested heating technologies (to enhance NAPL removal) on a bench-scale. A follow-on study was initiated in 2013 and further characterized the NAPL; a second phase of the study will be implemented in 2014 to test two technologies (in-situ stabilization/solidification and thermally enhanced NAPL extraction) in the field.                                                                                                        |

**Table 1. Previous Investigations, Treatability Studies, and Removal Actions** *(continued)*

| Date(s)      | Investigation/Study/Removal Action <sup>a</sup> | Investigation/Treatability Study/Removal Action Activities                                                                                                                                                                                            |
|--------------|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2012 to 2013 | Soil Characterization at Various Locations      | The study further characterized areas with soil contamination that significantly exceeded screening criteria (by at least five times). The characterization helped to delineate areas that may require excavation and offsite disposal in the future. |

Notes:

a = The documents listed are available in the Administrative Record and provide detailed information used to support remedy selection at Parcel E.

ACM = asbestos-containing material

ASTs = aboveground storage tanks

COPECs = chemicals of potential ecological concern

ERA = ecological risk assessment

FS = Feasibility Study

GPR = ground-penetrating radar

HHRA = human health risk assessment

HPNS = Hunters Point Naval Shipyard

HRA = Historical Radiological Assessment

IR = Installation Restoration

mg/kg = milligrams per kilogram

NAPL = nonaqueous-phase liquid

NRDL = Naval Radiological Defense Laboratory

PAH = polycyclic aromatic hydrocarbon

PCB = polychlorinated biphenyl

PCE = tetrachloroethene

RCRA = Resource Conservation and Recovery Act

RI = Remedial Investigation

SVE = soil vapor extraction

TCE = trichloroethene

TPH = total petroleum hydrocarbons

USTs = underground storage tanks

VOCs = volatile organic compounds

ZVI = zero-valent iron

Figure 7 identifies the locations of several removal actions conducted at Parcel E, which have addressed radiological contamination in numerous areas pursuant to a **Basewide Time-Critical Removal Action Memorandum**<sup>(9)</sup>. The removal action to address the radiologically impacted sites in Parcel E (outside of IR-02 and IR-03) began in 2009 and is scheduled for completion in 2015. All interim reports will be summarized in a final removal action completion report (RACR), which will be reviewed and approved by the FFA signatories and the California Department of Public Health (CDPH). Although the removal action will not be completed by the time this ROD is signed, the removal action is intended to achieve cleanup goals identical to the remedial action objectives (RAOs) specified in this ROD. If the removal action does not achieve its cleanup goals, cleanup will continue in accordance with the remedial action selected in this ROD until the RAOs are achieved. The ongoing removal action does not address IR-02 and IR-03 because nonradioactive chemicals in soil and shoreline sediment within these areas require remedial action, which will be performed as part of the selected remedy.

Figure 7. Removal Actions

Based on previous investigations and removal actions, the sources and extent of the remaining contamination in soil, shoreline sediment, and groundwater have been characterized adequately to select an appropriate remedy. [Section 2.3.1](#) summarizes the nature and extent of nonradioactive chemicals in soil and shoreline sediment, and [Section 2.3.2](#) summarizes the nature and extent of nonradioactive chemicals in groundwater. [Section 2.3.3](#) describes the nature and extent of NAPL at IR-03. [Section 2.3.4](#) describes the nature and extent of radionuclides in soil, shoreline sediment, and groundwater at Parcel E.

### 2.3.1. Nonradioactive Chemicals in Soil and Shoreline Sediment

Soil investigations at Parcel E identified metals, VOCs, SVOCs, PCBs, dioxins and furans, and TPH as the **chemicals in soil that exceeded screening criteria**<sup>(10)</sup> used in the RI and were present over large portions of Parcel E. The investigations of shoreline sediment indicated that concentrations of copper, lead, mercury, zinc, PCBs, and dichlorodiphenyltrichloroethane (DDT) exceeded screening criteria (used in the RI) in most locations along the Parcel E shoreline and are a **potential source of contamination to Parcel F**<sup>(11)</sup>. Contaminated sediments above msl will be addressed by the selected remedy for Parcel E. Contaminated sediments below msl will be addressed, as necessary, by the selected remedy for Parcel F, the Navy's property offshore of HPNS.

### 2.3.2. Nonradioactive Chemicals in Groundwater

Groundwater investigations at Parcel E have identified **groundwater plumes**<sup>(12)</sup> with concentrations of metals, VOCs, PCBs, and TPH that exceeded screening criteria used in the RI. Primary potential migration pathways for contaminated groundwater include migration and discharge of A-aquifer groundwater into San Francisco Bay and volatilization of A-aquifer groundwater (in areas within VOC plumes) into soil gas and then indoor air. The potential risk associated with these migration pathways is described in [Section 2.5](#). [Figure 8](#) shows the groundwater plumes at Parcel E that required further evaluation in the FS Report (as determined by the risk evaluations described further in [Section 2.5](#)). An additional groundwater plume, which contained benzene, was identified in IR-39. This plume, however, is attributed to past releases from the underground storage tanks at Building 709 (former Navy exchange gas station), thus it is being addressed under the Navy's TPH corrective action program.

Following identification of the VOC plumes ([Figure 8](#)) in the RI, the Navy performed additional studies (from 2009 to 2012) at these areas to better understand the extent of contamination and to evaluate potential cleanup technologies. The additional studies identified **VOCs in soil gas**<sup>(13)</sup> at concentrations that exceed risk-based screening levels. The VOCs reported in soil gas emanate from either contaminated soil or groundwater in the areas.

**Figure 8. Groundwater Plumes**

### 2.3.3. NAPLs at IR-03

Past investigations have identified **NAPL across large portions of the Former Oily Waste Ponds**<sup>(14)</sup> (referred to as IR-03) and adjacent portions of IR-02. Most of the NAPL is present at depths ranging from 11 to 18 feet below ground surface (bgs), with isolated locations where NAPL was found as shallow as 8 feet bgs and as deep as 25 feet bgs. The NAPL is highly viscous and contains a mixture of petroleum hydrocarbons and other organic chemicals (including PCBs and aryl phosphates in some locations). The high viscosity of NAPL limits its mobility; however, NAPL appears to be a continuing source to groundwater contamination, as evidenced by elevated chemical concentrations (most notably TPH and PCBs) in groundwater that may pose a risk to aquatic wildlife in the bay (discussed further in [Section 2.5](#)). In addition, groundwater monitoring wells located adjacent to the shoreline (bayside of the sheet-pile wall) contain measureable NAPL, indicating that NAPL could discharge to San Francisco Bay. [Section 2.8](#) discusses the remedial alternatives specific to NAPL at IR-03.

As noted in [Table 1](#), the Navy is conducting a study at IR-03, concurrent with this ROD, to further characterize the NAPL and test two technologies (in-situ stabilization/solidification and thermally-enhanced extraction) in the field. The first phase of this study was completed in 2013, and characterized the chemical composition and physical properties of the NAPL. The characterization findings, which identified some additional chemicals (aryl phosphates) that result in a denser NAPL when compared to other oily wastes, were used to develop an **approach for testing thermally-enhanced extraction**<sup>(15)</sup> in a manner that ensures the protection of human health and the environment. The second phase of the study will be completed in 2014 and will involve field testing of thermally-enhanced extraction and in-situ stabilization/solidification.

### 2.3.4. Radionuclides in Soil, Shoreline Sediment, and Groundwater

**Several radiological investigations**<sup>(16)</sup> have been conducted at radiologically impacted sites at Parcel E, and have included surface scans and collection of soil and groundwater samples for radiological analyses. The most extensive and recent of the radiological investigations, the Phase V investigation, involved the collection of more than 300 soil samples primarily within the location of current and former series 500 buildings and the Building 707 Triangle Area. Soil sample results identified two primary radionuclides of concern (ROCs) at these areas: cesium-137 (<sup>137</sup>Cs) and radium-226 (<sup>226</sup>Ra). For evaluation purposes in the radiological addendum to the FS Report, the activity level for each ROC was compared against the corresponding release criterion to provide a general assessment of the distribution of ROCs in surface soil at Parcel E. The assessment results, as identified in the radiological addendum to the FS Report, are as follows:

- The extent of <sup>137</sup>Cs in surface soil exceeding the release criterion (0.113 picocurie per gram [pCi/g]) was moderate.
- The extent of <sup>226</sup>Ra in surface soil exceeding the release criterion (1.0 pCi/g above the background activity level) was widespread.

As identified in the HRA, shoreline sediment (within the intertidal zone), subsurface soil, and structures at Parcel E are also considered radiologically impacted; however, data are inadequate to support a detailed evaluation of the nature and extent of radionuclides in shoreline sediment, subsurface soil, and structures. In the absence of such data, this ROD assumes that radiologically impacted sediment, subsurface soil, and structures, as identified in the HRA, will require remediation. As described in [Section 2.3](#), the radiologically impacted sites in Parcel E outside of IR-02 and IR-03 are being addressed through an ongoing removal action (initiated in 2009 and scheduled for completion in 2015). Although the radiological removal action will not be completed by the time this ROD is signed, the removal action is intended to achieve cleanup goals identical to the RAOs specified in this ROD. If the removal action does not achieve its cleanup goals, cleanup will continue in accordance with the remedial action selected in this ROD until the RAOs are achieved. The ongoing removal action does not address IR-02 and IR-03 because nonradioactive chemicals in soil and shoreline sediment within these areas will be addressed as part of the selected remedy. [Section 2.8](#) discusses the radiological remedial alternatives for IR-02 and IR-03.

The groundwater data set from previous [radiological groundwater investigations](#)<sup>(17)</sup>, performed from 2001 to 2002 and 2007 to 2009, consists of 159 samples collected from 37 A-aquifer wells and 4 samples collected from 1 B-aquifer well within Parcel E. The radionuclide groundwater data were evaluated by simple (non-statistical) threshold comparisons to fixed standards (drinking water criteria) and by statistical tests comparing the site data to fixed standards (one-sample statistical tests), if necessary. Through these comparisons, the radiological addendum concluded that groundwater does not appear to have been impacted by radionuclides at activity levels that warrant remedial action. However, nonradioactive chemicals in groundwater within IR-02 and IR-03 require remedial action, including monitoring, ICs, source removal, and containment. Future monitoring will include analysis for radionuclides in groundwater to demonstrate, consistent with the findings of previous radiological investigations, that radionuclides are not present in groundwater at activity levels that are both statistically significant and pose an unacceptable risk to human health and the environment (see [Section 2.7](#) for further information).

## **2.4. CURRENT AND POTENTIAL FUTURE SITE USES**

Parcel E is a former industrial use area with most areas subject to restricted access because of ongoing remediation. Building 606, located in the southeast portion of Parcel E, is the only occupied building at Parcel E; it is currently leased to the San Francisco Police Department. As described in [Section 2.1](#), the future use of Parcel E is described in the CCSF's [2010 redevelopment plan for HPNS](#)<sup>(4)</sup>, which identifies two future land use districts located partially in Parcel E: the Shipyard South Multi-Use District and the Shipyard Shoreline Open Space District. The Shipyard South Multi-Use District may be used for recreational, industrial, and residential purposes. The Shipyard Shoreline Open Space District may be used for active and passive recreation, plazas and promenades, wetlands restoration, and ancillary commercial use.

As discussed in [Section 2.1](#), the Navy subdivided the two land use districts into smaller reuse areas to facilitate the data presentation in the FS Report. The Navy-defined reuse areas in the portion of the Shipyard South Multi-Use District located in Parcel E are MU-1, MU-2, and MU-3. The Navy-defined reuse areas in the portion of the Shipyard Shoreline Open Space District located in Parcel E are EOS-1 through EOS-4, EOS-5A, EOS-5B, and EOS-5C. [Figure 5](#) presents the planned reuses and reuse areas within Parcel E. It should be noted that the data analysis and risk evaluations presented in the Revised RI Report were based on the 1997 “Hunters Point Shipyard Redevelopment Plan,” which included a different combination of future uses in Parcel E (including commercial and industrial uses). However, the Revised RI Report included an evaluation of residential exposures throughout Parcel E, which provides an adequate baseline for the risk evaluations.

Groundwater in the A-aquifer, as discussed in the Revised RI Report, is not suitable for use as [drinking water](#)<sup>(6)</sup>. Exposures to A-aquifer groundwater were evaluated based on transport of groundwater to San Francisco Bay. Groundwater in the B-aquifer was evaluated as a drinking water source, based on pertinent regulatory criteria, and was determined to have a potential for use as drinking water. However, as described in [Section 2.2](#), CCSF controls the future use of B-aquifer groundwater at HPNS, and the SFPUC does not provide for use of groundwater in this area of the city.

## 2.5. SUMMARY OF SITE RISKS

Contaminated media at Parcel E consist of soil, soil gas, shoreline sediment, and groundwater. The primary contaminant transport mechanisms are (1) leaching from soil to groundwater by infiltrating precipitation or as a result of fluctuating groundwater levels, (2) discharge from groundwater to surface water through direct discharge or via leaking utility lines, (3) volatilization from soil or groundwater to soil gas and then indoor air, and (4) transport of soil or shoreline sediment to surface water with overland flow of storm water.

[Figure 9](#) provides a general conceptual site model (CSM) for Parcel E. Based on the CSM, Parcel E was evaluated for potential risks to human health and the environment in the Revised RI Report, the FS Report, and the radiological addendum to the FS Report. [Section 2.5.1](#) presents the results of the human health risk assessment (HHRA). [Section 2.5.2](#) presents the results of the ecological risk assessments.

**Figure 9. Conceptual Site Model**

### 2.5.1. Human Health Risk Assessment

Based on a [CSM for human health<sup>\(18\)</sup>](#), a [quantitative HHRA<sup>\(19\)</sup>](#) was completed for soil, shoreline sediment, and groundwater at Parcel E. Potential [cancer risks and noncancer hazards<sup>\(20\)</sup>](#) were calculated based on reasonable maximum exposure (RME) assumptions recommended by EPA and DTSC. These assumptions are based on an RME rather than an average or medium range exposure assumption and provide a conservative and protective approach that estimates the highest health risks that are reasonably expected to occur at a site.

Cancer risk is the estimated probability that a person will develop cancer from exposure to site contaminants and is generally expressed as an upper-bound probability. For example, a 1 in 1,000,000 chance is a risk that for every 1,000,000 people, one additional cancer case may occur as a result of exposure to site contaminants. This risk estimate is termed excess cancer risk. The Navy adopted a conservative approach at Parcel E and evaluated action where potential excess cancer risk exceeded 1 in 1,000,000, which meets the most conservative end of the risk management range established by EPA.

Noncancer hazard is the risk of health effects other than cancer, and is expressed as a number called the hazard index (HI). An HI of 1 or less is considered an acceptable exposure level for noncancer health hazards. The Navy evaluated action at Parcel E areas with an HI greater than 1.

The HHRA specifies the [assumptions and uncertainties](#)<sup>(21)</sup> inherent in the risk assessment process attributed to a number of factors including the number of samples collected or their location, the literature-based exposure and toxicity values used to calculate risk, and risk characterization across multiple media and exposure pathways. The uncertainties can result in the overestimation or underestimation of the actual cancer risk or HI. In general, the risk assessment process is based on the use of conservative (health protective) assumptions that when combined are intended to overestimate the actual risk.

#### 2.5.1.1. Soil Risk Summary

Both [total excess and incremental excess risks](#)<sup>(22)</sup> were evaluated for exposure to soil. For the total risk evaluation, all detected chemicals, except for calcium, magnesium, potassium, and sodium (essential nutrients), were included as chemicals of potential concern (COPCs) regardless of concentration. The total excess risk evaluation provided an estimate of the risks posed by all chemicals at Parcel E, including those present at concentrations at or less than Hunters Point ambient levels (HPALs). The HPALs are an indicator for naturally occurring metals that are part of the soil and rock at the shipyard. For the incremental excess risk evaluation, the essential nutrients and metals with maximum detected concentrations less than HPALs were excluded as COPCs. The incremental excess risk evaluation provided an estimate of risks posed by all chemicals at Parcel E, except those that do not exceed HPALs.

Based on the [HHRA results for nonradioactive chemicals in soil](#)<sup>(23)</sup>, incremental excess cancer risks exceeded 1 in 1,000,000 and noncancer hazards were greater than 1 (see [Table 2](#)). In addition, incremental excess [cancer risks from exposure to radionuclides in soil](#)<sup>(24)</sup> exceeded 1 in 1,000,000 (see [Table 2](#)).

**Table 2. Incremental Excess Cancer Risks and Noncancer Hazards in Soil <sup>a</sup>**

| Parcel E Reuse Area | Exposure Scenario | Cancer Risk              |                | Noncancer Hazard Index |
|---------------------|-------------------|--------------------------|----------------|------------------------|
|                     |                   | Nonradioactive Chemicals | Radionuclides  |                        |
| EOS-1               | Recreational      | 1 in 10,000              | 7 in 1,000,000 | 10                     |
| EOS-2               | Recreational      | 9 in 1,000               | 3 in 10,000    | 1,700                  |
| EOS-3               | Recreational      | 1 in 1,000               | 2 in 100,000   | 3.2                    |
| EOS-4               | Recreational      | 3 in 10,000              | 7 in 1,000     | 9.6                    |
| EOS-5A              | Recreational      | 1 in 100,000             | --             | <1                     |
| EOS-5B              | Recreational      | 7 in 100,000             | --             | <1                     |
| EOS-5C              | Recreational      | --                       | --             | <1                     |
| MU-1                | Residential       | 6 in 1,000               | 7 in 1,000     | 130                    |
| MU-2                | Residential       | 3 in 1,000               | 9 in 10,000    | 54                     |

**Table 2. Incremental Excess Cancer Risks and Noncancer Hazards in Soil <sup>a</sup> (continued)**

| Parcel E<br>Reuse Area | Exposure<br>Scenario | Cancer Risk                 |               | Noncancer<br>Hazard Index |
|------------------------|----------------------|-----------------------------|---------------|---------------------------|
|                        |                      | Nonradioactive<br>Chemicals | Radionuclides |                           |
| MU-3                   | Residential          | 1 in 1,000                  | 8 in 10,000   | 65                        |

Notes: Reuse areas are shown on [Figure 5](#) and align with anticipated future use.

a = Listed risk value is maximum incremental risk in each area; risk is based on conditions before cleanup (including prior to interim removal actions, such as those related to radionuclides).

EOS = Parcel E open space (reuse area) MU = multi-use (reuse area) -- = not applicable (i.e., no chemicals of concern in the reuse area)

### 2.5.1.2. Shoreline Sediment Risk Summary

Total excess risks were evaluated for [direct exposure to shoreline sediment](#)<sup>(25)</sup>, as well as ingestion of shellfish along the shoreline. For the direct exposure pathway, PCBs were the only chemical with a risk greater than 1 in 1,000,000 (based on RME assumptions). Noncancer hazards for the direct exposure pathway were less than 1. For the shellfish ingestion pathway, the primary risk drivers associated with Parcel E shoreline sediments were arsenic, total PCBs, and dioxins, where cancer risks for these chemicals exceeded 1 in 1,000,000 (based on RME assumptions). Noncancer hazards for the shellfish ingestion pathway were greater than 1, and were attributed to total PCBs.

### 2.5.1.3. Groundwater Risk Summary

Both total and incremental excess risks were evaluated for exposure to groundwater. Based on the [HHRA results for nonradioactive chemicals in groundwater](#)<sup>(26)</sup>, incremental excess cancer risks exceeded 1 in 100,000 and noncancer hazards were greater than 1 (see [Table 3](#)).

**Table 3. Incremental Excess Cancer Risks and Noncancer Hazards, Groundwater Before Cleanup<sup>a</sup>**

| Reuse Area                                                       | Exposure Scenario | Cancer Risk  | Hazard Index |
|------------------------------------------------------------------|-------------------|--------------|--------------|
| Breathing Indoor Air from A-Aquifer Groundwater                  |                   |              |              |
| MU-1                                                             | Residential       | 2 in 1,000   | 11           |
| MU-2                                                             | Residential       | 1 in 1,000   | 4.6          |
| MU-3                                                             | Residential       | 8 in 100,000 | 2.9          |
| Drinking of or Showering with B-Aquifer Groundwater <sup>b</sup> |                   |              |              |
| MU-1                                                             | Residential       | --           | --           |
| MU-2                                                             | Residential       | 4 in 10,000  | 2.5          |
| MU-3                                                             | Residential       | --           | --           |

Notes:

a = Listed risk value is maximum incremental risk in Parcel E; risk is based on conditions before cleanup.

b = B-aquifer groundwater has a moderate potential to be used as a future drinking water source but is subject to local regulatory controls (as described in [Section 2.2](#)).

EOS = Parcel E open space (reuse area) MU = multi-use (reuse area) -- = not applicable (i.e., no chemicals of concern in the reuse area)

### 2.5.2. Ecological Risk Assessment

The Navy performed a **baseline ecological risk assessment**<sup>(27)</sup> (BERA) for soil and a **screening-level ecological risk assessment**<sup>(28)</sup> (SLERA) for shoreline sediment to evaluate risks to wildlife (such as small mammals, birds, and marine life) from exposure to soil and sediment. In addition, the Navy performed a SLERA to evaluate **risks to aquatic wildlife**<sup>(29)</sup> from exposure to potentially contaminated groundwater at Parcel E.

#### 2.5.2.1. BERA for Soil

The BERA compared soil data against toxicity benchmarks for selected ecological receptors. Results of the risk evaluation indicated carnivorous birds (such as the American kestrel) and small omnivorous mammals (such as the house mouse) may be at risk from ingested doses of copper, lead, and PCBs at Parcel E. However, the magnitude of the hazard quotient (HQ) (all less than 2.7) and the low quality of the habitat at Parcel E suggests that risk is neither immediate nor severe.

#### 2.5.2.2. SLERA for Shoreline Sediment

The SLERA for shoreline sediment evaluated whether or not chemicals detected along the shoreline pose an ecological risk to those receptors exposed to the narrow intertidal zone. All chemicals detected in shoreline sediment samples were screened to identify chemicals of potential ecological concern (COPECs). A toxicity-based approach was used to identify site-related chemicals that may pose risks to sensitive ecological receptors, including benthic invertebrates, birds, and mammals. Ingested doses were estimated for three birds (willet, surf scoter, and red tailed-hawk) and one mammal (house mouse). The SLERA identified the following COECs in shoreline sediment:

- Benthic invertebrates: copper, lead, mercury, zinc, PCBs, and DDT
- Birds (willet, surf scoter, and red tailed-hawk): PCBs
- Mammals (house mouse): cadmium, copper, molybdenum, zinc, and PCBs

#### 2.5.2.3. Risk Evaluation of Groundwater

The SLERA evaluated potential risks to aquatic wildlife from exposure to contaminated groundwater at Parcel E. Chemical concentrations in groundwater were screened against the assigned aquatic evaluation criteria, mainly comprising saltwater aquatic criteria, to identify COPECs for surface water quality. Site-specific data for select COPECs were then evaluated against **trigger levels**<sup>(30)</sup><sup>9</sup>, consistent with the methods used in recent FS reports at other HPNS parcels, to further confirm if the COPECs needed to be addressed in remedial alternatives. Based on concentrations exceeding trigger levels (as adjusted based on ambient

---

<sup>9</sup> Trigger levels were developed (in the FS Report for Parcel E) for specific groundwater plumes by applying attenuation factors to pertinent surface water quality criteria (as identified in pertinent surface water ARARs and, for select metals, adjusted for ambient levels). The attenuation factors vary based on several parameters (most notably, width of the contaminant plume and distance to the bay) and provide a conservative estimate of the advection and dispersion that reduces chemical concentrations as groundwater moves from an inland location to San Francisco Bay. Further information on the development of trigger levels is provided in the hyperlinked reference document ([Attachment 2](#)).

levels), the following chemicals (or groups of chemicals) pose a potential risk to aquatic wildlife exposed to contaminated groundwater at Parcel E:

- Metals: arsenic, copper, lead, nickel, and zinc
- PCBs and pesticides: Aroclor-1254, Aroclor-1260, 4,4'-dichlorodiphenyldichloroethene (DDE), and alpha-chlordane
- Total TPH: sum of detected concentrations of all TPH ranges (gasoline-range, diesel-range, and motor-oil range)

Figure 8 identifies the groundwater plumes where these chemicals are present at concentrations exceeding the corresponding trigger levels (as adjusted based on ambient levels). Two additional groundwater plumes, which contained metals, were identified at IR-05 and IR-12; however, groundwater concentrations at these plumes did not exceed the corresponding trigger levels, thus the plumes did not require further evaluation in the FS Report.

### 2.5.3. Basis for Response Action

The response actions selected in this ROD are necessary to protect the public health, welfare, or the environment from actual or potential releases of hazardous substances into the environment. The Navy, in partnership with EPA, DTSC, and the Water Board, considered all pertinent factors in accordance with CERCLA and NCP remedy selection criteria and determined that remedial action is necessary to clean up soil, shoreline sediment, groundwater, and radiologically impacted media (including soil, shoreline sediment, and structures) at Parcel E. In addition, remedial action is necessary to control the NAPL contaminant source at IR-03. This determination was made because:

- Based on the HHRA results for **nonradioactive chemicals in soil**<sup>(31)</sup>, shoreline sediment, and **groundwater**<sup>(32)</sup>, incremental excess cancer risks exceed 1 in 1,000,000 and noncancer hazards were greater than 1 (see [Tables 2 and 3](#)).
- Incremental excess cancer risks from exposure to radionuclides in soil exceed 1 in 1,000,000 (see [Table 2](#)).
- Based on the **SLERA results**<sup>(33)</sup>, chemical concentrations in shoreline sediment and groundwater in Parcel E pose a potential threat to wildlife.

The HHRA identified numerous nonradioactive COCs in soil present at concentrations that posed an unacceptable excess cancer risk or noncancer hazard (based on an evaluation of incremental risk). The elevated concentrations of several COCs (most notably arsenic, polycyclic aromatic hydrocarbons, and PCBs) were found to be dispersed over the different reuse areas at Parcel E. The widespread extent of these COCs prompted the Navy to consider a combination of removal and containment options in developing potential response actions. Specifically, the Navy identified an approach that proposed removal of the soil areas that posed the most significant risk to humans, and proposed containment for the remaining soil areas that posed a lower risk to humans.

In identifying potential soil areas for removal, the Navy focused the list of COCs to those nonradioactive chemicals present at concentrations that exceeded the **remediation goals**<sup>(34)</sup>, which generally correspond to an excess cancer risk of 1 in 1,000,000 or a noncancer HI of 1 (based on an evaluation of incremental risk), by a factor of at least 5 (these areas are referred to as Tier 1 and Tier 2 locations). Tier 1 locations contain COCs at concentrations greater than 10 times the remediation goals. Tier 2 locations contain COCs at concentrations greater than 5 times the remediation goals. Tier 1 and Tier 2 locations contain elevated concentrations of nonradioactive COCs that pose the most significant risk to humans. **Figure 10** on page 2-24 identifies the Tier 1 and Tier 2 locations, as well as TPH locations that contain TPH (commingled with CERCLA-regulated chemicals) at concentrations exceeding the petroleum source criterion (3,500 mg/kg). **Figure 10** also identifies an area, adjacent to the shoreline in the northwest portion of Parcel E, where the Navy is conducting a soil investigation that may identify additional Tier 1, Tier 2, and TPH locations. In addition, **Figure 10** highlights Building 406 and a portion of IR-04, which contain elevated concentrations of VOCs in soil gas that pose a potential risk to humans.

**Figure 10. Tier 1, Tier 2, and TPH Locations in Soil**

Table 4 identifies the COCs at the Tier 1 and Tier 2 locations, along with the soil remediation goals and soil action levels for each COC (i.e., corresponding to five times the remediation goal).

**Table 4. Chemicals of Concern at Tier 1 and Tier 2 Locations**

| Reuse Area                          | COCs                       | Soil Remediation Goal <sup>a</sup><br>(mg/kg) | Soil Action Level <sup>b</sup><br>(mg/kg) |
|-------------------------------------|----------------------------|-----------------------------------------------|-------------------------------------------|
| Open Space<br>(EOS-1 through EOS-5) | Aroclor-1254               | 0.74                                          | 3.7                                       |
|                                     | Aroclor-1260               | 0.74                                          | 3.7                                       |
|                                     | Arsenic                    | 11.1                                          | 55.5                                      |

## Notes:

a = Remediation goals for recreational exposure scenario (associated with future open space areas) and residential exposure scenario (associated with future mixed use areas) are detailed in [Table 5](#). Although not listed in this table, the total TPH remediation goal (3,500 mg/kg) is used to identify TPH locations that are a potential source to groundwater contamination.

b = The soil action level for each COC is equal to five times the corresponding remediation goal. Tier 1 and Tier 2 locations contain COCs at concentrations greater than the soil action levels.

c = Remediation goals for copper and zinc (in open space reuse areas EOS-1 through EOS-5) are based on [PSCs<sup>\(35\)</sup>](#) for terrestrial wildlife. Although copper and zinc are not COCs for the recreational exposure scenario, ecological benchmarks for these chemicals are being considered during response actions to address risk from the COCs identified in the human health risk assessment.

d = Soil action levels for copper and zinc are based on PSCs for terrestrial wildlife. Soil action levels for these metals are 5 times the PSC. Excavation of soil with concentrations exceeding these soil actions levels will reduce potential sources to groundwater contamination because copper and zinc are present in groundwater in select areas at concentrations that pose a risk to aquatic life in the bay.

bgs = below ground surface

BHC = benzene hexachloride

COC = chemical of concern

mg/kg = milligrams per kilogram

PSCs = protective soil concentrations

TPH = total petroleum hydrocarbons

In developing the response actions for radiologically impacted media, the Navy considered the historical operations and the available data on the distribution of radioactivity. At most radiologically impacted sites at Parcel E, radioactive contamination is present in shallow soil and is the result of historical operations at buildings or open storage areas. At these types of sites, removal by excavation is considered a practical and cost-effective means of preventing unacceptable exposure to humans. However, the operational history at IR-02 and IR-03 involved historical filling with soil and construction debris and intermittent disposal of various shipyard wastes, including radiological devices, and required an evaluation of a combination of removal and containment. The Navy focused the removal of ROCs to the surface of IR-02 and IR-03 because these areas posed the most significant risk to future recreational users. Following cleanup of ROCs within 1 foot of the existing ground surface, a cover (comprising clean imported soil and geosynthetic material) and ICs would effectively prevent unacceptable exposures to remaining concentrations of ROCs.

The risk evaluations identified several groundwater plumes containing nonradioactive chemicals that pose a potential risk to either humans or aquatic wildlife in San Francisco Bay. Groundwater plumes containing VOCs pose a potential risk to humans and are located in the inland portions of Parcel E (see [Figure 8](#)). In evaluating potential response actions, the Navy determined that remedial action, in the form of active treatment and monitoring, is needed to address this potential risk to humans. Groundwater plumes containing metals, PCBs, and TPH pose a potential risk to aquatic wildlife and are located near the shoreline (see [Figure 8](#)). In evaluating potential response actions, the Navy determined that remedial action, in the form of source removal, containment, and monitoring, is needed to address this potential risk to aquatic

wildlife. Remedial action at the groundwater plumes will be further evaluated in the remedial design (RD) using results from the ongoing groundwater monitoring program.

## 2.6. PRINCIPAL THREAT WASTE

According to EPA's "Guide to Principal Threat and Low Level Threat Wastes," principal threat wastes are those source materials considered to be highly toxic or highly mobile that generally cannot be reliably contained or would present a significant risk to human health or the environment should exposure occur. The **potential principal threat wastes at Parcel E**<sup>(36)</sup> consist of trichloroethene (TCE) at Building 406 and NAPL at IR-03. Source materials at these locations have migrated to A-aquifer groundwater at concentrations that pose a potential risk to humans (from TCE at Building 406) or aquatic wildlife in San Francisco Bay (from NAPL at IR-03). To address this potentially significant risk, removal or treatment of these source materials was evaluated as a component of the remedial alternatives for these areas. However, as described in [Section 2.3.3](#), the high viscosity of NAPL at IR-03 limits its mobility, which suggests that containment may be used at IR-03, in combination with removal and treatment, to address the potential risk associated with the NAPL source. [Section 2.8](#) discusses the remedial alternatives specific to NAPL at IR-03.

## 2.7. REMEDIAL ACTION OBJECTIVES

**RAOs**<sup>(37)</sup> are established based on attainment of regulatory requirements, standards, and guidance; contaminated media; COCs and COECs; potential receptors and exposure scenarios; and human health and ecological risks. Ultimately, the success of a remedial action is measured by its ability to meet the RAOs. Planned future land use is an important component in developing RAOs, and the RAOs for Parcel E are based on the CCSF's planned use for each reuse area, which is considered the reasonable anticipated end use of the property.

The RAOs for Parcel E were developed in conjunction with the regulatory agencies and are listed below by medium of concern.

### **Soil, Soil Gas, and Shoreline Sediment RAOs**

- Prevent exposure of humans to inorganic and organic chemicals in soil at concentrations exceeding the remediation goals (see [Table 5](#)) for the following exposure pathways:
  - Ingestion of, outdoor inhalation of, and dermal exposure to soil from 0 to 10 feet bgs by residents in areas zoned for mixed-use reuse
  - Ingestion of homegrown produce in native soil in areas zoned for mixed-use reuse
  - Ingestion of, outdoor inhalation of, and dermal exposure to soil from 0 to 2 feet bgs by recreational users in areas zoned for open space reuse
  - Ingestion of, outdoor inhalation of, and dermal exposure to soil from 0 to 10 feet bgs by construction workers in all areas

**Table 5. Remediation Goals for Nonradioactive Chemicals in Soil**

| Chemical of Concern               | Remediation Goal for Residential Exposure Scenario (mg/kg) | Remediation Goal for Recreational Exposure Scenario (mg/kg) | Remediation Goal for Construction Worker Exposure Scenario (mg/kg) |
|-----------------------------------|------------------------------------------------------------|-------------------------------------------------------------|--------------------------------------------------------------------|
| 1,2,4-Trichlorobenzene            | --                                                         | --                                                          | 230                                                                |

| Total TPH <sup>c</sup>     | 3,500                                                      | 3,500                                                       | 3,500                                                              |

Notes: The basis (risk-based or ambient level) for the remediation goals is presented in Section 3 of the Feasibility Study Report.

a = Remediation goals for copper and zinc (in open space reuse areas EOS-1 through EOS-5) are based on **protective soil concentrations<sub>(35)</sub>** for terrestrial wildlife. Although copper and zinc are not COCs for the recreational exposure scenario, ecological benchmarks for these chemicals are being considered during response actions to address risk from the COCs identified in the human health risk assessment.

b = Remediation goal for dioxins and furans is expressed as a TEQ, which is calculated by multiplying the concentration of each dioxin and furan congener by a toxicity equivalency factor established by the 2005 World Health Organization and based on each congener's toxicity relative to 2,3,7,8-tetrachlorodibenzo-p-dioxin.

c = The total TPH remediation goal is based on the petroleum source criterion for HPNS

BHC = benzene hexachloride

COC = chemical of concern

DDD = dichlorodiphenyldichloroethane

DDE = dichlorodiphenyldichloroethene

mg/kg = milligrams per kilogram

TEQ = toxic equivalent quotient

TPH = total petroleum hydrocarbons

-- = not applicable (i.e., not a chemical of concern under the exposure scenario)

- Prevent exposure of humans to VOCs in soil gas at concentrations that would pose unacceptable risk via indoor inhalation of vapors. **Table 7 of the final soil gas memorandum<sup>(38)</sup>** lists risk-based action levels for various volatile chemicals, including SVOCs and pesticides, that may pose an unacceptable risk via indoor inhalation of vapors. These soil gas action levels will be used for an initial risk-based screening of data collected during a future soil gas survey (such as the survey to be performed at Building 406 and VOC groundwater plumes following active treatment). After the initial risk-based screening, areas with unacceptable risk will be further evaluated using location-specific data (i.e., physical characteristics of the soil) to assess potential exposures consistent with the most current State of California and EPA vapor intrusion guidance. In addition, risks and hazards at these areas will be further characterized using the accepted methodology for risk assessments at HPNS. **Section 2.9.2.1** provides additional information on the future soil gas survey and potential actions that may be prompted based on the results of the risk and hazard evaluation.
- Prevent exposure of humans to COCs in shoreline sediment at concentrations exceeding the remediation goals in **Table 6**.
- Prevent exposure of benthic invertebrates, birds, and mammals to COECs in shoreline sediment at concentrations exceeding the remediation goals in **Table 6**.

**Table 6. Remediation Goals for COECs and COCs in Shoreline Sediment**

| COEC/COC              | Remediation Goal (mg/kg) |
|-----------------------|--------------------------|
| Cadmium               | 3.14                     |
| Copper                | 124                      |
| Lead                  | 218                      |
| Mercury               | 2.28                     |
| Molybdenum            | 2.68                     |
| Zinc                  | 158                      |
| Total DDT             | 0.0461                   |
| Total Aroclors (PCBs) | 0.2                      |

Notes:

COC = chemical of concern

COEC = chemical of ecological concern

DDT = dichlorodiphenyltrichloroethane

mg/kg = milligram per kilogram

PCBs = polychlorinated biphenyls

The RAOs for soil and shoreline sediment would be satisfied through actions involving removal, containment, monitoring, and ICs. The RAO for soil gas would be satisfied through actions involving active treatment (at Building 406 and other VOC groundwater plumes at Parcel E), monitoring, and ICs. Active treatment of soil gas would be performed at Building 406 until soil gas action levels are achieved or until systematic asymptotic conditions are reached without reasonable indication of further reduction based on system monitoring results. Active treatment of VOC groundwater plumes would also be performed to address unacceptable risk via indoor inhalation of vapors, and would be supplemented with monitored

natural attenuation (MNA) to ensure that natural processes are degrading the remaining VOCs. [Section 2.9.2](#) provides further information on the actions required to satisfy the RAOs for soil, soil gas, and shoreline sediment.

### **Groundwater RAOs**

- Prevent or minimize exposure of construction worker to VOCs in A-aquifer groundwater by dermal exposure and inhalation of vapors with chemicals exceeding remediation goals ([Table 7](#)).
- Prevent or minimize exposure of humans to COCs in the B-aquifer at concentrations exceeding remediation goals ([Table 7](#)) via the domestic use pathway.
- Prevent or minimize migration of arsenic, copper, lead, nickel, zinc, Aroclor-1254, Aroclor-1260, alpha-chlordane, and 4,4'-DDE to prevent discharge (into San Francisco Bay) that would result in concentrations exceeding corresponding [surface water quality criteria for aquatic wildlife](#)<sup>(39)</sup><sup>10</sup>.
- Prevent or minimize migration of A-aquifer groundwater containing total TPH concentrations greater than 1,400 micrograms per liter (µg/L) (where commingled with CERCLA-regulated substances) into San Francisco Bay.

**Table 7. Remediation Goals for Groundwater**

| Exposure Scenario                                     | Chemical of Concern        | Plume/Exposure Area                                                                                        | Remediation Goal (µg/L) |
|-------------------------------------------------------|----------------------------|------------------------------------------------------------------------------------------------------------|-------------------------|
| Construction Worker Exposure to A-Aquifer Groundwater | 1,2-Dichloroethene (total) | ▪ Building 406 VOC Plume                                                                                   | 270 <sup>a</sup>        |

|                                                    | Trichloroethene                                                    | <ul style="list-style-type: none"> <li>IR-03 Plume</li> <li>Building 406 VOC Plume</li> </ul>                                       | 5                       |
|                                                    | Vinyl chloride                                                     | <ul style="list-style-type: none"> <li>IR-03 Plume</li> <li>Building 406 VOC Plume</li> </ul>                                       | 0.5                     |
| Aquatic Wildlife Exposure to A-Aquifer Groundwater | Total TPH (goals vary based on distance from the bay) <sup>c</sup> | <ul style="list-style-type: none"> <li>IR-03 Plume</li> </ul>                                                                       | 1,400 to 20,000         |

Notes: The basis (risk-based, regulatory limit, or ambient level) for the remediation goals is presented in Section 3 of the FS Report (unless otherwise noted).

a = The remediation goals for select chemicals were revised (i.e., reduced slightly relative to the risk-based criteria in the FS Report) to ensure consistency with the ROD for HPNS Parcel C.

b = Remediation goals for select VOCs were added to this ROD because of their relationship to other VOCs (e.g., 1,1-dichloroethene and 1,2-dichloroethene are degradation products of trichloroethene) that were identified as chemicals of concern in the FS Report. The remediation goal for tetrachloroethene in A-aquifer groundwater is based on the risk-based criteria presented in the ROD for HPNS Parcel C. The remediation goals for 1,1-dichloroethene and 1,2-dichloroethene in B-aquifer groundwater are based on the State of California maximum contaminant limits.

c = The distance-based TPH criteria are as follows:

| Distance from shoreline (feet) | Total TPH (µg/L) | Distance from shoreline (feet) | Total TPH (µg/L) |
|--------------------------------|------------------|--------------------------------|------------------|
| 0–<25                          | 1,400            | 125–<150                       | 6,949            |
| 25–<50                         | 1,467            | 150–<175                       | 9,539            |
| 50–<75                         | 2,092            | 175–<200                       | 12,604           |
| 75–<100                        | 3,216            | 200–<225                       | 16,145           |
| 100–<125                       | 4,839            | ≥225                           | 20,000           |

HPNS = Hunters Point Naval Shipyard

IR = Installation Restoration

ROD = record of decision

TPH = total petroleum hydrocarbons

VOC = volatile organic compound

µg/L = micrograms per liter

The RAOs for groundwater would be satisfied through actions involving treatment, containment, monitoring, and ICs. As described previously, active treatment and MNA of VOC groundwater plumes would be performed to address unacceptable risk via indoor inhalation of vapors. Actions and decisions to address the indoor inhalation of vapors will be based on soil gas data and the soil gas action levels. [Section 2.9.2](#) provides further information on the actions required to satisfy the RAOs for groundwater.

**RAOs for NAPL at IR-03 (Former Oily Waste Ponds)**

- Prevent or minimize migration of NAPL to prevent discharge that would result in COEC concentrations greater than the [surface water quality criteria for aquatic wildlife<sup>\(39\)</sup>](#).
- Prevent or minimize migration of NAPL to prevent discharge that would result in total TPH groundwater concentrations greater than 1,400 µg/L into San Francisco Bay.

The COCs and COECs in soil, soil gas, shoreline sediment, and groundwater at IR-03 would be subject to the pertinent RAOs, as previously described. The RAOs for NAPL at IR-03 would be satisfied through actions involving removal, treatment, containment, monitoring, and ICs. In addition, active treatment of remaining contaminants in groundwater (following removal or treatment of NAPL) would also be performed to ensure compliance with the pertinent groundwater RAOs (regarding discharge of contaminants into San Francisco Bay). The active treatment would be supplemented with MNA to ensure that natural processes are degrading the remaining VOCs and TPH. [Section 2.9.2](#) provides further information on the actions required to satisfy the RAOs for NAPL at IR-03.

**Radiological RAO for Radiologically Impacted Media (soil, shoreline sediment, and structures)**

- Prevent exposure to ROCs at activity levels that exceed remediation goals (see [Table 8](#)) for all potentially complete exposure pathways (which include external exposure, ingestion, and inhalation of soil based on the [CSM for human health<sup>\(18\)</sup>](#)).

**Table 8. Remediation Goals for Radionuclides**

| Radionuclide  | Soil and Sediment <sup>a</sup> (pCi/g) <sup>a</sup> |                    | Surfaces                                    |                                       |
|---------------|-----------------------------------------------------|--------------------|---------------------------------------------|---------------------------------------|
|               | Industrial Worker                                   | Residential        | Equipment, Waste (dpm/100 cm <sup>2</sup> ) | Structures (dpm/100 cm <sup>2</sup> ) |
| Americium-241 | 5.67                                                | 1.36               | 100                                         | 100                                   |
| Cesium-137    | 0.113                                               | 0.113              | 5,000                                       | 5,000                                 |
| Cobalt-60     | 0.252 <sup>b</sup>                                  | 0.252 <sup>b</sup> | 5,000                                       | 5,000                                 |

| Radium-226    | 1.0 <sup>c</sup>                                    | 1.0 <sup>c</sup>   | 100                                         | 100                                   |

**Table 8. Remediation Goals for Radionuclides** *(continued)*

| Radionuclide | Soil and Sediment <sup>a</sup> (pCi/g) <sup>a</sup> |             | Surfaces                                    |                                       |
|--------------|-----------------------------------------------------|-------------|---------------------------------------------|---------------------------------------|
|              | Industrial Worker                                   | Residential | Equipment, Waste (dpm/100 cm <sup>2</sup> ) | Structures (dpm/100 cm <sup>2</sup> ) |
| Strontium-90 | 10.8                                                | 0.331       | 1,000                                       | 1,000                                 |
| Uranium-235  | 0.398                                               | 0.195       | 5,000                                       | 488                                   |

Notes: The basis (risk-based) for the RGs is presented in Section 3 of the radiological addendum to the FS Report.

a = RGs for two future use scenarios; however, the residential RGs will apply in all Parcel E areas. These more conservative RGs will enhance the protectiveness of the remedial action for Parcel E, particularly as it relates to future property transfer and the potential need to apply institutional controls for radionuclides.

b = RG for Cobalt-60 was revised to support efficient laboratory gamma spectroscopy analysis of soil samples. This revised RG maintains morbidity risks within the U.S. Environmental Protection Agency-defined acceptable range and permits an exposure level that does not increase the risk of cancer from a potential exposure to Cobalt-60.

c = Objective is 1 pCi/g above background per agreement with U.S. Environmental Protection Agency (established in "Final Basewide Radiological Removal Action, Action Memorandum – Revision 2006, Hunters Point Shipyard, San Francisco, California," dated April 21, 2006). The Radium-226 background level for surface soil is 0.633 pCi/g. The Radium-226 background level for storm drain and sewer lines is 0.485 pCi/g.

dpm/100 cm<sup>2</sup> = disintegrations per minute per 100 square centimeters

pCi/g = picocurie per gram

RG = remediation goal

The RAO for radiologically impacted media outside of IR-02 and IR-03 would be satisfied through actions involving removal. The RAO for radiologically impacted media within IR-02 and IR-03 would be satisfied through actions involving a combination of removal, containment, monitoring/maintenance, and ICs. The RAO for radiologically impacted media does not pertain to groundwater because, as described in [Section 2.3.4](#), previous investigations have not identified radionuclides in groundwater at activity levels that warrant remedial action. However, the selected remedy at IR-02 and IR-03 includes future monitoring to demonstrate, consistent with the findings of previous radiological investigations, that radionuclides are not present in groundwater at activity levels that are both statistically significant and pose an unacceptable risk to human health and the environment. The determination of statistical significance will be made in accordance with the substantive provisions of Title 22 California Code of Regulations § 66264.98(i). The duration of the groundwater monitoring for radionuclides will be determined in accordance with Title 22 California Code of Regulations § 66264.90(c). [Section 2.9.2](#) provides further information on the actions required to satisfy the RAOs for radiologically impacted media.

[Table 5](#) lists the remediation goals for COCs and COECs in soil. [Table 6](#) lists the remediation goals for COCs and COECs in shoreline sediment. [Table 7](#) lists the remediation goals for COCs in groundwater. [Table 8](#) the remediation goals for ROCs in radiologically impacted media. Remediation goals were not developed for COECs in groundwater because, except for total TPH, the water quality criteria referenced in the groundwater and NAPL RAOs are based on standards for aquatic wildlife in San Francisco Bay, apply to surface water at the interface of A-aquifer groundwater, and do not apply to in-situ A-aquifer groundwater at Parcel E. Plume-specific [trigger levels](#)<sub>(30)</sub><sup>11</sup> will be used as groundwater monitoring criteria

<sup>11</sup> Trigger levels were developed (in the FS Report for Parcel E) for specific groundwater plumes by applying attenuation factors to pertinent surface water quality criteria (as identified in pertinent surface water ARARs and, for select metals, adjusted for ambient levels). The attenuation factors vary based on several parameters (most notably, width of the contaminant plume and distance to the bay) and provide a conservative estimate of the advection and dispersion that reduces chemical concentrations as groundwater moves from an inland location to San Francisco Bay. Further information on the development of trigger levels is provided in the hyperlinked reference document ([Attachment 2](#)).

to evaluate the potential risk to aquatic wildlife in San Francisco Bay, but the RD may develop alternative monitoring criteria (using refined fate and transport modeling) to more rigorously assess the groundwater-to-surface water transport mechanism.

## 2.8. DESCRIPTION AND EVALUATION OF REMEDIAL ALTERNATIVES

The Navy screened a range of [general response actions and remedial technologies](#)<sup>(40)</sup> and used the retained technologies to develop alternatives in the FS to address contamination at Parcel E. In developing the remedial alternatives, the Navy evaluated site conditions and used experience and engineering judgment to formulate process options into the most plausible site-specific response actions. Remedial alternatives were developed and evaluated for the following contaminated media and source areas:

- Soil and shoreline sediment contaminated with nonradioactive chemicals
- Groundwater contaminated with nonradioactive chemicals
- NAPL contaminant source at IR-03
- Radiologically-impacted media (including soil, shoreline sediment, and structures)

Section 2.8.1 describes the remedial alternatives, and [Section 2.8.2](#) presents the results of the Navy's comparative analysis (performed in accordance with the NCP).

### 2.8.1. Description of Remedial Alternatives

[Table 9](#) presents the major components, details, and cost of each remedial alternative identified for soil and shoreline sediment, groundwater, NAPL at IR-03, and radiologically impacted media. The costs shown in [Table 9](#) are from the Final FS Report for the combined Parcels E and UC-3. No adjustments were made to this original cost analysis because Parcel UC-3 represents a negligible portion of the combined parcels (less than 1 percent for the soil alternatives and between 4 and 6 percent for the groundwater alternatives). Thus, the original cost estimate is valid for Parcel E.

**Table 9. Remedial Alternatives for Parcel E**

| Remedial Alternative                                                          | Approximate Cost <sup>12</sup>                                                                                                                   | Components of Remedial Alternative                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| GW-2                                                                          | <b>Capital Cost: \$0.28M<sub>(44)</sub></b><br>Total O&M Cost: \$2.9M<br>Present-Worth Cost: \$2.6M (2.7% discount rate)<br>Timeframe: 32 years  | Groundwater Monitoring: Implement long-term monitoring of groundwater to assess whether chemicals are migrating and to monitor changes in ambient conditions.<br>ICs: Impose ICs to limit the use of land or restrict activities that take place within an area.                                                                                                                                                                                                                                                                                                                |

<sup>12</sup> The approximate costs are consistent with the estimates provided in the Final FS Report for Parcel E and include small amounts attributed to implementation of the soil and groundwater alternatives at Parcel UC-3 (which was part of Parcel E at the time the FS Report was published). The approximate costs were not adjusted in this ROD to maintain consistency with the FS Report and because the proportion of these cost attributed to the soil and groundwater alternatives at Parcel UC-3 is very small (around 1 percent for the soil alternatives and between 4 and 6 percent for the groundwater alternatives).

**Table 9. Remedial Alternatives for Parcel E (continued)**

| Remedial Alternative                                                      | Approximate Cost <sup>12</sup>                                                                                                                  | Components of Remedial Alternative                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| GW-3                                                                      | <b>Capital Cost: \$1.2M<sub>(45)</sub></b><br>Total O&M Cost: \$3.8M<br>Present-Worth Cost: \$4.5M (2.7% discount rate)<br>Timeframe: 32 years  | <i>All of the same elements as Alternative GW-2, but would also include:</i><br>Groundwater Containment: Build below-ground barrier to limit groundwater flow from nearshore contaminant plumes (with PCBs and metals) into San Francisco Bay.<br>In-Situ Groundwater Treatment: Inject an organic compound (biological nutrients) at the source of groundwater contamination to stimulate biological activity to create conditions where VOCs are destroyed in groundwater. If determined necessary in the remedial design, a more aggressive form of in-situ treatment may be performed at the Building 406 TCE plume. This option would consist of injecting zero-valent iron (potentially mixed with biological nutrients) at the source of groundwater contamination to create conditions where VOCs are destroyed in groundwater.<br>Monitored Natural Attenuation: Implement long-term monitoring and studies of groundwater to assess whether chemicals are migrating and to evaluate the effects of treatment. |

## Notes:

a = The O&M activities associated with the radiological remedial alternatives are attributed to the soil cover, shoreline protection, and ICs at IR-02 and IR-03, and include inspection, landscaping maintenance, 5-year reviews, and IC implementation. However, these O&M activities are also required to implement the selected remedy for soil. Therefore, consistent with information presented in the Radiological Addendum to the FS Report, the costs associated with these O&M activities were evaluated in the FS Report as part of the analysis of the soil remedial alternatives.

CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act

ICs = institutional controls

IR = Installation Restoration

NAPL = nonaqueous-phase liquid

O&M = operation and maintenance

SVE = soil vapor extraction

TCE = trichloroethene

TPH = total petroleum hydrocarbons

VOC = volatile organic compound

## 2.8.2. Comparative Analysis of Alternatives

A comparative analysis of alternatives with respect to the **nine evaluation criteria**<sup>(54)</sup> is provided below. **Tables 10 through 13** provide a relative ranking of the alternatives for soil and shoreline sediment, groundwater, NAPL at IR-03, and radiologically impacted media, respectively. The results of the comparative analysis are briefly summarized on page 2-44.

**Table 10. Relative Ranking of Remedial Alternatives for Soil and Shoreline Sediment**

| <b>Balancing Criteria</b>                                    |                  |                                                                                                      |                                                                                                      |
| Long-Term Effectiveness and Permanence                       |                  |                                                                                                      |                                                                                                      |
| Reduction in Toxicity, Mobility, or Volume Through Treatment |                  |                                                                                                      |                                                                                                      |
| Short-Term Effectiveness                                     |                  |                                                                                                      |                                                                                                      |
| Implementability                                             |                  |                                                                                                      |                                                                                                      |
| Present-Worth Cost (\$M)                                     | 0                | 34.9                                                                                                 | 36.1                                                                                                 |
| <b>Modifying Criteria</b>                                    |                  |                                                                                                      |                                                                                                      |
| State Acceptance                                             |                  |                                                                                                      |                                                                                                      |
| Community Acceptance                                         |                  |                                                                                                      |                                                                                                      |

Notes:

Fill symbol by quarters from open (not acceptable) to full (excellent).

ARARs = applicable or relevant and appropriate requirements

CERCLA = Comprehensive Environmental Response, Compensation, and Liability Act

ICs = institutional controls

IR = Installation Restoration

***Threshold Criteria***

All alternatives, except for the no action alternatives (S-1, GW-1, O-1, and R-1) and Alternative GW-2, provide adequate protection of human health and the environment and comply with state and federal ARARs. Therefore, Alternatives S-2 through S-4, GW-3 and GW-4, O-2 through O-6, and R-2 and R-3 satisfy the two threshold criteria specified in the NCP and are eligible for selection as the final remedial action. The “no action” alternatives (S-1, GW-1, O-1, and R-1) and Alternative GW-2 would not provide adequate protection of human health and the environment and are not eligible for selection as the final remedial action.

***Primary Balancing Criteria***

Long-Term Effectiveness and Permanence. All alternatives, except for the no action alternatives (S-1, GW-1, O-1, and R-1) and Alternative GW-2, would be effective in the long-term. Of the soil alternatives, Alternative S-4 would be most effective in the long-term because the largest volume of soil contamination would be removed. Of the groundwater alternatives, Alternative GW-3 would be most effective in the long-term because it would use reliable and effective treatment technologies, as demonstrated by cleanup of groundwater at other HPNS parcels. Alternative GW-4 was rated slightly lower than Alternative GW-3 because the air sparging (proposed for the Building 406 TCE Plume) may be limited by the presence of heterogeneous soil, which poses challenges in adequately capturing VOC emissions from the unsaturated zone. For contamination at IR-03 (the Former Oily Waste Ponds), Alternative O-6 would be most effective in the long-term because the largest volume of the NAPL contaminant source would be removed. For radiologically impacted media at Parcel E, Alternatives R-2 and R-3 would be equally effective in the long-term because residual radiological contamination would be removed and, for IR-02 and IR-03, the final soil cover would protect people and wildlife from being exposed to remaining contamination. The permanent features of each alternative (such as covers) would be maintained as long as contamination that could pose an unacceptable risk remains at the site.

Reduction in Toxicity, Mobility, or Volume through Treatment. The alternatives include varying levels of treatment to address contamination in soil and groundwater, as well as contamination at IR-03 (the Former Oily Waste Ponds). Alternatives S-4, GW-3, O-4, and O-5 provide the highest performance in the way they reduce the toxicity, mobility, and volume of contaminants through treatment. Alternative GW-4 was rated slightly lower than Alternative GW-3 because the air sparging (proposed for the Building 406 TCE Plume) may be limited by the presence of heterogeneous soil, which poses challenges in effectively removing and treating VOCs from groundwater. The alternatives for radiologically impacted media focus on removing and containing contaminants at Parcel E and do not involve a significant amount of treatment. Therefore, Alternatives R-2 and R-3 would perform equally in the minimal way they reduce the toxicity, mobility, and volume of radiological contaminants through treatment.

Short-Term Effectiveness, Implementability, and Cost. Alternatives involving more active cleanup (such as excavation) generally pose more short-term risks (to humans and the environment), are more difficult to carry out, and are more expensive. This finding is illustrated by the different ratings for Alternatives S-2 and S-4

(see [Table 10](#)). In addition, the Navy's evaluation identified major differences between Alternative O-6 and Alternatives O-2, O-3, and O-4 relative to short-term effectiveness, implementability, and cost. In comparison with Alternatives O-2, O-3, and O-4, Alternative O-6 presents more short-term risks (for example, increased risk of accidents for site workers), would be more difficult to carry out, and would cost more. The ratings for Alternative O-6 were based on several factors, the most significant being the deep excavation (potentially up to 35 feet) required to completely remove the NAPL contaminant source. Alternatives O-2, O-3, and O-4 present fewer short-term risks, would be easier to carry out, and would cost significantly less in comparison with Alternative O-6. Alternative O-2 would be the easiest and least expensive because it involves only containment, while Alternatives O-3 and O-4 balance ease of implementation and cost because they would involve removing or treating the NAPL contaminant source without major excavations. For the alternatives addressing radiologically impacted media, Alternative R-2 would be easier to carry out when compared with Alternative R-3 because the soil cover (over about 45 acres comprising IR-02 and IR-03) would be 2 feet thick instead of 3 feet thick.

### ***Modifying Criteria***

State Acceptance. State involvement has been solicited throughout the CERCLA process. The State of California concurs with the Navy's selected remedial alternatives (Alternatives S-4, GW-3, O-4, and R-2).

Community Acceptance. Community acceptance is evaluated based on comments received from the public during the public comment period for the Proposed Plan. The Proposed Plan, which identified Alternatives S-4, GW-3, O-4, and R-2 as the preferred remedial alternatives, was presented to the community and discussed during a public meeting on February 28, 2013. Comments were also gathered during the public comment period from February 13 through April 1, 2013. In general, public comments expressed support for the Navy's selected remedial alternatives. [Attachment 3](#), the responsiveness summary, of this ROD addresses the public's comments and specific concerns about the selected remedial alternatives for NAPL at IR-03 (Alternative O-4) and radiologically impacted media at Parcel E (Alternative R-2). [Section 2.10](#) provides additional information on the Navy's community participation efforts for Parcel E.

## **2.9. SELECTED REMEDY**

### **2.9.1. Rationale for Selected Remedies**

The selected remedies for Parcel E are:

- **Soil and Shoreline Sediment – Alternative S-4:** Excavation and Offsite Disposal of Tier 1 and Tier 2 Locations, followed by Covers, SVE, Institutional Controls, and Shoreline Protection
- **Groundwater – Alternative GW-3:** Groundwater Containment, In-Situ Treatment, MNA, and Institutional Controls

- **NAPL at IR-03 – Alternative O-4:** Source Removal or Treatment, In-Situ Groundwater Treatment, Containment, MNA, and Institutional Controls
- **Radiologically Impacted Media – Alternative R-2:** Survey, Removal, and Disposal (with 2-foot-thick soil cover and ICs at IR-02 and IR-03)

The remedies were selected based on an evaluation of the remedial alternatives, as described in [Section 2.8](#), relative to the nine evaluation criteria. The selected remedies comply with the two threshold criteria and provide the best balance of tradeoffs with respect to the five balancing criteria. The Navy's evaluation of the two modifying criteria did not warrant changes to the preferred alternatives published in the Proposed Plan. The State of California, through DTSC and the Water Board, and segments of the community support Alternatives S-4, GW-3, O-4, and R-2. As detailed in [Attachment 3](#), the information presented by members of the community that do not support the preferred alternatives does not justify modification of them, or selection of a different alternative, based upon the community acceptance criteria.

The selected remedies will effectively reduce site risks by removing or treating significant amounts of contaminants and safely containing the remaining material. The cover and groundwater controls will prevent contact with hazardous materials remaining on site (following removal and treatment) at levels that might pose an unacceptable risk. The cover and shoreline protection will be designed to address potential erosion and earthquakes, in accordance with the substantive provisions of pertinent ARARs. In addition, the selected remedies will be subject to statutory reviews every 5 years, pursuant to CERCLA, to ensure that they remain protective of human health and the environment. The selected remedies allow the property to be used in the future in a manner consistent with CCSF's 2010 redevelopment plan and include monitoring and maintenance that would be performed as long as necessary to protect human health and the environment.

### 2.9.2. Description of Selected Remedy

The selected remedies for Parcel E will address soil, shoreline sediment, groundwater, NAPL, and residual radiological contamination. The four selected remedies are described below and will be **further developed in the RD**<sup>(55)</sup>.

#### 2.9.2.1. Removal, Treatment, and Containment of Soil and Shoreline Sediment (Alternative S-4)

Alternative S-4 includes excavation of Tier 1 and Tier 2 locations where remediation goals are exceeded (by more than five times) with offsite disposal at a permitted disposal facility. Alternative S-4 also includes excavation of TPH locations (that are commingled with CERCLA-regulated substances) where the remediation goal is exceeded, with offsite disposal at a permitted disposal facility. This alternative also provides for covers, ICs, and shoreline protection. In total, 109 areas in Parcels E are planned for excavation ([Figure 11](#)), with a total of approximately 42,000 cubic yards (about 3,250 truckloads) of soil estimated to be removed and disposed of at an approved offsite landfill. As described in [Section 2.5.3](#), the Navy is conducting a soil investigation adjacent to the shoreline in the northwest portion of Parcel E ([Figure 11](#)) that may identify additional Tier 1, Tier 2, and TPH locations requiring excavation and offsite disposal. The planned excavation areas generally range from 2 to 10 feet deep, but include isolated TPH locations adjacent to the Former Oily Waste Ponds that are up to 16 feet deep. The RD will further evaluate soil concentrations at

Tier 1, Tier 2, and TPH locations (using additional data collected during investigations performed in 2012 and 2013) and may refine the extent of the proposed excavations (based on the soil action levels that correspond to five times the remediation goals). The RD will also specify the collection of soil confirmation samples to ensure that the Tier 1, Tier 2, and TPH locations are adequately removed, so remaining chemical concentrations at these locations do not exceed the soil action levels (corresponding to five times the remediation goals; see [Table 4](#)) or the petroleum source criterion (3,500 mg/kg of total TPH). The areas of Parcel E with buried steam and fuel lines will be cleaned and closed.

At Building 406 in Parcel E, where volatile chemicals are present in soil and soil gas, an SVE system will be installed and operated to extract contaminated soil gas (using a vacuum technology) and treat the removed vapors (using adsorbent material like a charcoal filter). SVE would be performed at Building 406 until soil gas action levels are achieved or until systematic asymptotic conditions are reached without reasonable indication of further reduction based on system monitoring results. Following active treatment, soil gas monitoring will be performed at Building 406, and VOC groundwater plumes requiring treatment (as described in [Section 2.9.2.2](#)), to evaluate chemical concentrations in soil gas relative to risk-based action levels (as described in [Section 2.7](#)). As noted in [Section 2.3.2](#), a recent study (performed from 2009 to 2012) identified elevated concentrations of VOCs in soil and soil gas at IR-04 (near Building 810). The elevated VOC concentrations in soil and soil gas appear to be limited to a small area that is directly adjacent to a Tier 1 location where excavation and offsite disposal is required for metals and PCBs (see [Figure 11](#)). The RD will further evaluate VOCs in soil and soil gas in this area and may propose expanding the excavation at this Tier 1 location to address VOCs in vadose zone soil (up to 10 feet bgs), if deemed necessary to satisfy the soil gas RAO. Additionally, a soil gas survey will be conducted, following a planning process performed in consultation with the regulatory agencies, in Parcel E to:

- investigate soil gas in areas planned for mixed use where concerns continue about residual VOCs in soil (at concentrations that may pose an unacceptable risk via vapor intrusion);
- identify COCs for which risk-based numeric action levels for VOCs in soil gas would be established (based on a cumulative excess cancer risk of 1 in a million); and
- evaluate and map the extent to which areas with potential unacceptable risk via vapor intrusion require control (as described in [Section 2.9.2.5](#), areas with unacceptable vapor intrusion risk will be subject to institutional controls, and the potential risk will be reduced by engineering controls or other design alternatives that meet the specifications set forth in the ROD, RD reports, and LUC RD report).

**Figure 11. Soil Remediation Areas**

As described above, the selected remedy includes cleanup for TPH that are commingled with CERCLA-regulated substances. For areas where TPH in soil are not commingled with CERCLA-regulated substances or TPH remains after CERCLA cleanup is complete, the TPH cleanup would be conducted under the Navy's TPH Corrective Action Program for Parcel E and would not be addressed by the Navy's CERCLA program.

Durable covers would be applied across all of Parcel E as physical barriers to cut off potential exposure to residual contamination that remains in soil after excavation. Durable covers at Parcel E would consist of asphalt and concrete surfaces in the northern half of Parcel E (the Shipyard South Multi-Use District) and a 2-foot thick soil cover in the southern half and in small areas on the western edge of Parcel E (the Shipyard Shoreline Open Space District). The durable covers, which will be designed in the RD, will satisfy performance standards consistent with the pertinent state and federal ARARs (see [Attachment 4](#)), including those related to surface water drainage, erosion control, and slope stability. In addition, the cover design will also require the evaluation of subsurface methane, which was previously reported in isolated areas within IR-03 and IR-12, to determine if control measures (such as passive vents) are required to protect human health in accordance with Title 27 California Code of Regulations § 20921(a).

Two areas in Parcel E—IR-03 (the Former Oily Waste Ponds) and the northwest portion of IR-02—require additional actions to properly contain contaminants that remain in soil after excavation. A protective liner (consisting of high-density polyethylene) would be installed under the soil cover in these two areas to minimize water seeping into contaminated soil. The protective liners would work with the below-ground barriers (under Alternatives GW-3 and O-4) to minimize migration of contaminants to San Francisco Bay, as described in [Section 2.9.2.2](#).

In addition, contaminated sediment along the Parcel E shoreline would be excavated to a depth of at least 2.5 feet (which aligns with the [exposure depth for aquatic wildlife<sup>\(56\)</sup>](#) that may inhabit the shoreline) and disposed of at an approved offsite landfill. The shoreline excavations would be backfilled with natural materials (such as sand) and large rocks to prevent exposure to remaining contaminants in shoreline sediment (and to integrate with the durable covers at onshore areas). The shoreline adjacent to IR-03 and the northwest portion of IR-02 is steep and requires stronger protection. A rock revetment structure (about 2,400 feet long), consisting of large rocks placed on the shoreline slope, is proposed to prevent exposure to contaminated soil and shoreline sediment by controlling erosion and protecting the edge of the covered upland area. The remaining shoreline in Parcel E (about 2,400 feet long) has more gradual slopes and would be protected with natural materials (such as sand) over a protective rock layer to prevent exposure to contaminated soil and shoreline sediment. The covers and the shoreline protection features would be inspected and maintained regularly to ensure they remain intact. The Navy would also implement ICs after these activities for continued protection of public health and the environment and to ensure the integrity of the containment remedies (for example, soil covers).

### **2.9.2.2. Treatment and Containment of Groundwater (Alternative GW-3)**

Alternative GW-3 would achieve RAOs by actively treating VOC groundwater plumes at Parcel E using injected biological nutrients to accelerate the breakdown of VOCs to less toxic compounds. [Figure 12](#) on page 2-50 identifies the groundwater plumes to be treated. The Building 406 plume may require more aggressive treatment using injected zero-valent iron (potentially mixed with biological nutrients), if determined necessary in the RD to satisfy the soil gas RAO (as described in [Section 2.7](#)). The injection process will be developed in the RD and will be implemented in a manner that allows for regular optimization so that the RAOs are met in a timely, cost-effective manner while minimizing negative environmental effects (e.g., energy consumption, greenhouse gas emissions, and accident risk). The optimization process will be informed by performance monitoring data for various factors that are critical to successful in-situ treatment (e.g., changes in VOC concentrations within the groundwater plume, and geochemical conditions that are conducive to natural degradation of VOCs). Potential optimization measures may include modifying the amount or type of treatment material, or modifying the injection method to improve the distribution of the treatment chemicals. Active treatment will be performed until the technology is no longer the most cost-effective or environmentally sustainable option, at which point a recommendation will be made to transition to MNA. The recommended transition to MNA, which would be subject to approval by the FFA signatories, will need to demonstrate that natural processes are adequately degrading the remaining VOCs (to allow RAOs to be achieved in a timely manner), and that continued active treatment would be less cost-effective and environmentally sustainable (in comparison to MNA).

**Figure 12. Groundwater Remediation Areas**

As part of the performance monitoring, groundwater quality (as well as flow direction) will be monitored at the VOC groundwater plumes to evaluate the breakdown of VOCs to less toxic compounds, and soil gas will be monitored to evaluate concentrations relative to risk-based action levels (as described in [Section 2.7](#)). Groundwater monitoring will continue until chemical concentrations meet remediation goals, and soil gas monitoring will continue until chemical concentrations are less than risk-based action levels. ICs will be implemented to restrict access to and use of contaminated groundwater (both VOC groundwater plumes and other groundwater plumes near San Francisco Bay).

For groundwater plumes near San Francisco Bay containing metals and PCBs (at IR-02), a below-ground barrier will be constructed to control discharge of contaminated groundwater into the bay. The below-ground barrier would work with the protective liners (under Alternative S-4) to minimize migration of contaminants to San Francisco Bay. The below-ground barrier would decrease the groundwater flow gradient and consequently increase the residence time (for groundwater behind the barrier) during which chemical concentrations would be reduced through physical, chemical, and biological processes. The presence of the barrier would lead to hydraulic head buildup behind it, which would dissipate by lateral movement of groundwater around the barrier. In addition, the hydraulic head buildup behind the barrier

would be lower during high tides, when bay waters move inland through the tidal mixing zone. Groundwater quality (as well as flow direction) will be monitored at the plumes behind the below-ground barrier to ensure that contamination is not discharged into San Francisco Bay at concentrations greater than the corresponding [surface water quality criteria for aquatic wildlife](#)<sup>(39)</sup> (to comply with the groundwater RAO specified in Section 2.7). Plume-specific [trigger levels](#)<sup>(30)</sup><sup>13</sup> will be used as groundwater monitoring criteria to evaluate the potential risk to aquatic wildlife in San Francisco Bay, but the RD may develop alternative monitoring criteria (using refined fate and transport modeling) to more rigorously assess the groundwater-to-surface water transport mechanism.

### 2.9.2.3. Removal, Treatment, and Containment of NAPL at IR-03 (Alternative O-4)

Alternative O-4 would achieve RAOs by using a combination of technologies (such as excavation and offsite disposal, in-situ stabilization/solidification, or thermally-enhanced extraction) to remove or treat the NAPL contaminant source. The Navy will perform additional studies to select the best combination of technologies to cost-effectively remove or treat the NAPL contaminant source at IR-03; as described in [Section 2.3.3](#), the Navy is conducting a study at IR-03, concurrent with this ROD, to further characterize the the NAPL and test two technologies (in-situ stabilization/solidification and thermally-enhanced extraction) in the field. The FS Report assumed for cost-estimating purposes that the NAPL source removal and treatment activities would be limited to the area within the IR-03 site boundary (corresponding to the IR-03 area on [Figure 12](#) encircled by the green line), where the distribution of NAPL is the most extensive. NAPL associated with the Former Oily Waste Ponds is present outside the IR-03 boundary, and the cost estimates for Alternative S-4 assume these areas will be addressed by excavation and offsite disposal. The RD will evaluate the data from recent studies and determine the extent to which removal and treatment technologies can cost-effectively satisfy the NAPL RAOs (as described in [Section 2.7](#)). Based on this determination to be provided in the RD, the NAPL removal and treatment area may be increased or decreased, with the remaining NAPL contamination being addressed by containment, monitoring, and ICs.

As described for Alternative S-4, a 2-foot-thick soil cover with protective liner would be constructed to prevent exposure to remaining contaminants and limit groundwater infiltration. Also, as described for Alternative GW-3, a below-ground barrier would be constructed to control discharge of NAPL and contaminated groundwater into San Francisco Bay. Following removal or treatment of the NAPL, biological nutrients would be injected to create conditions where remaining contaminants in groundwater are broken down to less toxic compounds. As described for Alternative GW-3, the injection process will be developed in the RD, and will be implemented in a manner that allows for regular optimization so that the RAOs are met in a timely, cost effective manner while minimizing negative environmental effects (e.g., energy consumption, greenhouse gas emissions, and accident risk). The optimization process will be informed by performance monitoring data for various factors that are critical to successful in-situ treatment

---

<sup>13</sup> Trigger levels were developed (in the FS Report for Parcel E) for specific groundwater plumes by applying attenuation factors to pertinent surface water quality criteria (as identified in pertinent surface water ARARs and, for select metals, adjusted for ambient levels). The attenuation factors vary based on several parameters (most notably, width of the contaminant plume and distance to the bay) and provide a conservative estimate of the advection and dispersion that reduces chemical concentrations as groundwater moves from an inland location to San Francisco Bay. Further information on the development of trigger levels is provided in the hyperlinked reference document (Attachment 2).

(e.g., changes in contaminant concentrations within the groundwater plume, and geochemical conditions that are conducive to natural degradation of the remaining contaminants). Potential optimization measures may include modifying the amount or type of treatment material, or modifying the injection method to improve the distribution of the treatment chemicals. Active treatment will be performed until the technology is no longer the most cost-effective or environmentally sustainable option, at which point a recommendation will be made to transition to MNA. The recommended transition to MNA, which would be subject to approval by the FFA signatories, will need to demonstrate that natural processes are adequately degrading the remaining contaminants (to allow RAOs to be achieved in a timely manner), and that continued active treatment would be less cost effective and environmentally sustainable (in comparison to MNA).

Similar to Alternative GW-3, groundwater quality (as well as flow direction) will be monitored to ensure that contamination is not discharged into San Francisco Bay at concentrations greater than the corresponding [surface water quality criteria for aquatic wildlife<sup>\(39\)</sup>](#) (these criteria also include, consistent with the NAPL RAO in Section 2.7, a discharge limit for total TPH of 1,400 µg/L). Plume-specific [trigger levels<sup>\(30\)</sup>](#)<sup>14</sup> will be used as groundwater monitoring criteria to evaluate the potential risk to aquatic wildlife in San Francisco Bay, but the RD may develop alternative monitoring criteria (using refined fate and transport modeling) to more rigorously assess the groundwater-to-surface water transport mechanism. In addition, ICs would be implemented to restrict access to and use of contaminated groundwater.

#### **2.9.2.4. Removal and Containment of Radiologically Impacted Media (Alternative R-2)**

Alternative R-2 would achieve RAOs by performing the following actions: (1) scanning radiologically impacted areas at Parcel E that may include structures (requiring aboveground scans), former building sites (requiring surface scans), and buried storm drain and sewer lines (requiring subsurface scans); (2) decontaminating (and demolishing if necessary) buildings at Parcel E (demolition of small buildings may be performed if deemed the most cost-effective means of achieving the RAOs); (3) screening, separating, and disposing of radiologically contaminated debris and soil at an approved landfill; and (4) performing final surveys to demonstrate remediation goals have been met. The final radiological cleanup has been initiated (under a time-critical removal action) in all of Parcel E areas except IR-02 and IR-03 (see [Figure 7](#)). The Navy has also removed storm drain and sewer lines throughout most of Parcel E as part of the same radiological removal action. As described in [Section 2.3](#), the radiological removal action is scheduled for completion in 2015 and the results will be summarized in a final RACR, which will be reviewed and approved by the FFA signatories and CDPH. Although the radiological removal action will not be completed by the time this ROD is signed, the removal action is intended to achieve cleanup goals identical to the RAOs specified in this ROD. If the removal action does not achieve its cleanup goals, cleanup will continue in accordance with the remedial action selected in this ROD until the RAOs are achieved.

---

<sup>14</sup> Trigger levels were developed (in the FS Report for Parcel E) for specific groundwater plumes by applying attenuation factors to pertinent surface water quality criteria (as identified in pertinent surface water ARARs and, for select metals, adjusted for ambient levels). The attenuation factors vary based on several parameters (most notably, width of the contaminant plume and distance to the bay) and provide a conservative estimate of the advection and dispersion that reduces chemical concentrations as groundwater moves from an inland location to San Francisco Bay. Further information on the development of trigger levels is provided in the hyperlinked reference document (Attachment 2).

The ongoing removal action does not address IR-02 and IR-03 because nonradioactive chemicals in soil and shoreline sediment within these areas require remedial action, which would be performed concurrent with future radiological remediation. Alternative R-2 would achieve RAOs and address the radiologically impacted media in IR-02 and IR-03 by performing the following actions: (1) scanning the entire area for radioactivity to a depth of at least 1 foot; (2) removing residual radiological contamination to a depth of 1 foot (the maximum effective depth of the surface survey) and disposing of it at an approved landfill; (3) constructing a 2-foot-thick soil cover (as provided by the selected remedy for soil, Alternative S-4) to prevent exposure to remaining contaminants and installing a demarcation layer to mark the boundary between the existing surface and the soil cover (see [Figure 11](#)); (4) conducting regular inspections and maintenance (as provided by the selected remedy for soil, Alternative S-4) of the soil cover and adjoining shoreline protection features to ensure their integrity; and (5) implementing ICs to limit the use of land or restrict activities that take place within the area. Deeper soil excavation would be performed at IR-02 and IR-03, if necessary, to ensure that the residual radiological risk (i.e., the incremental excess cancer risks from exposure to radionuclides in soil) at the final ground surface (following installation of a demarcation layer and soil cover) is acceptable. The residual radiological risk at the final ground surface (based on residential exposure) would be within the risk management range specified in the NCP ( $10^{-6}$  to  $10^{-4}$ ). In preparing the RD, the Navy would work closely with the regulatory agencies to develop specific protocols for determining when deeper soil excavation is needed to ensure that the residual radiological risk at the final ground surface is acceptable. In addition, the Navy would perform radiological risk modeling, in conjunction with the final radiological surveys, to verify that the residual radiological risk is acceptable. Buried storm drain and sewer lines in IR-02 and IR-03 would remain in place because the soil cover and ICs would prevent exposure to residual radiological contamination in these lines. Also, future groundwater monitoring would be performed in IR-02 and IR-03 to demonstrate, consistent with the findings of previous radiological investigations, that radionuclides are not present in groundwater at activity levels that are both statistically significant and pose an unacceptable risk to human health and the environment. The determination of statistical significance will be made in accordance with the substantive provisions of Title 22 California Code of Regulations § 66264.98(i). The duration of the groundwater monitoring for radionuclides will be determined in accordance with Title 22 California Code of Regulations § 66264.90(c).

#### **2.9.2.5. Monitoring, Maintenance, and Institutional Controls**

Each of the selected remedies includes the monitoring and maintenance activities that would be performed as long as necessary to protect human health and the environment and to comply with the substantive provisions of pertinent state and federal ARARs (see [Attachment 4](#)). In addition, the selected remedy will be subject to statutory reviews every 5 years pursuant to CERCLA to ensure that it remains protective of human health and the environment.

The Navy would also implement ICs, which are legal and administrative mechanisms for the continued protection of human health and the environment. In Parcel E, the objectives of the ICs are to implement land use and activity restrictions that are used to limit the exposure of future landowner(s) or user(s) of the property to hazardous substances present on the property and in groundwater, and to ensure the integrity of the remedial action, including any current or future remedial or monitoring systems such as monitoring wells and

subsurface groundwater control barriers. Institutional controls are required on a property where the selected remedial action results in contamination remaining at the property above levels that allow for unlimited use and unrestricted exposure. The ICs for Parcel E would restrict the development, land use, and activities on Parcel E property as described in this ROD. These ICs would be maintained until the concentrations of hazardous substances in soil and groundwater are at such levels to allow for unrestricted use and exposure. Implementation of ICs at Parcel E includes requirements for monitoring and inspections and reporting to ensure compliance with land use or activity restrictions. Figure 13 presents the area requiring institutional controls (ARIC) for nonradioactive chemicals, which comprises all of Parcel E. Figure 12 also identifies the ARIC for radionuclides (pink shading on Figure 13; also referred to as the radiological ARIC), which consists of all of IR-02 and IR-03. Outside of the radiological ARIC, potential radioactive contamination exceeding the remediation goals would be removed, thus these areas would not require ICs regarding exposure to radioactivity.

**Figure 13. Area Requiring Institutional Controls**

The Navy has determined that it will rely on proprietary controls in the form of environmental restrictive covenants as provided in the “Memorandum of Agreement between the United States Department of the Navy and the California Department of Toxic Substances Control” (hereinafter referred to as the “Navy/DTSC MOA”).

More specifically, land use and activity restrictions will be incorporated into two separate legal instruments as provided in the Navy/DTSC MOA:

1. Restrictive covenants included in one or more Quitclaim Deeds from the Navy to the property recipient.
2. Restrictive covenants included in one or more “Covenant to Restrict Use of Property” entered into by the Navy and DTSC as provided in the Navy/DTSC MOA and consistent with the substantive provisions of Title 22 California Code of Regulations § 67391.1.

The “Covenant(s) to Restrict Use of Property” will incorporate the land use and activity restrictions into environmental restrictive covenants that run with the land and that are enforceable by DTSC against future transferees. The Quitclaim Deed(s) will include the identical land use and activity restrictions in environmental restrictive covenants that run with the land and that will be enforceable by the Navy against future transferees.

The land use and activity restrictions in the “Covenant(s) to Restrict Use of Property” and Quitclaim Deed(s) shall be further defined in the land use control remedial design (LUC RD) report that would be prepared by the Navy and reviewed and approved by the other FFA signatories. The LUC RD report shall be referenced in the applicable Covenant to Restrict Use of Property and Deed. CCSF may prepare a risk management plan (RMP) to be approved by the FFA signatories that may set forth certain requirements and protocols used to conduct restricted activities that shall be overseen by the FFA signatories (and CDPH for restricted activities conducted within the radiological ARIC).

In addition to being set forth in the “Covenant(s) to Restrict Use of Property” and Quitclaim Deed(s) as described above, restrictions applied to specified portions of the property will be described in findings of suitability to transfer.

### ***Access***

The Deed and Covenant shall provide that the Navy and other FFA signatories, where applicable, and for CDPH in the radiological ARIC, and their authorized agents, employees, contractors, and subcontractors shall have the right to enter upon HPNS Parcel E to conduct investigations, tests, or surveys; inspect field activities; or construct, operate, and maintain any response or remedial action as required or necessary under the cleanup program, including but not limited to monitoring wells, pumping wells, treatment facilities, and cap and containment systems.

### ***Implementation***

The Navy shall address and describe implementation and maintenance actions for ICs, including periodic inspections and reporting requirements, in the preliminary and final RD reports to be developed and submitted to the other FFA signatories for review pursuant to the FFA (see “Navy Principles and Procedures for Specifying, Monitoring and Enforcement of Land Use Controls and Other Post-ROD Actions” attached to January 16, 2004 Department of Defense memorandum titled “Comprehensive Environmental Response,

Compensation and Liability Act [CERCLA] Record of Decision [ROD] and Post-ROD Policy”). The preliminary and final RD reports are primary documents as provided in Section 7.3 of the FFA.

The Navy is responsible for implementing, maintaining, reporting on, and enforcing ICs. Although the Navy may later transfer these procedural responsibilities to another party by contract, property transfer agreement, or through other means, the Navy shall retain ultimate responsibility for integrity of the remedy.

### ***Land Use and Activity Restrictions***

The following paragraphs describe the IC objectives to be achieved through land use and activity restrictions to ensure that any necessary measures to protect human health and the environment and the integrity of the remedy have been undertaken.

#### **General Activity Restrictions**

The following restricted activities throughout HPNS Parcel E must be conducted in accordance with the “Covenant(s) to Restrict Use of Property,” Quitclaim Deed(s), the Operation and Maintenance Plan(s), LUC RD report and, if deemed necessary, the RMP and any other work plan or document approved in accordance with these referenced documents:

- a. “Land disturbing activity,” which includes but is not limited to (1) excavation of soil and sediment; (2) construction of roads, utilities, facilities, structures, and appurtenances of any kind; (3) demolition or removal of “hardscape” (for example, concrete roadways, parking lots, foundations, and sidewalks); (4) any activity that involves movement of soil to the surface from below the surface of the land; and (5) any other activity that causes or facilitates the movement of groundwater known to be contaminated with radionuclides or nonradioactive chemicals. Land-disturbing activities are not intended to include placement of additional clean, imported fill on top of the soil cover that the Navy will construct at HPNS Parcel E.
- b. Alteration, disturbance, or removal of any component of a response or cleanup action (including but not limited to pump-and-treat facilities, revetment walls and shoreline protection, and soil cap/containment systems); groundwater extraction, injection, and monitoring wells and associated piping and equipment; or associated utilities.
- c. Extraction of groundwater and installation of new groundwater wells.
- d. Removal of or damage to security features (e.g., locks on monitoring wells, survey monuments, fencing, signs, or monitoring equipment and associated pipelines and appurtenances).

In addition, the following activities are prohibited throughout HPNS Parcel E:

- a. Growing vegetables, fruits, and any edible items in native soil for human consumption. Plants for human consumption may be grown if they are planted in raised beds (above the CERCLA-approved cover) containing non-native soil. Trees producing edible fruit (including trees producing edible nuts) may also be planted provided they are grown in containers with a bottom that prevents the roots from penetrating the native soil.
- b. Use of groundwater.

*Activity Restrictions Relating to Soil and Associated VOC Vapors at Specific Locations within Parcel E*

Any proposed construction and occupancy of enclosed structures within the ARIC for VOC vapors must be approved by the FFA signatories in accordance with the “Covenant to Restrict Use of the Property,” Quitclaim Deed, and LUC RD to ensure that the risks of potential exposures to VOC vapors are reduced to acceptable levels that are adequately protective of human health. The ARIC for VOC vapors currently includes the entire ARIC for nonradioactive chemicals (both the green and pink shaded areas) shown on [Figure 13](#).

The reduction in potential risk can be achieved through engineering controls or other design alternatives that meet the specifications set forth in the ROD, RD reports, and LUC RD report. When construction of enclosed structures or reuse of an existing building is proposed in an ARIC for VOC vapors, the FFA signatories must approve the design of the vapor control system built into foundations. In addition, enclosed structures within the ARIC for VOC vapors at Parcel E shall not be occupied until the Owner has requested and obtained FFA signatory approval (through approval of a RACR or similar document) that any necessary engineering controls or design alternatives have been properly constructed and are operating successfully.

The FFA signatories may modify the ARIC as soil contamination areas and groundwater contaminant plumes that are producing unacceptable vapor inhalation risks are reduced over time or in response to further soil, vapor, and groundwater sampling and analysis for VOCs that establishes that areas now included in the ARIC do not pose unacceptable potential exposure risk to VOC vapors.

*Additional Land Use Restrictions for IR-02 and IR-03 and Other Areas Designated for Open Space Reuse*

In addition to the specific activities prohibited below, IR-02 and IR-03 would be restricted to open space and recreational uses, unless written approval for other uses is granted by the FFA signatories and CDPH. In addition, the following land uses would be specifically prohibited unless written approval for such uses is granted by the FFA signatories and the CDPH in accordance with the “Covenant(s) to Restrict Use of the Property,” Quitclaim Deed(s), and LUC RD report:

- a. A residence, including any mobile home or factory built housing, constructed or installed for use as residential human habitation.
- b. A hospital for humans.
- c. A school for persons under 21 years of age.
- d. A daycare facility for children.

The restricted land uses identified above shall also apply to property areas in the Shipyard Shoreline Open Space District, as identified in the CCSF’s 2010 redevelopment plan for HPNS, unless written approval for such uses is granted by the FFA signatories in accordance with the “Covenant(s) to Restrict Use of the Property,” Quitclaim Deed(s), and LUC RD report. Parcel E property areas within the Shipyard Shoreline Open Space District are identified as Redevelopment Blocks EOS-1, EOS-2, EOS-3, EOS-4, EOS-5A, EOS-5B, and EOS-5C ([Figure 5](#)).

*Additional Activity Restrictions Related to Radionuclides at Parcel E*

Exposure to radionuclides in the radiological ARIC, comprising IR-02 and IR-03 (see [Figure 13](#)), would be prevented by three separate components: (1) an engineered cover, consisting of clean imported fill and (in some areas) a low hydraulic conductivity layer, to provide adequate shielding against residual radioactivity; (2) permeable geosynthetic fabric to serve as a demarcation layer between soil cover and underlying soil with residual radioactivity; and (3) ICs to implement land use and activity restrictions necessary to limit the exposure to radiological hazardous substances and to ensure the integrity of the remedial action.

In addition to the land use and activity restrictions specified above, the following activity restriction would apply in the radiological ARIC.

- a. Land-disturbing activities within the radiological ARIC, as defined above and including installation of water lines, storm drains, or sanitary sewers below the demarcation layer, are strictly prohibited unless approved in writing by the FFA signatories and the CDPH. Any proposed land-disturbing activity within the ARIC for radionuclides shall be described in a work plan that will include but not be limited to a radiological work plan, the identification of a radiological safety specialist, a soil management plan, soil sampling and analysis requirements, and a plan for offsite disposal of any excavated radionuclides by the transferee in accordance with federal and state law. This work plan must also specify appropriate procedures for the proper identification and handling of material potentially presenting an explosive hazard<sup>15</sup>. This work plan must be submitted to and approved in writing by the FFA signatories and CDPH in accordance with procedures (including dispute resolution procedures) and timeframes that will be set forth in the Parcel E Operations and Maintenance Plan (OMP) and LUC RD Report.
- b. Following implementation of an approved land-disturbing activity within the radiological ARIC, the integrity of the cover/cap must be restored upon completion of excavation as provided in the OMP, LUC RD report, or similar document. A completion report describing the details of the implementation of the work plan, sampling and analysis (if required), offsite disposal (if required), and the restoration of the integrity of the cover/cap must be submitted to and approved in writing by the FFA signatories and CDPH in accordance with procedures (including dispute resolution procedures) and timeframes that will be set forth in the OMP and LUC RD Report.
- c. For land-disturbing activities, as defined above and including installation of water lines, storm drains, or sanitary sewers above the demarcation layer, the LUC RD report, the OMP, or, if deemed necessary, the RMP or a project-specific work plan will list the procedures for ensuring that the cover is not disturbed or breached. The specific design of the cover shall be agreed to in the RD. Installation of water lines, storm drains, or sanitary sewers in any additional clean, imported fill placed on top of the soil cover that the Navy has constructed at the Property is not intended to be restricted if the property owner demarcates the interface between the preexisting cover and any new imported soil.

---

<sup>15</sup> Previous radiological removal actions in IR-02 encountered material potentially presenting an explosive hazard that required inspection by qualified unexploded ordnance technicians and handling/disposal in accordance with Department of Defense guidelines. This prior finding necessitates similar protocols for future land-disturbing activities within the radiological ARIC (which includes all of IR-02 and IR-03).

At the time of transfer, the areas that require this restriction will be surveyed to define the legal metes and bounds for inclusion in the property transfer documents. No variance or exemption from this restriction shall be allowed unless written approval is provided by the FFA signatories and CDPH. The OMP or LUC RD report shall address any necessary additional soil and radiological management requirements; for example, inspections, monitoring, and reporting requirements for portions of Parcel E in the radiological ARIC.

### **2.9.3. Expected Outcomes of the Selected Remedy**

Once the selected remedies have been implemented, risks to human health and the environment under the planned future uses will be acceptable and the RAOs will be achieved. Removal and offsite disposal of soil, shoreline sediment, NAPL, and radiologically impacted media in selected areas will reduce site risks, and the cover will prevent contact with remaining contamination that might pose an unacceptable risk. Treatment of soil gas, groundwater, and NAPL in selected areas will reduce concentrations of nonradioactive chemicals and reduce their migration potential. The groundwater remedy is expected to achieve the remediation goals presented in [Table 7](#) via active treatment and MNA of VOCs in groundwater to restore the aquifer quality by reducing or immobilizing the mass of COCs in groundwater to levels that do not pose a threat to human health through the inhalation exposure pathway. As described in [Section 2.9.2.2](#), active treatment will be performed until the technology is no longer the most cost-effective or environmentally sustainable option, at which point MNA will be relied upon to degrade the remaining VOCs (following approval by the FFA signatories). Although active treatment of groundwater (with MNA) is expected to reduce VOC and SVOC vapors released from groundwater, ICs for vapor intrusion may be needed at some locations at Parcel E (as discussed in [Section 2.9.2.5](#)). Furthermore, the Navy intends to permanently prohibit use of groundwater at Parcel E through implementation of ICs.

The remedy for radiologically impacted media includes surveys, decontamination, excavation, and offsite disposal. Removal of contaminants from radiologically impacted buildings and former building sites with documented radiological impacts and removal of potential radiologically impacted sanitary and storm sewers and soil are expected to result in a reduction of the potential risks to levels less than the remediation goals presented in [Table 8](#) associated with exposure to ROCs.

The selected remedies will take a relatively short period of time to implement and will use readily available technologies and labor. Following implementation, long-term monitoring, MNA, and maintenance will ensure the continued protection of human health and the environment. In addition, ICs will restrict potential exposure to contaminated soil, shoreline sediment, and groundwater and the restrictions will be consistent with the planned future use of Parcel E.

### **2.9.4. Statutory Determinations**

In accordance with the NCP, the selected remedies meet the following statutory determinations.

- **Protection of Human Health and the Environment** – The selected remedies will adequately protect human health and the environment by preventing exposure to COCs and COECs through (1) removal and offsite disposal of soil, shoreline sediment, NAPL, and radiologically impacted media to significantly reduce risks in selected areas; (2) treatment of soil gas, groundwater, and NAPL to reduce the potential for contaminant migration in selected areas; and (3) installation and monitoring of soil and groundwater containment systems (including durable covers and below-ground barriers) and the implementation of ICs.
- **Compliance with Applicable or Relevant and Appropriate Requirements (ARARs)** – CERCLA § 121(d)(1) states that remedial actions on CERCLA sites must attain (or the decision document must justify the waiver of) any federal or more stringent state environmental standards, requirements, criteria, or limitations that are determined to be legally applicable or relevant and appropriate. The selected remedies for Parcel E will comply with the substantive provisions of the federal and state requirements identified as ARARs. The chemical-, location-, and action-specific ARARs for the selected remedy are summarized in [Attachment 4](#).
- **Cost-Effectiveness** – As specified in the NCP, the cost-effectiveness of a remedy is determined in two steps. First, the overall effectiveness of a remedial alternative is determined by evaluating the following three of the five balancing criteria: (1) long-term effectiveness and permanence; (2) reduction in toxicity, mobility, or volume through treatment; and (3) short-term effectiveness. The overall effectiveness is then compared to cost to determine whether a remedy is cost-effective. The selected remedies have a high overall effectiveness because, relative to the other remedial alternatives, they offer a high degree of long-term effectiveness in a manner that maximizes the use of treatment (to reduce the toxicity, mobility, or volume of contaminants) and minimizes short-term risks. The selected remedies will provide high overall effectiveness proportional to their costs. For example, Alternatives S-4 and GW-3 offer improved overall effectiveness for a modest incremental cost increase (relative to other alternatives). Therefore, the selected remedies are considered cost-effective. In contrast, Alternative O-6 is not considered cost-effective because its lower overall effectiveness (relative to Alternative O-4) is accompanied by a significant incremental cost increase (nearly 50 percent relative to Alternative O-4).
- **Use of Permanent Solution and Alternative Treatment Technologies (or Resource Recovery Technologies) to the Maximum Extent Practicable** – The Navy has determined that the selected remedies represent the maximum extent to which permanent solutions and treatment are practicable at this site. The selected remedies include treatment components to reduce toxicity, mobility, or volume of VOCs in soil gas and groundwater at various locations, as well as NAPL at IR-03. For the soil remedy, the Navy concluded that, because soil contamination is widely dispersed across the parcel, a containment remedy combined with excavation of more highly contaminated soil represents the maximum extent to which permanent solutions can be used in a cost-effective manner. For the NAPL at IR-03, the Navy concluded that the selected remedy (Alternative O-4) provides the best balance of tradeoffs relative to the five balancing criteria: (1) long-term effectiveness and permanence; (2) reduction in toxicity, mobility, or volume through treatment; (3) short-term effectiveness; (4) implementability; (5) and cost. Alternative O-4 provides a high degree of long-term effectiveness, although not as high as Alternative O-6, because the NAPL contaminant source would be removed and treated, and the final soil cover, protective liner, and below-ground barrier (for groundwater) would protect people and wildlife from being exposed to remaining contamination. Alternative O-4 provides the highest degree of short-term effectiveness and implementability because it uses proven and accepted technologies

that can be implemented more quickly and readily than the other alternatives, most notably Alternative O-6, thereby reducing the short-term risks to site workers and the surrounding community. Alternative O-4 would cost significantly less than Alternative O-6. The selected remedies are expected to be permanent and effective in light of the anticipated land use.

- **Preference for Treatment as a Principal Element** – The selected remedy for soil and shoreline sediment does not satisfy the statutory preference for treatment<sup>16</sup> as a principal element because no cost-effective means of treating the large quantity of low-level soil contamination is available and the quantities of soil to be excavated cannot be treated in a cost-effective manner. With the exception of soil gas treatment (via SVE), the soil and shoreline sediment remedy would not reduce the toxicity, mobility, or volume of contaminants through treatment, but would provide for offsite disposal of more highly contaminated soil at a facility, which would minimize the potential for those hazardous substances to migrate or otherwise pose a threat. The selected remedy for groundwater and NAPL at IR-03 satisfies the statutory preference for treatment as a principal element of the remedy; that is, it would reduce the toxicity, mobility, or volume of contaminants through treatment as a principal element. The selected remedy for radiologically impacted media does not include treatment as a principal element because no technology is available to reduce the toxicity or volume of radionuclides in contaminated soil or building materials.
- **Five-Year Review Requirements** – Statutory five-year reviews pursuant to CERCLA § 121 and the NCP will be conducted because the selected remedies may leave contamination in place at Parcel E above levels that allow for unrestricted use and unlimited exposure. Five-year reviews for Parcel E will follow the ongoing schedule of five-year reviews established for other remedies in place at HPNS (the next five-year review for HPNS will be completed in 2018).

### 2.9.5. Documentation of Significant Changes

No significant changes were made to the ROD from the information presented in the Proposed Plan.

## 2.10. COMMUNITY PARTICIPATION

Community participation at HPNS includes public meetings, public information repositories, an IR Program website, newsletters and fact sheets, public notices, and site tours. The Community Involvement Plan for HPNS provides detailed information on community participation for the IR Program and documents interests, issues, and concerns raised by the community regarding ongoing investigation and cleanup activities at HPNS. The Navy held a community meeting on February 2, 2010, to solicit community input on updating the Community Involvement Plan for HPNS. The Navy used this input in preparing an update to the **Community Involvement Plan**<sup>(57)</sup>, which was finalized in May 2011. The Navy is currently working on another update to the community involvement plan, which is scheduled for completion in summer 2013.

Starting in January 2010, the Navy began conducting bimonthly Community Technical Meetings to discuss the technical aspects of the CERCLA milestone documents with community members (and with

<sup>16</sup> As defined in the NCP (Title 40 Code of Federal Regulations § 300.5), “treatment technology” means any unit operation or series of unit operations that alters the composition of a hazardous substance or pollutant or contaminant through chemical, biological, or physical means so as to reduce toxicity, mobility, or volume of the contaminated materials being treated. Treatment technologies are an alternative to land disposal of hazardous wastes without treatment.

participation from the BCT). Documents and relevant information relied upon in the remedy selection process are made available for public review in the public information repositories (listed at the end of this section) or on the [IR Program website](#)<sup>(58)</sup>.

Community participation is also solicited through public mailings, including newsletters, fact sheets, public notices, and proposed plans, which are designed to broadly disseminate information throughout the local community. Public mailings for HPNS are sent to more than 2,000 groups and individuals that have added their names to the community mailing list, including residents in the local Hunters Point-Bayview community; city, state, and federal officials; regulatory agencies; and other interested groups and individuals. Previous updates and fact sheets have included general program information such as the status of environmental investigations and cleanup activities at each HPNS parcel. In addition, the Navy has held periodic site tours of HPNS to better explain the status of cleanup activities to interested community members.

For Parcel E, a significant effort was made to inform the public of the remedy proposed in the Proposed Plan and selected in this ROD. Prior to making the Proposed Plan available for public review, public notices of the meeting and availability of documents was placed in the *San Francisco Chronicle* on February 10, 2013; the *San Francisco Bayview* on February 1, 2013; and *Sun-Reporter* on February 7, 2013. The Proposed Plan, along with [the associated fact sheet](#)<sup>(59)</sup>, was distributed to recipients on the community mailing list beginning on February 12, 2013.

In accordance with CERCLA § 113 and § 117, the Navy provided a public comment period from February 13, 2013, to April 1, 2013, for the proposed remedial action described in the Proposed Plan for Parcel E. A public meeting to present the Proposed Plan was held from 6:00 to 9:00 p.m. on February 28, 2013. At the public meeting, the Navy gave presentations on the conditions at Parcel E and representatives from the Navy and regulatory agencies were available to answer questions. A [transcript of the public meeting](#)<sup>(60)</sup> prepared by a court reporter is part of the Administrative Record for this ROD and is available on the CD for this ROD. Responses to spoken comments received during the public meeting and written comments received during the public comment period are included in the Responsiveness Summary in [Section 3](#).

Key supporting documents that pertain to Parcel E and a complete index of all Navy HPNS documents are available at the following information repositories:

## Section 3. Responsiveness Summary

---

The responsiveness summary is the third component of a ROD; its purpose is to summarize information about the views of the public and regulatory agencies on both the remedial alternatives and general concerns about Parcel E submitted during the public comment period. It documents in the record how public comments were integrated into the decision-making process. The participants in the public meeting, held on February 28, 2013, included community members and representatives of the Navy, EPA, DTSC, and the Water Board. Questions and concerns received during the meeting were addressed at the meeting and are documented in the meeting transcript. Responses to comments provided at the meeting and received during the public comment period by the Navy, EPA, DTSC, or the Water Board are included in the responsiveness summary ([Attachment 3](#)). In addition, responses to comments received on the draft version of this ROD are provided in [Attachment 5](#).

### 2.2.1. HPS and Surrounding Land Use

The main portion of HPS is situated on a long headland located in the southeastern part of San Francisco, extending eastward into San Francisco Bay (see [Figure 1-1](#)). HPS is bounded on the north, south, and east by the bay and on the west by the Bayview/Hunters Point district of San Francisco. HPS consists of 866 acres: 420 acres on land and 446 acres under water in the bay.

Parcel E includes about 139 acres of relatively flat shoreline and lowland coast along the southwestern portion of HPS (see [Figure 1-2](#)). Parcel E is bounded to the north by non-Navy property, to the east by Parcels D-1, G, and UC-1, to the south by intertidal shoreline areas along San Francisco Bay, and to the west by Parcel E-2 and non-Navy-property. Parcel E contains 44 buildings, and the adjoining offshore area contains 14 ship berths and 2 piers.

Historically, most of Parcel E was used as industrial support area, consisting of supply and public works facilities for HPS. Shoreline areas at Parcel E were used to store construction and industrial materials, as well as to dispose of industrial waste and construction debris. The NRDL used several Parcel E buildings during the 1950s and 1960s to conduct practical and applied research on radiation decontamination methods and on the effects of radiation on living organisms and natural and synthetic materials. The NRDL ceased operations in 1969 ([NAVSEA, 2004](#)). Many operations conducted by the Navy at Parcel E are well documented, including the locations where routine and planned activities and waste disposal occurred. Undocumented activities also may have been conducted, such as storage of materials and equipment, short-term industrial activities, and waste disposal ([TtEMI, LFR, and U&A, 1997](#)). The Revised RI Report evaluated all available environmental data and made conservative conclusions regarding the nature and extent of contamination, particularly in areas where possible contamination may have resulted from undocumented activities ([Barajas & Associates, 2008b](#)).

### 2.2.2. Parcel E Historic Areas

No structures within Parcel E have been identified as qualifying for placement on the National Register of Historic Places ([TtEMI, 1998a and 1998b](#)). Enclosure 2 of the Memorandum of Agreement among the Navy, the Advisory Council on Historic Preservation (ACHP), and the State Historic Preservation Office (SHPO) identified archaeologically sensitive zones at HPS ([Navy, ACHP, and SHPO, 2000](#)). Based on this archaeological inventory, a historic shellmound site may be present along Crisp Avenue in the northwest portion of Parcel E (north of IR-75, a formerly used defense site). ## NAVY ANNOUNCES PROPOSED PLAN

The U.S. Navy encourages the public to comment on its **Proposed Plan**\* for cleanup of Parcels E and UC-3 at Hunters Point Naval Shipyard (HPNS) in San Francisco, California (see Figure 1). Parcel E includes a former industrial support area, consisting of supply and public works facilities for HPNS. Parcel E also includes shoreline areas used to dispose of industrial waste and construction debris. Parcel UC-3 consists of Crisp Road and an adjoining railroad right-of-way. Parcel UC-3 was formerly part of Parcel E; however, this planned utility corridor is now designated as a separate parcel for remedy selection. Two separate **Records of Decision (RODs)** will be prepared for Parcel E and Parcel UC-3, although both are discussed in this Proposed Plan. This approach will allow the final cleanup at Parcel UC-3 to be completed sooner than the final cleanup at Parcel E, which is more complicated.

This Proposed Plan presents several remedial alternatives for the final cleanup actions and identifies the Navy's **Preferred Alternatives**. The Navy and the **U.S. Environmental Protection Agency (EPA)**, in consultation with the **California Environmental Protection Agency's Department of Toxic Substances Control (DTSC)** and **San Francisco Bay Regional Water Quality Control Board (Water Board)**, will co-select **remedial actions** for Parcels E and UC-3 in the RODs after reviewing and considering all information submitted during the public comment period. The Navy may modify the Preferred Alternatives or select other remedial alternatives presented in this Proposed Plan based on new information or public comments. Therefore, the public is encouraged to review and comment on all of the alternatives presented in this Proposed Plan. A final decision will not be made until all comments submitted during the review period are considered. See how to comment in the box below.

This Proposed Plan summarizes the remedial (cleanup) alternatives evaluated by the Navy and explains the reasons for identifying the preferred alternative to address contamination at Parcels E and UC-3. The Navy estimates the cost of the preferred alternatives to be \$105.5 million. The Navy proposes the following cleanup actions at Parcel E:

- Remove and dispose of contaminated soil and shoreline sediment in selected areas.
- Separate and dispose of materials and soil with **residual radiological contamination**.
- Remove or treat contaminated material at the **Former Oily Waste Ponds**.

- Operate a **soil vapor extraction (SVE)** system to remove and treat **volatile organic compounds (VOCs)** in soil and **soil gas** at Building 406.
- Install durable covers to prevent contact with soil containing **metals** (found throughout the fill material quarried from local rock and soil) and chemical or radiological contamination (found at low levels in areas not proposed for excavation).
- Protect the shoreline using natural materials (such as sand) and large rocks.

Figure 1. Location of HPNS.

### How to Comment on the Proposed Plan for Parcels E and UC-3

- Provide written comments no later than March 15, 2013, by one of the following methods:  
E-mail: keith.s.forman@navy.mil  
Fax: (619) 532-0995  
Mail: See address on page 28
- Attend the public meeting and provide verbal or written comments:  
February 28, 2013, from 6:00 p.m. to 8:00 p.m.  
Southeast Community Facility Commission  
Building, Alex L. Pitcher, Jr. Room  
1800 Oakdale Avenue in San Francisco

Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California

| IR Site     | IR Site Significant Features           | Corresponding Redevelopment Block(s) | Past Activities and Potential Sources                                                                                                                                                                                                                                  |
|-------------|----------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IR-12       | Triple A Sites 3 and 4 <sup>(a)</sup>  | EOS-1, EOS-5A, MU-1, and MU-3        | Scrap yard used to store scrap metal, drums, pipe lagging, liquid waste, and batteries (Triple A Site 3); disposal trench for waste liquids and concrete pad where waste liquid drums were crushed (Triple A Site 4)                                                   |
| IR-13       | Triple A Sites 5 and 15 <sup>(a)</sup> | MU-1                                 | Oily soil pile and drums containing waste liquids (Triple A Site 5); sandblast waste storage (Triple A Site 15)                                                                                                                                                        |
| IR-36 North | Buildings 400 and 405                  | MU-1, MU-2, and MU-3                 | Disposal of construction debris; storage of solvents in Buildings 400 and 405, decommissioned ship parts and equipment                                                                                                                                                 |
| IR-36 South | Buildings 406, 413, and 414            | MU-1 and MU-2                        | Degreasing operations, including solvent releases from floor drains (Building 406); waste oil drums stored in Building 413; stained oily area between Buildings 413 and 414 where drums of waste oil were stored                                                       |
| IR-36 West  | Buildings 371, 704, and 709            | MU-1                                 | Automotive repair shop stored oils, solvents, acids, and battery solutions (Building 704); area around Buildings 371 and 704 used to store vehicles, equipment, and two ASTs for oils and solvents; former Navy Exchange gas station (Building 709) with 7 former USTs |
| IR-38       | Former Buildings 507 and 508           | EOS-4 and MU-2                       | Formerly contained buildings used by NRDL as a biological laboratory (Building 507) and health physics office (Building 508)                                                                                                                                           |
| IR-39       | Buildings 707, and 708                 | MU-1 and MU-2                        | Pole-mounted transformer (Building 707); buildings used by NRDL for animal research (Building 707) and as a Biomedical Facility (Building 708)                                                                                                                         |
| IR-40       | Building 527                           | EOS-4                                | Pier 2 and electrical substation (Building 527)                                                                                                                                                                                                                        |

**Table 2-1. IR Sites and Redevelopment Blocks (continued)**  
Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California

| IR Site              | IR Site Significant Features                                                | Corresponding Redevelopment Block(s)             | Past Activities and Potential Sources                                                                                                                                                                                                                                                        |
|----------------------|-----------------------------------------------------------------------------|--------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IR-45 <sup>(b)</sup> | Steam line system                                                           | EOS-1, EOS-2, EOS-3, EOS-4, MU-1, MU-2, and MU-3 | Triple A is suspected of having used the steam line system to transport waste oil from Berth 29 in Parcel D and Dry Dock 4 in Parcel C to Building 521 and former AST S-505 (SFDA, 1986; DHS, 1988).                                                                                         |
| IR-47 <sup>(b)</sup> | Fuel distribution lines                                                     | EOS-3 and EOS-4                                  | Fuel was transported from Berth 29 in Parcel D to Building 521 and former AST S-505. Triple A is suspected of having used the fuel lines to transport waste oil from Berth 29 in Parcel D to Building 521, former AST S-505, and the former oil reclamation ponds (IR-03) (SFDA, 1986).      |
| IR-50 <sup>(b)</sup> | Storm drain and sanitary sewer systems                                      | All                                              | Potential radioactive contamination at systems associated with former NRDL sites (NAVSEA, 2004).                                                                                                                                                                                             |
| IR-51 <sup>(b)</sup> | Former electrical transformer locations                                     | --                                               | Transformers located throughout HPS were removed from their original locations in 1988 (HLA, 1990b). All remaining transformers were inspected, inventoried, and sampled (TtEMI, 1998b). IR-51 soil data were evaluated as part of the physical IR site in which the samples were collected. |

**Table 2-1. IR Sites and Redevelopment Blocks (continued)**  
**Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California**

Notes: Information provided in table from Table 1-2 in the Final Revised RI Report for Parcel E (Barajas & Associates, Inc., 2008b).

- (a) During its occupancy of HPS, Triple A allegedly generated hazardous substances and wastes at the shipyard and allegedly engaged in the improper disposal of hazardous substances and wastes at various locations throughout Parcel E; further information is provided in the Revised Remedial Investigation Report for Parcel E (Barajas & Associates, 2008)
- (b) Facility-wide IR site that was established for the former utility network at HPS

-- = not applicable

AST = aboveground storage tank

DHS = Department of Health Services

HLA = Harding and Lawson Associates

HPS = Hunters Point Shipyard

IR = Installation Restoration

NAVSEA = Naval Sea Systems Command

NRDL = Naval Radiological Defense Laboratory

SFDA = San Francisco District Attorney

TtEMI = Tetra Tech EM Inc.

UST = underground storage tank

|---|-------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## 3.5 HYDROGEOLOGY

This section briefly discusses the local hydrogeologic setting and Parcel E hydrostratigraphy, groundwater flow patterns, hydraulic characteristics, and tidal effects at Parcel E. The original RI Report discusses in detail the regional hydrogeologic setting ([Tetra Tech, LFR, and U&A 1997](#)).

### 3.5.1 Local Hydrogeologic Setting and Parcel E Hydrostratigraphy

Two aquifers and one water-bearing zone are present at HPS: (1) the A-aquifer, (2) the B-aquifer, and (3) the bedrock water-bearing zone. Additionally, an aquitard composed of the Bay Mud separates the A-aquifer from the B-aquifer over most of Parcel E.

This section summarizes the A-aquifer, the Bay Mud aquitard, the B-aquifer, and the bedrock water-bearing zone present at Parcel E. The relationships between the stratigraphic and hydrostratigraphic units at Parcel E are presented in the table below.

| Stratigraphic Unit                                 | Corresponding Hydrostratigraphic Unit   |
|----------------------------------------------------|-----------------------------------------|
| Artificial Fill ( $Q_{af}$ )                       | A-aquifer <sup>a</sup>                  |
| Undifferentiated Upper Sand Deposits ( $Q_{uus}$ ) | A-aquifer <sup>a</sup>                  |
| Bay Mud ( $Q_{bm}$ )                               | Aquitard <sup>b</sup>                   |
| Undifferentiated Sedimentary Deposits ( $Q_u$ )    | B-aquifer <sup>c</sup>                  |
| Franciscan Complex Bedrock ( $K_f$ )               | Bedrock Water-Bearing Zone <sup>d</sup> |

Notes:

- a Hydrostratigraphic unit comprises permeable portions of the Artificial Fill and Undifferentiated Upper Sand deposits, and includes weathered portions of the bedrock that directly underlie saturated Artificial Fill or Undifferentiated Upper Sand deposits and localized areas where Undifferentiated Upper Sand deposits are interbedded with Bay Mud deposits.
- b Hydrostratigraphic unit also includes low-permeability Artificial Fill deposits.
- c Unit comprises the permeable portions of the Undifferentiated Sedimentary deposits.
- d Unit consists of portions of saturated bedrock that are not in direct contact with the A- or B-aquifers.

#### 3.5.1.1 A-Aquifer

The A-aquifer primarily consists of the extremely heterogeneous Artificial Fill described in [Section 3.4.2.1](#), although the A-aquifer may also include (1) Undifferentiated Upper Sands (where present); (2) sandy units within the Bay Mud, when these units are hydraulically connected to the A-aquifer; and (3) the upper weathered bedrock zone, when the A-aquifer directly overlies bedrock (such as in the southeastern portion of Parcel E at Building 521).

The A-aquifer covers almost all of Parcel E, from a few feet to over 50 feet thick (see cross section G-G' on [Figure 3-6](#)). However, the lateral continuity of the A-aquifer is disrupted by numerous low-permeability zones because of the heterogeneous nature of the Artificial Fill (see cross sections C-C' and D-D' on [Figures 3-4 and 3-5](#)). The A-aquifer is unconfined throughout most of Parcel E, but semiconfined conditions may exist in many places where fine-grained sediments below the water table overlie more permeable materials, as shown in cross sections C-C', D-D', and G-G' on [Figures 3-4, 3-5, and 3-6](#). Depth to groundwater ranges from 4 to 15 feet bgs, with an average depth to groundwater across Parcel E of about 8 feet bgs.

The A-aquifer is separated from the B-aquifer and the bedrock water-bearing zone by the Bay Mud aquitard, except for the northern portion of Parcel E in the vicinity of Buildings 809 and 810 (see cross sections C-C' and D-D' on [Figures 3-4 and 3-5](#)), and the southeastern portion of Parcel E in the vicinity of Building 521 (see cross section I-I' on [Figure 3-6](#)), where the Bay Mud aquitard is absent. The A-aquifer directly overlies shallow weathered bedrock at two bedrock highs (see [Section 3.4.2.5](#)), where both the Bay Mud aquitard and the B-aquifer are absent. As shown on cross section I-I' on [Figure 3-6](#) by color shading, shallow bedrock in contact with A-aquifer is considered part of this aquifer.

Groundwater flow in the A-aquifer at HPS is complex because of the high variability in hydraulic properties of the subsurface fill materials, tidal influences, effects of storm drain and sanitary sewer systems, and variations in topography and drainage. Large variations in hydraulic properties result from variations in fill type, soil texture, degree of compaction, and distribution of sediments. Groundwater in the A-aquifer at HPS generally flows radially toward San Francisco Bay, except where reversed because of the possible influence of leaking storm and sanitary sewer utility lines and along the shoreline where tidal influences are apparent ([Tetra Tech, LFR, and U&A 1997](#)). Groundwater flow in the A-aquifer is discussed in more detail in [Section 3.5.2.1](#), and the hydraulic characteristics of the A-aquifer are discussed in [Section 3.5.3.1](#).

#### **3.5.1.2 Bay Mud Aquitard**

The Bay Mud aquitard, composed mostly of clay and silt, typically separates the A-aquifer from the underlying B-aquifer. The Bay Mud deposits range from 5 to 76 feet thick under most of Parcel E, with the maximum thickness of 76 feet at boring DMB241. A Bay Mud thickness contour (isopach) map is provided on [Figure 3-7](#). This figure shows that the aquitard is absent in the northern portion of Parcel E, along Crisp Avenue, and in the areas of the bedrock highs (see [Section 3.4.2.3](#)). The aquitard is generally thickest in the southern portion of the parcel, along the shoreline.

#### **3.5.1.3 B-Aquifer**

The B-aquifer in Parcel E is composed of the permeable portions of the Undifferentiated Sediments (see [Section 3.4.2.4](#)), consisting of a sequence of relatively thick (about 30 to 40 feet), laterally continuous layers of sand and silty and clayey sand (see cross sections A-A', D-D', and G-G' on [Figures 3-4, 3-5, and 3-6](#)), which are separated by laterally continuous layers of silt and

clay. Across all of Parcel E, monitoring wells were installed in the uppermost portion of the B-aquifer primarily because its lower portions are overlain by layers of silts and clay and, therefore, are less likely to be affected by contamination from site activities. Therefore, in this report the discussion of the B-aquifer mainly refers to its uppermost portion.

The uppermost B-aquifer generally corresponds to the upper 20- to 40-foot thick layer of sand and silty sand of Undifferentiated Sedimentary deposits (see cross-section A-A' on [Figure 3-4](#)). The B-aquifer is generally confined by the Bay Mud aquitard, which separates it from the A-aquifer across most of Parcel E. The aquitard is absent along the northern border of Parcel E, (see [Figure 3-7](#) and cross sections C-C' and D-D' on [Figures 3-4 and 3-5](#)). In these locations, the A- and B-aquifers are in hydraulic communication, and behave as a single aquifer. As indicated by color shading on cross sections, the upper portion of the saturated weathered bedrock that is in direct contact with the more permeable layers of the B-aquifer is considered part of the B-aquifer. These upper weathered portions of the Franciscan Complex bedrock are more similar to porous sedimentary media than the deeper portions of massive and fractured bedrock. Groundwater flow in the poorly weathered and unweathered bedrock is limited to the fracture zones, which minimizes the amount of available groundwater. The fractured, unweathered bedrock is not considered an aquifer because of its limited flow capability and low storage capacity.

#### **3.5.1.4      *Bedrock Water-Bearing Zone***

Deeper portions of saturated fractured bedrock that are not in direct contact with the A- or B-aquifers are hydrostratigraphically classified as the bedrock water-bearing zone. The cross sections identify the portions of bedrock considered to be part of the A- or B-aquifers; other portions of bedrock are considered to be the bedrock water-bearing zone ([Tetra Tech 2004c](#)).

### **3.5.2              Groundwater Flow Patterns**

This section discusses the pattern of groundwater flow at Parcel E, including the A-aquifer, uppermost B-aquifer, and the bedrock water-bearing zone. Water levels were measured during the wet and dry seasons during periods of low tidal fluctuation to minimize the impact of the tides on groundwater elevations. Additionally, this section summarizes the vertical flow of groundwater at Parcel E and recharge and discharge of groundwater in each aquifer and water-bearing zone.

#### **3.5.2.1      *A-Aquifer Flow***

Groundwater levels in the A-aquifer are generally higher during the wet season (winter and spring) than during the dry season (summer and fall), indicating that precipitation is a primary recharge source for groundwater in the A-aquifer. Additional recharge sources for the A-aquifer are discussed in [Section 3.5.2.5](#). [Figure 3-9](#) shows A-aquifer groundwater elevations measured during the wet season (on February 20, 2002), and [Figure 3-10](#) shows A-aquifer groundwater elevations measured during the dry season (on November 18, 2004).

|   |                |                             |                                                                                                                                                                                         |
|---|----------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6 | Drinking water | Section 2.2 and Section 2.4 | Final Revised Remedial Investigation Report for Parcel E, Hunters Point Shipyard, San Francisco, California. Barajas & Associates, Inc. May 2008. Section 3.6, pages 3-18 through 3-20. |
|---|----------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- Based on typical hydraulic conductivities and gradients measured at Parcel E, the estimated average groundwater velocities in the A-aquifer are 408 ft/yr and in the B-aquifer are 2 ft/yr. Because of the heterogeneity of the A-aquifer, groundwater flow rates are expected to vary over several orders of magnitude.
- The bedrock water-bearing zone is a fractured, massive rock matrix that consists of serpentinite and greenstone, with lesser amounts of shale, greywacke, and chert. The upper portions are generally highly weathered to a friable, gravelly clay to clayey gravel and are considered part of the overlying A- or B-aquifer. The poorly weathered to unweathered fractured bedrock is not considered an aquifer because of its limited flow capability and low storage capacity.
- The A-aquifer tidal influence zone in Parcel E generally extends about 100 to 400 feet inland from the Bay but extends up to 600 feet inland at the southeastern tip of Parcel E.
- The tidal mixing zone, where groundwater discharging from Parcel E physically mixes with the Bay water during the tidal cycle, extends at least 70 feet inland and was not observed in the next closest well studied at 335 feet inland from the shoreline.

### 3.6 GROUNDWATER BENEFICIAL USE EVALUATION

This section summarizes the evaluation of beneficial use of groundwater in the A-aquifer and B-aquifer at Parcel E. [Appendix F](#) provides a detailed discussion of the beneficial use evaluation of groundwater at Parcel E.

The following beneficial use evaluations were previously conducted for Parcel E:

- **Parcel E RI and FS Reports.** The original Parcel E RI and FS Reports evaluated beneficial use of groundwater and concluded that A-aquifer and B-aquifer groundwater underlying Parcel E had a beneficial use only as a source of water recharge to the South Bay ([Tetra Tech, LFR, and U&A 1997](#); [Tetra Tech 1998a](#)).
- **Revised Final Groundwater Beneficial Use Determination for the A-Aquifer in Parcels C, D, and E.** The Parcel E beneficial use evaluation was updated in 2001. The updated evaluation identified groundwater areas that met federal and state groundwater classification criteria and recommended further evaluation of the beneficial use of groundwater in the FS with respect to site-specific factors (SSF) ([Tetra Tech 2001](#)). EPA provided nine SSFs to the Navy ([EPA 1999](#)).
- **Letter to Water Board Requesting A-Aquifer Exemption.** The Navy requested exemption of the A-aquifer at HPS from consideration as a municipal or domestic water supply source in a letter to the Water Board, dated August 11, 2003 ([Navy 2003](#)). On September 25, 2003, the Water Board concurred that A-aquifer groundwater at HPS meets the TDS exemption criteria in the SWRCB Sources of Drinking Water Resolution No. 88-63 ([Water Board 2003](#); [SWRCB 1988](#)).

EPA has not concurred with the Water Board's letter. As such, the evaluation of the municipal and domestic drinking water beneficial uses of Parcel E groundwater presented in [Appendix F](#) of this Revised Parcel E RI Report focuses on the A-aquifer with respect to federal criteria and the B-aquifer with respect to federal and state criteria. The Basin Plan also provides for agricultural and industrial beneficial uses for groundwater at the site.

The primary drinking water beneficial use evaluation criteria are TDS content and well yield. The federal TDS and well yield criteria are TDS content less than 10,000 milligrams per liter (mg/L) and sustained yield of 150 gallons per day (gpd). The state TDS and well yield criteria are TDS content less than 3,000 mg/L and sustained yield of 200 gpd. At Parcel E, the A-aquifer exceeds the federal TDS content criteria with a mean A-aquifer TDS content of 10,309 mg/L (approximately 40 percent of Parcel E area is underlain by groundwater with TDS content above 10,000 mg/L); meets the federal well yield criteria with potential well yields of 1,720 to 72,000 gpd; and is exempt from the state criteria. Based on limited data, the B-aquifer generally is expected to meet the federal and state TDS content and well yield criteria. [Figure 3-15](#) shows the maximum A-aquifer TDS concentrations. [Figure F-2](#) in [Appendix F](#) shows the maximum TDS concentrations in the B-aquifer. The TDS content is below 3,000 mg/L in four of the six B-aquifer wells. [Table 3-7](#) provides a summary of TDS information.

In addition to the primary drinking water beneficial use criteria, EPA provided nine SSFs for inclusion in the beneficial use evaluation ([EPA 1999](#)). The table below summarizes the beneficial use evaluation with respect to EPA's nine SSFs. The conclusions for the B-aquifer are based on limited information. [Appendix F](#) provides detailed descriptions of each criterion and the evaluation of each criterion for the A- and B-aquifers.

| Site-Specific Factors                                        | Potential for A-Aquifer Drinking Water Beneficial Use | Potential for B-Aquifer Drinking Water Beneficial Use |
|--------------------------------------------------------------|-------------------------------------------------------|-------------------------------------------------------|
| Aquifer Thickness                                            | Low                                                   | Moderate                                              |
| Actual TDS Levels                                            | Low                                                   | Moderate to High                                      |
| Actual Groundwater Yield                                     | High                                                  | High                                                  |
| Depth to Groundwater                                         | Low                                                   | Moderate                                              |
| Proximity to Saltwater and Potential for Saltwater Intrusion | Low                                                   | Moderate                                              |
| Quality of Underlying Water-bearing Units                    | Low                                                   | Insufficient data                                     |
| Existence of Institutional Controls on Aquifer Use           | Low                                                   | Low                                                   |
| Historic and Current Groundwater Use                         | Low                                                   | Low                                                   |
| Cost of Cleanup to Federal Drinking Water Standards          | Low                                                   | High                                                  |

Based on the federal groundwater classification criteria and the evaluation of SSFs, the weight of evidence indicates that the A-aquifer and the B-aquifer have low potential for use as potable water supplies at Parcel E. However, for the purposes of the HHRA (see [Section 5.1](#) and [Appendix I](#)), exposure pathways associated with domestic use of the B-aquifer (for example, ingestion) are assumed to be complete and are assessed for potential risks. This assumption provides an additional measure of conservatism with respect to the protection of human health at HPS.

In addition, based on the SSF evaluation, the A-aquifer is not a viable source of drinking water, and federal maximum contaminant levels (MCL) are not applicable or relevant and appropriate requirements (ARAR) for the CERCLA action. Furthermore, based on the SSF evaluation, the B-aquifer has potential beneficial use as drinking water across most of the site, and MCLs are ARARs; however, City controls prevent use of groundwater at the site. Agricultural beneficial use of the A- and B-aquifer groundwater is limited to areas with TDS at concentrations less than 1,500 mg/L for irrigation and less than 10,000 mg/L for livestock. Both the A- and B-aquifers have potential industrial beneficial use.

### **3.7 ECOLOGY**

This section describes the terrestrial and aquatic ecological habitat (including flora and fauna) identified at Parcel E. This ecological information is used to assess adequately exposure pathways and potential risks to ecological receptors. The ecological habitat description in this section was derived from several different projects that entailed site walkthrough inspections at HPS. The following reports document these projects:

- Preliminary Draft ERA Data Summary Report ([HLA 1991b](#)), which listed species reported to be present at HPS
- Phase 1A ERA Report ([PRC 1994a](#)), which identified habitats and species present at HPS
- Parcel E ERA Validation Study ([Tetra Tech and LFR 2000a](#)), which entailed collecting tissue samples from plants and animals to complete the baseline ecological risk assessment (BERA) and update the assessment of habitat types and included observation of species present at Parcel E
- Wetlands Delineation and Functions and Values Assessment ([Tetra Tech 2003c](#)), which delineated all wetlands at HPS, assessed their functions and values, and included observation of species present at Parcel E

Risks to terrestrial ecological receptors only are evaluated in this Revised Parcel E RI Report (see [Section 5.0](#)). Risks to aquatic ecological receptors are evaluated as part of investigations at Parcel F. A preliminary evaluation of the potential for groundwater to impact the Bay is presented in [Section 4.3](#).

#### **3.7.1 Terrestrial Flora**

Parcel E is characterized by patches of ruderal vegetation, industrial areas, and wetlands (freshwater, saline emergent, and intertidal) and intertidal areas ([PRC 1994a](#)). Each type of area is discussed below and is shown on [Figure 3-3](#).

|   |                           |             |                                                                                                                                                              |
|---|---------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7 | Groundwater flow patterns | Section 2.2 | Final Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California. ERRG. August 2012. Section 2.2.7.3, pages 2-16 through 2-18. |
|---|---------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|

of Undifferentiated Sedimentary deposits. The B-aquifer is generally confined by the Bay Mud aquitard, which separates it from the A-aquifer across most of Parcel E. The aquitard is absent along the northern border of Parcel E. In these locations, the A- and B-aquifers are in hydraulic communication and behave as a single aquifer.

Deeper portions of saturated fractured bedrock that are not in direct contact with the A- or B-aquifers are hydrostratigraphically classified as the bedrock water-bearing zone. The fractured, unweathered bedrock is not considered an aquifer because of its limited flow capability and low storage capacity.

Groundwater monitoring has been limited to the uppermost B-aquifer, and no monitoring has been required in the lower portions of the B-aquifer or the bedrock WBZ. The A-aquifer and uppermost B-aquifer present at HPS are potentially affected by contamination from Parcel E.

#### 2.2.7.2. Hydraulic Characteristics

The calculated hydraulic conductivities of the A-aquifer at Parcel E range from 2.7 feet per day (ft/day) to 1,520 ft/day (Barajas & Associates, Inc., 2008b; TtEMI, 2004b). The 1,520 ft/day value is likely not representative of aquifer characteristics because (1) the value was calculated solely from recovery data collected from a pumping well; (2) documentation on this pumping test does not indicate the duration of the test; and (3) no observation wells were included or drawdown in the observation wells was insufficient to calculate hydraulic conductivity, suggesting that the cone of depression for this test may have been limited. If this value is considered an outlier, the actual range for hydraulic conductivities in the A-aquifer at Parcel E would be 2.7 to 510 ft/day (Barajas & Associates, Inc., 2008b). Based on average hydraulic conductivities and gradients measured in the A-aquifer, the estimated average groundwater velocity in the A-aquifer is 408 feet per year (ft/yr).

The calculated hydraulic conductivities in the B-aquifer ranged from 0.18 to 3.1 ft/day. Based on the average hydraulic conductivity and gradients measured in the B-aquifer, the estimated average groundwater velocity for the B-aquifer is approximately 2 ft/yr. Only two slug tests were performed for the bedrock-water bearing zone, and calculated hydraulic conductivities were 0.34 and 0.12 ft/day. The slug tests assumed a porous medium such as sand, rather than the fractured porosity of the bedrock. Therefore, these calculated values are, at best, approximations of the flow velocity (Barajas & Associates, Inc., 2008b).

#### 2.2.7.3. Groundwater Flow

This section discusses the pattern of groundwater flow at Parcel E, including the vertical flow of groundwater and recharge and discharge of groundwater in each aquifer and water-bearing zone. During previous investigations, water levels were measured during wet and dry seasons during periods of low tidal fluctuation to minimize the effect of tides on groundwater elevations. Water levels continue to be

monitored on a quarterly basis using similar procedures. The ongoing water level data should be reevaluated, prior to preparing the remedial design, to verify groundwater flow directions.

A-aquifer groundwater flow patterns at Parcel E are complex. The predominant flow directions have historically been influenced by two major features: (1) a groundwater depression along the boundary between Parcels E and G, and (2) a groundwater divide in the central shoreline area. The natural flow of groundwater toward San Francisco Bay from the topographically high area of the former Parcel A has typically been disrupted by these two features. The groundwater depression is most likely the residual effect of groundwater infiltrating damaged sanitary sewer lines during pumping at a nearby lift station. The sanitary sewer lift station, located at the former Parcel A, ceased operation in May 2007. The lateral extent of the groundwater depression had decreased from approximately 73 acres in May 2007 to 5 acres in March 2008 ([CE2-Kleinfelder Joint Venture, 2008b](#)). In March 2009, the groundwater depression was nearly nonexistent at 0.1 acres, indicating that natural hydrogeological conditions were being reestablished ([CE2-Kleinfelder Joint Venture, 2009b](#)). The influence of the groundwater divide along the central shoreline area remains unchanged. [Figure 2-2](#) presents the groundwater elevations for A-aquifer wells in Parcel E for March 2009, which show the reduced size of the groundwater depression along the boundary between Parcels E and G.

Two groundwater mounds are associated with groundwater flow within the A-aquifer: one mound (about 2,000 feet long) is parallel to the shoreline in the central portion of Parcel E and extends into Parcel E-2; and one is a small mound in the southeastern portion of Parcel E that coincides with the bedrock high at Building 521. Groundwater on the inland side of the first mound flows to the south-southeast toward bay at an average gradient of less than 0.001 feet per foot (ft/ft). Groundwater on the bayward side flows toward San Francisco Bay at an average gradient of 0.011 ft/ft. Groundwater has historically flowed radially away from the second mound at an average gradient of 0.018 ft/ft ([Barajas & Associates, Inc., 2008b](#)); however, recent groundwater elevations have indicated limited influence on groundwater flow (likely the result of lower than normal rainfall in recent years). Groundwater levels in the A-aquifer are generally higher during the wet season (winter and spring) than during the dry season (summer and fall), indicating that precipitation is a primary recharge source for groundwater in the A-aquifer.

The groundwater flow direction in the uppermost B-aquifer appears to be to the southeast at a gradient of 0.002 ft/ft ([Barajas & Associates, Inc., 2008b](#)). [Figure 2-3](#) presents groundwater elevations for B-aquifer wells in Parcel E for the March 2008 measurement event. Similar to the A-aquifer, groundwater elevations in the uppermost B-aquifer are generally higher in the wet season than in the dry season.

Groundwater elevations in the B-aquifer wells are generally higher than in the A-aquifer wells indicating an upward vertical hydraulic gradient. Based on data in the Revised RI Report ([Barajas & Associates, Inc., 2008b](#)), the differences in groundwater elevations are more pronounced in the northeastern portion of the parcel near the Parcel G boundary and less pronounced near the shoreline. Additionally, elevation

differences are more pronounced during the wet season than the dry season. The B-aquifer appears to exhibit an upward vertical gradient; however, the Bay Mud aquitard separates the B-aquifer from the A-aquifer across most of Parcel E, suggesting little hydraulic communication between the two aquifers in areas where the aquitard is present (Barajas & Associates, Inc., 2008b).

The groundwater elevation has only been measured in one bedrock water-bearing zone well (February 2002). Given the limited data, the direction of groundwater flow in the bedrock water-bearing zone is unknown, but it is assumed to follow the regional flow pattern from the upland areas toward San Francisco Bay (Barajas & Associates, Inc., 2008b).

The primary sources of recharge to the A-aquifer in Parcel E are (1) infiltration of precipitation and ponded runoff in unpaved areas, (2) leakage from utility supply lines, (3) intrusion of bay water, (4) horizontal flow (lateral influx or baseflow) of groundwater from areas upgradient of Parcel E, and (5) vertical flow of water in some areas from the underlying B-aquifer. Discharge from the A-aquifer occurs through lateral flow to San Francisco Bay (outflux).

The primary source of recharge to the B-aquifer in Parcel E is considered to be (1) infiltration of precipitation and ponded runoff in outcrop areas in the northern portion of Parcels E and E-2 and (2) horizontal groundwater flow (baseflow) from upgradient areas to the north and west of Parcel E. The upper B-aquifer may discharge to San Francisco Bay in some areas (TtEMI, 2004b), although the deeper B-aquifer may have connate water (i.e., water trapped in sediment or rock at the time of deposition), with discharge to the surface or to the bay limited or prevented by overlying confining layers.

Recharge to the bedrock water-bearing zone is similarly derived from infiltration of precipitation at outcrop areas to the north and northwest of Parcels E and E-2. Groundwater in the bedrock water-bearing zone likely discharges into the B-aquifer (recharging the B-aquifer) at upgradient contacts.

#### 2.2.7.4. Tidal Effects

Tidal effects at HPS have been studied and generally categorized into either tidal influence or tidal mixing. Tidal influence refers to the hydraulic response of near-shore groundwater by daily tidal action. Tidal influence is measured at near-shore groundwater wells and quantified as tidal fluctuations (difference in near-shore groundwater level between consecutive high and low tides), mean tidal efficiency (the ratio of tidally induced changes in groundwater levels to the tidal changes in the surface water), and mean time lag (time difference between the tidal changes in the surface water body and corresponding changes in groundwater levels). Tidal mixing refers to the influx and mixing of San Francisco Bay's saline surface water into near-shore groundwater by daily tidal action; this results in degradation of groundwater with a significant increase of total dissolved solids (TDS) to above 10,000 milligrams per liter (mg/L). Figure 3-14 in the Revised RI Report for Parcel E shows the location of the tidal influence and tidal mixing zone study wells in Parcel E (Barajas & Associates, Inc., 2008b).

In addition, based on the SSF evaluation, the A-aquifer is not a viable source of drinking water, and federal maximum contaminant levels (MCL) are not applicable or relevant and appropriate requirements (ARAR) for the CERCLA action. Furthermore, based on the SSF evaluation, the B-aquifer has potential beneficial use as drinking water across most of the site, and MCLs are ARARs; however, City controls prevent use of groundwater at the site. Agricultural beneficial use of the A- and B-aquifer groundwater is limited to areas with TDS at concentrations less than 1,500 mg/L for irrigation and less than 10,000 mg/L for livestock. Both the A- and B-aquifers have potential industrial beneficial use.

### 3.7 ECOLOGY

This section describes the terrestrial and aquatic ecological habitat (including flora and fauna) identified at Parcel E. This ecological information is used to assess adequately exposure pathways and potential risks to ecological receptors. The ecological habitat description in this section was derived from several different projects that entailed site walkthrough inspections at HPS. The following reports document these projects:

- Preliminary Draft ERA Data Summary Report ([HLA 1991b](#)), which listed species reported to be present at HPS
- Phase 1A ERA Report ([PRC 1994a](#)), which identified habitats and species present at HPS
- Parcel E ERA Validation Study ([Tetra Tech and LFR 2000a](#)), which entailed collecting tissue samples from plants and animals to complete the baseline ecological risk assessment (BERA) and update the assessment of habitat types and included observation of species present at Parcel E
- Wetlands Delineation and Functions and Values Assessment ([Tetra Tech 2003c](#)), which delineated all wetlands at HPS, assessed their functions and values, and included observation of species present at Parcel E

Risks to terrestrial ecological receptors only are evaluated in this Revised Parcel E RI Report (see [Section 5.0](#)). Risks to aquatic ecological receptors are evaluated as part of investigations at Parcel F. A preliminary evaluation of the potential for groundwater to impact the Bay is presented in [Section 4.3](#).

#### 3.7.1 Terrestrial Flora

Parcel E is characterized by patches of ruderal vegetation, industrial areas, and wetlands (freshwater, saline emergent, and intertidal) and intertidal areas ([PRC 1994a](#)). Each type of area is discussed below and is shown on [Figure 3-3](#).

#### **3.7.1.1 Ruderal Vegetation**

Ruderal habitat (weedy, dominated by nonnative species) is the largest habitat type at Parcel E, making up about 30 percent of the area (see [Figure 3-3](#)). Recent field observations indicated that conditions ranged from areas cluttered with concrete, patches of pavement, and other debris to undeveloped areas characterized by scattered shrubs. The scattered shrubs consisted mostly of fennel (*Foeniculum vulgare*), pampas grass (*Cortaderia selloana*), and Scotch broom (*Cytisus scoparius*) interspersed with nonnative grasses such as wild oats (*Avena fatua*), perennial ryegrass (*Lolium perenne*), and barley (*Hordeum* spp.). Nonnative herbaceous plants are also present, including wild radish (*Raphanus sativa*), black mustard (*Brassica nigra*), vetch (*Vicia* sp.), plantain (*Plantago lanceolata*), dock (*Rumex crispus* and *R. conglomeratus*), and St. John's wort (*Hypericum* sp.). Some native plants, such as coyote brush (*Baccharis pilularis*), California broom (*Lotus scoparius*), and cheeseweed (*Malva sylvestris*), have also been observed in Parcel E. Vegetation generally is denser and more diverse at IR-02 Northwest, IR-02 Central, and IR-11/14/15 than elsewhere at Parcel E ([Tetra Tech and LFR 2000a](#)).

#### **3.7.1.2 Industrial Areas**

About 65 percent of Parcel E is covered by pavement, associated pavement debris, hardpan soil, and former industrial buildings (see [Figure 3-3](#)). Some industrial areas are sparsely vegetated with pampas grass and fennel ([Tetra Tech and LFR 2000a](#)).

#### **3.7.1.3 Beach, Intertidal Areas, and Wetlands**

The remaining 5 percent of Parcel E consists of beach area, intertidal areas, and five discontinuous wetland areas, which vary in length and width along the shoreline ([Tetra Tech and LFR 2000a](#); [Tetra Tech 2003c](#)). These areas primarily consist of intertidal salt marsh and saline emergent wetlands separated by segments of riprap. The largest areas of intertidal salt marsh are at the extreme eastern and western ends of Parcel E shoreline. Emergent saline wetlands are present in only one area along the Parcel E shoreline: the extreme southeast corner of the property. The dominant plants in both the salt marsh and emergent saline wetlands are saltgrass and pickleweed. No special-status plant species are expected to be present within these habitat types at Parcel E ([Tetra Tech, LFR, and U&A 1997](#)).

### **3.7.2 Terrestrial Fauna**

The following sections discuss the terrestrial fauna that potentially occur at Parcel E, including mammals, birds, reptiles and amphibians, and terrestrial invertebrates.

#### **3.7.2.1 Mammals**

Signs of pocket gopher (*Thomomys bottae*) burrows and the western harvest mouse (*Reithrodontomys megalotis*) have been observed at Parcel E. Red foxes (*Vulpes fulva*) have been observed at HPS and may be present at Parcel E. Bats also have been observed at HPS and

probably live in abandoned buildings at Parcel E (HLA 1991b). Based on information gathered during the Parcel E Validation Study, it does not appear that the salt marsh harvest mouse occurs at Parcel E at HPS. Raccoons probably visit the shoreline area in search of food but are not expected to live within Parcel E. No special status mammal species have been observed or are expected to occur at Parcel E (Tetra Tech, LFR, and U&A 1997; Tetra Tech and LFR 2000a).

### **3.7.2.2 Birds**

Ruderal and landscaped habitats at HPS typically support resident and migratory birds common to urban areas of northern California. Previous surveys at HPS identified granivorous (seed-eating) species such as the house finch (*Carpodacus mexicanus*) and purple finch (*Carpodacus purpureus*), but most bird species observed at HPS are insectivores or insect-eating omnivores, such as the western meadowlark (*Sturnella neglecta*), northern mockingbird (*Mimus polyglottos*), and bushtit (*Psaltiriparus minimus*). The red-tailed hawk and American kestrel (*Falco sparverius*) were observed numerous times at Parcel E.

Previous surveys noted that the turkey vulture (*Cathartes aura*) was observed foraging in ruderal and landscaped habitat at HPS. Intertidal and saline emergent wetlands may be used by shorebirds and wading birds such as the willet (*Catoptrophorus semipalmatus*), killdeer (*Charadrius vociferous*), great blue heron (*Ardea herodias*), and double-crested cormorant (*Phalacrocorax auritus*) (HLA 1991b).

The following special-status bird species were observed at HPS during previous surveys: peregrine falcon (*Falco peregrinus*), a state endangered species; double-crested cormorant, a state species of special concern; and loggerhead shrike (*Lanius ludovicianus*), a state species of special concern (HLA 1991b). The Navy conducted a thorough biological assessment of the potential occurrence of species protected under the Endangered Species Act at Parcel E (Tetra Tech 2004b).

### **3.7.2.3 Reptiles and Amphibians**

Ruderal and landscaped habitats at HPS are used by reptile species such as the gopher snake (*Pituophis melanoleucus*), western fence lizard (*Sceloporus occidentalis*), and coast garter snake (*Thamnophis elegans terrestris*), which have been observed in the area. The oak salamander (*Aneides lugubris lugubris*) and California slender salamander (*Batrachoseps attenuatus*) may also occur in nonnative grassland and near freshwater wetland habitats (PRC 1994a). No special-status reptiles or amphibians have been observed or are expected to occur at HPS (Tetra Tech, LFR, and U&A 1997; Tetra Tech and LFR 2000a).

### **3.7.2.4 Terrestrial Invertebrates**

Terrestrial invertebrates such as earthworms, grasshoppers, spiders, beetles, and other insects use ruderal and landscaped habitats at Parcel E. The parcel is dominated by non-native vegetation growing on fill material in an arid, disturbed setting. No special-status invertebrates are expected to occur at Parcel E (Tetra Tech and LFR 2000a).

### 3.7.3 Aquatic Fauna

Aquatic fauna are organisms that live in the shoreline area of Parcel E. The major groups of organisms that use the shoreline habitat are invertebrates and birds (discussed above).

Aquatic invertebrates hide under the rocks and feed on other small invertebrates or plant materials, such as crustacean crabs and isopods. Mussels (usually *Mytilus edulis*) have been observed at low tide attached to the rocks. Barnacles attach to rocks and to the shells of mussels, and can be seen at low tide (Tetra Tech and LFR 2000a). In comments to the Navy, EPA reported that harbor seals (*Phoca vitulina*) have been observed pulling out onto a concrete platform just southeast of the metal debris reef area. Sea lions (*Zalophus californianus*) have also been observed in the Bay near Parcel E (EPA 2007).

## 3.8 CONCEPTUAL SITE MODEL

This section describes the CSM developed for Parcel E. The purpose of the CSM is to illustrate and describe a basic understanding of potential sources of contamination and media pathways, and possible receptors based on available site information. The CSM is not intended to provide details or quantification of these potential sources and pathways. However, it is intended to provide the framework for characterizing site contamination and assessing risks. More detailed information about potential sources and pathways is presented in Section 4.3 for each redevelopment block and further information on exposure pathways and potential risks are presented in Section 5.0. The CSM developed for Parcel E includes the following:

- Generalized subsurface conditions
- Potential sources of contamination
- Potentially affected media, migration and exposure pathways, and receptors

### 3.8.1 Generalized Subsurface Conditions

The subsurface conditions at Parcel E can be illustrated by two generalized cross sections presented on Figures 3-16 and 3-17. Figure 3-16 shows typical subsurface conditions throughout Parcel E. The figure illustrates the aquifer system consisting of A- and B-aquifers that are separated by the Bay Mud aquitard, except for in the northernmost portion of Parcel E, where the aquitard is not present. The aquifer system at Parcel E is underlain by bedrock that slopes from former Parcel A toward the Bay.

Two locations at Parcel E are less typical but have somewhat similar subsurface structure: (1) Building 406 area and (2) Building 521 area. Figure 3-17 shows the second generalized subsurface conditions presented at Parcel E. At the Building 406 area, bedrock can be as shallow as 9 feet bgs and is overlain by silty and clayey gravel of Artificial Fill. Except for a relatively

## ACTION MEMORANDUM

---

**Hunters Point Shipyard  
San Francisco, California 94124**

**April 21, 2006**

**Subject: Final Action Memorandum for Time-Critical Removal Action of  
Radiological Materials in Soils, Debris, or Structures at Hunters Point  
Shipyard, San Francisco, California**

**Site Status: National Priorities List: listed in November 1989;  
Parcel A was transferred in December 2004**

**Removal Category: Time-Critical Removal Action  
CERCLIS ID: CA1170090087  
Site ID: 0902722**

### **I. PURPOSE**

The purpose of this Action Memorandum (AM) is to document for the administrative record the U.S. Department of Navy's (Navy) decision to undertake time-critical removal actions (TCRAs), at areas throughout the base that may contain localized radioactive contamination in soils, debris/slag, and buildings at Hunters Point Shipyard (HPS), as identified in the *Historical Radiological Assessment, Volume II, Use of General Radioactive Materials, 1939-2003, Hunters Point Shipyard (HRA)*. The Department of Defense has the authority to undertake Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) response actions, including removal actions, under Title 10 of the United States Code (USC) Section (§)§2701- 2705 and the federal Executive Order 12580. Further, this removal action is consistent, to the maximum extent possible, with Chapter 6.8 of California Health and Safety Code (Ca-HSC).

The proposed removal actions described in this AM will substantially eliminate identified pathways of exposure to radioactive contamination for surrounding populations and nearby ecosystems, such as nearby wetlands and the San Francisco Bay. Removal actions performed per this AM are anticipated to be complete cleanups to, or below, the cleanup goals specified in this document.

Removal actions performed per this AM are deemed consistent with (1) the factors set forth within the National Oil and Hazardous Substances Pollution Contingency Plan (NCP) Title 40 of the Code of Federal Regulations (CFR) Part 300, and (2) Chapter 6.8, Ca-HSC, based on the findings below.

Threats to public health or welfare:

- Nearby human populations may be affected by exposure to low-level radioactive materials.
- Low-level radioactive materials may migrate or be released because of their presence near the surface.
- Low-level radioactive materials may migrate or be released because of weather conditions.

Threats to the environment:

- Nearby animals, and food chains may be affected by exposure to low-level radioactive materials.
- Radioactive materials can have very long half-lives. Their release into the environment could be detrimental.

No nationally significant or precedent setting issues exist for this site.

## **II. SITE CONDITIONS AND BACKGROUND**

This section describes the site history and background of HPS, summarizes each action conducted to date, and presents the findings of previous characterizations of radioactivity at HPS.

### **A. SITE DESCRIPTION**

The following sections summarize characteristics of the site, any releases or threatened releases of contaminants, and the status of the site on the National Priorities List (NPL).

#### **1. Removal Site Evaluation**

To date, several radiological site investigations have been conducted at HPS to assess the presence of radioactive materials remaining from past operations associated with shipyard operations, the Naval Radiological Defense Laboratory (NRDL) and ship decontamination and maintenance procedures. Those investigations delineated certain areas at which low-level radioactive contaminants were found, and some of those areas have been addressed under a previous radiological removal action.

As investigations continue, additional areas throughout HPS are being considered for their potential to contain low-level radioactive contamination. This AM addresses those potential areas through proposed removal and off-site disposal actions.

Three general types of media exist in which radioactive contamination may be found:

1. Soils
2. Debris/Slag
3. Buildings: walls, foundations, slabs, and so on
4. Sanitary sewer and storm drain systems

Examples of previously identified low-level radioactive contamination include anomalies found in soils near buildings; debris/slag containing embedded radium dials; and surface contamination on concrete slabs, walls, and piping associated with buildings.

#### **2. Physical Location**

HPS is located in the City and County of San Francisco, California, shown on Figure 1. HPS is situated on a long promontory in southeast San Francisco, extending eastward into San Francisco Bay. The primary mission of HPS was naval shipyard activities. HPS consists of 848 acres, 416 acres of which are on land, and is divided into six parcels (B, C, D, E, E-2, and F) to facilitate environmental investigation and cleanup activities. A seventh parcel, Parcel A, was conveyed to the City of San Francisco in December 2004.

The climate is characterized as temperate, or Mediterranean, which typically has moist mild winters and dry summers. The average annual precipitation in the area is 21.79 inches. The precipitation occurs mostly during the months of December, January, and February. There are public residences within a mile radius of HPS and the nearest major thoroughfare is I-280, located roughly 5 miles west of the site.

### **3. Site Characteristics**

HPS is a federally owned facility, which began using radioactive materials in the early 1940s. Radioactive materials were used in shipyard operations and NRDL research. In 1969, radiological studies by NRDL ended, and NRDL buildings were decontaminated and cleared for unrestricted reuse to the standards of the time. Shipyard operations ceased in 1974. The Navy also conducted ship decontamination, repair, and dismantling activities, which generated radium dial and sandblast grit waste streams. During NRDL operations, the Navy managed a radioactive waste disposal program, which included removal of high-level and low-level radioactive materials from HPS for transport and disposal of the materials to an off-site ocean-bottom disposal area.

As a result of past radiological operations, some buildings have been found to contain low-level radioactive contaminants and radium dials have been found embedded in both debris and slag, or buried in disposal areas. Hazardous materials have also been found at HPS. The site was placed on the NPL in 1989, pursuant to CERCLA, as amended by the Superfund Amendments and Reauthorization Act of 1986.

In 1991, HPS was slated for closure pursuant to the terms of the Defense Base Closure and Realignment Act of 1990 (Public Law 101-510). Closure of HPS includes conducting environmental remediation activities and transfer of the property to the City of San Francisco for future non-defense reuse.

### **4. Release or Threatened Release into the Environment of a Hazardous Substance or Pollutant or Contaminant**

The radioisotopes encountered to date, and likely to be encountered during future investigations, include americium-241, cobalt-60, strontium-90, cesium-137 (and daughter products), europium-152, europium-154, plutonium-239, radium-226, tritium, thorium-232, and uranium-235 (and daughter products), which are hazardous substances, as defined by §101(14) of CERCLA, and pollutants or contaminants, as defined by §101(33) of CERCLA.

Because of the presence of low-level radioactive materials in areas exposed to erosion and weathering, a threat of migration and release to surrounding populations and the environment could exist.

To date, almost all radioactive materials encountered at HPS have been isolated from human contact and located in restricted-access areas. However, the threat of release does exist because of the persistence of radioactive materials in areas designated for future unrestricted use and areas that may be affected by weather and erosion.

Removal actions conducted in accordance with this AM are therefore designed to (1) substantially reduce ionizing radiation to cleanup goals and (2) eliminate identified pathways of exposure to ionizing radiation.

### **5. National Priorities List Status**

HPS was placed on the NPL on November 21, 1989, with a Hazard Ranking Score of 48.77. Parcel A was delisted in February 1999 and transferred in December 2004. Each parcel has undergone, or is undergoing, a CERCLA remedial investigation and feasibility study (RI/FS). RI/FSs have been completed for Parcels A and B, and an Addendum to the Technical Memorandum in Support of Record of

Decision Amendment (TMSRA) is being prepared for Parcel B. RI/FSs are currently being conducted for Parcels C, D, E and E-2. Radiological Addenda will be issued subsequent to the RI/FSs for the remaining parcels at HPS.

## **6. Maps, Pictures, and Other Geographical Representations**

Figure 1 shows the location of HPS, and Figure 2 presents all currently known radiologically impacted areas at HPS. Many radiological areas have already been addressed by previous investigations and by previous radiological removal actions.

### **B. OTHER ACTIONS TO DATE**

Several radiological investigations and radiological removal actions have been conducted at HPS. The following sections summarize those actions.

#### **1. Previous Actions**

Five phases of radiological investigations, as well as interim investigations, were performed at HPS, beginning in 1991. Phases I and II delineated the surface and subsurface distribution of radium-containing devices. Phases III and IV recommended and performed the removal of anomalies near Buildings 364, 509, 529, and 707 in Parcels D and E. Phase V conducted radiological surveys and remedial actions in Parcels B, C, D, and E. Each investigation is summarized below.

##### **1.1 Phase I**

In 1991, the Phase I radiological investigation to evaluate the extent of radium-containing devices identified in a surface radiation survey was conducted by Harding Lawson Associates (1990) in 1988. The Phase I investigation included Installation Restoration (IR) Sites 01/21, 02, 03 and portions of IR Sites 11/14/15.

Over 300 radium-containing point sources were detected in a centralized area in IR-02 Northwest during the Phase I investigation, and additional anomalies were observed in IR-01/21 and IR-02 Southeast. A dial with anomalously high gamma activity was also found on the door of a combination safe in IR-11/14/15.

Thirteen soil samples collected from the disposal area in IR-02 Northwest contained radium-226 at concentrations exceeding background levels. One soil sample collected from IR-01/21 and two soil samples collected from IR-02 Southeast contained radium-226 at concentrations exceeding background levels (PRC Environmental Management, Inc. [PRC], 1992).

The Phase I investigation concluded that elevated gamma activity was a result of the presence of radium-containing devices in surface soil at scattered locations at IR-01/21 and on the surface and in the subsurface of the centralized disposal area in IR-02 Northwest, which extends into IR-02 Central.

The Phase I radiation investigation recommended an investigation of the subsurface distribution of radium-containing devices in soil in IR-02 Northwest, removal of the combination safe from IR-11/14/15, and further investigation of radioactive analytes in groundwater. The first and second recommendations have been performed, and the third is ongoing.

##### **1.2 Phase II**

The Phase II radiological investigation was conducted in 1993 to delineate the subsurface distribution of radium-containing devices in the IR-01/21 landfill and in the disposal areas in IR-02 Northwest and IR-02

Central. Field activities included excavation of trenches and test pits, collection of soil samples, and collection of air samples (PRC, 1996).

Excavation activities at the disposal area in IR-02 Northwest and in IR-02 Central revealed 111 discrete subsurface gamma-emitting point sources, all located within a well-defined disposal area. A large amount of industrial and construction debris was also found mixed with soils in the disposal area. Radium-containing devices and industrial debris were detected at the surface in IR-01/21, but not in the subsurface of IR-01/21 or at the beach and intertidal areas of IR-02 Northwest (PRC, 1996).

The Phase II radiological investigation concluded that the disposal area in IR-02 Northwest and IR-02 Central was the primary disposal area for all radium-containing devices generated at HPS as a result of ship repair and maintenance activities, and that radium-containing devices were only present on the surface of the landfill in IR-01/21.

### **1.3 Phase III**

The Phase III radiological investigation was conducted in 1997 to address concerns about the use, storage, and disposal of radioactive materials during past NRDL operations at HPS. The goal of the Phase III investigation was the eventual release, for unrestricted use, of all remaining buildings and sites not previously released, including three formerly used defense sites. Radiological surveys were conducted within and around Buildings 506, 509, 517, and 529.

The Phase III radiological investigation recommended the following actions (Tetra Tech EM, Inc. [TtEMI], 1997):

- Excavation of a potential buried point source behind Building 529
- Excavation of an area with an anomalous count rate of 9,374 counts per minute near Building 509
- Further study of Buildings 364 and 707 (TtEMI, 1997)

All Phase III recommendations were implemented in the Phase IV investigation, or removal action.

### **1.4 Phase IV**

The Phase IV radiological investigation was conducted in 1999 to quantify ambient concentrations of specific radionuclides and to further characterize two radiological sites located near Buildings 364 and 707. The goal of the Phase IV investigation was free release, for industrial use, of the areas located near Buildings 364 and 707.

The Phase IV investigation recommended the following actions:

- Removal of a cesium-137 spill site near Building 364
- Removal of anomalies near the former locations of Buildings 509, 529, and 707

Both Phase IV recommendations were implemented in the remedial action, which began in February 2001.

### **1.5 Interim Investigations Between Phase IV and Phase V**

Three interim investigations were conducted after the Phase IV radiological investigation and before the Phase V radiological investigation. Available information for each investigation is summarized below:

### **1.5.1 1999 October IT Corporation Investigation**

Sandblast waste was discovered and removed from an excavation site at IR-07. Five samples were collected and analyzed for radioactivity. Results were indicative of background concentrations. Several other areas containing sandblast waste have been investigated and sampled since this investigation. To date, none of the sandblast waste has been found to contain radionuclide concentrations above normal background levels.

### **1.5.2 2001 TtEMI Investigation**

In June and July 2001, TtEMI contracted a survey of the Gun Mole Pier (Regunning Pier). Gamma and beta measurements were obtained on the surface of the pier to determine whether elevated radioactivity levels remained from previous operations. The measurement points were based on a newly found drawing, indicating the previous location of the concrete test pad and NRDL barge on the pier. Gamma levels were measured using a portable detection instrument equipped with a sodium iodide (NaI) scintillation probe. The measurements were made both in a systematic grid pattern and biased locations specifically over drains, surface cracks, and other unusual features.

Surface radioactivity at selected locations was also measured using a Geiger-Mueller detector sensitive to beta radiations.

Findings indicated that only background levels of radioactivity were present in the areas surveyed.

### **1.5.3 NWT Interim Investigation and Removal Action**

During 2001, New World Technology (NWT) performed a removal action at the tank vault behind Building 364. The tanks, piping, and support equipment had been previously removed, and the remaining vault surfaces had been identified as exceeding site release criteria. After the concrete vault was removed, surveys and soil sampling indicated that no residual contamination remained that exceeded site release criteria.

Additionally, a Characterization Survey of the Parcel E shoreline was performed. The shoreline survey encompassed areas within approximately 50 feet on either side of the mean tide line. Several areas were noted during the survey that exceeded background gamma radiation levels, most significantly the areas known as the "Metal Debris Reef" and "Metal Slag Area." Samples obtained from those locations identified radium-226 as the contaminant. Although no removal actions were taken at the time of the survey, the Navy is still investigating and considering removal actions.

## **1.6 Phase V Investigations**

Beginning in January 2002, NWT conducted Scoping and Characterization Surveys, soil and other media sampling programs, remediations, and Final Status Surveys at various open areas and in various buildings at HPS in accordance with *Multi-Agency Radiation Site Survey and Investigation Manual* (MARSSIM) guidelines. The investigations and surveys were in support of the release of buildings or areas that had been identified as areas where radioactive materials had been used or areas where remedial actions to remove known contamination had occurred.

Each site was assessed for potential radionuclides of concern with surveys designed according to the MARSSIM area classification (Class 1, 2, or 3). The extent of the surveys depended upon the classification of the area. Class 1 surveys covered 100 percent of the area, Class 2 surveys covered 50 percent of the area, and Class 3 surveys covered 20 percent of the area. If contamination was found in a Class 3 area, a 100 percent Characterization Survey was conducted followed by remediation as appropriate. A Class 1 Final Status Survey followed any remediation.

## 1.7 Historical Radiological Assessment

The HRA was conducted to evaluate all previous uses of radioactive materials at HPS and to assess their potential to impact the site. The final version of the HRA was issued in August 2004. Based on the recommendations of the HRA, a total of 84 HPS sites have been designated as “impacted.” This indicates that the site has a potential for radioactive contamination based on historic information or is known to contain radioactive contamination. These impacted sites, broken out by parcel, include:

- Parcel B – 14 sites
- Parcel C – 12 sites
- Parcel D – 19 sites
- Parcel E – 33 sites
- Parcel F – 2 sites
- Off-Base Facilities – 1 site
- Base-Wide Areas – 3 sites

## 2. Current Actions

Current radiological actions at HPS include TCRAs and surveys that were initiated under this AM and implementation of recommended actions identified in the HRA. These actions are described below.

### 2.1 TCRAs

Three TCRAs are currently being conducted on site in accordance with the requirements of the CERCLA and the National Oil and Hazardous Substances Pollution Contingency Plan (NCP).

#### **Metal Debris Reef / Metal Slag Area**

The TCRA at the Metal Debris Reef in Parcel E and Metal Slag Area in Parcel E-2 involves the removal of radioactively contaminated metal debris and slag.

As described in *Final Removal Action Design and Implementation Work Plan, Metal Debris Reef and Metal Slag Areas* [Tetra Tech EC, Inc. (TtEC), 2005a], this TCRA includes radiological surveying and remediation, excavation of metal slag and debris, site restoration, and waste disposal.

#### **PCB Hot Spot**

The TCRA for the Polychlorinated Biphenyl Hot Spot Soil Excavation Site (PCB Hot Spot) in Parcel E-2 involves the removal of soils containing PCBs, total petroleum hydrocarbons (TPH), and any radioactive contaminants.

As described in *Final Removal Action Design and Implementation Work Plan, PCB Hot Spot Soil Excavation Site* (TtEC, 2005b), this TCRA includes radiological surveying and remediation, excavation of PCB- and TPH-contaminated soil, site restoration, and waste disposal.

#### **IR-02 Northwest and Central**

This TCRA is for the extraction of debris and soil containing radioactive contaminants present in the IR-02 Northwest and Central area of Parcel E.

As described in *Final Removal Action Design and Implementation Work Plan, TCRA for IR-02 Northwest and Central* (TtEC, 2005c), this TCRA includes radiological surveying and remediation, excavation of soil and debris, site restoration, and waste disposal.

## **2.2 Radiologically Impacted Site Surveys**

### **Building 322**

This survey was performed to support release of the building for demolition and disposal. After the building was demolished, a Final Status Survey was performed that allowed release of the site for unrestricted reuse.

### **Building 819**

This survey was performed to determine if residual radioactivity was present at the site. The survey was designed so that if no contamination was found above the release criteria, the data could be used to support release of the site for unrestricted reuse. The report is currently under review and a final determination will be made in 2006.

### **Building 114 Site**

The Building 114 Site is the former location of the demolished Building 114. This survey was performed to determine if residual radioactivity is present at the site. The survey was designed using the *Base-wide Radiological Work Plan* (TtEC, 2005d) so that if no contamination is found above the release criteria, the data could be used to support unrestricted reuse. The report is currently being prepared for review by the regulatory agencies.

### **Building 146**

This survey was performed to determine if residual radioactivity is present at Building 146. The survey was designed using the *Base-wide Radiological Work Plan* (TtEC, 2005d) to allow unrestricted reuse if no contamination was found above the release criteria. The report is currently being prepared for review by the regulatory agencies.

## **C. STATE AND LOCAL AUTHORITIES ROLE**

The California Department of Health Services (DHS) and U.S. Environmental Protection Agency (EPA) have actively participated in the radiological investigations and the radiological removal actions at HPS. In the past, EPA has provided site-specific input for the establishment of removal action cleanup goals and investigative strategies.

The California Environmental Protection Agency Department of Toxic Substances Control (DTSC) and California Regional Water Quality Control Board, San Francisco Bay Region (Water Board) are also regulatory agency stakeholders.

### **1. State and Local Actions to Date**

As previously discussed, federal Executive Order 12580 delegates to the Department of Defense the President's authority to undertake CERCLA response actions. Congress further outlined this authority in its Defense Environmental Restoration Program Amendments, which can be found at 10 USC §2701-2705. Both CERCLA §120(f) and 10 USC §2705 require Navy facilities to ensure that state and local officials be given timely opportunity to review and comment on Navy response actions. CERCLA §120 further requires the Navy to apply state removal and remedial action law requirements at its facilities.

Accordingly, DHS, DTSC, and Water Board have provided technical advice and oversight during phases of the RI/FS process, during previous radiological investigations, and during current and future radiological removal actions.

## **2. Potential for Continued State or Local Response**

DHS, Water Board, and DTSC deferred to EPA for development of cleanup goals for the previous radiological removal action. Those cleanup goals were also chosen for this removal action. DHS, Water Board, and DTSC will continue to provide input through review of radiological documents and participation in the Base Realignment and Closure (BRAC) Cleanup Team.

## **III. THREATS TO PUBLIC HEALTH, WELFARE, OR THE ENVIRONMENT AND STATUTORY AND REGULATORY AUTHORITIES**

In accordance with the NCP, the following threats must be considered in determining the appropriateness of a removal action (40 CFR §300.415[b][2]):

- Actual or potential exposure to hazardous substances, pollutants, or contaminants of nearby populations, animals, and food chains
- Actual or potential contamination of drinking water supplies and sensitive ecosystems
- Hazardous substances, pollutants, or contaminants in drums, barrels, tanks, and other bulk storage containers that may pose a threat of release
- High levels of hazardous substances or pollutants or contaminants in soils largely at, or near, the surface that may migrate
- Weather conditions that may cause hazardous substances, pollutants, or contaminants to migrate or to be released
- Threat of fire or explosion
- Other situations or factors that may pose threats to human health or the environment

### **A. THREATS TO PUBLIC HEALTH OR WELFARE**

Three potential threats to public health or welfare exist:

- Nearby human populations may be affected by exposure to low-level radioactive materials.
- Low-level radioactive materials may migrate or be released because of their presence near the surface.
- Low-level radioactive materials may migrate or be released because of weather conditions.

Because of the possible adverse health effects from ionizing radiation (EPA, 1998) and the long decay periods (half-lives) for many radionuclides, removal and off-site disposal is considered the most effective option for most of the radioactive contaminants found at HPS. Physical removal of radioactive materials will ensure that the potential for diffuse radioactivity is reduced to levels that meet or are below cleanup goals.

### **B. THREATS TO THE ENVIRONMENT**

Two potential threats to the environment exist:

- Nearby animals and food chains may be affected by exposure to low-level radioactive materials.
- Radioactive materials can have very long half-lives; therefore, their release into the environment could be detrimental.

Physical removal of radioactive materials from HPS also provides the most effective option for mitigation of threats to the environment from ionizing radiation.

#### **IV. DETERMINATION OF ENDANGERMENT**

Results of radiological investigations conducted to date (TtEMI, 1997; 2000a) demonstrate that current conditions at HPS may present immediate and severe threats to the aquatic ecosystem, public health, welfare, or the environment.

Actual or threatened releases of radioactive materials from HPS, if not addressed by implementing the response action selected in this AM, may present an imminent and substantial endangerment to public health, welfare, or the environment. The primary endangerment mechanism is through migration: If radioactive contaminants migrate, they have the potential to contaminate water and soils. Water and soil contamination could be long lasting, since some radionuclides have half-lives in the tens of thousands of years.

The HRA provides a comprehensive review and assessment of the affect of past radiological operations at HPS.

#### **V. PROPOSED ACTIONS AND ESTIMATED COSTS**

The following sections summarize the actions proposed for any TCRA performed per this AM.

##### **A. PROPOSED ACTION**

The proposed action for localized radioactive material present at HPS is to physically remove it and dispose of the material at an off-site disposal facility. For purposes of this AM, localized is defined as any area less than approximately 3 acres in which radioactive material is the primary risk driver. The definition for “localized” is based on the results of past radiological investigations, the size of the radium dial disposal area in IR-02 Northwest and IR-02 Central, and the size of the intertidal debris area; these areas are assumed to be the largest probable areas this AM would address.

Estimates on the quantity of radioactive materials that will be removed per this AM remain pending, until more accurate information is gathered. Removal actions performed per this AM will comply with the off-site policy by using a fully licensed off-site disposal facility for low-level radioactive waste.

Removal actions performed per this AM are subject to the cleanup goals listed in Table 1, for soils/debris, surfaces, and water, respectively. Before initiating a removal action per this AM, the area being considered will be characterized using real-time radiation detection devices or soil sampling and analyses.

MARSSIM guidance is being used to apply the cleanup goals. Table 2 lists additional radionuclides that could be encountered at HPS, based on information from the HRA. If these additional radionuclides are encountered during surveys or removal actions, cleanup goals will be derived using regulatory involvement.

Areas where radioactive contamination may be too pervasive to conduct a localized removal action, where radioactive contamination is not the primary risk driver, or where excavation activities pose a high risk to workers, will be addressed as part of the ongoing CERCLA process. The IR-01/21 landfill is one example of an area that has multiple risk drivers, has a large affected area, and would pose excessive hazards to workers performing excavation activities.

Table 3 provides a listing of radiologically impacted sites at HPS that were identified in the HRA (NAVSEA, 2004). Table 3 does not include those sites in the former Parcel A that have received

regulatory release or the Formerly Used Defense Sites (FUDS). The remaining impacted sites (Buildings 813 and 819) in the former Parcel A have been reassigned to Parcel D after the Parcel A boundary was adjusted. Assessments of potentially contaminated media and migration pathways, as well as recommended actions are detailed in Table 3. The impacted sites listed in Table 3 will be addressed under this AM.

## **1. Proposed Action Description**

Physical removal and off-site disposal of radioactive materials will follow the general steps listed below for three types of environmental media in which radioactive contamination is likely to be encountered at HPS. Removal actions will be preceded by preparation of site-specific work plans or task-specific plans in consonance with the *Base-Wide Radiological Work Plan* (TtEC, 2005d). To the extent practicable, radioactive materials will be segregated from other materials (such as construction debris or nonaffected soils) to minimize radioactive waste stream generation.

- **Soils**
  - Delineation of radioactive contamination using real-time radiation detection instruments or soil sampling and analyses
  - Excavation of radioactive materials and proper off-site disposal
  - Soil confirmation sampling and analyses; comparison of results against cleanup goals listed in Table 1 using MARSSIM methodology
  - Site backfilling and restoration
- **Debris/Slag**
  - Delineation of contamination, or general area of suspected contamination, using real-time radiation detection instruments or sampling and analyses
  - Collection and segregation of radioactive materials
  - Proper off-site disposal of materials
  - Comparison of remediated area against cleanup goals listed in Table 1, depending on the surrounding environmental media (soils or surfaces) using MARSSIM methodology
  - Site backfilling or restoration
- **Concrete Surfaces (walls, slabs, and foundations)**
  - Delineation of radioactive contamination using real-time radiation detection instruments or wipe samples and analyses
  - Decontamination of surfaces by acid or solvent washing or mechanical removal such as scabbling (scabbling will be preferred in order to reduce mixed-waste stream generation)
  - Proper off-site disposal
  - Comparison of residual radioactivity to the cleanup goals listed in Table 1, using MARSSIM methodology

**Note:** if surface decontamination is not technically feasible, the entire structure may be removed and disposed of appropriately.

If radiological areas are found in or near wetlands or intertidal areas, removal actions will be modified to minimize the affect to those areas.

The following laboratory analyses are associated with characterization of the radioactive materials that may be addressed by this AM:

- Isotopic americium, plutonium (238 and 239), thorium (228 and 232) and uranium (234, 235, 238) analyses
- Gamma spectroscopy analyses
- Strontium analyses
- Gross alpha/beta analysis
- Swipes for removable contamination (including tritium)

Removal actions performed under this AM will not include institutional controls (ICs); therefore, any ICs which may be required will be discussed in the CERCLA Record of Decision. Radiological sites not addressed under this AM will continue to have restricted access, until a final remedy is selected.

Post-removal site controls will not be required following removal actions performed per this AM, since the intent of each removal action is to reduce radioactive contaminants to or below the cleanup goals.

## **2. Contribution to Remedial Performance**

Removal of radioactive contamination per this AM will allow for the ongoing CERCLA process to address any remaining contamination and will avoid future “mixed waste” (waste with both chemical and radioactive contamination). Each removal action taken per this AM is an interim action, and that the final action for radiological site cleanup will be selected in the Record of Decision. Removal actions taken per this AM will also take into account the City of San Francisco’s reuse plan for the site.

## **3. Description of Removal Alternative**

Several removal action alternatives were considered for use in this AM; however, physical removal and proper off-site disposal was the only viable alternative retained for evaluation.

Other actions such as in-place stabilization, and removal and consolidation in the closed HPS industrial landfill, were considered; however, those alternatives would not physically remove the contamination (requiring long operation and maintenance [O&M] periods), would involve large costs, or would require restricted reuse of certain areas of HPS for long periods of time.

The steps required to remove and properly dispose of low-level radioactive materials at an approved off-site facility were detailed in Section V.A.1.

Removal and proper disposal of radioactive materials will provide a timely response and the best option for protection of human health and the environment. Previous radiological soil removals have been completed within several months, and achievement of cleanup goals ensures that human health risks related to radioactive materials are eliminated from the site in question.

Sections 3.1 and 3.2 summarize the criteria used to evaluate the proposed alternative and results of the evaluation.

### **3.1 Evaluation Criteria**

Three criteria were used to evaluate the removal and disposal alternative proposed in this AM: effectiveness, implementability, and cost.

### **Effectiveness**

Three general factors were considered in evaluating effectiveness: (1) overall protection of human health and the environment, (2) short-term effectiveness, and (3) long-term effectiveness and permanence.

### **Implementability**

This criterion addresses the technical and administrative feasibility of implementing the removal action. Items evaluated include (1) the availability of services and materials required during implementation of the action, (2) the institutional or social concerns that could preclude the action, and (3) state and community concerns that could affect implementation. The following factors were considered:

- Technical feasibility: the ease or difficulty of implementing the alternative and the reliability of the technology
- Administrative feasibility: activities, such as obtaining waivers or permits, requiring coordination with other offices and agencies

### **Cost**

This criterion is concerned with the estimated costs of the alternatives, and is based on previous radiological removal actions for soils and building surfaces. O&M costs were not considered in the cost evaluation since removal actions will be performed in less than a year, and no follow-on costs are associated once this removal action has been completed.

## **3.2 Evaluation of Proposed Removal and Off-site Disposal Action**

The removal and off-site disposal alternative provides the highest degree of effectiveness, is feasible to implement, and is also economically feasible.

### **Effectiveness**

Removal and off-site disposal provides the highest degree of protection for human health and the environment by physically removing the materials from HPS. Removal and off-site disposal will also comply with chemical-, action-, and location-specific ARARs.

### **Implementability**

This alternative does not have administrative constraints and has few technical constraints. Most of the radioactive contamination identified at HPS to date has been in localized areas. Surface scans performed in the past have found point-source anomalies and specific disposal areas containing radioactive contamination. Subsurface investigations have found concentrated areas where disposal of dials or other radioactive materials occurred. Physical removal is very feasible for these types of situations. If large quantities of radioactive materials are found, physical removal and off-site disposal may have significant technical constraints. Any areas found to contain large quantities of low-level radioactive waste will not be addressed by this AM, but will be evaluated further in the ongoing CERCLA process.

### **Cost**

Unit costs for labor, mobilization, and site remediation are comparable with a standard soil removal and disposal project involving chemical contamination. The unit cost for disposal of radioactive materials is on average greater than the unit cost of chemical contamination in soils; however, the cost does not become prohibitive unless very large volumes of radioactive materials are removed and disposed. Further details regarding the unit costs for this alternative are provided in Section V.B.

#### **4. Engineering Evaluation and Cost Analysis**

Since this is a TCRA, an engineering evaluation and cost analysis is not applicable.

#### **5. Applicable or Relevant and Appropriate Requirements**

Section 300.415(j) of the NCP provides that removal actions must attain applicable or relevant and appropriate requirements (ARARs) to the extent practicable, considering the exigencies of the situation.

Section 300.5 of the NCP defines applicable requirements as cleanup standards, standards of control, and other substantive environmental protection requirements, criteria or limitations promulgated under federal or state environmental or facility siting laws that specifically address a hazardous substance, pollutant, contaminant, remedial action, location or other circumstances at a CERCLA site.

Section 300.5 of the NCP defines relevant and appropriate requirements as cleanup standards, standards of control and other substantive requirements, criteria, or limitations promulgated under federal or state environmental or facility siting laws that, while not “applicable” to a hazardous substance, pollutant, or contaminant, remedial action, location, or other circumstances at a CERCLA site, address problems or situations sufficiently similar to those encountered at the CERCLA site and are well-suited to the particular site.

Because CERCLA on-site response actions do not require permitting, only substantive requirements are considered as possible ARARs. Administrative requirements such as approval of, or consultation with administrative bodies, issuance of permits, documentation, reporting, record keeping, and enforcement are not ARARs for CERCLA actions confined to the site.

Only those state standards that are identified by a state in a timely manner and are more stringent than federal requirements may be applicable or relevant and appropriate.

There are three types of ARARs: contaminant-specific, location-specific, and action-specific. The first type includes contaminant-specific requirements. These ARARs set limits on concentrations of specific hazardous substances, contaminants, and pollutants in the environment. Examples of this type of ARAR are ambient water quality criteria and drinking water standards. The second type of ARAR includes location-specific requirements that set restrictions on certain types of activities based on site characteristics. These include restrictions on activities in wetlands, floodplains, and historic sites. The third type of ARAR includes action-specific requirements. These are technology-based restrictions that are triggered by the type of action under consideration. Examples of action-specific ARARs are Resource Conservation and Recovery Act regulations for waste treatment, storage, and disposal.

ARARs must be identified on a site-specific basis from information about specific chemicals at the site, specific features of the site location, and actions that are being considered as removal actions.

The ARARs used to prepare this AM are presented in Appendix A.

The cleanup goals presented in this AM were derived by considering the following:

- Soil cleanup goals: EPA decay-corrected PRGs (EPA, 1991)
- Radium-226 contamination in soils: per agreement with EPA
- Radioactive contamination on structures: These limits are based on 25 millirem per year (mrem/y), using RESRAD or Atomic Energy Commission’s (AEC’s) *Regulatory Guide 1.86* (1974), whichever is lower.

- Radioactive contamination on surfaces designated as equipment or waste: These limits are based on AEC's *Regulatory Guide 1.86*. Limits for removable surface activity are 20 percent of these values.
- Application of soils, debris, and surface cleanup goals to sites: MARSSIM guidance (EPA et al., 2001)
- Radioactive contamination in wastewater: A release criterion for water has been derived from *Radionuclides Notice of Data Availability Technical Document* (EPA, 2000) by comparing the limits from two criteria and using the most conservative limit.

The cleanup goals derived for the project are considered to be the most conservative available. For example, use of EPA decay-corrected preliminary remediation goals (PRGs) for soil removal actions is more conservative than use of other federal ARARs listed in Appendix A.

## 6. Project Schedule

Individual removal action project schedules will be generated as each site is identified for survey or removal of radioactive materials. Based on previous removal actions for radioactive materials, field events are expected to last from 1 to 4 months. Prior to commencing fieldwork, detailed work plans/task-specific plans and health and safety plans will be generated. Following field events, analytical reports, data validation reports, or summary reports will also be generated to summarize actions taken.

## B. ESTIMATED COSTS

The Navy has made a present worth estimate of the removal action costs. The Navy has estimated the cost to complete the required radiological removal actions at \$60 million. The estimated costs include the direct and indirect capital costs. The items listed below are considered capital costs. They are based on a previous removal action, which removed and disposed of 13 cubic yards of contaminated soils. Costs for removal actions involving debris or surfaces will be comparable, if the quantity of radioactive materials disposed of is similar.

### Estimated Costs – Typical 13-cubic-yards Soil Removal Action

#### Direct Capital Costs

|                                       |          |
|---------------------------------------|----------|
| Construction/Equipment/Materials:     | \$17,000 |
| Soil excavation (\$75.00/cubic yard): | \$ 1,275 |
| Transport and disposal:               | \$21,250 |
| Analytical (12 confirmation samples)  | \$ 5,400 |

#### Indirect Capital Costs

|                               |          |
|-------------------------------|----------|
| Work plans, engineering, etc. | \$ 2,000 |
|-------------------------------|----------|

|                             |          |
|-----------------------------|----------|
| Soils Removal Action Total: | \$46,925 |
|-----------------------------|----------|

## VI. EXPECTED CHANGE IN THE SITUATION SHOULD ACTION BE DELAYED OR NOT TAKEN

If action should be delayed or not taken, exposure of human populations to low-level radioactive materials may occur. Contamination may spread from HPS to nearby areas from wind erosion, surface water runoff, or other erosion mechanisms. Migration of radioactive contamination could result in an

increased health risk to local populations because of prolonged exposure to low-level radioactive materials.

Since the half-lives of radioactive contaminants can range up to tens of thousands of years, the associated risk could be very long term, and migration over this time period may result in a greater volume of material to be remediated. This would also result in an increase in treatment or disposal costs.

## **VII. PUBLIC INVOLVEMENT**

This document will be added to the Administrative Record (Appendix B) and will be made available for public review at the following locations:

San Francisco Public Library  
Government Documents  
100 Larkin Street  
San Francisco, California 94102

Anna E. Waden Library  
5075 Third Street  
San Francisco, California 94124

## **VIII. OUTSTANDING POLICY ISSUES**

No outstanding policy issues exist for this removal action.

## **IX. RECOMMENDATION**

To date, the Navy has not acquired evidence identifying other potentially responsible parties (PRP) at this site. However, information acquired in the future, including but not limited to, information acquired during the implementation of this removal action or future response actions at the site, could result in the identification of other PRPs.

This AM was prepared in accordance with current EPA and Navy guidance documents for TCRAs under CERCLA. The purpose of this AM is to identify and analyze removal actions to address localized radioactive contamination in soils, debris/slag and buildings base-wide.

Based on the analysis of the removal action alternatives completed in Section V.A.3, the recommended removal action is removal of radioactive contamination from localized areas in soils, debris/slag, and buildings, followed by appropriate off-site disposal at a fully licensed low-level radioactive waste disposal facility. This alternative will apply to localized areas throughout HPS, provide a high degree of protection for human health and the environment, does not have significant administrative or technical constraints, and is not cost prohibitive.

This decision document represents the selected removal action for HPS located in San Francisco, California, developed in accordance with CERCLA, as amended, and is consistent with the NCP. This decision is based on the Administrative Record for the site (included in Appendix B).

**Notes:**

<sup>a</sup> These limits are based on AEC *Regulatory Guide 1.86* (1974). Limits for removable surface activity are 20 percent of these values.

<sup>b</sup> These limits are based on 25 mrem/yr, using RESRAD-Build Version 3.3 or *Regulatory Guide 1.86*, whichever is lower.

<sup>c</sup> The resulting dose is based on modeling using RESRAD-Build Version 3.3 or RESRAD Version 6.3, with radon pathways turned off.

<sup>d</sup> EPA PRGs for two future-use scenarios.

<sup>e</sup> The on-site and off-site laboratory will ensure that the MDA meets the listed release criteria by increasing sample size or counting time as necessary. The MDA is defined as the lowest net response level, in counts, that can be seen with a fixed level of certainty, customarily 95 percent. The MDA is calculated per sample by considering background counts, amount of sample used, and counting time.

# TABLE 1

## RELEASE CRITERIA

- <sup>f</sup> Based on EPA-decay corrected PRGs for commercial reuse and a previous action memorandum (TtEMI, 2000a, 2001).
- <sup>g</sup> Limit is 1 pCi/g above background, per agreement with EPA.
- <sup>h</sup> Release criteria for water have been derived from *Radionuclides Notice of Data Availability Technical Document*, (EPA, 2000) by comparing the limits from two criteria and using the most conservative limit.
- <sup>i</sup> Limit is for total radium concentration.

AEC – Atomic Energy Commission

cm<sup>2</sup> – square centimeters

dpm – disintegrations per minute

EPA – U.S. Environmental Protection Agency

MDA – minimum detectable activity

mrem/yr – millirem per year

pCi/g – picocurie per gram

pCi/L – picocurie per liter

PRG – preliminary remediation goal

TtEMI – Tetra Tech EM, Inc.

**Notes:**

- H High = Evidence of contamination in the media or migration pathway has been identified.
- L Low = The potential for contamination in the type of media or migration pathway is remote.
- M Moderate = The potential for contamination in the media or migration pathway exists, although the extent has not been fully assessed.
- N None = Evidence of contamination in the specific media or migration pathway has not been found, or known contamination has been removed, and surveys indicate that the media or migration pathway meets today's release criteria.

#### LEGEND

- NAVY PROPERTY BOUNDARY (OFFSHORE)
- PARCEL BOUNDARY
- IMPACTED SANITARY SEWER SYSTEM
- IMPACTED STORM DRAIN SYSTEM
- IMPACTED BUILDINGS OR SITES
- DEMOLISHED IMPACTED BUILDINGS/STRUCTURES
- DEMOLISHED BUILDINGS/STRUCTURES
- IMPACTED SITES THAT HAVE OBTAINED REGULATORY RELEASE
- IMPACTED FUDS SITES
- NON-IMPACTED BUILDINGS WITHIN AN IMPACTED SITE, RADIOLOGICAL PRECAUTIONS MAY BE REQUIRED

#### NOTE

IMPACTED SITES ARE SITES THAT HAVE KNOWN RADIOLOGICAL CONTAMINATION OR WHERE SITE HISTORY INDICATES THAT RADIOLOGICAL CONTAMINATION MAY BE PRESENT.

| <b>Chemical-specific<sup>a</sup> ARAR</b>                                     |                                                                                                                                                                                                                                                                                                                                                                   |                       |                          |                                                                                                                                                                                                                             |
| Health and Environmental Standards for Drinking Water                         | MCLs for radionuclides <ul style="list-style-type: none"> <li>• Combined radium-226 and radium-228 – 5 pCi/L</li> <li>• Gross alpha (including radium-226 but excluding radon and uranium) – 15 pCi/L</li> <li>• Tritium – 20,000 pCi/L</li> <li>• Strontium-90 – 8 pCi/L</li> <li>• Beta and photon – 4 mrem/yr</li> <li>• Uranium – 30 µg/L</li> </ul>          | 40 CFR §141.66        | Applicable               | This requirement is applicable to the wastewater limits established for the site.                                                                                                                                           |
| Radiological Criteria for Unrestricted Use at Closing NRC Licensed Facilities | A site will be considered acceptable for unrestricted use if the residual radioactivity that is distinguishable from background radiation results in TEDE to an average member of the critical group that does not exceed 25 mrem/yr, including that from groundwater sources of drinking water, and that the residual radioactivity has been reduced to ALARA.   | 10 CFR § 20.1402      | Relevant and Appropriate | The Navy would apply this requirement, with the exception that 15 mrem/yr TEDE is substituted for 25 mrem, as ALARA.                                                                                                        |
| Radiological Criteria for License Termination Under Restricted Conditions     | As a condition for license termination with restricted site use, the licensee must demonstrate that further reductions in residual radioactivity necessary to comply with the provisions of 10 USC § 20.1402 would result in net public or environmental harm or were not being made because the residual levels associated with restricted conditions are ALARA. | 10 CFR § 20.1403(a)   | Relevant and Appropriate | Potentially relevant and appropriate for a restricted land use scenario since radioactive materials may be left on site at fill areas.                                                                                      |
| Radiological Criteria for License Termination Under Restricted Conditions     | As a condition for license termination with restricted site use, the licensee must make provisions for legally enforceable institutional controls that provide reasonable assurance that the TEDE from residual radioactivity distinguishable from background to the average member of the critical group will not exceed 25 mrem/yr.                             | 10 CFR § 20.1403(b)   | Applicable               | Restricted land use scenarios may be used in areas that are associated with fill and surveys will not be performed at depths greater than 1 foot below ground surface. The 25 mrem/yr will still apply to the surface dose. |

**APPENDIX A**

**POTENTIAL FEDERAL AND STATE APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS  
AND TO-BE-CONSIDERED CRITERIA FOR POTENTIALLY CONTAMINATED SITES  
AT HUNTERS POINT SHIPYARD**

| <b>Regulation</b>                                        | <b>Requirement</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <b>Citation<sup>b</sup></b>        | <b>ARAR<br/>Determination</b> | <b>Comments</b>                                                                                                                                                                        |
|----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Chemical-specific<sup>a</sup> ARAR (Continued)</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                    |                               |                                                                                                                                                                                        |
| Alternate Radiological Criteria for License Termination  | Alternate criteria are allowed for license termination as long as assurance is provided that public health and safety would continue to be protected and that it is unlikely that the dose from all man-made sources combined, other than medical, would be more than the 100 mrem/yr limit of subpt. D, by submitting an analysis of possible sources of exposure; to the extent practical restrictions on site use are employed according to the provisions of § 20.1403 in minimizing exposures at the site; and doses are reduced to ALARA levels, taking into consideration any detriments such as traffic accidents expected to potentially result from decontamination and waste disposal. | 10 CFR §20.1404(a)(1) - (a)(3)     | Applicable                    | Sites will be dose modeled to show that residual radioactivity present does not exceed 25 mrem/yr. Therefore, members of the public are not expected to receive more than 100 mrem/yr. |
| Dose Limits for Individual Members of the Public         | Requires that the TEDE to individual members of public not exceed 0.1 rem from licensed operation: construction, operation, and decommissioning of commercial reactors and fuel cycle facilities; possession, use, processing, exporting, and certain aspects of transporting nuclear materials and waste; and siting, design, construction, operations, and closure of waste disposal sites.                                                                                                                                                                                                                                                                                                     | 10 CFR §20.1301(a)(1)              | Applicable                    | This requirement is a health-based standard that is applicable for exposure to members of the public during removal actions.                                                           |
| ALIs and DACs of Radionuclides for Occupational Exposure | Establishes limits for effluent releases to unrestricted area particularly in the implementation of the provisions of §20.1302, which implement the radiation dose limits for the public as listed in 10 CFR §20.1301                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | 10 CFR pt. 20, Appendix B, Table 2 | Applicable                    | This requirement is applicable to all removal actions performed as gaseous emissions of radionuclides may occur and is addressed by 10 CFR §20.1301.                                   |
| <b>Location-specific ARAR</b>                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                    |                               |                                                                                                                                                                                        |
| Federal Coastal Zone Management Act                      | This act specifies that federal actions that affect the coastal zone must be consistent with the policies of the San Francisco Bay Conservation and Development Commission's federally approved coastal management program.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | 16 USC 1456(c)(1)(A)               | Applicable                    | This requirement is applicable to all removal actions performed in proximity to San Francisco Bay.                                                                                     |

## APPENDIX A

**POTENTIAL FEDERAL AND STATE APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS  
AND TO-BE-CONSIDERED CRITERIA FOR POTENTIALLY CONTAMINATED SITES  
AT HUNTERS POINT SHIPYARD**

|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Action-specific ARAR</b>                                         |                                                                                                                                                                                                                                                                                                                                      |                       |                          |                                                                                                                                 |
| Storage and Control of Licensed Material                            | The licensee shall secure from unauthorized removal or access licensed materials that are stored in controlled or unrestricted areas.                                                                                                                                                                                                | 10 CFR §20.1801       | Relevant and Appropriate | Potentially relevant and appropriate for a restricted land use scenario since waste will be left on site.                       |
|                                                                     | The licensee shall control and maintain constant surveillance of licensed material that is in a controlled or unrestricted area and that is not in storage.                                                                                                                                                                          | 10 CFR §20.1802       | Relevant and Appropriate | Potentially relevant and appropriate for sites where radioactive material may remain on site if the site can meet the criteria. |
| Protection of the General Population from Releases of Radioactivity | Performance objectives for the land disposal of LLRW. Concentrations of radioactive material that may be released to the general environment must not result in an annual dose exceeding 25 mrem to the body or any organ of a member of the general public.                                                                         | 10 CFR §61.41         | Applicable               | Applicable for sites where radioactive materials may remain on site if the site can meet the criteria.                          |
| Protection of the Individuals from Inadvertent Intrusion            | Design, operation, and closure of the land disposal facility must ensure protection of any individual inadvertently intruding into the disposal site and occupying the site or contacting the waste at any time after active institutional controls over the disposal site are removed.                                              | 10 CFR §61.42         | Relevant and Appropriate | Potentially relevant and appropriate for sites where radioactive waste may remain on site if the site can meet the criteria.    |
| Protection of Individuals During Operation                          | Every reasonable effort shall be made to maintain radiation exposures ALARA.                                                                                                                                                                                                                                                         | 10 CFR §61.43         | Applicable               | Potentially relevant and appropriate for sites where radioactive waste will remain on site.                                     |
| Stability of the Disposal Site After Closure                        | The disposal facility must be sited, designed, used, operated, and closed to achieve long-term stability of the disposal site and to eliminate to the extent practicable the need for ongoing active maintenance of the disposal site following closure so that only surveillance, monitoring, or minor custodial care are required. | 10 CFR §61.44         | Relevant and Appropriate | Potentially relevant and appropriate for a site with radionuclides.                                                             |

| <b>Action-specific ARAR (Continued)</b>        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                             |                               |                                                                                                                                                                                                                                           |
| Waste Disposal by Release into Sanitary Sewage | A licensee may discharge licensed material into sanitary sewerage if each of the following conditions is satisfied: the material is readily soluble in water; and the quantity that the licensee releases into the sewer in 1 month divided by the average monthly volume of water released does not exceed the concentration listed in Table 3 of appendix B to pt. 20; and if more than one radionuclide is released, the licensee shall determine the fraction of the limit in Table 3 of appendix B to pt. 20 represented by discharges into sanitary sewerage by dividing the actual monthly average concentration of each radionuclide released by the licensee into the sewer by the concentration of that radionuclide listed in Table 3 of appendix B to pt. 20; and the sum of the fractions for each radionuclide required by paragraph (a)(3)(i) of this section does not exceed unity; and the total quantity of licensed and other radioactive material that the licensee releases into the sanitary sewerage system in a year does not exceed 5 Ci (185 GBq) of hydrogen-3, 1 Ci (37 GBq) of carbon-14, and 1 Ci (37 GBq) of all other radioactive materials combined. | 10 CFR §20.2003             | Relevant and Appropriate      | The Navy would apply this requirement, with the exception that waste water discharged to the sanitary sewer system will meet the release criteria established in Table 1, which is more conservative than the values listed in this ARAR. |

## APPENDIX A

### POTENTIAL FEDERAL AND STATE APPLICABLE OR RELEVANT AND APPROPRIATE REQUIREMENTS AND TO-BE-CONSIDERED CRITERIA FOR POTENTIALLY CONTAMINATED SITES AT HUNTERS POINT SHIPYARD

#### *Notes:*

- <sup>a</sup> Many potential action-specific ARARs contain chemical-specific limitations and are addressed in the action-specific ARAR tables.
- <sup>b</sup> Only the substantive provisions of the requirements cited in this table are potential ARARs.

#### *Abbreviations and Acronyms:*

µg/L – microgram per liter  
ALARA – as low as reasonably achievable  
ALI – Annual Limit of Intake  
ARAR – applicable or relevant and appropriate requirement  
CFR – Code of Federal Regulations  
Ci – curie  
DAC – derived airborne concentration  
GBq – gigabecquerel  
LLRW – low-level radioactive waste  
MCL – Maximum Contaminant Level  
mrem – millirem  
mrem/yr – millirem per year  
Navy – U.S. Department of the Navy  
NRC – Nuclear Regulatory Commission  
pCi/L – picocurie per Liter  
pt. – part  
subpt. – subpart  
TEDE – total effective dose equivalent  
USC – United States Code

**RESPONSE TO COMMENTS ON  
REVISED FINAL BASEWIDE RADIOLOGICAL REMOVAL ACTION  
ACTION MEMORANDUM  
DATED FEBRUARY 14, 2006  
HUNTERS POINT SHIPYARD  
SAN FRANCISCO, CALIFORNA**

Comments dated: Sent via e-mail on March 24, 2006

Comments by: Thomas P. Lanphar, Senior Hazardous Substance Scientist  
Office of Military Facilities  
Department of Toxic Substances Control (DTSC)

**SPECIFIC COMMENTS**

**Comment 1:** *Section I. Purpose, page 1 and Section III, Threats to Public Health, Welfare, or the Environment and Statutory and Regulatory Authorities, page 9: While DTSC agrees that interim actions are often appropriate for the removal of radiological contamination at Hunters Point, DTSC continues to disagree with the Navy on the application of Time Critical Removal Actions. Please explain how the planned removal actions meet the requirements of Code of Federal Regulations Section 300.415(b)(4).*

**Response 1:** Title 40 Code of Federal Regulations (CFR) 300.415(b)(4) states the following:

“Whenever a planning period of at least six months exists before on-site activities must be initiated, and the lead agency determines, based on a site evaluation, that a removal action is appropriate:

- (i) The lead agency shall conduct an engineering evaluation/cost analysis (EE/CA) or its equivalent. The EE/CA is an analysis of removal alternatives for a site.
- (ii) If environmental samples are to be collected, the lead agency shall develop sampling and analysis plans that shall provide a process for obtaining data of sufficient quality and quantity to satisfy data needs. Sampling and analysis plans shall be reviewed and approved by EPA. The sampling and analysis plans shall consist of two parts:
  - (A) The field sampling plan, which describes the number, type, and location of samples and the type of analyses; and

- (B) The quality assurance project plan, which describes policy, organization, and functional activities and the data quality objectives and measures necessary to achieve adequate data for use in planning and documenting the removal action.”

First, the Department of the Navy (DON) has determined that the only acceptable alternative to address potential radioactive contamination in sewer and storm drain lines is excavation, survey, and appropriate disposal. In situ survey is not possible due to the limitations of field screening devices. The DON must also address the California Department of Health Services requirements for free release, based on the intended property reuse. These requirements include scanning all overburden soil above the drain lines in addition to the lines themselves. Since the DON concluded that only one alternative is applicable to the drain lines, an equivalent cost estimate was provided in the Action Memorandum. In this sense, an EE/CA would be a redundant document.

Second, the DON has provided a Sampling and Analysis Plan to the Base Realignment and Closure (BRAC) Cleanup Team (BCT) for review. This meets the Title 40 CFR 300.415(b)(4)(ii) requirement.

**Comment 2:**

***Section II, C, 2. Potential for Continued State or Local Response, page 9:*** *DTSC does not defer to US EPA for the development of cleanup goals for radiological removal actions. The remediation of radiological contaminated sites at Hunters Point must meet the requirement of CERCLA and Chapter 6.8 of California Health and Safety Code. This includes the evaluation of risks from sites in a report such as a Remedial Investigation Report, the evaluation of remedial alternatives in a Feasibility Study and a final selection of a remedial action, or no further action in a Record of Decision. The DTSC must concur with the Record of Decision, which will include the selection of a final remedy for radiological sites. Please elaborate on DTSC extended role in remedial decisions involving radiological sites being remediated under CERCLA at Hunters Point.*

**Response 2:**

The DON concurs with DTSC’s role in approving remedial decisions involving radiological sites being remediated under CERCLA at Hunters Point Shipyard. The DON fully acknowledges the role of DTSC as a full-fledged BCT partner, as outlined in the Federal Facilities Agreement.

**Comment 3:**

**Section V.A.3, Contribution to Remedial Performance, page 12:**  
*This section states that the Navy intention is that the removal actions are the final radiological remedy for each site. Please add that the each radiological site cleanup will be later evaluated to determine if the level of cleanup achieved is appropriate for a final remedy or if additional remediation is necessary.*

**Response 3:**

The Final Action Memorandum – Revision 2006 will be edited to clarify that the removal action is an interim action and that the final action for radiological site cleanup will be selected in the Record of Decision.

**RESPONSE TO COMMENTS ON  
REVISED FINAL BASEWIDE RADIOLOGICAL REMOVAL ACTION  
ACTION MEMORANDUM  
DATED FEBRUARY 14, 2006  
HUNTERS POINT SHIPYARD  
SAN FRANCISCO, CALIFORNA**

Comments dated: March 17, 2006

Comments by: James Ricks, Project Manager, Superfund Division (SFD 8-1)  
U.S. Environmental Protection Agency (EPA), Region IX

**SPECIFIC COMMENTS**

**Comment 1:** *Section II.A.2, Physical Location, Page 2: Since the conveyance of Parcel A to the City of San Francisco, Hunters Point Shipyard (HPS) is no longer 936 acres. Please update the text to reflect the current size of HPS.*

**Response 1:** The sentence has been revised to read “HPS consists of 848 acres, 416 acres of which are on land, .....”

**Comment 2:** *Section II.A.4, Release or Threatened Release into the Environment of a Hazardous Substance or Pollutant or Contaminant, Page 3: It is unclear why daughter products are no longer listed; the 2001 Action Memorandum included “cesium-137 (and daughter products)” and “uranium-235 (and daughter products).” In addition, it appears that text is missing from the first paragraph since there are two “and” statements. Please include daughter products or explain why they have been dropped from the 2006 Action Memorandum. Also, please revise the first paragraph for clarity.*

**Response 2:** The text has been revised to include the daughter products for uranium and cesium. Also, the first paragraph has been revised for clarity. In addition, the text and Table 1 have both been updated to reflect the appropriate isotopes listed in both places.

**Comment 3:** *Section II.A.5, National Priorities List Status, Page 3: The text does not reflect the most current CERCLA status of Parcel B, specifically that the Feasibility Study is being redone so that the Record of Decision can be amended. Please update the status of Parcel B.*

- Response 3:** The text has been changed to “RI/FSs have been completed for Parcels A and B, and an Addendum to the Technical Memorandum in Support of Record of Decision Amendment (TMSRA) is being prepared for Parcel B. RI/FSs are currently being conducted for Parcels C, D, E, and E-2.”
- Comment 4:** ***Section V.A, Proposed Action, Page 10:** The last paragraph states, “Table 3 does not include those sites that were in the former Parcel A,” but it is unclear if this statement refers to the former Building 322, which was demolished, or if it refers to radiologically impacted sites for which parcel boundaries were readjusted to move them out of Parcel A. It is also possible that the community and others could read this paragraph and conclude that there are still radiologically impacted sites in Parcel A. Please revise this paragraph to clarify whether there are still radiologically impacted sites in Parcel A and to discuss the fact that the Parcel A boundary was adjusted to move radiologically impacted sites into other parcels.*
- Response 4:** The last paragraph, second sentence has been changed to: “Table 3 does not include those sites in the former Parcel A that have received regulatory release or the Formerly Used Defense Site (FUDS). The remaining impacted sites (Buildings 813 and 819) in the former Parcel A have been reassigned to Parcel D after the Parcel A boundary was adjusted.”
- Comment 5:** ***Section V.B., Estimated Costs, Page 15:** The costs are the same as those in the 2001 plan, but there has been inflation and the cost of construction materials has increased. Please update the cost estimate to reflect 2006 costs.*
- Response 5:** The costs that have been presented on Page 15 reflect changes due to inflation (a volume/cost increase) and a reduction in the volume of material remediated from 20 cubic yards to 13 cubic yards (a cost decrease). The combined effects of these changes result in the overall cost to remain about the same.
- Comment 6:** ***Table 1, Release Criteria:** During the recent Base Realignment and Closure (BRAC) Cleanup Team (BCT) meeting, the Navy agreed to update the release criteria for Cesium-137 to reflect the current preliminary remediation goal (PRG) of 0.113 picoCuries per gram (pCi/g). Please update this table with the PRG for Cesium-137.*
- Response 6:** Release Criteria for Cesium-137 for Soil for Outdoor Worker and Residential have been changed to 0.113 picoCuries per gram.

**Comment 7:**

***Figure 2, Base-Wide Impacted Buildings, Sites, Sanitary and Storm Drain Sewer Systems:*** It is unclear why the figure does not include IR-02 Northwest and Central (the Radium Dial Disposal Area) and the Metal Slag Area in the IR-01 panhandle, since radiological removal actions are still being done at these sites. Please include IR-02 Northwest and Central and the Metal Slag Area on Figure 2.

**Response 7:**

The intent of this figure is to show the impacted buildings and sites at Hunters Point Shipyard. The specific areas within the impacted sites that are currently undergoing radiological removal action, such as IR-02 Northwest and Central, Metal Slag area, PCB Hot Spot, and Metal Debris Reef, are covered by referencing Parcels E and E-2 impacted buildings and sites.

**RESPONSE TO COMMENTS ON  
REVISED FINAL BASEWIDE RADIOLOGICAL REMOVAL ACTION  
ACTION MEMORANDUM  
DATED FEBRUARY 14, 2006  
HUNTERS POINT SHIPYARD  
SAN FRANCISCO, CALIFORNIA**

Comments dated: March 24, 2006

Comments by: Department of Health Services, State of California (DHS)  
Environmental Management Branch

**GENERAL COMMENTS**

**Comment 1:** *Similar comments have been submitted previously in other reviews of the Navy's documents.*

**Response 1:** The Navy is aware of the State of California Department of Health Services previous comments on similar documents. The Navy intends to continue responding to DHS comments in an accurate and timely manner to sustain a shared vision for completing the radiological work with appropriate regulatory guidance.

**SPECIFIC COMMENTS**

**Comment 1:** *Section II.B.1.4, Phase V, Page 5: Using criteria for a "free release, for industrial use," will not guarantee a release for unrestricted use from the State of California. (See Specific Comment 2).*

**Response 1:** The Navy understands that using criteria for industrial re-use will not guarantee a free release. Appropriate release criteria for industrial and residential re-use has been established in Table 1. The Navy intends to use the release criteria as clean-up goals for the radiologically impacted sites at Hunters Point that are consistent with the planned reuse presented in the San Francisco Redevelopment Agency's (SFRA) Reuse Plan.

**Comment 2:** *Section II.B.1.5.3, NWT Interim Investigation and Removal Action, Page 6: If the Navy is requesting an unrestricted release from the State of California, the "site release criteria" will need to show that removal actions cleaned the site to as low as reasonably achievable (ALARA). Any averaged residual contamination concentrations when modeled should not exceed a dose of 25 millirem per year (mrem/year). The "Table 1, Release Criteria" will need to reflect these values.*

**Response 2:**

The Navy understands that using criteria for industrial re-use will not guarantee a free release. Appropriate release criteria for industrial and residential re-use has been established in Table 1. The Navy intends to use the release criteria as clean-up goals for the radiologically impacted sites at Hunters Point, which is ALARA.

In addition, the Navy intends to model the resulting residual radioactivity at the site to demonstrate the resulting dose is below 25 millirem per year. Table 1 will be revised to incorporate the resulting dose received at the release criteria identified. These release criteria are also consistent with the SFRA Reuse Plan.

**Comment 3:**

**Section II.C.0, STATE AND LOCAL AUTHORITIES ROLE, Page 8:** *As stated numerous times, the CDHS does not defer to the U.S. EPA with regard to unrestricted release requirements. Our dose assessment will be based on ALARA and residual contamination. The averaged residual contamination data used for your dose model should reflect representative sampling of the site.*

**Response 3:**

The Navy understands that the State of California Department of Health Services does not defer to the U.S. EPA for unrestricted release requirements. As stated in the previous response, the Navy intends to model the resulting residual contamination data, which will reflect representative sampling at the site, to demonstrate the resulting dose is below 25 millirem per year.

Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California

| 1997<br>Redevelopment<br>Block | 2010<br>Redevelopment<br>Block | IR Site(s)                          | Triple A<br>Site(s) | Nature and Extent Summary (with RI Report Reference Citation)                                                                                                                                                                   |
|--------------------------------|--------------------------------|-------------------------------------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EOS-4                          | N/A                            | IR-52 (partial),<br>IR-56 (partial) | None                | The screening process identified no areas that exceeded Parcel E screening criteria for soil. (Section 4.3.12)                                                                                                                  |
| EOS-5                          | Railroad<br>Right-of-Way       | IR-52 (partial)                     | None                | The screening process identified no contiguous areas that exceeded Parcel E screening criteria for soil. However, at one isolated boring location (IR52B009) six SVOCs exceeded industrial screening criteria. (Section 4.3.13) |

Notes: Information from Final Revised Remedial Investigation Report for Parcel E (Barajas & Associates, 2008b)

IR = Installation Restoration

PCBs = polychlorinated biphenyls

SVOCs = semivolatile organic compounds

TPH = total petroleum hydrocarbons

VOCs = volatile organic compounds

## Notes:

- 1 Residential and industrial screening criteria for soil are risk-based concentrations calculated based on the human health exposure pathways, exposure assumptions, and toxicity values identified in the HHRA (see [Appendix I](#)).
- 2 HPALs were derived by calculating the 95 percent UCL on the 95th percentile of a data set that included metals results for soil samples collected at Parcels B, C, D, and E in uncontaminated areas. HPALs are site-specific ambient concentrations for metals, representing a concentration that about 5 percent of all ambient results would exceed (PRC 1995).
- 3 Applies to data from A-aquifer (exposure to groundwater from inhalation of VOCs migrating through the subsurface to indoor air [vapor intrusion]) (see [Appendix I](#)).
- 4 Applies to data from B-aquifer (exposure to groundwater through domestic use, including ingestion and dermal contact).
- 5 Applies to data from B-aquifer: MCLs are drinking water standards published by EPA (2003) and by the California State Department of Health Services in Title 22 of the *California Code of Regulations* Sections 64431-64444.
- 6 The surface water screening criteria selection rationale is presented in [Table 4-2](#).
- 7 HGALs were derived by calculating the 95 percent UCL on the 95th percentile value for each metal data set based on analytical results for groundwater samples collected at Parcels B, C, D, and E. HGALs are site-specific ambient concentrations for metals, representing a concentration that about 5 percent of all ambient results would exceed (PRC 1996).
- 8 PQLs (0.33 mg/kg) for several PAHs in soil and groundwater are greater than residential soil screening criteria and appropriate groundwater criteria. The screening criterion for these PAHs is the greater of the appropriate screening criterion or the PQL. PQL are considered the lowest concentrations that can be accurately measured and are used as screening criteria when greater than the risk-based criteria. Qualified data below the PQL are reported and mapped as detected concentrations.
- 9 TTPH soil criterion include: [Soil Source Criteria](#), applicable to all reuse zones at Parcel E, TTPH concentration of 3,500 mg/kg in soil at depths ranging from 0 to 10 feet bgs; and the presence of measurable free product (greater than 0.01 feet) in groundwater or soil (either as LNAPLs or DNAPLs). (Shaw Environmental, Inc. 2007).
- 10 TTPH groundwater criteria in µg/L are based on distance from the shoreline in feet and range from 1,400 µg/L (from 0 to 50 feet) to 20,000 µg/L (for greater than 250 feet) (Shaw Environmental, Inc. 2007).
- 11 TTPH is the sum of the concentrations of TPH as gasoline, TPH as diesel, and TPH as motor oil; or is the sum of TPH as unknown purgeables and TPH as unknown extractables, whichever is greater.
- a The primary objective of the screening criteria developed for shoreline sediments was to delineate the release of copper, lead, and PCBs resulting from site activities that could be a source of contamination to sediments in adjacent Parcel F (offshore). Only selected sediment screening criteria are listed in the table. See [Appendix G](#) for details regarding the sediment screening process.
- b Ambient concentration based on an 85th percentile of 100 percent fines.
- c Values based on Long and Morgan (1991).
- d Values based on Long and others (1995).
- e Screening value from EPA (1996).

## 6.0 CONCLUSIONS AND RECOMMENDATIONS

The purpose of the shoreline investigation was to evaluate if contamination along the Parcels E and E-2 shoreline has migrated (or has the potential to migrate) to sediments in adjacent Parcel F (offshore) and to identify areas within the shoreline that pose an unacceptable ecological risk.

Concentrations of copper and lead in sediments along the Parcels E and E-2 shoreline are a potential source of contamination to Parcel F in all areas except the Panhandle Area and IR-02 Southeast. Aroclors should be evaluated as a potential source of contamination in the Landfill Area and IR-02-Northwest, where the average concentrations of Aroclors exceeded the ambient concentration for nearshore sediment in San Francisco Bay ([Water Board 2003](#)).

Evaluation of PCB data showed that a definitive connection between onshore sources and offshore sediments could not be established, even though the congener patterns in onshore and offshore sediments were consistent. The geochemical assessment to evaluate the inter-element correlations between metals located in sediments of the shoreline and offshore area was not particularly diagnostic for linking contaminant sources and sinks, although contaminant distribution patterns in Parcel F are highly suggestive of contaminants originating from the shoreline along Area X of the South Basin. Additionally, although erosion and overland transport of contaminants from Parcels E and E-2 may be minor compared with the sediment load from San Francisco Bay, some influx of metals from the Parcels E and E-2 shoreline to Parcel F is likely.

Groundwater discharge was evaluated as a potential pathway for migration of metals and PCBs from Parcels E and E-2 to Parcel F. However, groundwater in contact with contaminated soils at depth in Parcels E and E-2 is unlikely to contribute to metals contamination in offshore sediments because of the limited solubility of metals in site groundwater. Review of metals data for groundwater samples collected from nearshore wells confirmed the low concentrations (10 micrograms per liter) of dissolved metals in site groundwater. Likewise, transport of PCBs by the groundwater pathway is severely limited by their chemical and physical properties.

Benthic invertebrates, birds, and mammals are at risk from exposure to PCBs in surface and subsurface sediment along the Parcels E and E-2 shoreline. Benthic invertebrates in surface and subsurface sediment may be adversely affected by exposure to copper, lead, zinc, and DDTs. In subsurface sediment, mercury may pose an additional risk to benthic invertebrates. Ingestion of sediment and prey that contain cadmium, copper, molybdenum, zinc, and PCBs may pose a risk to the house mouse.

Based on the results of the technical memorandum, the following recommendations are made for the Parcels E and E-2 shoreline:

- Source control measures are warranted along the Parcels E and E-2 shoreline, particularly in the metal slag area of the Panhandle Area, the Landfill Area, and IR-02 Northwest.
- Ecological risk to invertebrates, birds, and mammals in the shoreline warrants the evaluation of remedial alternatives for the intertidal sediments along the entire Parcels E and E-2 shoreline.

chemical sampling results are evaluated in conjunction with the development of the soil alternatives (Section 4). Sample locations with chemical concentrations exceeding the risk-based criteria, consistent with the amended redevelopment plan, are identified on Figure 4-2. These data are used to identify areas requiring further remedial action, which are discussed in Sections 4.2.3.1 and 4.2.4.1.

Additional post-excavation soil samples were collected and analyzed for cesium-137, radium-226, and strontium-90 (the radionuclides of concern identified in the HRA [NAVSEA, 2004]). Analytical results for all post-excavation soil samples met the specified RROs.

### 2.3.3. Groundwater Plume Delineation Update

The Revised RI Report used data collected through December 2004 to delineate A-aquifer groundwater plumes for metals, VOCs, PCBs, and TPH (see Figures 4-3 through 4-6 and Figure 6-2 in the Revised RI Report [Barajas & Associates, Inc., 2008b]). Since that time, groundwater data have been collected on a quarterly basis as part of the BGMP. The BGMP includes wells located within and in the vicinity of some of the RI plumes. Where available, these data were evaluated to determine if the plume delineations established in the Revised RI Report have significantly changed since 2004. In addition, as discussed in Section 2.1.3.4.2, additional groundwater data were collected as part of a GWTS conducted at several of the VOC plumes at Parcel E. The data used for this evaluation are summarized in Tables 2-9 through 2-12. Where appropriate, the plume delineations presented in the Revised RI Report were adjusted using updated data from the BGMP (from March 2005 to October 2009) and Phase I of the GWTS (April and November 2009). The following sections summarize the results of this evaluation for each of the aforementioned analytical groups. A complete list of all groundwater plumes and their associated redevelopment block, identifying wells, and plume constituents is shown in Table 2-13. The Revised RI Report did not identify any B-aquifer plumes at Parcel E, and data collected during the ongoing BGMP have confirmed that B-aquifer plumes are not present at Parcel E.

#### 2.3.3.1. Metals

During the RI, plumes were delineated for the following metals detected in A-aquifer groundwater above screening criteria: copper, lead, nickel, and zinc. In total, two plumes and three composite plumes (i.e., plumes comprising more than one chemical) were presented in the Revised RI Report. The evaluation of the updated BGMP data (from March 2005 to October 2009) at the metals plumes in Parcel E is summarized below and shown on Figure 2-5.

- **IR-02 Northwest Metals Plume** – Samples were collected recently from wells IR02MW373A and IR02MW126A during the BGMP. In January 2006, copper concentrations in well IR02MW126A increased to nearly 36 times the Hunters Point groundwater ambient level (HGAL) and then gradually decreased to below the HGAL by late 2007. Copper was not detected at concentrations exceeding laboratory reporting limits during the most recent three sampling events (May 2009 through October 2009). However, it is assumed that the composite plume (copper, lead, nickel, and zinc) has not changed since the RI plume delineation.
- **IR-05 Metals Plume** – No wells within or near this plume were sampled recently during the BGMP. Because no additional groundwater data exist, the composite (copper and zinc) RI plume delineation was not changed.
- **IR-12 Nickel Plume** – No wells within or near this plume were sampled recently during the BGMP. Because no additional groundwater data exist, the RI plume delineation was not changed.
- **IR-02 Central Nickel Plume** – Samples were collected recently from well IR02MWB-2 during the BGMP. In September 2008, nickel concentrations in well IR02MWB-2 increased to nearly twice the HGAL, and increased to nearly three times the HGAL in March 2009. However, because these concentrations are within the range of concentrations used in the RI plume delineation, the RI plume delineation was not changed.
- **IR-02 Southeast Metals Plume** – Samples were collected recently from wells IR02MW300A, IR02MW175A, and IR02MW179A during the BGMP. Copper and zinc concentrations detected in IR02MW300A remained consistent between 2004 and 2005, and were greater than the corresponding RI screening criteria. This well was decommissioned in 2005 prior to the Metal Debris Reef removal action and was replaced in 2007 with well IR02MW301A. Copper and zinc concentrations in well IR02MW301A from May 2007 to March 2009 were less than the corresponding RI screening criteria. Concentrations in IR01MW175A and IR02MW179A showed no expansion or migration of the composite plume delineation in the northeast and northwest directions, respectively. Therefore, it is assumed that the Metal Debris Reef removal action was successful in removing the contaminant source and the composite RI plume has been attenuated below the RI screening criteria. Lead was detected at wells IR02MW175A, IR02MW179A, and IR02MW301A in July 2008 at concentrations ranging from 14.7 to 18.4 micrograms per liter (µg/L). These lead concentrations are not attributed to site contamination because (1) they do not significantly exceed the HGAL (14.4 µg/L) and are generally consistent with variations in naturally occurring concentrations identified at other HPS sites; (2) the low lead concentrations were reported at wells located hydraulically upgradient and downgradient of the primary contaminant source (i.e., the Metal Debris Reef), which was previously removed; and (3) the lead concentrations in July 2008 represent a temporal anomaly because lead has not exceeded the HGAL at any of these wells (as well as former well IR02MW300A) during numerous sampling events performed since 1992 (see [Appendix A](#)).

As summarized above, it is assumed that for the purposes of the FS evaluation, none of the composite RI plume delineations for metals have changed, except for the IR-02 Southeast Metals Plume, since the RI was performed. The metals plume delineations considered in the FS evaluation are shown on [Figure 2-5](#).

### 2.3.3.2. VOCs

During the RI, plumes were delineated for the following VOCs detected in A-aquifer groundwater at concentrations above screening criteria: benzene, chloroform, 1,1-DCE, PCE, and TCE. In total, seven plumes and one composite plume (i.e., plumes comprising more than one chemical) were presented in the Revised RI Report. The effects of the BGMP and GWTS data evaluation on the VOC plume delineations in the Revised RI Report is summarized below and shown on [Figure 2-6](#).

- **IR-02 Northwest Benzene Plume** – Samples were collected recently from well IR02MW126A during the BGMP. Benzene concentrations in IR02MW126A were consistent between 2004 and 2008. Therefore, it is assumed that the RI plume delineation has not changed.
- **IR-03 Benzene Plume** – Samples were collected from well IR03MW342A during the BGMP through the second quarter of 2008. Benzene concentrations in IR03MW342A were consistent between 2004 and the second quarter of 2008. Otherwise, no recent data since 2004 are available in and around this plume. Therefore, it is assumed that the RI plume delineation has not changed.
- **IR-12 Benzene Plume** – Samples were collected in 2009 from wells IR12MW13A, IR12MW18A, and IR12MW19A and in 2005 from well IR12MW17A during the BGMP. In addition, samples were collected from 11 direct-push sampling locations to evaluate baseline conditions during the GWTS. Concentrations in the center of the plume (IR12MW17A) decreased to less than reporting limits in 2005; however, the reporting limits for benzene exceeded the PRG for this location. Based on 2009 data from the GWTS, the plume appears to have migrated to the north and south. Because of the lack of recent data in the center of the plume, the RI plume delineation was expanded in the north and south directions to reflect the baseline data collected during the GWTS.
- **IR-39 Benzene Plume** – Samples were collected recently from well IR39MW21A, in the northeastern portion of the plume, and from well IR39MW36A, located northeast of the plume, during the BGMP. Data from well IR39MW21A are within the range of historical concentrations used to delineate the plume, and data from IR39MW36A reveal that the plume has not expanded in the northeast direction. Otherwise, no recent data since 2004 are available in and around this plume. Therefore, it is assumed the RI plume delineation has not changed.
- **Building 406 TCE Plume** – Samples were collected recently from wells IR36MW125A, IR36MW126A, IR36MW127A, IR36MW128A, PA36MW04A, IR36MW122A, and IR36MW121A during the BGMP. In addition, samples were collected from 23 direct-push sampling locations and 13 newly-installed monitoring wells to evaluate baseline conditions during the GWTS (prior to injection of ZVI). TCE concentrations at all wells sampled after 2004 generally remained consistent except at IR36MW125A, where TCE concentrations rose from 110 µg/L in late 2004 to between 500 µg/L and 7,600 µg/L in 2005 and 2006, and declined to 1,300 µg/L in April 2009. The RI plume delineation was adjusted to reflect the southwestern expansion of the plume, as refined with data collected prior to the ZVI injection. The pre-injection data serve as a conservative basis for the plume delineation used in this FS Report. The post-injection groundwater data show that ZVI has reduced TCE concentrations, and additional post-injection data are being collected during the BGMP.

- **IR-04 TCE Plume** – Samples were collected recently from well IR04MW37A during the BGMP. TCE concentrations in IR04MW37A were consistent between 2004 and 2009. In addition, samples were collected from seven direct-push sampling locations to evaluate baseline conditions during the GWTS. The RI plume delineation was adjusted to the south, as refined with data collected during the GWTS.
- **IR-56 TCE Plume** – Samples were collected recently from well IR74MW01A, located south of IR-74 boundary within IR-56, during the BGMP. In addition, samples were collected from five direct-push sampling locations to evaluate baseline conditions during the GWTS. Data from well IR74MW01A and the GWTS indicate that the RI plume delineation has not changed.
- **IR-12 PCE Plume** – Samples were collected recently from wells IR04MW13A (located within Parcel E-2), IR12MW14A, and IR12MW19A during the BGMP. In addition, samples were collected from 19 direct-push sampling locations and four newly-installed monitoring wells to evaluate baseline conditions during the GWTS (prior to injection of ZVI). The RI plume delineation was adjusted to the north and west to reflect the additional data collected prior to the ZVI injection, including the upgradient extent within Parcel E-2. The pre-injection data serve as a conservative basis for the plume delineation used in this FS Report. The post-injection groundwater data show that the ZVI has reduced PCE concentrations, and additional post-injection data are being collected during the BGMP.

Of the eight VOC plume delineations presented in the Revised RI Report, three (IR-12 Benzene Plume, IR-12 PCE Plume, and Building 406 TCE Plume) were adjusted for purposes of the FS evaluation based on data collected since 2004. The adjusted plume delineations are shown on [Figure 2-6](#).

Risks from exposure to groundwater in the A-aquifer from vapor intrusion (for residential and industrial receptors) and from trenching (for the construction worker receptor) were evaluated in the Revised RI Report for eight VOC risk plume-based areas. As discussed in Section 5.1.1.2 of the Revised RI Report, the risk plumes were delineated using a different methodology than that used to delineate the plumes as presented on [Figure 2-5 \(Barajas & Associates, Inc., 2008b\)](#). The risk assessment results for the vapor intrusion pathway indicated that risk from exposure to VOCs in the A-aquifer exceeded the excess lifetime cancer risk threshold of 1E-06 and noncancer HI threshold of 1.0 in several redevelopment blocks at Parcel E. The groundwater vapor intrusion risks are presented on Figure 5-8 of the Revised RI Report.

Since the time the HHRA was conducted for Parcel E, more recent guidance documents for the assessment of health risks from vapor intrusion have become available ([California Environmental Protection Agency, 2005](#); [Navy, 2008](#); [U.S. Department of Defense \[DoD\], 2009](#)). The new guidance documents specify a preference for the use of soil gas data over groundwater data in evaluating the vapor intrusion pathway because soil gas data represent a direct measurement of the contaminant that will migrate to indoor air and reduces the uncertainty related to partitioning of the contaminant to the vapor phase. The preference for soil gas data over groundwater data is also reflected in EPA's vapor intrusion guidance, which was used as a basis to conduct the inhalation risk assessment at Parcel E ([EPA, 2002](#)).

To comply with the new guidance and to identify exposure areas that indicate a risk associated with soil vapor intrusion, the Navy initiated a basewide soil gas investigation in 2010. The investigation includes collection and analysis of soil vapor samples from locations at Parcel E that have identified soil or groundwater subsurface impacts. Soil vapor samples will be collected over 100-by-100 foot grids over Parcel E, with one soil vapor sample collected from every grid that has potential subsurface impacts. Data collected during the investigation will be compared with soil gas action levels currently being developed by the Navy ([Chadux et al., 2010](#)). The action levels will be used to evaluate potential risk from vapor intrusion, as well as identify areas where institutional controls or additional action may be required. The soil gas investigation is being performed in two phases, with the work in Parcel E slated for implementation during the second phase in 2014.

It should be noted that the benzene plumes in IR-02 Northwest and IR-03 are located in open space redevelopment blocks. These plumes were conservatively delineated in the Revised RI Report based on screening criteria (based on the vapor intrusion pathway for future industrial users); however, the human health risk assessment (HHRA) in the Revised RI Report clarified that the vapor intrusion exposure scenario was incomplete for the planned open space reuse in these redevelopment blocks ([Barajas & Associates, Inc., 2008b](#)). Based on this conclusion, as well as the fact that VOC concentrations do not exceed aquatic evaluation criteria (see [Appendix A](#)), this FS Report does not further evaluate these VOC plumes beyond evaluating ARARs and institutional controls for groundwater within the open space redevelopment blocks in this FS Report.

It should also be noted that evaluation of the IR-39 Benzene Plume is deferred to the TPH corrective action program because the former USTs at Building 709 (former Navy exchange gas station) are the source of this contamination.

#### **2.3.3.3. PCBs**

During the RI, one plume in A-aquifer groundwater was delineated for the PCB Aroclor-1254 (IR-02 Northwest PCB Plume). No wells within or near this plume were sampled during the BGMP. It is assumed that the RI plume delineation has not changed. The Aroclor-1254 plume delineation considered in the FS evaluation is shown on [Figure 2-7](#). PCBs have also been detected in groundwater within the IR-03 TPH plume at concentrations warranting further evaluation in the FS. PCBs were detected in samples collected from well IR03MW218A2 between 2004 and the second quarter of 2008; samples were not collected from this well following the second quarter 2008. [Appendix A](#) identifies the PCBs and other non-petroleum chemicals detected in IR-03 groundwater at concentrations that may pose a risk to aquatic wildlife in the bay.

#### 2.3.3.4. TPH

During the RI, one plume in A-aquifer groundwater was delineated for TPH (IR-03 TPH Plume). Samples were collected from well IR03MW218A2, located in the center of the plume, during the BGMP. TPH concentrations in IR03MW218A2 increased by nearly 50 percent between 2004 and 2008. Otherwise, no post-2004 data are available in and around this plume. Considering the lack of recent data along the plume's perimeter, it is assumed that the RI plume delineation has not changed. The TPH plume delineation considered in the FS evaluation is shown on [Figure 2-7](#). It should be noted that the lack of BGMP data from IR-03 is associated with the fact that many of the wells located within the IR-03 plume contain free product and are not available for sampling.

### 2.4. CONCEPTUAL SITE MODEL

This section summarizes the CSM developed for Parcel E in the Revised RI Report ([Barajas & Associates, Inc., 2008b](#)). The purpose of the CSM is to illustrate and describe a basic understanding of potential sources of contamination and media pathways and to identify possible receptors based on available site information. The CSM is not intended to provide details or quantification of these potential sources and pathways. However, it is intended to provide the framework for characterizing site contamination and assessing risks. More detailed information about the CSM is presented in the Revised RI Report ([Barajas & Associates, Inc., 2008b](#)). Figure 3-18 in the Revised RI Report presents the CSM of the release mechanisms, affected media, and exposure pathways associated with Parcel E. The CSM developed for Parcel E includes the following:

- Generalized subsurface conditions
- Potential sources of contamination
- Potentially affected media
- Migration and exposure pathways
- Receptors (humans and wildlife)

#### 2.4.1. Generalized Subsurface Conditions

The subsurface geology and hydrogeology at Parcel E are discussed in [Sections 2.2.6 and 2.2.7](#), respectively. The aquifer system beneath Parcel E consists of A- and B-aquifers that are separated by the Bay Mud aquitard except for in the northernmost portion of Parcel E, where the aquitard is not present. The aquifer system at Parcel E is underlain by bedrock that slopes from former Parcel A toward San Francisco Bay. Bedrock depth ranges from less than 5 feet at the northwestern border of Parcel E (in gas monitoring probes installed along Crisp Avenue) to about 280 feet at the south-central portion of Parcel E, along the bay shoreline. Two exceptions are the Building 406 area and Building 521 area, where bedrock can be as shallow as 9 feet bgs and 15 feet bgs, respectively. The slopes of elevated

|    |                  |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

of 3 SVE wells and 15 vapor monitoring wells, operated for 3 months beginning in May 2001 (IT Corporation, 2002). Trichloroethene (TCE) was found to be the predominant volatile organic compound (VOC) in vadose zone soil. The cumulative VOC mass removed during the test performance period was estimated at 7 pounds, with over 90 percent of the VOC mass attributed to TCE (IT Corporation, 2002). This estimate was substantially higher than the initial amount of TCE assumed to be present in soil within the study area, indicating the potential presence of more extensive TCE contamination in the vadose zone. No soil samples were collected after operation of the SVE system; however, based on comparison of the estimated mass of TCE removed with original estimates of TCE in soil, additional investigation was recommended to further characterize the extent of VOCs in the vadose zone beyond the treatability study area (IT Corporation, 2002). Based on the results of the study, SVE appeared to be an effective remedial technology to remove VOCs from vadose zone soil.

#### 2.1.3.4.2. 2009 and 2010 Zero Valent Iron Groundwater Treatability Study

In 2009 and 2010, the Navy performed a groundwater treatability study (GWTS) to evaluate the effectiveness of zero-valent iron (ZVI) injection in treating groundwater contamination at Parcel E. The GWTS was implemented in two phases: (1) a plume characterization phase, during which groundwater and soil vapor samples were collected to better delineate the groundwater plumes identified in the Revised RI Report (Phase I), and (2) treatment of select plumes using ZVI (Phase II) (Shaw, 2011).

Phase I of the study was conducted between April and November 2009 and consisted of initial characterization of the following plumes identified in the Revised RI Report: IR-04, IR-12 tetrachloroethene (PCE) plume, IR-12 benzene plume, Building 406 TCE plume (at IR-36 South), and IR-56 TCE plume (Shaw, 2011). Phase I included collection and analysis of (1) baseline groundwater samples from existing monitoring wells, (2) groundwater samples from direct-push borings and new wells installed for the GWTS, (3) soil vapor samples from soil vapor points installed for the GWTS, and (4) soil samples collected from direct-push borings. Based upon the Phase I characterization, ZVI injections were not recommended for the IR-04 TCE plume, IR-56 TCE plume, and the IR-12 benzene plume because concentrations of COCs did not significantly exceed their respective project-specific goals. In addition, the IR-12 benzene plume was not a candidate for ZVI injection because the plume is composed mainly of fuel-related hydrocarbons that would not be effectively treated by ZVI. Also, soil vapor data identified elevated concentrations of VOCs at several locations under Building 406 (Shaw, 2011). ZVI injections were recommended for two plumes (IR-12 PCE plume and Building 406 TCE plume) based on the Phase I characterization results.

For the two plumes, areas where VOCs were detected at concentrations greater than 10 times their respective project-specific goals were targeted for ZVI injections. At the Building 406 TCE plume (between January and March 2010), a total of 104,461 pounds of microscale ZVI was injected through 91 injection points and 400 gallons of nanoscale ZVI (approximately 5,440 pounds of ZVI) was injected through 4 injection points. At the IR-12 PCE plume, approximately 20,205 pounds of microscale ZVI were injected through 17 injection points in December 2009. Groundwater and soil vapor samples were collected at 2 weeks, 6 weeks, and 12 weeks after ZVI injections were completed at both plumes. The post-injection monitoring data indicated that, at several injection areas, ZVI was capable of reducing VOC concentrations to meet the project-specific goals; however, the study concluded that additional monitoring was needed at the plume areas to better assess post-injection groundwater conditions (Shaw, 2011). The Navy continues to collect groundwater data at the IR-12 PCE plume and Building 406 TCE Plume under the Basewide Groundwater Monitoring Program (BGMP). In addition, the Navy has initiated a follow-on study to collect additional soil and soil vapor data in high-concentration VOC areas at the Building 406 TCE Plume; the study is planned for implementation in 2012.

#### 2.1.3.5. Radiological Program

Radioactive materials are present at HPS from past shipyard and NRDL operations and decontamination of ships that participated in atomic weapons testing (NAVSEA, 2004). These radioactive materials are defined as CERCLA hazardous substances and therefore must be addressed under the IR Program. To do so, the Navy established a basewide radiological program for HPS under the authority of the “Final Action Memorandum for Time-Critical Removal Action of Radiological Materials in Soils, Debris, or Structures at Hunters Point Shipyard, San Francisco, California” (Navy, 2006a). The goal of the action memorandum is to eliminate substantially identified pathways of exposure to radioactive contamination for surrounding populations and nearby ecosystems. This goal will be accomplished through site investigations and removal actions. “Mixed-waste” sites where chemicals and radioactive materials are both present will be addressed as part of the radiological actions to the extent practical, thereby simplifying the remedy evaluation and selection and accelerating the cleanup and transfer of HPS.

Remedial action may be required at mixed-waste sites, where it is not practical to eliminate pathways of exposure to radioactive contamination during removal actions. This FS Report evaluates potential remedies for mixed-waste sites to limit or eliminate potential exposures to COCs and COECs in soil, shoreline sediment, and groundwater. Potential remedies for mixed-waste sites will be refined as appropriate in a radiological addendum to this FS Report to ensure their protectiveness of humans and wildlife from exposure to radioactive contamination. In addition, potential remedies for areas affected by only radioactive materials will be evaluated in the radiological addendum to this FS Report. The radiological addendum and ROD for Parcel E will select remedies that address radiological and mixed waste issues.

|----|------------------------------------------------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------|

**Nonaqueous-phase liquids (NAPL).** The nature and extent evaluation identified extensive NAPL at IR-03, the former oil reclamation ponds located within Redevelopment Block EOS-3 (formerly Redevelopment Block EOS-2 in the Revised RI Report and Draft FS Report). Characterization work performed in 1996, prior to the IR-03 removal action involving construction of a sheet-pile wall and low-permeability cap (see [Section 2.1.3](#) and [Table 2-4](#)), reported free-phase petroleum as deep as 25 feet bgs ([IT Corporation, 1997a](#)). From January through April 1991, NAPL was measured on seven separate occasions in four wells (IR03MW218A1, IR03MWO-1, IR03MWO-2, and IR03MWO-3) at IR-03. Product thickness ranged from a minimum of 0.07 feet in well IR03MW218A1 to a maximum of 6.93 feet in well IR03MWO-2 ([Barajas & Associates, Inc., 2008b](#)). In 1991, approximately 25 gallons of floating product and 70 gallons of waste oil were recovered from the four wells ([Barajas & Associates, Inc., 2008b](#)).

In 2002, the extent of NAPL was further evaluated at IR-03 during the Phase III groundwater data gaps investigation ([Barajas & Associates, Inc., 2008b](#)). NAPL was found in nine IR-03 wells IR-03, at thicknesses ranging from less than 0.01 feet (in well IR03MWO-1) to 10.85 feet (in well IR03MW370A). The NAPL was described as highly viscous and consisted of a 2:1 ratio of diesel- to motor oil-range TPH ([Barajas & Associates, Inc., 2008b](#)). Under the current BGMP, NAPL measurements are taken annually (generally during the 3rd or 4th quarter) at a select group of wells where NAPL has been present historically. During the most recent monitoring and sampling event for which NAPL measurements were taken (September 2009), NAPL measurements in the IR-03 area ranged from 0.16 feet (in well IR03MW226A) to 4.62 feet (in well IR03WMO-3) ([CE2-Kleinfelder Joint Venture, 2010b](#)). A conceptual cross section depicting the location and occurrence of NAPL at IR-03 is presented as [Figure 2-8](#).

During 2004, the Navy conducted a focused investigation and cleanup action along the Parcel E shoreline, and no discharge of NAPL was observed. In addition, riprap along the IR-03 shoreline is covered in concrete, which prevents direct contact with NAPL and contaminated soil. The available information is adequate to document the general nature of NAPL at IR-03 (such as the range of thicknesses and viscosities) and provide a preliminary indication of the extent of NAPL. The Navy performed additional characterization of NAPL at IR-03 in September and October 2011 in accordance with a work plan that was approved by the regulatory agencies ([ITSI, 2011](#)). The Navy is preparing a report, concurrent with the final version of this FS Report, summarizing the results of the additional characterization and the bench-scale treatability study that was performed under the same project. The Navy expects that the additional characterization will refine the nature and extent of NAPL at IR-03; however, once the findings of the study are reviewed, the Navy will consult with the regulatory agencies to determine whether additional characterization is required prior to the remedial design (RD).

In addition to IR-03, light NAPL has been identified at four other wells in Parcel E (IR12MW21A, IR14MW13A, PA36MW08A, and IR39MW21A), each of which contain only TPH and thus are being addressed by the TPH corrective action program.

## EXECUTIVE SUMMARY

An In-Situ Thermal Remediation (ISTR) using Thermal Conduction Heating (TCH) pilot study is planned at Hunters Point Naval Shipyard Installation Restoration (IR) Site 03 (IR-03) to aggressively remove mobile Non Aqueous Phase Liquid (NAPL) that potentially may threaten San Francisco Bay. ISTR is used to alter subsurface conditions to mobilize and extract NAPL from the subsurface, therefore the technology performance objectives are based on achieving mass removal assessed as reductions in NAPL saturation. The objective of this pilot study is to examine the effectiveness of ISTR using TCH to extract and treat all mobile NAPL within the target treatment zone (TTZ). This goal will be measured as a reduction in average total NAPL saturation in soil to levels below residual saturation.

TCH is a technology that relies on heater wells to generate heat, which propagates into the surrounding formation by thermal conduction to soil, groundwater, and NAPL matrices. Heat transfer through the TTZ volume is driven by temperature gradients. Steam agitation (steam stripping) and a reduction of NAPL viscosity are the primary drivers of NAPL mobilization and removal, especially in the saturated zone, where NAPL will become buoyant and rise to the top of the water table to be extracted via multi-phase extraction (MPE). Additionally, extracted and treated water will be reinjected around the perimeter of the TTZ as a hydraulic control, to limit the flux of groundwater into the TTZ and prevent the lateral migration of heated NAPL outside of the TTZ.

The pilot study treatment area encompasses approximately 1,900 square feet (sq ft) of the former oily waste pond, with the west end of the treatment area bounded by an existing sheet pile wall, which was found to provide good hydraulic control during the pre-design characterization. Active heating will be performed from ground surface to approximately 25 feet below ground surface (ft bgs). Below is a summary of the Pilot study dimensions:

- Treatment area - 1,900 square feet (sq ft)
- Upper depth of treatment - 5 ft bgs
- Lower depth of treatment - 20 ft bgs
- Treatment volume – 1,056 cubic yards (cu yd)
- Upper depth of heating - 0 ft bgs
- Lower depth of heating - 25 ft bgs
- Heated volume - 1,760 cu yd.

The pilot study well field will be composed of:

- TCH heater wells (vertical): 46 TCH heater wells supply heat by thermal conduction from just below the ground surface to a depth of 25 ft bgs (5 feet below target treatment depth)
- MPE wells (vertical): 14 MPE wells will be located throughout the TTZ, and will act as the primary NAPL extraction points
- Co-Located Vacuum Extraction wells (vertical): 46 Vacuum extraction wells are co-located with all of the TCH heater wells. These vacuum extraction points provide

- pneumatic control during subsurface heating, and their operation may be adjusted at any time in the project to provide precise pneumatic control of the subsurface
- Horizontal Vacuum Extraction wells: Horizontal vacuum extraction wells will be laid atop the ground surface, in gravel, to provide pneumatic control of the upper most heated zone, just below the insulating surface cover. These vacuum extraction points are designed to provide pneumatic control during subsurface heating, but their operation may be adjusted at any time in the project to provide precise pneumatic control of the subsurface
- Reinjection wells: 7 reinjection wells will be located around the north, east, and south boundaries of the ISTR TTZ. Extracted water will be treated (details on treatment method provided in Section 4) and reinjected to provide hydraulic control
- Temperature and Pressure Monitoring Points: 10 points are used to document heating and pressure effectiveness. Thermocouples are placed at 5 ft intervals from 5 ft bgs to 25 ft bgs within the TTZ.
- Pressure Monitoring Points: An additional 4 points (installed 0 ft bgs to 1 ft bgs) are used to measure vadose zone pressures on the boundary of the TTZ.

The target thermal heating operating temperature is 212 degrees Fahrenheit (°F) (100°C). This temperature will result in contaminants being mobilized, dissolved, desorbed and/or volatilized. NAPL viscosity will decrease as subsurface temperature increases, and steam agitation (steam stripping) will assist in NAPL mobilization. The more mobile NAPL will slowly rise to the top of the water table, where it will be extracted via the MPE wells. The extracted liquid will be run through a LNAPL/DNAPL/water phase separator to separate any free-phase liquid from the water. The remaining water stream will be treated with a liquid granular activated carbon (LGAC) system, then re-heated (using a heat exchanger) before it is re-injected into the reinjection wells.

Some of the volatile organic chemicals (e.g. lighter chain hydrocarbons, chlorobenzene) may volatilize into vapor phase during heating. The resultant contaminant-laden vapors will be recovered via the network of vapor extraction and MPE wells, and subsequently treated with an off-gas treatment system. The vapor extraction wells are connected via a manifold piping network, and a vacuum is applied to the manifold system to ensure vapor capture and control. Extracted off-gas will then be directed through a vapor liquid separator / knock out tank, to begin the separation of off-gas into condensable and non-condensable fractions. The off-gas will continue through the vapor treatment system, passing through a large air-to-air heat exchanger to further reduce its temperature. The resultant off-gas will travel through a positive displacement blower system with an aftercooler, and then, finally, the contaminated vapors will pass through three vapor phase granular activated carbon (VGAC) vessels, capturing the contaminants. The presence of NAPL with a neutral density (1 gram per milliliter [g/mL]) collected from within the ISTR TTZ was comprised of a mixture of primarily diesel-range hydrocarbons (C9-C16) at 39.6%, motor oil-range hydrocarbons (C28-C40) at 11.9%, mixed aryl phosphates at 48.2% with lower amounts (<0.1%) of entrained polychlorinated biphenyls (PCBs), naphthalene and dichlorobenzene compounds was observed during the pre-design characterization testing. The relatively high fraction of mixed aryl phosphates may be one reason the NAPL was “heavy” as the density of these compounds is typically reported between 1.185-1.202 at 25°C. One potential issue with neutrally buoyant NAPL is that it can be more difficult to separate from the aqueous phase resulting in lower removal efficiencies during the NAPL separation portion of the above

ground treatment system. Therefore, more LGAC may be required to treat the system effluent.

The mix of naphthalene with more volatile petroleum hydrocarbon fractions in the off-gas stream may also lower the overall effectiveness of the VGAC due to competitive absorbency of these compounds. Because of these concerns, the final design included the following modifications (1) an additional (third) VGAC vessel, and (2) increased capacity of the VGAC vessels. Off-gas sampling from the vapor treatment system will ensure that the substantive requirements of a Bay Area Air Quality Management District (BAAQMD) compliance per applicable or relevant and appropriate requirement (ARAR) guidelines.

During the active heating period (estimated at 120 days), a minimum of 4,529 million British thermal units (MMBTUs) of propane and 249,000 kilowatt hours (kWh) of electricity will be delivered to the treatment system. Electricity will be generated onsite by temporary generators. The effluent treatment system is expected to treat up to  $3.68\text{E}+07$  cubic feet of extracted off-gas, and treat up to  $4.76\text{E}+05$  gallons of extracted liquid during the course of the project. Up to 31,000 pounds (lbs) of GAC, including both VGAC and LGAC, are projected to be used for contaminant removal in the effluent treatment system.

| <p>1. During the September 30, 2013 meeting, it was stated that the NAPL recovered from this site “sometimes separates into LNAPL and DNAPL fractions” (see slide 26). This suggests that during heating of the NAPL in the subsurface, DNAPL is likely to form. It is not likely that DNAPLs composed of some of the constituents found in this NAPL, which includes PCBs and chlorobenzenes, would become an LNAPL again at temperatures up to 100oC. This has important implications for the project since the pilot system is currently designed to collect LNAPL and cannot recover significant quantities of DNAPL.</p> <p>NAPL recovered from different portions of the ISTR pilot study treatment area could be measured for density as a function of temperature. If significant DNAPL formation is shown within the target treatment zone as a result, the pilot study system should be re-designed to recover DNAPL, as well as LNAPL. The Bay Mud below the fill material at this site will likely stop downward migration of DNAPL. However, under this scenario of significant DNAPL formation, the multiphase extraction (MPE) wells and heater wells must be extended in order to heat and recover the DNAPL. The MPE wells must have a sump that extends into the Bay Mud and a bottom loading pump to collect and recover the DNAPL.</p> | <p><i>The design and operation of the multiphase extraction (MPE) wells allows for recovery of nonaqueous phase liquid (NAPL), (including dense nonaqueous phase liquid (DNAPL), by controlling the pumping rates and the subsequent dewatering within the well. Over the course of operations, if DNAPL comes into the wells it would be recovered by increasing the pumping rates and lowering the stinger to the bottom of the MPE well as the well is dewatered. As provided in the data package submitted with the final design, the composition of the NAPL was determined to be primarily diesel, motor oil and aryl phosphates. Therefore, the aryl phosphates are believed to be the primary component of the DNAPL within the system. Concentrations of chlorobenzenes and PCBs were detected in the NAPL samples, but at concentrations well below percent levels and at levels unlikely to form separate DNAPLs.</i></p> <p><i>The system operation will be modified to include sampling of the DNAPL for density within different parts of the treatment area. The MPE wells will be extended down to approximately 23 feet and a 1 foot sump will be added at the bottom of the wells for collection of any DNAPL. However, the current plan is to heat the treatment volume down to 25 feet. It is believed that this is a sufficient depth to recover the NAPL within the treatment zone due to:</i></p> <ol style="list-style-type: none"> <li><i>1. Hydraulic profile tooling (HPT) data illustrate that the hydraulic conductivity transitions 1-3 orders of magnitude between 23 and 25 feet below ground surface (bgs) within the highly saturated NAPL zone (at HPT-02 and HPT-03). In fact, at HPT-02, the HPT could not inject any water below 25 feet bgs and at HPT-03 could not inject any water below 22 feet bgs. This suggests this depth is the transition to the Bay Mud. See attached figure illustrating the HPT results and the revised conceptual screened interval for the MPE wells. A more detailed revision of the MPE well construction diagrams will be provided in the Final ISTR Design and is attached as Figure 12. This permeability contrast is believed sufficient to prevent further downward vertical migration of any DNAPL.</i></li> </ol> |

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | <p>2. <i>The soil boring screening and sampling indicate that contaminant levels decline dramatically below 20 feet bgs as indicated by soil staining, PID screening and soil sampling. The borehole logs have been attached for reference and soil sample results were submitted with the Draft ISTR Design.</i></p> <p>3. <i>Completing a significant proportion of the MPE well screens and extracting from the low conductivity silty clay and clay is better avoided, if possible, to prevent significant silt and clay from entering the above ground treatment system, which fouls up the system and makes operations more difficult. Therefore, the MPE well screens will be completed to the transition zone to the low permeability silt and clay sediment but will not extend into the clay.</i></p> |
| <p>2. During the September 30, 2013 meeting, it was stated that understanding the site hydrogeology and the nature and extent of the contamination is critical to a successful treatability evaluation (Slide 4). Slide 6 lists the site characterization and data gap activities taken in 2013; however, much of the data collected was not presented during the September 30, 2012 meeting or in the ISTR Design. Data that was to have been collected, but was not presented, includes the results from three HPT/CPT borings in the ISTR area, groundwater hydraulic heads from which groundwater flow direction and rate can be determined, and site stratigraphy and heterogeneity information. This information is critical to the design and evaluation of the ISTR pilot study. All of the characterization data pertinent to the ISTR treatment area should be included in this document, and the conceptual site model (CSM) for the treatment zone should be updated to incorporate this data.</p> | <p><i>Attached is a data package that includes the cone penetrometer (CPT) and HPT data, a figure illustrating the boring locations (Figure A-1), and the borehole logs of the borings advanced within the ISTR treatment zone. The revised final design will be updated to include a discussion of these data, including hydraulic gradients.</i></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <p>3. Additional information on the evaluation of the ISTR pilot system and on adjustments to the operational timeframe is found in the Final Response to BCT Comments sent out June 5, 2013, but is not contained in either the ISTR Design or the Final NAPL Treatment Pilot Study Workplan (see comment #5 below). For example, Section 4.3.4 gives a schedule for operation of the ISTR pilot study that does not allow for longer operating times if NAPL is still being recovered, while page 28 of the Final Response to BCT Comments sent out June 5, 2013 allows for adjustments to the operational time frame. It is recommended that the ISTR Design contain all of the critical design information including operation</p>                                                                                                                                                                                                                                                                         | <p><i>The Final Design was intended to describe how the physical components of the ISTR system changed based on new information obtained during pre-design characterization. The intent of the document is not to discuss operational timeframes. The thermal treatment system operational approach discussed in the <b>Final NAPL Treatment Pilot Study Work Plan (June 2013)</b> and the response to comments will be adhered to and nothing in the Final Design submittal changes the planned operational timeframe nor decisions for shutting down operations described in that document.</i></p>                                                                                                                                                                                                           |

|    |                                     |               |                                                                                                                                                                                                                 |

| 16 | Several radiological investigations | Section 2.3.4 | Final Radiological Addendum to the Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California. ERRG and RSRS. August 2012. Sections 2.3.1.1 and 2.3.1.2, pages 2-29 through 2-43. |
|----|-------------------------------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Approximately 44,500 cubic yards of soil and debris was removed and disposed of off site as part of this removal action. Out of this total volume, 533 cubic yards of soil and fire brick was segregated as radiologically impacted. Also, 40 radiological devices, 78 cubic yards of metal debris, and 19 pieces of other radioactively contaminated debris were identified within the removal area (TtECI, 2007b). In addition to this radiologically impacted debris, 110 drums and 537 assorted waste containers were recovered from the central portion of the removal area and were characterized prior to off-site disposal. The drums, which were discovered in varying degrees of decay, contained grease, oil, soil, asphalt, and tar substances. Waste characterization data indicated that the drums contained various chemicals, including PCBs. Two of the drums contained mixed waste with radiological contamination. The small containers contained various laboratory chemicals, ranging from strong acids and bases to solvents, alcohols, and inorganic salts (TtECI, 2007b).

Post-excavation soil samples were collected and analyzed for  $^{137}\text{Cs}$ ,  $^{226}\text{Ra}$ , and  $^{90}\text{Sr}$  (the ROCs for IR-01/21 and IR-02). Analytical results for all post-excavation soil samples met the specified RROs. Post-excavation soil data are presented in the “Final Removal Action Completion Report, PCB Hot Spot Soil Excavation Site” (TtECI, 2007b). Radiological analytical results are provided in Appendix M of the RACR, with sampling locations depicted on Figures 4-10 through 4-11 of the RACR.

## 2.3. NATURE AND EXTENT OF RADIONUCLIDES IN SOIL AND GROUNDWATER

The soil and groundwater data derived from the various radiological investigations, as discussed in Section 2.2, were used to evaluate the nature and extent of ROCs in soil and groundwater at Parcel E. The nature and extent evaluation presented in this section documents that an adequate amount of data exist to support a screening-level human health risk assessment (HHRA) based on the planned reuse of Parcel E and to evaluate remedial alternatives for Parcel E. As identified in the HRA (NAVSEA, 2004), shoreline sediment (within the intertidal shoreline zone) and structures at Parcel E are also considered radiologically impacted; however, data are inadequate to support a detailed evaluation of the nature and extent of radionuclides in shoreline sediment and structures. In the absence of such data, this radiological addendum assumes that the radiologically impacted shoreline sediment and structures, as identified in the HRA, will require remedial option analysis (in Sections 3, 4, and 5).

### 2.3.1. Nature and Extent of Radionuclides in Soil (and associated structures)

#### 2.3.1.1. Potential Sources of Radioactive Contamination and Impacted Media

Table 1 identifies each of the radiologically impacted areas at Parcel E and the ROCs at each area. Section 2.1.2 discussed the radiological operations at each impacted area and identified the potential sources of radioactive contamination. Two general sources of potential radioactive contamination exist at Parcel E: NRDL activities at the former 500 series buildings, Building 707 Triangle Area, and other buildings formerly occupied by NRDL; and historic waste disposal activities that occurred mainly along the shoreline, primarily IR-02. Additional radiological activities at Parcel E include:

- Practical and applied research on radiation decontamination methods and on the effects of radiation on living organisms and natural and synthetic materials, primarily conducted within the former 500 series buildings and within the Building 707 Triangle Area
- Disposal of radioluminescent commodity items (such as dials, gauges, and deck markers) within IR-02 and IR-03
- Disposal of industrial debris and metal slag with radioactive anomalies at the Metal Debris Reef
- Potential discharge of small amounts of low-level radioactive liquids into drains at NRDL buildings (potentially leading to sanitary sewer, storm drain, and septic sewer lines)

The HRA evaluated the potential for residual radioactive contamination at each impacted site based on historical information, previous radiological survey results, and site reconnaissance (NAVSEA, 2004). Table 2, as excerpted from the HRA, identifies the potential for various media (for example, surface soil, subsurface soil, groundwater, etc.) to contain radioactive contamination. As shown in Table 2, surface and subsurface soil are the most likely media to contain radioactive contamination at Parcel E.

#### 2.3.1.2. Radionuclides Detected in Soil

The following paragraphs briefly discuss the detections of radionuclides in soil at Parcel E. The following discussion is focused on the results from the Phase V investigation, which evaluated whether residual radioactivity on the surface met the predetermined release criterion as summarized below.

- $^{226}\text{Ra}$ : 1 pCi/g greater than background, not to exceed 2 pCi/g<sup>3</sup>
- $^{90}\text{Sr}$ : 10.8 pCi/g
- $^{137}\text{Cs}$ : 0.13 pCi/g<sup>4</sup>
- $^{241}\text{Am}$ : 5.67 pCi/g
- $^{239}\text{Pu}$ : 14.0 pCi/g
- $^{235}\text{U}$ : 0.398 pCi/g
- $^{60}\text{Co}$ : 0.060 pCi/g

These release criteria were considered equivalent to EPA preliminary remediation goals (PRGs) for outdoor worker exposure to soil, based on agreements with EPA. For  $^{226}\text{Ra}$  and  $^{137}\text{Cs}$ , the outdoor worker release criteria are identical to the release criteria for future residents. The outdoor worker release criteria for  $^{90}\text{Sr}$ ,  $^{241}\text{Am}$ ,  $^{239}\text{Pu}$ ,  $^{235}\text{U}$ , and  $^{60}\text{Co}$  are greater than the residential release criteria; however, these differences were accounted for in this radiological addendum because (1) no radiologically impacted sites were eliminated from further evaluation (as part of the remedial option analysis in Sections 3, 4, and 5)

<sup>3</sup> The  $^{226}\text{Ra}$  release criterion was 5 pCi/g when the Phase V investigation was started but was subsequently reduced to 1 pCi/g above background; the uncertainty related to this change in criterion is discussed in Section 2.5.4.

<sup>4</sup> The  $^{137}\text{Cs}$  release criterion applied to this survey when conducted in 2002 is slightly higher than the one used today (0.113 pCi/g); however, this change does not directly impact the results of this survey.

based on the results from the Phase V data, and (2) the remedial option analysis considered both the outdoor worker and residential release criteria in developing remediation goals.

The discussion of radionuclide data presented in the following paragraphs is limited to the sites for which radiological data are available; to date, radiological data have not been collected at each radiologically impacted site discussed in [Section 2.1.2](#) and identified in [Table 2](#). In the absence of such data, this radiological addendum assumes that radiologically impacted subsurface soil, as identified in the HRA (NAVSEA, 2004), will require remedial option analysis (in [Sections 3, 4, and 5](#)).

### ***Redevelopment Block MU-1***

#### **Building 707 and 707 Triangle Area**

In 1969, NRDL conducted a radiological survey at Building 707; the building was decontaminated to background levels and released by NRDL for unrestricted reuse (TtEMI, LFR, and U&A, 1997). In January 1970, Building 707 was inspected and cleared by AEC for unrestricted reuse (TtEMI, LFR, and U&A, 1997).

In 1978, RASO conducted a survey consisting of alpha and beta-gamma scans and wipe sampling for alpha and beta-gamma activity. No areas of elevated radioactivity were identified in the building.

In 1997, the concrete pad adjacent to Building 707 was surveyed during the Phase III investigation (TtEMI, LFR, and U&A, 1997). The investigation consisted of a surface gamma walkover survey of the pad and surrounding area, collection and analysis of concrete and asphalt samples from 27 locations surrounding the pad, and collection and analysis of 52 wipe samples from the concrete pad. Thirteen (B707SS04 through B707SS16) of the 27 surface sampling locations were located on the asphalt. Soil samples were collected under two asphalt sampling locations (B707SS04 and B707SS14).

Two areas on the pad and two areas on the asphalt near the pad exhibited elevated gamma readings exceeding background. The two anomalous areas on the pad were located approximately 10 feet apart and had gamma count readings of 18,640 and 21,115 cpm, above the average background rate of 5,800 cpm for concrete. The two anomalous areas off the pad were located to the southeast of the pad on the asphalt near “J” Street. Gamma count readings (32,300 and 17,300 cpm) at these anomalies exceeded the background activity of 7,600 cpm for asphalt cover.

To further evaluate the anomalies, asphalt and concrete samples were collected from these areas. Three of the four anomalies were sampled; only one sample was collected from the pad because of the proximity of the two anomalies. The laboratory results indicated elevated activities of  $^{137}\text{Cs}$ ,  $^{226}\text{Ra}$ , thorium-228, and thorium-232 exceeding their respective screening criteria (TtEMI, LFR, and U&A, 1997). The activities of  $^{137}\text{Cs}$  ranged from 4,300 pCi/g to 7,000 pCi/g, exceeding the Navy’s  $^{137}\text{Cs}$

criterion for hot spots of 100 pCi/g.  $^{226}\text{Ra}$  activities ranged from 51 to 61 pCi/g, exceeding the Navy's criterion of 5 pCi/g at the surface.

No radioisotopes were reported in the soil samples at activities exceeding background, except for one sample analyzed for  $^{40}\text{K}$ , which was reported at an activity of 16 pCi/g, exceeding the background activity of 10 pCi/g. Gross alpha and gross beta measurements from the wipe samples did not exceed the acceptable contamination criteria for maximum activity, average activity, or removable acceptable surface activity. Based on the results of the Phase III investigation, additional investigation was recommended in the area of the concrete pad to address the anomalies.

In 1999, the Building 707 concrete pad was further investigated as part of the Phase IV investigation. The investigation included collection and analysis of 28 asphalt and concrete samples and 28 soil samples from areas near the anomalies identified in the Phase III investigation (TtEMI, 2000). At each of the anomalous locations, one sample was collected from the "hottest" area (as determined by 2-inch sodium iodide detector), three samples were detected in a 1-meter concentric ring from the central sampling location, and five samples were collected in a 4-meter ring from the central sampling location. At each sampling location, the concrete or asphalt was cored and sampled and underlying soil or soil aggregate was sampled. In addition, 10 asphalt and concrete samples and 10 soil samples were collected as background samples.

Results of the sampling indicated several radionuclides of concern ( $^{241}\text{Am}$ ,  $^{137}\text{Cs}$ ,  $^{60}\text{Co}$ , europium-152 [ $^{152}\text{Eu}$ ], europium-154 [ $^{154}\text{Eu}$ ], and  $^{235}\text{U}$ ) were present exceeding background by more than three standard deviations. To evaluate whether the Building 707 concrete pad area would require remediation, radionuclide activities were compared against site-specific derived concentration guideline levels (DCGLs) and decay-corrected PRGs. DCGLs were calculated for the ROCs exceeding background using RESRAD.  $^{137}\text{Cs}$  was the only radionuclide that exceeded the site-specific DCGL of 13.1 pCi/g; the highest reported activity of  $^{137}\text{Cs}$  was 84.2 pCi/g in sample location 707A1. The average activity of  $^{137}\text{Cs}$  exceeded the PRG of 0.13 pCi/g. The maximum reported activities of  $^{241}\text{Am}$ ,  $^{152}\text{Eu}$ ,  $^{154}\text{Eu}$ , and  $^{235}\text{U}$  exceeded their respective PRGs; however, the average activities did not exceed the PRGs. The human health risk, calculated using RESRAD, posed by radioactive isotopes at the Building 707 concrete pad site ranged from 9E-06 to 1E-05 and is within the acceptable risk range (TtEMI, 2000).

In 2002, a MARSSIM scoping survey was conducted at the location of the Building 707 concrete pad area during the Phase V investigation. The designed surveillance area for the concrete pad was organized into 12 survey units, with each unit designated as a Class I area with a surface area not more than 100 square meters ( $\text{m}^2$ ). Survey methods included static and scan measurements for gamma radiation, static and scan measurements for alpha and beta radiation, exposure rate measurements, and analysis of solid samples. Two solid samples were collected from each of the 12 survey units.  $^{137}\text{Cs}$  exceeded the release criterion in 4 of the 12 survey units, with a maximum reported activity of 0.277 pCi/g in survey unit G.  $^{226}\text{Ra}$

exceeded the release criterion in 7 of the 12 survey units, with a maximum reported activity of 3.892 pCi/g in survey unit D. Based on the results of the Phase V investigation, a characterization survey and subsequent remedial action were recommended for the site.

The MARSSIM scoping survey also included the location of the Triangle Area during the Phase V investigation. The designed surveillance area for the Triangle Area was organized into seven survey units, with each unit designated as a Class I area with a surface area not more than 2,000 m<sup>2</sup>. Survey methods included static and scan measurements for gamma radiation, static and scan measurements for alpha and beta radiation, exposure rate measurements, and analysis of solid samples. Sixteen solid samples were collected from each survey unit except for grid ATI, from which two samples were collected. <sup>137</sup>Cs and <sup>226</sup>Ra exceeded the release criteria in each of the seven survey units. The maximum reported activities were 113.960 pCi/g for <sup>137</sup>Cs and 6.640 pCi/g for <sup>226</sup>Ra, both located in survey unit ATI. <sup>235</sup>U was also reported in each of the survey units at activities ranging from 0.519 pCi/g (survey unit API) to 1.615 pCi/g (survey unit ATI). Based on the results of the Phase V investigation, characterization surveys and subsequent remedial action were recommended for the site.

A final status survey was conducted in Building 707 during the Phase V survey. The survey consisted of collecting 16 static readings from each of 17 survey units within the building, with each survey unit not more than 100 m<sup>2</sup>. The mean net alpha static measurements ranged from -9 to 4 dpm/100 cm<sup>2</sup> within the survey units, with maximum net alpha measurements ranging from -6 to 19 dpm/100 cm<sup>2</sup>. Mean net beta static measurements ranged from -352 to 314 dpm/100 cm<sup>2</sup> within the survey units, with maximum net beta measurements ranging from 68 to 779 dpm/100 cm<sup>2</sup>. In addition, 16 static readings were collected from each of 10 survey units in the kennels, with each survey unit not more than 100 m<sup>2</sup>. The mean net alpha static measurements ranged from -4 to 24 dpm/100 cm<sup>2</sup> within the survey units, with maximum net alpha measurements ranging from 14 to 109 dpm/100 cm<sup>2</sup>. Mean net beta static measurements ranged from 215 to 582 dpm/100 cm<sup>2</sup> within the survey units, with maximum net beta measurements ranging from 479 to 1,294 dpm/100 cm<sup>2</sup>.

### ***Redevelopment Block MU-2***

#### **Building 406**

In 2002, a MARSSIM scoping survey was conducted in Building 406 during the Phase V investigation. The survey consisted of collecting 16 alpha and beta static readings from each of 57 survey units within the building. The mean net alpha static measurements ranged from -9 to 16 dpm/100 cm<sup>2</sup> within the survey units, with maximum net alpha measurements ranging from 3 to 57 dpm/100 cm<sup>2</sup>. Mean net beta static measurements ranged from -839 to 1,625 dpm/100 cm<sup>2</sup> within the survey units, with maximum net beta measurements ranging from -442 to 2,656 dpm/100 cm<sup>2</sup>. Areas containing <sup>226</sup>Ra exceeding release criteria were identified, remediated, and the building was resurveyed.

### Building 414

In 2002, a MARSSIM scoping survey was conducted at the location of Building 414 during the Phase V investigation. The investigation consisted of collection and analysis of two surface soil samples near the building for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ .  $^{137}\text{Cs}$  did not exceed the release criterion, with a maximum activity of 0.043 pCi/g.  $^{226}\text{Ra}$  exceeded the release criterion in one of the two samples, with a maximum activity of 1.822 pCi/g.

### Building 506 Site

Building 506 was first surveyed in 1955 as part of the NRDL decommissioning survey (NAVSEA, 2004). The NRDL release letter indicates the building was released for unrestricted reuse, with the caveat that a radiation monitor must accompany working parties on the sewer systems for monitoring until the drain lines are replaced. No other information is available regarding the 1955 NRDL survey at Building 506.

In 1969, NRDL conducted a radiological survey at Building 506 (TtEMI, LFR, and U&A, 1997). Results of wipe samples collected in rooms 35 and 35A indicated the presence of  $^3\text{H}$  contamination, and several other areas and pieces of equipment were also contaminated with  $^3\text{H}$ . Detectable contamination was removed by washing the affected areas and dismantling contaminated equipment, and contaminated areas were steam cleaned following decontamination. All radioactive waste and dismantled equipment was packaged and disposed of off site. Following completion of decontamination, Building 506 was resurveyed by NRDL personnel, and wipe samples indicated the site was decontaminated to background levels. In December 1969, Building 506 was inspected and cleared by the AEC for unrestricted reuse (TtEMI, LFR, and U&A, 1997).

In 1978, RASO conducted a survey consisting of alpha and beta-gamma scans and wipe sampling for alpha and beta-gamma activity. Three isolated locations of beta-gamma activity were detected, which were less than NRC guidelines.

In 1997, the location of former Building 506 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of 15 surface soil and 3 asphalt samples near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in soil or asphalt samples at activities exceeding background. Release of the Building 506 Area was not recommended because a potential buried point source was encountered behind Building 529, which was previously discussed above in the summary of the Building 529 Area.

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 506 during the Phase V investigation. Nine surface soil samples were collected near the former building and analyzed at the on-site laboratory for  $^{241}\text{Am}$ ,  $^{137}\text{Cs}$ , and  $^{226}\text{Ra}$ .  $^{241}\text{Am}$  and  $^{137}\text{Cs}$  activities did not exceed the release

criteria, with maximum reported activities of 0.197 and 0.069 pCi/g, respectively.  $^{226}\text{Ra}$  exceeded the release criterion in two of the nine samples, with a maximum reported activity of 2.175 pCi/g.

#### Building 507 Site

Building 507 was first surveyed in 1955 as part of the NRDL decommissioning survey and was released for unrestricted reuse (NAVSEA, 2004). In December 1969, Building 507 was inspected and cleared by AEC for unrestricted reuse (TtEMI, LFR, and U&A, 1997).

In 1997, the location of former Building 507 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of six surface soil samples near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in the surface soil samples at activities exceeding background, except for one sample analyzed for  $^{40}\text{K}$ , which was reported at an activity of 11 pCi/g, slightly exceeding the background activity of 10 pCi/g. Based on the results of the Phase III survey, the Building 507 Area was recommended to be released for unrestricted reuse.

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 507 as part of the Phase V investigation. Four surface soil samples were collected from a Class 3 Survey Unit near the former building and analyzed at the on-site laboratory for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ ; one sample was also sent to an off-site laboratory for independent gamma quality assurance.  $^{137}\text{Cs}$  did not exceed the release criterion in any of the samples, with a maximum reported activity of 0.099 pCi/g.  $^{226}\text{Ra}$  exceeded the release criterion in one of the samples, with a reported activity of 4.402 pCi/g. Based upon the results of the scoping survey, New World Technology (NWT) concluded the original classification of the Building 507 was incorrect, and further characterization of the site should be performed to identify the extent of residual contamination, with remediation and a Class I survey to be completed after characterization is complete.

#### Building 508 Site

Building 508 was first surveyed in 1955 as part of the NRDL decommissioning survey and was released for unrestricted reuse (NAVSEA, 2004). In December 1969, Building 508 was inspected and cleared by AEC for unrestricted reuse (TtEMI, LFR, and U&A, 1997).

In 1997, the location of former Building 508 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of seven surface soil samples near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in the

surface soil samples at activities exceeding background. Based on the results of the Phase III survey, the Building 508 Area was recommended to be released for unrestricted reuse.

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 508 as part of the Phase V investigation. Four surface soil samples were collected from a Class 3 Survey Unit near the former building and analyzed at the on-site laboratory for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ ; one sample was also sent to an off-site laboratory for independent gamma quality assurance.  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$  activities did not exceed the release criteria in any of the samples, with maximum reported activities of 0.1267 and 1.0577 pCi/g, respectively. Statistical test applications and solid sample analysis results indicated the residual activity at the Building 508 site did not exceed the release criteria.

#### Building 520 Site

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 520 during the Phase V investigation. The investigation consisted of collection and analysis of three surface soil samples near the former building. The analysis of collected field data and solid sample analysis indicated the residual activity at Building 520 exceeded the release criteria, with  $^{226}\text{Ra}$  reported at a maximum activity of 1.978 pCi/g at sample location S-1. According to the HRA, the radium contamination was found near the foundation of Building 520, indicating contamination was likely present in the drain system (NAVSEA, 2004). NWT recommended that sample location S-1 should be remediated, and new systematic samples should be collected in the area. NWT further recommended the area should be reclassified as a Class 1 or Class 2 area for survey purposes.

#### Building 529 Site

In 1969, NRDL conducted a radiological survey at Building 529; radiation was not detected in the building (TtEMI, LFR, and U&A, 1997). The stainless steel holding tank was decontaminated, and results from wipe samples following decontamination indicated the tank was decontaminated to background levels. Following decontamination, the tank was moved from the vicinity of Building 529. In December 1969, Building 529 was inspected and cleared by the AEC for unrestricted reuse (TtEMI, LFR, and U&A, 1997).

In 1978, RASO conducted a survey consisting of alpha and beta-gamma scans and wipe sampling for alpha and beta-gamma activity. No areas of elevated radioactivity were identified in the building (TtEMI, LFR, and U&A, 1997).

In 1997, the location of former Building 529 was surveyed during the Phase III investigation (TtEMI, LFR, and U&A, 1997). The investigation consisted of a surface gamma walkover survey and collection and analysis of four surface soil samples near the former building. One elevated gamma radiation reading was observed to the southwest of the former building, between former Buildings 529 and 520 near the foundation of former Building 520. The location of the elevated gamma reading was excavated to a depth of 12 inches bgs and gamma activity increased with depth, although no source was

found. At the surface, the gamma count reading was 11,205 cpm; at 4 inches, the count was 13,130 cpm; and at 12 inches, the count was 18,394 cpm, nearly three times background. Although the gamma anomaly was located near the foundation of former Building 520, it was associated in the Phase III investigation with former Building 529, since former Building 520 was not included in the Phase III investigation. Additional investigation was recommended to evaluate the area for the potential presence of a buried radium-containing device.

No radioisotopes were reported in the soil samples at activities exceeding background, except for one sample analyzed for potassium-40 ( $^{40}\text{K}$ ), which was reported at an activity of 13 pCi/g, slightly exceeding the background activity of 10 pCi/g.

In 2002, a MARSSIM scoping survey at the location of former Building 529 during the Phase V investigation; contaminated underground piping was found in the area. Three surface soil samples were collected and analyzed at the on-site laboratory for  $^{241}\text{Am}$ ,  $^{137}\text{Cs}$ , and  $^{226}\text{Ra}$ ; one sample was also analyzed for  $^{90}\text{Sr}$ . Radionuclide activities did not exceed the release criteria in any of the three soil samples.

#### Shack 79 Site

In 2002, a MARSSIM Class 3 scoping survey was conducted at the Shack 79 Site during the Phase V investigation. Two surface soil samples were collected near the former building and analyzed at the on-site laboratory for  $^{241}\text{Am}$ ,  $^{137}\text{Cs}$ , and  $^{226}\text{Ra}$ .  $^{241}\text{Am}$  and  $^{137}\text{Cs}$  activities did not exceed the residential release criteria, with maximum reported activities of 0.236 and 0.137 pCi/g, respectively.  $^{226}\text{Ra}$  exceeded the release criterion in one of the two samples, with a maximum reported activity of 2.007 pCi/g.

#### Shack 80 Site

In 2002, a MARSSIM scoping survey was conducted at the Shack 80 Site during the Phase V investigation. Two surface soil samples were collected from a Class 3 survey unit near the former building and analyzed at the on-site laboratory for  $^{241}\text{Am}$ ,  $^{137}\text{Cs}$ , and  $^{226}\text{Ra}$ .  $^{241}\text{Am}$  activities did not exceed the residential release criterion, with a maximum reported activity of 0.269 pCi/g.  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$  exceeded the release criteria in both samples, with maximum reported activities of 39.682 and 6.156 pCi/g, respectively. Based on the results of the scoping survey, remedial actions were performed at the site.

Following remedial actions, 16 soil samples were collected from a Class 1 survey unit at the Shack 80 site.  $^{137}\text{Cs}$  exceeded the release criterion in five samples, with a maximum reported activity of 2.4293 pCi/g.  $^{226}\text{Ra}$  exceeded the release criterion in six samples, with maximum reported activity of 2.953 pCi/g. Based on the results of the Class 1 survey, additional remedial actions were performed at the site, and 16 additional samples were collected from a Class 2 survey unit to identify any potential contamination beyond the building footprint boundary.  $^{137}\text{Cs}$  exceeded the release criteria in 11 samples, with a maximum reported activity of 7.7129 pCi/g.  $^{226}\text{Ra}$  exceeded the release criteria in 12 samples, with maximum reported activity of 4.467 pCi/g.

***Redevelopment Block MU-3******Building 701 Site***

In 1991, the location of former Building 701 was surveyed during the Phase I investigation (TtEMI, LFR, and U&A, 1997). No radiological anomalies were found in the area.

In 2002, a MARSSIM scoping survey was conducted at the Building 701 Site during the Phase V investigation. Six surface soil samples were collected near the former building, and six subsurface soil samples were collected from a depth of 12 inches. Soil samples were analyzed at the on-site laboratory for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ .  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$  activities did not exceed the release criteria, with maximum reported activities of 0.039 and 1.206 pCi/g, respectively.

***IR-04***

In 2002, a MARSSIM scoping survey was conducted at IR-04 during the Phase V investigation. The area was divided into five survey units: three designated as a Class 1 area, encompassing up to 2,000 m<sup>2</sup> each, and two designated as a Class 2 buffer area surrounding the Class 1 areas. Sixteen soil samples were collected from each survey unit, for a total of 80 samples, and were analyzed at the on-site laboratory for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ .  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$  activities exceeded the release criteria in all survey units, with maximum reported activities of 1.039 pCi/g (in survey grid C) and 4.205 pCi/g (in survey grid D), respectively. Based on the results of the scoping survey, additional characterization and remedial action was recommended for the site.

***Redevelopment Blocks EOS-1 through EOS-4******Building 509 Site***

In 1997, the location of former Building 509 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of five surface soil samples and one asphalt sample near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in the surface soil or asphalt samples at activities exceeding background, except for one sample analyzed for  $^{40}\text{K}$ , which was reported at an activity of 15 pCi/g, exceeding the background activity of 10 pCi/g. Release of the Building 509 Site was not recommended because elevated gamma readings were measured between former Buildings 509 and Building 517, which is discussed further below.

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 509 as part of the Phase V investigation. Six surface soil samples were collected from a Class 3 Survey Unit near the former building and analyzed at the on-site laboratory for  $^{137}\text{Cs}$ .  $^{137}\text{Cs}$  activities did not exceed the release criterion in any of the samples, with a maximum reported activity of 0.0632 pCi/g. Statistical test applications and solid sample analysis results indicated the residual activity at the Building 509 Site met the release criteria.

### Building 510 and 510A Sites

Building 510 was first surveyed in 1955 as part of the NRDL decommissioning survey, and was released for unrestricted reuse ([NAVSEA, 2004](#)).

In 1997, the location of former Building 510 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of six surface soil samples near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in the surface soil samples at activities exceeding background, except for one sample analyzed for  $^{40}\text{K}$ , which was reported at an activity of 11 pCi/g, slightly exceeding the background activity of 10 pCi/g. Based on the results of the Phase III investigation, the Building 510 Site was recommended to be released for unrestricted reuse.

In 1997, the location of former Building 510A was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of two surface soil samples near the former building. Several 1-minute gamma count measurements exceeded the background activity; however, these measurements could not be associated with an anomaly and were considered to be caused by variances in background activity. No radioisotopes were reported in the surface soil samples at activities exceeding background. Based on the results of the Phase III investigation, the Building 510A Site was recommended to be released for unrestricted reuse.

In 2002, a MARSSIM scoping survey was conducted at the location of former Buildings 510 and 510A as part of the Phase V investigation. Five surface soil samples were collected from a Class 3 survey unit near the former buildings and analyzed at the on-site laboratory for  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$ .  $^{137}\text{Cs}$  and  $^{226}\text{Ra}$  activities did not exceed the release criteria in any of the samples, with maximum reported activities of 0.0406 and 1.644 pCi/g, respectively. Statistical test applications and solid sample analysis results indicated the residual activity at the Building 510 and 510A site met the release criteria.

### Building 517 Site

In January 1970, Building 517 was inspected and cleared by AEC for unrestricted reuse ([TtEMI, LFR, and U&A, 1997](#)).

In 1978, RASO conducted a survey consisting of alpha and beta-gamma scans and wipe sampling for alpha and beta-gamma activity. No areas of elevated radioactivity levels were identified in the building.

In 1997, the location of former Building 517 was surveyed during the Phase III investigation. The investigation consisted of a surface gamma walkover survey and collection and analysis of three surface soil samples near the former building. One gamma count measurement (9,000 cpm) slightly above background (6,500 cpm) was observed near the northeast corner of the former building. No radioisotopes

were reported in the surface soil samples at activities exceeding background, except for one sample analyzed for  $^{232}\text{thorium}$ , which was reported at an activity of 0.96 pCi/g, slightly exceeding the background activity of 0.87 pCi/g. Based on the results of the Phase III investigation, the area around the elevated gamma count reading at Building 517 was recommended to be further assessed.

In 2002, a MARSSIM scoping survey was conducted at the location of former Building 517 during the Phase V investigation. Two surface soil samples were collected near the former building and analyzed for  $^{137}\text{Cs}$  and  $^{60}\text{Co}$ . The analysis of collected field data and solid sample analysis indicated the residual activity at the Building 517 met the release criteria; however, additional soil samples were recommended because the scan minimum detectable concentration for one of the isotopes of concern could not be achieved.

#### IR-02

In 1988, Harding Lawson Associates conducted a preliminary surface radiation survey to determine if radioactivity levels at HPS posed unacceptable exposure risks to RI fieldworkers. Project activities included a surface gamma survey for radiation at surface locations at Parcel E. The surface gamma survey was conducted at predetermined on- and off-site locations to obtain background measurements, and at the nodal points of a 50- by 50-foot grid over the entire IR-02 area. Gamma readings were measured at the ground surface and at 1 meter above ground surface at each grid node and along grid lines.

An area of five anomalous gamma readings in IR-02 was also surveyed in more detail using a 10- by 10-foot grid spacing, as well as a ground scanning method (NAVSEA, 2004). Twenty-four elevated readings were detected using the 10-by-10 foot grid spacing, and 8 more were identified using the ground scanning method. Anomalies detected between grid nodes were recorded, mapped, and included in a database. Anomalously high gamma radiation readings were only observed within a portion of IR-02 Northwest, which was characterized by surface debris and machinery parts. These anomalies were observed at small, isolated locations, suggesting the presence of discrete point sources of radioactivity such as buried  $^{226}\text{Ra}$ -containing devices (Harding Lawson Associates, 1990).

In 1991, the Phase I radiological investigation was initiated to confirm the nature and extent of  $^{226}\text{Ra}$ -containing devices in the disposal area at IR-02 Northwest. The Phase I investigation consisted of the following tasks: (1) a surface gamma walkover survey to establish the extent and locations of an anomalously high gamma readings found in the survey performed by Harding Lawson Associates; (2) collection of soil samples to establish whether radioisotopes other than  $^{226}\text{Ra}$  were present at Parcel E; (3) collection of radon flux canister samples to assess the potential presence of radon gas that may be associated with  $^{226}\text{Ra}$ -containing devices; and (4) air sampling to determine whether airborne radioactive contaminants posed a health risk to workers at HPS or the surrounding community.

To conduct the surface gamma walkover survey, a local grid coordinate system was developed to map and relocate radioactive material detected during the surface walkover survey. Each grid section was 300-feet by 300-feet square, with each section further subdivided into 30-foot by 30-foot subgrids. During the Phase I SCRS, gamma readings exceeding two times the background level were considered potential radioactive point source anomalies associated with buried radium-containing devices (PRC, 1992). When elevated gamma readings were observed, the location, gamma measurements, and exposure measurements were recorded and a biased soil sample was collected to identify the radioisotopes. To provide additional characterization information, systematic soil samples were also collected at random locations throughout Parcel E at a sampling frequency of one sample per 2 acres.

During the surface walkover survey, over 300  $^{226}\text{Ra}$ -containing point sources were observed in a centralized area at IR-02 Northwest that extended approximately 50 feet across the site boundary into IR-02 Central. The anomalous area was approximately 600 feet by 600 feet in size, and was centered approximately 500 feet west of Building 600. Various  $^{226}\text{Ra}$ -containing devices were observed on the ground surface at IR-02 Northwest and were removed prior to soil sample collection. A few anomalously high gamma readings were also recorded in the intertidal area at IR-02 Northwest (PRC, 1992). Radioactive point source anomalies were not found at IR-03 or IR-11/14/15; a combination safe found at IR-11/14/15 had an anomalously high gamma activity associated with a dial on the door (PRC, 1992).

In total, 76 soil samples were collected from IR-02 within the current Parcel E boundary, and 3 soil samples were collected from IR-11/14/15. Thirteen soil samples collected from the disposal dump area at IR-02 Northwest exhibited  $^{226}\text{Ra}$  activities above background, ranging from 4 to 3,900 pCi/g.

In addition to the soil sampling, 158 radon flux canister samples were collected at ground surface locations at or near selected radioactive anomalies and other areas with elevated gamma activity. Ten of the samples were collected at IR-14, and 148 samples were collected at IR-02. Flux canister samples were analyzed for radon gas, a radioactive gas emitted into soil from the decay of  $^{226}\text{Ra}$ . The analytical results were quantified as a radon flux rate value in pCi/m<sup>2</sup>-s. Analytical results for the 158 radon flux canister samples collected at Parcel E are summarized below.

- Twenty-one samples had no detectable levels of radon gas, with radon flux rates quantified as 0 pCi/m<sup>2</sup>-s
- Seventy-eight samples exhibited very low levels of radon gas at or below the average background radon flux rate (0.17 pCi/m<sup>2</sup>-s)
- Nineteen samples exhibited low levels of radon gas within twice the average background flux rate, with radon flux rates ranging from 0.18 to 0.34 pCi/m<sup>2</sup>-s

- Five samples exhibited slightly elevated levels of radon gas within three times the average background flux rate, with radon flux rates ranging from 0.35 to 0.45 pCi/m<sup>2</sup>-s
- Thirty-five samples exhibited elevated levels of radon gas greater than three times the average background flux rate, with radon flux rates ranging from 0.47 to 74.96 pCi/m<sup>2</sup>-s

The 35 samples with elevated levels of radon gas were collected directly above areas with elevated gamma activity and were surrounded by nearby canister samples with very low or low levels of radon gas. The average radon flux rate (2.07 pCi/m<sup>2</sup>-s) measured at Parcel E during the Phase I investigation is well below the average radon emission rate (20 pCi/m<sup>2</sup>-s) specified in the Uranium Mill Tailings Radiation Control Act (40 CFR § 192.02[b][1]).

In 1991, Phase I particulate air monitoring was conducted to evaluate the background airborne particulate alpha and beta radioactivity levels at several locations, including Parcel E. Particulate air samples were collected from 35 locations at HPS, including Parcel E. The gross alpha and gross beta airborne particulate concentrations were well within safety standards for airborne concentrations of general radioactive materials in outdoor air (PRC, 1992).

In 1993, the Phase II radiological investigation was initiated at IR-02 to further investigate the distribution of <sup>226</sup>Ra-containing devices identified during the Phase I investigation. Thirty-four 15-foot-deep test pits and 3 100-foot-long trenches were excavated at IR-02. Twelve test pits and 2 trenches were found to contain a total of 111 gamma-emitting point source anomalies. In total, 96 point sources, or approximately 90 percent, of the <sup>226</sup>Ra-containing devices were found between the surface and 6.5 feet bgs. The remainder of the point sources was found distributed between 6.5 feet bgs and until Bay Mud was encountered; no point sources or elevated gamma count rates were found after Bay Mud was encountered.

Anomalous gamma count readings as high as 988,000 cpm were recorded during the investigation. Thirteen soil samples were collected from the trenches and test pits; <sup>226</sup>Ra activity in soil samples collected from the trenches and test pits ranged from 46.28 pCi/g in the sample collected from test pit IR02TP17 to 20,949 pCi/g in the sample collected from test pit IR02TP23. A total volume of approximately 6,080 cubic feet of soil and debris was excavated from the test pits and trenches during the Phase II investigation and disposed of off-site at a licensed facility. The subsurface distribution of <sup>226</sup>Ra-containing devices associated with the point sources was confined to an area approximately 400 feet by 250 feet in size, to a maximum depth of 9 feet bgs. Based on the results of the Phase II investigation, approximately 148,000 cubic feet of soil was estimated to contain radioactive sources.

Gross alpha or gross beta radioactivity was not reported above background levels during low-, medium-, and high-volume air sampling conducted during the Phase II investigation (PRC, 1996).

In 1993, EPA's National Air and Radiation Environmental Laboratory analyzed 13 soil samples from IR-02 Northwest to determine particle size, radionuclide distribution, and radionuclide content (EPA, 1994). Three of the samples exhibited elevated levels of  $^{226}\text{Ra}$ , with a maximum activity of 318 pCi/g reported in sample A, which was collected from the disposal area. The remainder of the samples exhibited  $^{226}\text{Ra}$  at activities comparable with background.  $^{226}\text{Ra}$  was found to be approximately equal between particle size fractions in some of the samples, and sometimes preferring smaller fractions, indicating contamination by oxidation or fragmentation. The study concluded that based on background activities in 10 of the samples, a significant volume of soil at IR-02 Northwest may contain background levels of  $^{226}\text{Ra}$ . The study further concluded that particle size separation could be accomplished by hydro-classification or a similar technology to remove radium sources, with removal of soil in the immediate vicinity of the radium sources.

### 2.3.1.3. Fate and Transport of Radioactive Chemicals in Soil

Radioactive chemicals, also referred to as radionuclides, are unstable and undergo spontaneous transformations at a constant rate by releasing energy until a stable state is reached. This transformation process is known as radioactive decay and is accompanied by the emission of at least one or more charged particles (for example, alpha and beta particles) or gamma rays. Alpha particles can travel only short distances and cannot penetrate human skin; the risks from alpha particles are from internal exposure of the particle from either inhalation or ingestion. Beta particles are generally absorbed in the skin and do not pass through the entire body, but in high enough quantities can cause cataracts to the lens of the eye. Gamma ray radiation can penetrate the human body with enough energy for the photon to interact with the body's cells. The table below lists the ROCs, their half-lives, and major radiations emitted when decaying (NAVSEA 2004). The radionuclides potentially present in Parcel E were either (1) buried along with excavated fill materials while increasing the footprint of HPS; (2) residue from decontamination of ships or workers; (3) residual contamination as a result of NRDL experiments or tests in structures or land areas; (4) residual contamination from shipyard operations; or (5) released into the sanitary sewers and storm drains.

| Radionuclide  | Half-Life        | Radiation Emitted During Decay           |
|---------------|------------------|------------------------------------------|
| Americium-241 | 7,370 years      | Alpha and beta particles                 |
| Cesium-137    | 30 years         | Beta particles, gamma rays               |
| Cobalt-60     | 5.3 years        | Beta particles, gamma rays               |
| Hydrogen-3    | 12.35 years      | Beta particles                           |
| Plutonium-239 | 24,100 years     | Alpha particles, x-rays                  |
| Radium-226    | 1,600 years      | Alpha and beta particles, and gamma rays |
| Strontium-90  | 29.1 years       | Beta particles                           |
| Uranium-235   | 70,400,000 years | Alpha particles, x-rays                  |

|    |                                                |                      |                                                                                                                                                                                                  |
|----|------------------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 17 | <b>Radiological groundwater investigations</b> | <b>Section 2.3.5</b> | Final Radiological Addendum to the Feasibility Study Report for Parcel E, Hunters Point Shipyard, San Francisco, California. ERRG and RSRS. August 2012. Section 2.3.2, pages 2-44 through 2-48. |
|----|------------------------------------------------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Each potential ROC is transported through the environment differently. Residual radioactivity, resulting from the disposal or discharge of radioactive material, may be present at Parcel E in soil. Residual radioactivity from soil may be transported to other secondary media; the degree of this potential transport is governed by the properties of each ROC, which are summarized briefly in [Table 4](#).

## **2.3.2. Nature and Extent of Radionuclides in Groundwater**

The groundwater data derived from the 2001/2002 and 2007 to 2009 radiological investigations, as discussed in [Section 2.2](#), were used to evaluate the nature and extent of ROCs in groundwater at Parcel E. The nature and extent evaluation presented in this section documents that an adequate amount of data exist to determine whether or not groundwater contains radionuclides at concentrations that warrant further analysis in this radiological addendum. Additional information on the nature and extent of nonradioactive chemicals in groundwater at Parcel E is presented in the Final Revised RI Report ([Barajas & Associates, 2008](#)).

### **2.3.2.1. Summary of 2001/2002 Groundwater Investigation**

The radiological groundwater investigation performed in 2001 and 2002 as part of the Phase III GDGI collected isotope-specific data from 24 A-aquifer monitoring wells within Parcel E. The investigation was intended to supplement data collected during previous investigations for radiological indicator parameters (gross alpha and gross beta) because the nonspecific results for gross alpha and gross beta did not allow the Navy to distinguish between natural and potentially site-related components of radioactivity in shallow groundwater (within what is referred to as the “A-aquifer”). [Figure 6](#) identifies the monitoring wells sampled during the 2001 and 2002 groundwater investigation.

The analytical data were evaluated by simple (nonstatistical) threshold comparisons to a fixed standard and by statistical tests comparing the site data with background data (two-sample statistical tests) and with fixed standards<sup>5</sup> (one-sample statistical tests) ([TtEMI, 2004](#)). To conduct the statistical analysis, the analytical data were compiled by study area. The data set used for IR-02 consisted of 18 wells, for a total of 36 samples, and the data set used for IR-03 consisted of 2 wells, for a total of 4 samples. The data from IR-14 were grouped with the data from IR-34 and IR-71, located in Parcel D, for a total of 6 wells and 12 samples. The statistical test results are summarized by data set as follows:

<sup>5</sup> Maximum contaminant levels (MCL) as outlined in Title 40 Code of Federal Regulations Part 141 were used as drinking water standards in the evaluation. For radionuclides other than radium and uranium, the drinking water comparison standard was calculated from the 4 mrem/year dose standard.

**IR-02**

- A simple threshold comparison of groundwater data from IR-02 for radionuclides with drinking water or other standards indicated the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities from one well (IR02MW101A2) exceeded the drinking water standard of 5 picocuries per liter (pCi/L). Thirty samples from a total of 16 wells exhibited activities of  $^{40}\text{K}$  greater than 50 pCi/L, which is the standard for gross beta.
- Statistical testing comparing groundwater data from IR-02 and background areas indicated that the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities statistically exceeded the background data sets using a parametric statistical test (two-sample t-test), but did not statistically exceed the drinking water standard using a one-sample t-test.
- Statistical testing comparing groundwater data from IR-02 indicated that  $^{40}\text{K}$  activities statistically exceeded the background data sets using the two-sample t-test, both including and excluding bay water samples.  $^{40}\text{K}$  activity occurs naturally in seawater at about 300 pCi/L, as beta emissions, and bay water samples collected for this investigation produced an average of 280 pCi/L for  $^{40}\text{K}$ . The arithmetic mean of  $^{40}\text{K}$  activity at IR-02 was significantly lower, at 184.2 pCi/L.
- Statistical testing comparing groundwater data from IR-02 and background areas, excluding bay samples, indicated that the site data sets for  $^{228}\text{Ac}$ ,  $^{40}\text{K}$ , and for the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities, statistically exceeded the background data sets using a nonparametric statistical test (Wilcoxon rank sum test).

**IR-03**

- A simple threshold comparison of groundwater data from IR-03 for radionuclides with drinking water or other standards indicated the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities from two wells (IR03MW218A2 and IR03MW218A3) exceeded the drinking water standard of 5 pCi/L. Four samples from a total of two wells exhibited activities of  $^{40}\text{K}$  greater than 50 pCi/L.
- Statistical testing comparing groundwater data from IR-03 and background areas indicated that the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities statistically exceeded the background data sets using a two-sample t-test, but did not statistically exceed the drinking water standard using a one-sample t-test.
- Statistical testing comparing groundwater data from IR-03 indicated that  $^{40}\text{K}$  activities statistically exceeded the background data sets using the two-sample t-test, both including and excluding bay water samples.  $^{212}\text{Pb}$  activities significantly exceeded background levels, both including and excluding bay water samples.
- Statistical testing comparing groundwater data from IR-03 and background areas, excluding bay samples, indicated that the site data sets for  $^{228}\text{Ac}$ ,  $^{40}\text{K}$ ,  $^{212}\text{Pb}$ , and the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities statistically exceeded the background data sets using the Wilcoxon rank sum test.

### Other Areas

- A simple threshold comparison of groundwater data from other areas, including IR-14, IR-34, and IR-71, for radionuclides with drinking water or other standards indicated the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities did not exceed the drinking water standard of 5 pCi/L. Five samples from a total of four wells exhibited activities of  $^{40}\text{K}$  greater than 50 pCi/L.
- Statistical testing comparing groundwater data from other areas indicated that 125-antimony ( $^{125}\text{Sb}$ ) and thallium-208 ( $^{208}\text{Th}$ ) activities statistically exceeded the background data sets using a parametric statistical test (two-sample t-test).
- Statistical testing comparing groundwater data from other areas and background areas, including bay samples, indicated that the site data sets for the sum of  $^{125}\text{Sb}$  statistically exceeded the background data sets using the Wilcoxon rank sum test. When bay samples were excluded,  $^{125}\text{Sb}$ ,  $^{40}\text{K}$ , and  $^{208}\text{Th}$  statistically exceeded background.

The results indicated the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities exceeded the drinking water standard at select wells in IR-02 and IR-03; however, based on the results of the one-sample statistical tests, the mean activities of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  at both IR-02 and IR-03 did not statistically exceed the drinking water standard. The investigation also concluded that naturally occurring  $^{40}\text{K}$  in seawater is the main contributor to beta emissions measured in groundwater samples from nearshore monitoring wells within Parcel E. The gross beta values historically reported for samples collected from nearshore wells were dominated by beta emissions from natural  $^{40}\text{K}$  in seawater, not beta emissions from radium isotopes. Background seawater contains the highest average activity of  $^{40}\text{K}$  (280 pCi/L, beta) of all data groups, followed by nearshore IR sites, where saltwater intrusion has resulted in brackish groundwater conditions. This intrusion has altered the composition of nearshore groundwater, with corresponding changes in the radiological quality (especially gross beta emissions). The results of the radiological groundwater investigation are detailed in the Parcel E Groundwater Summary Report ([TtEMI, 2004](#)).

#### 2.3.2.2. Summary of 2007 to 2009 Groundwater Investigation

Beginning in the first quarter 2007, groundwater samples from six A-aquifer wells in Parcel E were collected and analyzed for radionuclides as part of the BGMP. Groundwater samples were collected and analyzed on a quarterly basis through the first quarter 2009. In addition, a supplemental data collection event was conducted at Parcel E in 2008 to further evaluate the nature and extent of radionuclides in groundwater. In June and July 2008, groundwater samples were collected from an additional eight monitoring wells (seven in the A-aquifer and one in the deeper B-aquifer) and submitted to an off-site laboratory for radionuclide analyses of  $^{137}\text{Cs}$ ,  $^{226}\text{Ra}$ , and  $^{90}\text{Sr}$ . In addition, samples collected from monitoring well IR12MW14A were evaluated for  $^{239}\text{Pu}$ . In the first quarter 2009, samples were collected from 12 A-aquifer wells and analyzed for  $^{137}\text{Cs}$ ,  $^{226}\text{Ra}$ , and  $^{90}\text{Sr}$ . An additional sample was collected from monitoring well IR12MW14A for analysis of  $^{239}\text{Pu}$ . Samples from A-aquifer monitoring well IR36MW09A and B-aquifer monitoring well IR36MW123B were analyzed exclusively for  $^{226}\text{Ra}$ . No

additional radionuclide data were collected through the first quarter 2010, the most recent quarter for which data is available.

The radionuclide groundwater data collected in 2007 through 2009 were compiled as part of this radiological addendum and were evaluated, similar to the 2002 investigation, by simple (non-statistical) threshold comparisons to a fixed standard (such as drinking water standards) and by statistical tests comparing the site data to fixed standards (one-sample statistical tests), if necessary. To evaluate whether radionuclide activities exceeded drinking water standards, a tiered approach was used. Initially, the data were compiled and compared against drinking water standards using a simple threshold comparison. If the maximum activity in any of the samples exceeded the drinking water standard, a one-sample statistical test (t-test) was conducted to evaluate if the mean radionuclide activities statistically exceeded the drinking water standard.

The simple threshold comparison with drinking water standards revealed the following:

- $^{137}\text{Cs}$  was reported in 11 of the 87 samples in the data set, at activities ranging from 0.451 to 3.83 pCi/L. All reported activities were below the drinking water standard of 80 pCi/L.
- $^{239}\text{Pu}$  was not reported in any of the three samples in the data set.
- $^{226}\text{Ra}$  was reported in 15 of the 88 samples in the data set, at activities ranging from 0.482 to 1.27 pCi/L. All reported activities were below the drinking water standard of 5 pCi/L.
- $^{90}\text{Sr}$  was reported in 7 of the 37 samples in the data set, at activities ranging from 0.672 to 2.22 pCi/L. All reported activities were below the drinking water standard of 8 pCi/L.

Based on the results of the comparison, radionuclide activities in groundwater at Parcel E do not exceed drinking water standards. Since drinking water standards were not exceeded in any of the samples, the one-sample statistical test was not conducted.

### 2.3.2.3. Conclusions from Groundwater Investigations

The reported activities for radionuclides using current data, collected from 2007 to 2009, do not exceed drinking water standards. The results from the 2001/2002 investigation indicated the sum of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  activities exceeded the drinking water standard at select wells in IR-02 and IR-03; however, based on the results of the one-sample statistical tests, the mean activities of  $^{226}\text{Ra}$  and  $^{228}\text{Ra}$  at both IR-02 and IR-03 did not exceed the drinking water standard. In addition, the comparison of radionuclide data from A-aquifer groundwater with drinking water standards is a conservative evaluation performed because of the lack of alternative comparison criteria. This conservative evaluation is not representative of potential exposures to future site users because, as documented in Section 2 and Appendix F of the Revised RI Report ([Barajas & Associates, Inc., 2008](#)), A-aquifer groundwater is not a potential source of drinking water. Based on the results of the comparison of radionuclide groundwater data with drinking water

standards, groundwater does not appear to have been impacted by radionuclides at concentrations that warrant further evaluation in the FS.

These findings are consistent with the HRA that, as summarized in [Table 2](#), determined that a low potential existed for radioactive contamination in Parcel E groundwater based on historical information ([NAVSEA, 2004](#)). However, the Revised RI Report concluded that nonradioactive chemicals in groundwater required remedial option analysis ([Barajas & Associates, Inc., 2008](#)). The FS Report evaluates remedial alternatives for groundwater that include monitoring, institutional controls, source removal, and containment ([ERRG, 2012](#)). As a conservative measure, future monitoring will include analysis for radionuclides in groundwater to verify the conclusions of this radiological addendum.

## 2.4. CONCEPTUAL SITE MODEL

The CSM is an understanding of the dynamics of the site's environmental concerns and serves as a basis of the development of the RAO. The CSM is used to understand potential sources of contamination, migration pathways, and human receptors that the RAOs are intended to address. The conceptual site model for the nonradiological risk assessment is described in Section 2.4 of the Final Parcel E FS Report ([ERRG, 2012](#)). This section summarizes the CSM specific to the radiological risk assessment, and is discussed in detail in Section B3 of [Appendix B](#). The radiological CSM summarizes the sources of radioactive chemicals on site and presents the affected environmental media, the potential receptors, and potential exposure pathways through which receptors may receive radiological doses.

The computer code RESRAD Model Version 6.5 (Argonne National Laboratory [[ANL](#)], 2009) was used to perform dose and risk modeling of radiologically impacted sites at Parcel E. RESRAD was used to model the risk associated with radiologically impacted soil areas. RESRAD uses the isotopes specified as ROCs and automatically includes the long-lived daughter products of these isotopes. RESRAD incorporates various exposure pathways, and the user has the option of selecting or excluding specific pathways based upon the anticipated receptors, activities, and land use patterns. The radiological CSM for Parcel E is presented on Figure B-1 of [Appendix B](#) and indicates which pathways were considered active in the radiological risk assessment. Radiological pathways that are not active for this analysis are excluded from the CSM.

### 2.4.1. Sources of Site Contaminants

Details on the historical activities at Parcel E that contributed to the existing radiological contamination are presented in [Section 2.1](#) of this addendum. The primary potential sources of radiological contamination at Parcel E are past shipyard and NRDL operations, decontamination of ships that participated in atomic weapons testing, and the disposal of radioluminescent devices.

- Notes:
- C Potentially complete exposure pathway
  - I Incomplete or negligible exposure pathway
  - IR Installation Restoration
  - VOC Volatile organic compound
  - \* See subsurface soil exposure pathways
  - (1) Complete exposure pathway, but not evaluated in the HHRA. The Navy plans to complete a focused soil gas survey to address this pathway prior to finalizing the Feasibility Study for Parcel E, as necessary.
  - (2) Addressed in Uncertainty Analysis (see Section 19.0)

Tables I1-1, I1-2, I1-3, and I1-4 of [Attachment I1](#) present analytical data summary statistics for each total risk COPC. Tables I2-1, I2-2, I2-3, and I2-4 of [Attachment I2](#) present analytical data summary statistics for each incremental risk COPC. Tables I3-1 through I3-8 of [Attachment I3](#) list the COPCs for groundwater and present analytical data summary statistics for each groundwater COPC. In these tables, statistics are developed separately for each grid with analytical data.

## 15.0 EXPOSURE ASSESSMENT

An exposure assessment identifies potential human receptors that could be exposed to site-related chemicals, as well as the routes, magnitude, frequency, and duration of the potential exposures. The principal objective of this evaluation is to identify reasonable maximum exposures (RME). As defined by [EPA \(1989\)](#), the RME is the maximum exposure that is reasonably expected to occur at a site. The potential human receptors and potentially complete exposure pathways for the identified receptors were presented in [Section I3.0](#), Conceptual Site Model. The remainder of this section describes the process used to estimate EPCs and to quantify pathway-specific RME chemical intakes for each receptor. Central tendency exposures were not evaluated in this revised baseline HHRA.

### 15.1 EXPOSURE POINTS AND EXPOSURE POINT CONCENTRATIONS

Potential exposure points are identified based on anticipated population activity patterns and the relationship of the activities to the presence of contaminated media. A location is identified as an exposure point if a human might contact (for example, ingest) a contaminated medium (for example, soil) at that location. For evaluation of exposures to soil and exposure to groundwater not associated with risk plumes, each residential and industrial grid was considered a separate exposure point for this HHRA. For each of the groundwater risk plumes, the area encompassed by each risk plume (see [Attachment I3](#) to this appendix) was considered a separate groundwater exposure point. Potential exposure to COPCs is assumed to occur uniformly throughout each exposure point.

The concentration in the medium (for example, subsurface soil) that a receptor may be exposed to is called the EPC. EPCs were calculated for all COPCs in all media sampled: surface soils (0 to 2 feet bgs), subsurface soils (0 to 10 feet bgs), A-aquifer groundwater, and B-aquifer groundwater. The methods used to calculate EPCs for soil and groundwater are described below in [Sections I5.1.1 and I5.1.2](#), respectively.

As shown in the conceptual site model (see [Figure I-1](#)), chemicals in soil may be transferred to outdoor air from wind erosion or volatilization, or to vegetation from root uptake. Chemicals in groundwater may be transferred to outdoor air in a construction trench from volatilization, indoor air from vapor intrusion, and indoor air from volatilization of groundwater during

domestic use. Sample data for outdoor and indoor air, and vegetation were not available for Parcel E. EPCs in outdoor air (from particulate and volatile chemicals in soil), indoor air (from groundwater vapor intrusion and volatilization), outdoor air in a construction trench (from volatile chemicals in groundwater), and homegrown produce (from root uptake of chemicals in soil) were estimated using the methods described in [Section I5.1.3](#).

#### **I5.1.1 EPCs for Soil**

The 95 percent upper confidence limit (95 UCL) of the arithmetic mean was used as the EPC for each soil COPC, unless the maximum value was less than the 95 UCL, in which case, the maximum concentration was used as the EPC. The 95 UCL for each soil COPC in each grid was calculated using the following methodology. This methodology is consistent with the approach used for the soil HHRA in the Draft Final RI Report for Parcel E ([PRC, LFR, and U&A 1997](#)), and follows the methodology recently re-established for soil HHRAs for HPS ([Tetra Tech 2003; Navy 2004](#)):

- Statistical testing was conducted to determine data distribution for sample sizes with a minimum of four samples and four detections. For samples sizes less than 50 with at least four detections, the Shapiro-Wilk W-test was used to determine the distribution of the data. For sample sizes greater than or equal to 50 with at least four detections, the D'Agostino test was used to determine the distribution of the data.
- For data found to be normally or lognormally distributed, 95 UCLs were calculated using [EPA \(1992\)](#) guidance.
- If distribution testing showed that data follow a non-parametric distribution, then a 95 UCL was calculated for both a normal and lognormal distribution following EPA guidance ([EPA 1992](#)) and the higher of the two 95 UCL values was selected as the representative 95 UCL.
- For samples sizes with less than four samples, distribution testing was not conducted and the maximum concentration was used as the EPC.

In accordance with EPA guidance, one-half of the reporting limit was used as a proxy value for nondetectable (below the reporting limit) results in calculating the 95 UCL concentration ([EPA 1989](#)). EPCs for each total risk assessment COPC in surface soil and subsurface soil are shown in [Tables I1-1, I1-2, I1-3, and I1-4](#) of [Attachment I1](#). EPCs for each incremental risk assessment COPC in surface soil and subsurface soil are shown in [Tables I2-1, I2-2, I2-3, and I2-4](#) of [Attachment I2](#). These tables also present the results of the distribution testing for each COPC and the calculated 95 UCLs.

Although more recent guidance regarding calculation of EPCs is available (see [Section I5.1.2](#)), the previous guidance provided by [EPA \(1992\)](#) was used to calculate EPCs for soil in this revised HHRA in accordance with the recent methodology established for soil HHRAs for HPS ([Tetra Tech 2003; Navy 2004](#)). In many cases, because of the relatively few sample points and

detections for each grid (that is, less than four samples and four detected results), the maximum concentration is used as the EPC, resulting in a conservative estimate of potential risks.

### **I5.1.2 EPCs for Groundwater**

Separate EPCs for groundwater were developed to evaluate exposure areas associated with risk plumes and exposure areas not associated with risk plumes (see [Section I4.3.2](#)). To evaluate exposures associated with the groundwater risk plumes, the lesser of the 95 UCL or maximum concentration was used as the EPC for each COPC present in each risk plume. The methods used to calculate 95 UCLs for each risk plume are described below. [Tables I3-1 through I3-8 of Attachment I3](#) present analytical data summary statistics for each risk plume-based exposure area.

For exposure areas not associated with risk plumes (that is, for areas with monitoring wells that do not fall within the risk plume boundaries delineated in [Attachment I3](#)), the maximum detected concentration was used as the EPC. [Tables I3-9, I3-10, and I3-14 of Attachment I3](#) present analytical data summary statistics, including maximum concentrations (EPCs), for exposure areas not associated with risk plumes.

The methods used to calculate EPCs for groundwater associated with risk plumes is based on “Calculating Exposure Point Concentrations at Hazardous Waste Sites” ([EPA 2002b](#)) and *ProUCL Version 3.0 User Guide* ([Singh, Singh, and Maichle 2004](#)). Because the groundwater data set for the HHRA consisted of samples collected over a number of years (that is, the last 12 rounds of sampling), to reduce the influence of historical nondetected results on the EPCs, only detected results were used for calculation of the EPCs for groundwater. Nondetected results (that is, U-qualified data), were not included in the EPC calculation. For data sets with fewer than six samples, statistical estimations lack statistical power and cannot be confidently estimated ([EPA 2000](#)). Therefore, the maximum detected concentration was used as the EPC for data sets with fewer than six detections, rather than six samples. A 95 UCL was used as the EPC for COPCs in groundwater associated with risk plumes for data sets consisting of six or more detections. The following methods were used to calculate the underlying distribution for each chemical, population summary statistics, and EPCs.

**Distribution tests:** Distribution testing was conducted for all samples with at least six measurements. Formal tests were conducted using well-established goodness-of-fit tests. The Shapiro-Wilk W-Test ( $n \leq 50$ ) and Lilliefors Test ( $n > 50$ ) were used to evaluate normal and lognormal distributions. The Anderson-Darling and Kolmogorov-Smirnov Test were used to evaluate gamma distributions ([Singh, Singh, and Maichle 2004](#); [EPA 2002b](#)). A Type I error rate ( $\alpha$ ) of 0.05 (equivalent to 5 percent) was used to interpret the significance of each test. A Type I error rate of 0.05 means that there is a 5 percent chance that the null hypothesis will be rejected when it is true, thus leading to the false conclusion.

Chemical data confirmed as following a normal, lognormal, or gamma distribution based on the outcome of the two goodness-of-fit tests are listed as “normal (N)”, “lognormal (L),” or “gamma (G)” in the summary tables (see [Tables I3-1 through I3-8 and I3-11 through I3-13 of Attachment I3](#)). Chemical data that were not confirmed as following one of these three distributions are listed as “nonparametric (NP)” in the summary tables.

**Calculation of Population Parameters and Selection of the EPC:** The one-sided UCLs on the mean were calculated for chemicals with at least six samples. Recommendations in [Singh, Singh, and Maichle \(2004\)](#) are based on three properties measured for individual samples: (1) best-fit distribution, (2) relative degree of skewness, and (3) relative sample size. The recommendations for calculating an EPC for normal, gamma, lognormal, and nonparametric distributions are provided by the ProUCL software ([EPA 2004b](#)). EPCs for data that follow a normal distribution or that exhibit low skewness (standard deviation of the natural logarithms of the data less than 0.50) are based on calculation of a UCL using the Student’s t- statistic. After a sample-by-sample evaluation of the three properties described above, a UCL is calculated based on one of the parametric or nonparametric methods listed below.

| Parametric Methods                                       | Nonparametric Methods    |                                |
|----------------------------------------------------------|--------------------------|--------------------------------|
| Student's t UCL                                          | Chebyshev inequality UCL | Central Limit Theorem          |
| Approximate gamma UCL                                    | Bootstrap t UCL          | Modified-t statistic           |
| Adjusted gamma UCL                                       | Hall's bootstrap UCL     | Adjusted-Central Limit Theorem |
| Land's H-UCL                                             | Modified-t UCL           | Percentile bootstrap           |
| Minimum Variance                                         | Standard Bootstrap UCL   | Jackknife UCL                  |
| Unbiased Estimator (Minimum Variance Unbiased Estimator) |                          |                                |
| Chebyshev UCL                                            |                          |                                |

The UCL calculated using the Minimum Variance Unbiased Estimator Chebyshev or nonparametric Chebyshev method can be based on a 95, 97.5, or 99 percent one-sided UCL. The 95 UCLs calculated for groundwater are shown in [Tables I3-1 through I3-8 and I3-11 through I3-13 of Attachment I3](#). These tables also present the results of the distribution testing for each chemical. If the calculated 95 UCL was greater than the maximum concentration, then the maximum concentration was used as the EPC.

### I5.1.3 Exposure Point Concentrations for Media Not Sampled

As discussed in [Sections I3.0 and I5.1](#), COPCs in soil and groundwater may be transferred to outdoor air, indoor air, and vegetation (homegrown produce) from the following transfer mechanisms:

- Wind erosion of particulate chemicals from soil to outdoor air
- Volatilization from soil to outdoor air

- Vapor intrusion from groundwater to indoor air
- Volatilization from groundwater to indoor air during domestic use
- Volatilization from groundwater to outdoor air in a construction trench
- Uptake of chemicals in soil through plant roots into homegrown produce

Samples were not collected for outdoor air, indoor air, or vegetation at Parcel E. In the absence of direct measurements of chemical concentrations in air and vegetation, models were used to estimate EPCs in outdoor air, indoor air, and homegrown produce as a result of the above transfer mechanisms. These models are discussed below. EPCs for indoor air as a result of vapor intrusion of groundwater and volatilization from domestic use of groundwater were not calculated because a risk-based screening assessment was used to quantify risks from exposure to COPCs in groundwater (see [Section I7.2](#)).

#### **15.1.3.1 Outdoor Air – Particulate COPCs Released from Soil**

EPCs of particulates released from soil to outdoor air were estimated using soil EPCs as the source term and the methodology provided by EPA Region 9 in its memorandum describing the derivation of PRGs ([EPA 2004a](#)). To derive the EPCs in outdoor air, the EPC for soil was multiplied by the reciprocal of the [EPA \(2004a\)](#) default particulate emission factor of 1.316E+09 cubic meters per kilogram, which is a non-chemical-specific value that relates chemical concentrations in soil to airborne concentrations that may be inhaled.

#### **15.1.3.2 Outdoor Air – Volatile COPCs Released from Soil**

Chemical-specific volatilization factors, which relate concentrations of volatile chemicals in soil to airborne concentrations that may be inhaled, were used to estimate concentrations in outdoor air from volatile COPCs in soil. Volatilization factors were taken from the EPA Region 9 guidance ([EPA 2004a](#)) and are summarized in [Table I-2](#). To estimate EPCs in outdoor air, the soil EPC was multiplied by the reciprocal of the volatilization factor.

#### **15.1.3.3 Indoor Air – Vapor Intrusion of Volatile COPCs in Groundwater**

Subsurface vapor intrusion of volatile COPCs in groundwater into a hypothetical residential or standard industrial building was evaluated for the industrial and residential exposure scenarios. A risk-based screening assessment was used to calculate risks from groundwater vapor intrusion, based on groundwater EPCs developed for each A-aquifer risk plume and non-plume exposure area, and risk-based screening levels (RBSL) for groundwater vapor intrusion provided in [EPA \(2002a\)](#) guidance. [Section I7.2](#) provides further details on this approach. Because a risk-based screening assessment approach was used to evaluate groundwater vapor intrusion, EPCs were not modeled for indoor air from EPCs in groundwater.

#### **15.1.3.4 Indoor Air – Volatilization of COPCs in Groundwater during Domestic Use**

Volatilization of volatile COPCs in groundwater into household air during domestic use of groundwater was evaluated for the residential exposure scenario, based on groundwater EPCs developed for the B-aquifer. A risk-based screening assessment was used to calculate risks from domestic use of groundwater, based on groundwater EPCs and PRGs for tap water developed by EPA Region 9 ([EPA 2004a](#)). [Section 17.2](#) provides further details on this approach. Because a risk-based screening assessment approach was used to evaluate risks from domestic use of groundwater, EPCs were not developed for indoor air based on volatilization of COPCs in groundwater during domestic use.

#### **15.1.3.5 Outdoor Air – Volatile COPCs Released from Groundwater in a Construction Trench**

Chemical-specific volatilization factors that relate concentrations of volatile chemicals in groundwater accumulated in a construction trench to airborne concentrations that may be inhaled by construction workers were used to estimate EPCs from volatile COPCs in groundwater. Calculation of the volatilization factors for this scenario were based on guidance from [Virginia Department of Environmental Quality \(2005\)](#), which provides a combination of a vadose zone model to estimate volatilization of gaseous COPCs from groundwater into a trench, and a box model to estimate dispersion of the COPCs from the air inside the trench into aboveground air. A full description of the models used to estimate volatilization into a construction trench is provided in [Attachment I5](#) to this appendix.

#### **15.1.3.6 Homegrown Produce – Uptake of COPCs in Soil through Plant Roots**

Ingestion of COPCs that are transferred from soil to homegrown produce via uptake through plant roots was evaluated for the residential exposure scenario. Direct measurements of chemical concentrations in homegrown produce are not available for Parcel E because homegrown produce is not currently grown at Parcel E. EPCs for homegrown produce were calculated based on EPCs for COPCs in soil and soil-to-plant uptake factors (UF) that estimate the root uptake of inorganic and organic chemicals in soil and translocation of chemicals to edible plant parts ([U.S. Department of Energy 1984](#)). [Table I-3](#) lists the UFs for each COPC in soil.

For inorganic COPCs, UFs were obtained from [U.S. Department of Energy \(1984\)](#). To estimate EPCs in homegrown produce from inorganic COPCs, the soil EPC was multiplied by the UF.

For nonvolatile organic COPCs, equations from Cal/EPA were used to derive the UFs ([Cal/EPA 2003](#)). These equations relate the octanol-water partition coefficient ( $K_{ow}$ ) and the organic carbon-water partition coefficient ( $K_{oc}$ ) of the contaminant and the fraction of organic carbon ( $F_{oc}$ ) in the soil to calculate the UF. The equation used to calculate the UF is as follows:

$$UF = \frac{(0.03 \times K_{ow}^{0.77}) + 0.82}{(K_{oc})(F_{oc})} \quad (I-1)$$

where

|          |   |                                                                         |
|----------|---|-------------------------------------------------------------------------|
| $UF$     | = | Soil-to-plant uptake factor                                             |
| $K_{ow}$ | = | Octanol-water partition coefficient (cubic centimeters per gram)        |
| $K_{oc}$ | = | Organic carbon-water partition coefficient (cubic centimeters per gram) |
| $F_{oc}$ | = | Fraction organic carbon in soil (unitless)                              |

$F_{oc}$  was assumed to be 0.1, a value appropriate to soil used for the production of food crops (Cal/EPA 2003). If  $K_{oc}$  values are unavailable, they were estimated based on chemical-specific  $K_{ow}$  values using the following equation (Lyman and others 1990):

$$\text{Log } K_{oc} = \text{log } K_{ow} - 0.21 \quad (I-2)$$

Consistent with EPA guidance, a correction factor was applied to lipophilic COPCs (EPA 1998). For this HHRA, lipophilic chemicals were defined as PCBs, PAHs, pesticides, and semivolatile organic compounds. EPA (1998) recommends a correction factor of 0.01 for lipophilic COPCs (log  $K_{ow}$  greater than 4); that is, for lipophilic COPCs, the UF calculated using Equation I-1 should be multiplied by the correction factor of 0.01 to calculate a corrected UF. For COPCs with a log  $K_{ow}$  less than 4, EPA does not recommend use of a correction factor. Table I-3 lists the UFs for nonvolatile organic COPCs derived using the above equations and the values and sources of the chemical data used to derive the UFs.

Risks associated with VOCs were not evaluated in the homegrown produce pathway. VOCs are typically low-molecular-weight chemicals that do not persist or bioaccumulate in the environment (EPA 1994b). In addition, VOCs are expected to be lost during soil tilling, planting, and food preparation activities such as peeling, cooking, and cleaning.

## **I5.2 CHEMICAL INTAKE ESTIMATES**

Estimates of exposure are based on the EPCs (as described in Section I5.1) and scenario-specific assumptions and intake parameters. Consistent with EPA guidance (EPA 1995), exposure estimates (intakes) were calculated for an RME scenario for each receptor and exposure pathway and are expressed in terms of milligrams of chemical per kilogram body weight per day (mg/kg-day). The RME represents the highest exposure reasonably expected to occur and is calculated using the 95 UCL and the RME exposure parameters.

EPA-derived exposure algorithms were used to estimate the chemical intakes for each route of exposure. Equation I-3 is a generic equation for calculating chemical intake as follows (EPA 1989):

$$I = \frac{C \times CR \times EF \times ED}{BW \times AT} \quad (I-3)$$

where

|    |   |                                                                                                                                                                                                                                                                                                                                     |
|----|---|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| I  | = | Intake: the amount of chemical at the exchange boundary (mg/kg-day)                                                                                                                                                                                                                                                                 |
| C  | = | Chemical concentration: the EPC (for example, mg/kg for soil)                                                                                                                                                                                                                                                                       |
| CR | = | Contact rate: the amount of contaminated medium contacted per unit of time or event; may be the ingestion rate, inhalation rate, or dermal contact rate (for example, milligram per day for the ingestion rate of soil)                                                                                                             |
| EF | = | Exposure frequency: how often the exposure occurs (days per year)                                                                                                                                                                                                                                                                   |
| ED | = | Exposure duration: the number of years in which a receptor comes in contact with the contaminated medium (years)                                                                                                                                                                                                                    |
| BW | = | Body weight: the average body weight of the receptor over the exposure period (kilograms)                                                                                                                                                                                                                                           |
| AT | = | Averaging time: the period over which exposure is averaged (days); for carcinogens, the averaging time is 25,550 days on the basis of a lifetime exposure of 70 years (average life expectancy), and for noncarcinogens, the averaging time is equal to the exposure duration multiplied by the number of days in a year (365 days) |

Pathway-specific variations of Equation I-3 were used to calculate intakes of COPCs in soil for residential, industrial, recreational, and construction worker receptors, and COPCs in groundwater for construction worker receptors. [Tables I-4 through I-9](#) present the pathway-specific equations and receptor-specific exposure assumptions used to calculate intakes. The calculation of chemical intake for the dermal contact with soil exposure pathway (all receptors) requires chemical-specific dermal absorption factors; these factors are shown in [Table I-2](#). The calculation of chemical intake for the dermal contact with groundwater exposure pathway (construction worker) requires chemical-specific permeability constants; these factors are shown in [Table I-10](#).

Chemical intakes from groundwater exposure pathways for residential receptors (ingestion, inhalation during household use, and vapor intrusion) and industrial receptors (vapor intrusion) were not calculated because a risk-based screening assessment was used to quantify risks from exposure to COPCs in groundwater for these receptors (see [Section I7.2](#)).

## Section B5. Exposure Assessment

---

An exposure assessment identified potential human receptors that could come into contact with radiologically impacted areas, as well as the exposure routes, magnitude, frequency, and duration of the potential exposures. The principal objective of this evaluation is to identify reasonable maximum exposures (RMEs). As defined by [EPA \(1989\)](#), the RME is the maximum exposure that is reasonably expected to occur at a site. The potential human receptors and potentially complete exposure pathways for the identified receptors were presented in [Section B3](#), Conceptual Site Model. The remainder of this section describes the process used to estimate exposure point concentrations (EPCs) and to quantify pathway-specific RME radiological exposures for each receptor.

The nonradiological HHRA in the Revised Final Parcel E RI Report provides both total and incremental risk associated with chemical constituents ([Barajas & Associates, Inc., 2008](#)). To combine nonradiological risk and radiological risk, the same approach used in the RI Report to calculate chemical risk must be taken; namely, calculating total risk from ROCs inclusive of background and calculating incremental risk from the ROCs present at levels that do not include background. Consistent with EPA and Navy guidance, both total and incremental risk were evaluated.

### B5.1. EXPOSURE POINTS AND EXPOSURE POINT CONCENTRATIONS

Similar to the nonradiological HHRA, exposure points are identified based on anticipated population activity patterns and the relationship of the activities to the presence of contaminated media. For this radiological risk evaluation, each of the individual radiologically impacted sites for which data are available was considered a separate exposure point. Soil radiological data from each of the survey units collected during the Phase V investigation, along with data collected during the Phase I investigation, were grouped into individual data sets. The summary statistics for each radiologically impacted site for which data are available are presented in [Table B-4](#).

Sample locations that have been physically removed during the time-critical removal actions at IR-02 Northwest and Central, the IR-02 Southeast Metal Debris Reef Area, and the Polychlorinated Biphenyl Hot Spot Area were removed from each data set.

**B5.2. RESRAD**

Radiological dose and risk were estimated for each of the radiologically impacted sites for which data are available. Individual RESRAD runs were conducted for each site, using the maximum reported activity of each ROC evaluated during the Phase V and Phase I investigations. [Table B-5](#) presents the modeled dose and risk estimates for the receptors for each site, based upon anticipated reuse. For residential and recreational receptors, the risk values presented in [Table B-5](#) are the sum of the risk for the adult and child receptors, as carcinogenic risk is cumulative. The dose values presented are the higher of the adult and child receptors. The RESRAD modeling runs are presented in [Attachment B1](#). [Table B-6](#) presents the modeled dose and risk estimates for each site, based on residential reuse.

To estimate the incremental risk from impacted soil areas, background concentrations of the ROCs were subtracted from the maximum activity values. As indicated in [Section B4](#), sample results from the reference areas indicated mean background levels of 0.049 pCi/g for  $^{137}\text{Cs}$ , 0.818 pCi/g for  $^{226}\text{Ra}$ , and 0.18 pCi/g for  $^{90}\text{Sr}$ . To estimate the total radiological risk, the maximum activity values were used as the EPC, without subtracting the background values.

The current methodology for assessing risks from exposure to dioxins, furans, and dioxin-like PCBs involves application of TEFs to measured concentrations to calculate a toxicity equivalency quotient (TEQ), rather than use of TEFs to calculate adjusted cancer SFs. The uncertainties associated with the TEF methods applied in this HHRA on the risk results are discussed in [Section I9.6](#).

## **I6.5 LEAD**

No RfD or SF is currently available for evaluating health risks from exposure to lead. Therefore, the HHRA evaluated the potential for human health effects from exposure to lead by comparing EPCs for lead with (1) a HPS-specific risk-based concentration for lead for residential and recreational receptors and (2) the EPA Region 9 industrial PRG for lead for industrial and construction worker receptors. [Section I7.4](#) and [Attachment I6](#) detail the methodology used to evaluate lead.

## **I7.0 RISK CHARACTERIZATION METHODS**

The final step in this revised baseline HHRA is the characterization of the potential risks associated with exposure to COPCs. Risks from exposure to soil for all receptors and from construction worker exposure to groundwater were characterized using the methodology provided in [EPA \(1989\)](#) risk assessment guidance for Superfund sites; [Section I7.1](#) details this methodology. Risks from industrial and residential exposure to groundwater were characterized using a risk-based screening assessment approach; [Section I7.2](#) presents this methodology. [Section I7.3](#) discusses interpretation of hazard and risk levels. [Section I7.4](#) discusses the risk characterization approach for lead. The results of the risk characterization for Parcel E are presented in [Section I8.0](#).

### **I7.1 RISK CHARACTERIZATION FOR SOIL EXPOSURES AND CONSTRUCTION WORKER EXPOSURE TO GROUNDWATER**

The general methodology for estimating cancer risks and HIs for soil exposures for all receptors and construction worker exposure to groundwater follows the methodology provided in [EPA \(1989\)](#) guidance and is presented in [Section I7.1.1](#) for cancer risks and in [Section I7.1.2](#) for noncancer health hazards.

#### **I7.1.1 Characterization of Cancer Risks**

Risks associated with exposure to chemicals classified as carcinogens are estimated as the incremental probability that an individual will develop cancer over a lifetime as a direct result of an exposure ([EPA 1989](#)). The estimated risk is expressed as a unitless probability.

Three steps are used in estimating cancer risks for chemicals classified as carcinogens. First, the chemical intake is multiplied by the chemical-specific SF to derive a cancer risk estimate for a single chemical and pathway. The calculation is based on the following relationship:

$$\text{Chemical-Specific Cancer Risk} = \text{Intake (mg/kg-day)} \times \text{SF (mg/kg-day)}^{-1} \quad (\text{I-4})$$

Second, the individual chemical cancer risks are assumed to be additive to estimate the cancer risk associated with exposure to multiple carcinogens for a single exposure pathway, as follows:

$$\text{Pathway-Specific Cancer Risk} = \sum \text{Chemical-Specific Cancer Risk} \quad (\text{I-5})$$

Third, pathway-specific risks are summed for each receptor to estimate the total cancer risk. For exposures scenarios for which both an adult and child receptor are evaluated (that is, residential and recreational), the estimated cancer risk is based on the sum of the risk estimated for the adult receptor plus the child receptor. Hence, for the residential receptor, the estimated cancer risk is based on the sum of the risk estimated for the adult resident and the child resident. Likewise, for the recreational receptor, the estimated cancer risk is based on the sum of the risk estimated for the adult recreational user and the child recreational user.

### 17.1.2 Characterization of Noncancer Hazards

The potential for exposure that may result in adverse health effects other than cancer is evaluated by comparing the intake with an RfD for chemicals that are not classified as carcinogens and for those carcinogens known to cause adverse health effects other than cancer. A three-step approach is used as described below:

Calculate a chemical-specific hazard quotient (HQ) based on the following equation:

$$\text{Hazard Quotient} = \frac{\text{Intake (mg/kg-day)}}{\text{RfD (mg/kg-day)}} \quad (\text{I-6})$$

Next, sum the HQs for all chemicals to evaluate the potential for noncancer health effects from simultaneous exposure to multiple chemicals, yielding an HI as follows:

$$\text{Hazard Index} = \sum \text{HQ} \quad (\text{I-7})$$

Third, sum pathway-specific HIs to estimate a total HI for each receptor.

The total noncancer HI for the residential and recreational receptors is based on the total HI estimated for the child receptor because the intake for children of soil, groundwater, and air per unit body mass is higher (hence, noncancer HIs for a child receptor are always higher than noncancer HIs for an adult receptor for similar exposures).

## 17.2

### RISK CHARACTERIZATION FOR RESIDENTIAL AND INDUSTRIAL EXPOSURE TO GROUNDWATER

Residential and industrial receptors were evaluated for exposure to groundwater from vapor intrusion. Residential receptors were also evaluated for exposure to groundwater from domestic use. Based on agreement between the EPA, DTSC, and [Navy \(2004\)](#), the assessment of risks from these exposure pathways is based on a risk-based screening assessment.

The risk-based screening assessment is a streamlined approach that uses the ratio of EPCs to RBSLs. For this HHRA, the EPA Region 9 PRGs for tap water were used as RBSLs to calculate cancer risks and noncancer HIs from residential exposure to B-aquifer groundwater from domestic use ([EPA 2004a](#)). Screening levels for groundwater vapor intrusion were used to estimate cancer risks and HIs from residential and industrial exposure to A-aquifer groundwater ([EPA 2002a](#)). Both the EPA tap water PRGs and screening levels for groundwater vapor intrusion are risk-based concentrations that correspond to a cancer risk of 1E-06 or an HI of 1 based on standardized equations that combine standard exposure assumptions and EPA toxicity values.

The risk estimates developed using the risk-based screening approach represent the risk for all exposure pathways evaluated by the RBSLs (that is, the tap water PRGs and groundwater screening levels for groundwater vapor intrusion). These risk estimates are numerically equivalent to risk estimates obtained using the [EPA \(1989\)](#) “forward calculation methodology,” which involves calculating risks using contaminant concentrations, exposure assumptions, and toxicity values (see [Section I6.0](#)), if the exposure pathways and assumptions used to derive the RBSLs are the same as those used in the forward calculations.

The EPA tap water PRGs were used as RBSLs in this HHRA to evaluate domestic use of groundwater for the residential receptor ([EPA 2004a](#)). The tap water PRGs are used to evaluate residential exposure to groundwater from ingestion and from inhalation of VOCs released from groundwater to indoor air during household use. The PRGs do not account for exposure from dermal contact with groundwater; [Section I9.4](#) addresses the uncertainties associated with exclusion of this exposure pathway on the risk results.

Screening levels for groundwater vapor intrusion provided in Table 2c of EPA’s “Guidance for Evaluating the Vapor Intrusion to Indoor Air Pathway from Groundwater and Soils (Subsurface Vapor Intrusion Guidance)” ([EPA 2002a](#)) were used to evaluate cancer risks and noncancer hazards from groundwater vapor intrusion. The following factors were considered in the use of the [EPA \(2002a\)](#) screening levels for groundwater vapor intrusion in the risk-based screening assessment for groundwater:

- The screening levels provided in Table 2c of [EPA \(2002a\)](#) risk assessment guidance for Superfund sites are based on generic attenuation factors that assume minimum reduction of contaminant concentrations due to diffusive, advective, and other attenuating mechanisms. These conditions are similar to groundwater and soil conditions at HPS, where groundwater is relatively shallow and vadose zone soils are fairly coarse (see [Section 3.0](#) of the Revised Parcel E RI Report).
- The screening levels provided in Table 2c of [EPA \(2002a\)](#) risk assessment guidance for Superfund sites for some chemicals are based on federal maximum contaminant levels; for these chemicals, an RBSL was calculated following the methodology provided in [EPA \(2002a\)](#) guidance for deriving screening levels for vapor intrusion, and the calculated screening level was used in lieu of the maximum contaminant level.
- The screening levels provided in Table 2c of [EPA \(2002a\)](#) risk assessment guidance for Superfund sites are considered protective of residential exposure. For evaluation of industrial exposures, vapor intrusion screening levels were calculated using the methodology provided in [EPA \(2002a\)](#) guidance and the assumptions provided in [Table I-6](#) of this appendix for industrial worker exposure to air.

[Section I6.0](#) discusses the hierarchy toxicity criteria used in the HHRA; [Tables I-11 and I-12](#) list the toxicity criteria for each COPC. The [EPA \(2004a\)](#) Region 9 PRGs for tap water and [EPA \(2002a\)](#) screening levels for groundwater vapor intrusion were recalculated for this HHRA to be based on the same toxicity criteria listed in these tables; methodologies provided by [EPA \(2004a, 2002a\)](#) directives were used for the calculations. [Table I-13](#) lists the groundwater RBSLs used for this HHRA.

Cancer risks and noncancer hazards were calculated by comparing site EPCs of each COPC to the corresponding RBSL, as detailed in the following text.

### **I7.2.1 Characterization of Cancer Risks**

For COPCs that are carcinogens, the cancer risk associated with exposure to a single chemical is calculated as follows:

$$\text{Cancer risk} = (\text{EPC}/\text{RBSL}) \times 10^{-6} \quad (\text{I-8})$$

where:

|      |   |                                                           |
|------|---|-----------------------------------------------------------|
| EPC  | = | Exposure point concentration (microgram per liter [µg/L]) |
| RBSL | = | Risk-based screening level (µg/L)                         |

At a given exposure area, individuals may be exposed to more than one chemical. The total risk from exposure to multiple chemicals is calculated using the following equation:

$$\text{Total risk} = 10^{-6} \times \{EPC_1/RBSL_1 + EPC_2/RBSL_2 + \dots EPC_n/RBSL_n\} \quad (\text{I-9})$$

where:

Total risk = Total carcinogenic risk from exposure to all chemicals (unitless)

$EPC_n$  = Exposure point concentration of chemical  $n$  ( $\mu\text{g/L}$ )

$RBSL_n$  = RBSL for chemical  $n$  ( $\mu\text{g/L}$ )

### 17.2.2 Characterization of Noncancer Hazards

For COPCs not classified as carcinogens and for carcinogens known to cause adverse health effects other than cancer, the potential for receptors to develop adverse health effects is evaluated by comparing EPCs with noncancer RBSLs as follows:

$$\text{Hazard quotient} = EPC/RBSL \quad (\text{I-10})$$

where

EPC = Exposure point concentration ( $\mu\text{g/L}$ )

RBSL = Risk-based screening level ( $\mu\text{g/L}$ )

To evaluate the potential for noncancer effects from exposure to multiple chemicals, the HQs for all chemicals are summed, yielding an HI as follows:

$$\text{Hazard index} = EPC_1/RBSL_1 + EPC_2/RBSL_2 + \dots + EPC_n/RBSL_n \quad (\text{I-11})$$

where:

$EPC_n$  = Exposure point concentration of chemical  $n$  ( $\mu\text{g/L}$ )

$RBSL_n$  = RBSL for chemical  $n$  ( $\mu\text{g/L}$ )

## 17.3 INTERPRETATION OF HAZARD AND RISK LEVELS

EPA guidance on exposure levels considered protective of human health is presented to aid in the interpretation of the results of the risk assessment. In the National Oil and Hazardous Substances Pollution Contingency Plan, EPA defined general remedial action goals for sites on the National Priorities List (Title 40 of the *Code of Federal Regulations* Part 300.430). The goals include a range for residual cancer risk, which is “an excess upper-bound lifetime cancer risk to an individual of between  $10^{-4}$  and  $10^{-6}$ ,” or 1 in 10,000 to 1 in 1,000,000. The goals set

out in the National Oil and Hazardous Substances Pollution Contingency Plan are applied once a decision to remediate a site has been made. A more recent EPA directive provides additional guidance on the role of the HHRA in supporting risk management decisions, and in particular, determining if remedial action is necessary (EPA 1991). Specifically, the guidance states, “Where cumulative carcinogenic risk to an individual based on reasonable maximum exposure for both current and future land use is less than  $10^{-4}$ , and the noncancer HQ is less than 1, action generally is not warranted unless there are adverse environmental impacts.” EPA Region 9 has stated, however, that action may be taken to address risks between  $10^{-4}$  and  $10^{-6}$ . In addition, DTSC has stated that it considers  $1E-06$  as the point of departure for risk management decisions. To be protective of human health, the BCT has chosen to use  $10^{-6}$ , the lower end of the residual  $10^{-4}$  to  $10^{-6}$  risk range set out in the National Oil and Hazardous Substances Pollution Contingency Plan, as a threshold level for cancer risks for HPS.

An HI of less than 1.0 indicates that adverse noncancer health effects are not expected. In accordance with EPA guidance (EPA 1989), the HHRA further evaluated exposure areas with total HIs that exceeded 1. Noncancer health effects associated with exposure to multiple COPCs may not be cumulative if the COPCs affect different target organs or systems within the body. Therefore, for exposure areas with HI values that exceeded 1 based on the summed HIs from multiple COPCs, the HHRA segregates the HI by target organ or system and assumes that the potential for noncancer health effects exists only if the highest total segregated HI for a target organ or system exceeded 1. Table I-14 identifies the target organs affected by each COPC for Parcel E; this information was used, as necessary, to segregate HIs by target organ. Information on target organs was obtained from Integrated Risk Information System (EPA 2005), Health Effects Assessment Summary Tables (EPA 1997), Provisional Peer-Reviewed Toxicity Values database (EPA 2004c), and the Agency for Toxic Substances and Disease Registry (2005).

#### **17.4 EVALUATION OF LEAD**

The HHRA evaluated the potential for human health effects from exposure to lead by comparing EPCs for lead with an HPS-specific risk-based concentration for lead (155 mg/kg) for residential and recreational receptors and the EPA (2004a) Region 9 industrial PRG for lead (800 mg/kg) for industrial and construction worker receptors. The HPS risk-based concentration for lead was developed using the Cal/EPA (1999b) LeadSpread model and EPA’s Integrated Exposure Uptake Biokinetic model. The methodology for development of the HPS risk-based concentration for lead is presented in Attachment I6 to this appendix. The Region 9 industrial PRG for lead was developed by EPA using EPA’s adult lead model (EPA 1996). These models are designed to predict the soil lead concentration associated with a target blood lead level of 10 micrograms per deciliter, the EPA threshold level of concern (EPA 1994a). Adverse health effects are not expected to occur from exposure to lead below the risk-based concentration or PRG.

|    |                               |               |                                                                                                                                                                                                                                                                                                                                                                                  |

## I9.0 UNCERTAINTY ANALYSIS

Varying degrees of uncertainty at each stage of the HHRA arise from assumptions made in the risk assessment and the limitations of the data used to calculate risks. Uncertainty and variability are also inherent in the exposure assessment, toxicity values, and risk characterization. [Table I-25](#) lists both general and site-specific uncertainties associated with this HHRA.

The effect of uncertainties is overestimation or underestimation of the actual cancer risk or HI. In general, the risk assessment process is based on use of conservative (health-protective) assumptions that when combined, are intended to overestimate the actual risk. However, a small possibility exists that risks were underestimated.

The remainder of this discussion focuses on the following uncertainties specific to this HHRA:

- The influence of metals in soil at or below ambient levels on this HHRA
- Use of a SF for TCE developed by Cal/EPA, rather than the EPA provisional SF for TCE
- Assumption that the exposure area for groundwater vapor intrusion risks is consistent with the risk plume boundaries delineated for groundwater COPCs
- Dermal contact with groundwater for the residential exposure scenario
- Use of generic, non-site-specific RBSLs to calculate risks from groundwater vapor intrusion
- Risk estimates for exposure to dioxins, furans, and dioxin-like PCBs

### I9.1 METALS IN SOIL BELOW AMBIENT LEVELS

To account for the contribution of naturally occurring concentrations of metals at HPS, both total risks and incremental risks were assessed for exposure to soil. The total risk evaluation for soil included all chemicals regardless of concentration, except for the essential nutrients calcium, magnesium, potassium, and sodium. For the incremental risk evaluation, the above essential nutrients and metals with maximum measured concentrations below HPALs were excluded as COPCs.

The differences in risk and hazard results between the total risk evaluation and the incremental risk evaluation are attributed to the risks and hazards associated with ambient levels of metals at HPS. At ambient concentrations (that is, HPALs), some metals at HPS are associated with cancer risks exceeding 1E-06 and noncancer hazards exceeding 1.0. [Table I-26](#) presents the cancer risks and noncancer hazards associated with exposure to metals at concentrations equal to

HPALs; risks and hazards are presented in this table for each of the exposure scenarios associated with planned reuse (residential, industrial, recreational). As shown in [Table I-26](#), the contribution of ambient levels of metals to cancer risk and HI estimates is significant. For example, the cancer risk associated with residential exposure to arsenic at a concentration equal to the HPAL for arsenic (11.1 mg/kg) is 2.9E-04. The HI associated with residential exposure to manganese at a concentration equal to the HPAL for manganese (1,431 mg/kg) is 1.7. Collectively, all metals at ambient levels contribute to a cancer risk of 3E-04 for a residential receptor, and 3E-05 for industrial and recreational receptors. For noncancer hazards, metals at ambient levels collectively contribute to an HI of 11 for residential receptors, 0.2 for industrial receptors, and 0.7 for recreational receptors.

This evaluation of risks and hazards associated with metals at concentrations equivalent to HPALs shows that the total risk evaluation, which includes metals present at concentrations at or below HPALs, likely overestimates risks and hazards associated with Navy releases of chemicals. This is because of the presence of these metals at concentrations at or below HPALs in many exposure areas at Parcel E. While the incremental risk evaluation excludes risks and hazards from metals for which maximum concentrations do not exceed HPALs, the results of the incremental evaluation should be considered with the information contained in [Table I-26](#), as the contribution of ambient levels to risks and hazards at HPS is significant for some metals.

## **I9.2 SLOPE FACTOR FOR TRICHLOROETHENE**

As discussed in [Section I6.0](#), the provisional cancer SFs derived by EPA (2001) for TCE, although more conservative than the SFs derived by Cal/EPA, were not used in the HHRA. The draft risk assessment that is the basis for the provisional EPA SFs for TCE is being reviewed currently by the National Academy of Sciences, and as such, does not represent EPA policy. For this HHRA, the SFs developed by Cal/EPA were used to evaluate cancer risks from exposure to TCE. Uncertainties specific to the provisional cancer SFs for TCE were analyzed in this HHRA because the difference between the provisional SFs for TCE and the Cal/EPA SFs for TCE is significant, and can affect the risk results. [Attachment I7](#) contains a detailed discussion of the uncertainties associated with the SFs for TCE.

## **I9.3 BOUNDARIES FOR VAPOR INTRUSION RISKS**

As discussed in [Section I4.3.2](#), risk plume boundaries for evaluation of groundwater vapor intrusion were established based on delineation of volatile COPCs in the A-aquifer to nondetectable (below reporting limit) levels, and vapor intrusion risks were applied to each residential and industrial grid encompassed by the boundaries of the risk plumes. This approach assumes that the exposure area for groundwater vapor intrusion risks is consistent with the risk plume boundaries; however, EPA states that it is reasonable to assume that subsurface vapors may migrate laterally up to 100 feet ([EPA 2002a](#)). [Figure I-8](#) portrays the potential lateral extent, or 100-foot “inhalation risk buffer zone” to which the groundwater vapor intrusion risks calculated for Parcel E may extend. In this figure, the risk plume boundaries delineated in [Section I4.3.2](#) were expanded laterally in each direction by 100 feet to account for the distance

that vapors may travel laterally from a groundwater source. This inhalation risk buffer zone was also applied to non-plume well locations with volatile COPCs (see [Figure I-8](#)).

Preferential pathways, which consist of utility conduits, subsurface drains, and buried pipelines that intersect vapor sources or vapor migration pathways, may allow subsurface vapors to migrate more than 100 feet laterally ([EPA 2002a](#)). These preferential pathways are considered significant if they are associated with a high gas permeability and are of sufficient volume and proximity to a building such that the pathways may influence vapor intrusion into the building ([EPA 2002a](#)). [Figure I-9](#) shows the subsurface utilities at Parcel E; these utilities may influence the extent to which subsurface vapors may migrate beyond the 100-foot inhalation risk buffer zone depicted in [Figure I-8](#).

#### **I9.4 DERMAL CONTACT WITH GROUNDWATER FOR RESIDENTIAL SCENARIO**

As discussed in [Section I7.2](#), tap water PRGs were used in this HHRA to evaluate domestic use of groundwater for the residential receptor. The tap water PRGs are used to evaluate residential exposure to groundwater from ingestion and from inhalation of VOCs released from groundwater to indoor air during household use. The tap water PRGs are limited to an assessment of exposure to groundwater from the oral and inhalation exposure pathways, and do not account for exposure from the dermal exposure pathway.

To address the uncertainties associated with exclusion of the dermal exposure pathway on the risk results for residential domestic use of groundwater, the potential for intake of COPCs from the dermal exposure pathway relative to intake of COPCs from the oral exposure pathway was evaluated using information provided in [EPA \(2004d\)](#) guidance on the relative percentage of dermal exposure compared to oral exposures for non-volatile COPCs. This information is presented in the table below for the non-volatile COPCs identified for the B-aquifer. In this table, exposure from the oral route is represented by ingestion of two liters of water per day ([EPA 2004d](#)). Although several volatile COPCs were identified for the B-aquifer, partitioning risks between oral and dermal exposures for volatile COPCs is not necessary because the tap water PRGs account for the inhalation route of exposure. Non-volatile COPCs for the B-aquifer were limited to metals. Information was not available for several metals identified as COPCs for the B-aquifer (aluminum, cobalt, iron, molybdenum, and zinc).

| Chemical of Potential Concern | Dermal/Oral (%)* | Chemical of Potential Concern | Dermal/Oral (%)* |
|-------------------------------|------------------|-------------------------------|------------------|
| Antimony                      | 3.5              | Manganese                     | 8.8              |
| Arsenic                       | 0.55             | Nickel                        | 2.6              |
| Barium                        | 7.5              | Selenium                      | 1.8              |
| Cadmium                       | 10.5             | Thallium                      | 0.52             |
| Chromium                      | 40               | Vanadium                      | 20               |
| Copper                        | 0.92             |                               |                  |

Source: [EPA \(2004d\)](#)

This evaluation above shows that risks from exposure to groundwater in the B-aquifer, which were calculated using a risk-based screening assessment and EPA Region 9 tap water PRGs, may be slightly to moderately underestimated for some metals in the B-aquifer (from 0.52 for thallium to 40 percent for chromium). However, the effect of this underestimate is not significant because the overall cancer risk and noncancer HI for domestic use of groundwater in the B-aquifer were found to exceed the risk and hazards thresholds of 1E-06 and 1.0, respectively, for each of the three B-aquifer groundwater plumes and the three nonplume exposure areas.

## **19.5 SCREENING LEVELS FOR GROUNDWATER VAPOR INTRUSION**

Based on agreements between the EPA, DTSC, and [Navy \(2004\)](#), the generic RBSLs provided in Table 2c of [EPA \(2002a\)](#) guidance for evaluating vapor intrusion were used in this HHRA to calculate risks for the groundwater vapor intrusion exposure pathway. This approach was used in lieu of site-specific modeling with the [Johnson-Ettinger \(1991\)](#) vapor model because the [EPA \(2002a\)](#) model assumptions (such as depth to groundwater and soil physical properties) used to calculate the generic screening criteria are similar to the properties of soil and groundwater at HPS. Site conditions at HPS (shallow depth to groundwater and coarse soils; see [Section 2.0](#) of the Revised Parcel E RI Report) do not differ significantly enough from conditions assumed for the generic screening values to warrant detailed modeling using the Johnson-Ettinger model.

To evaluate whether use of the generic values would represent conditions at HPS and would not result in a significant overestimate of potential risks, the Navy evaluated risks from vapor intrusion for selected groundwater risk plumes at HPS using both generic [EPA \(2002a\)](#) risk-based screening values for vapor intrusion and site-specific modeling. The results of this evaluation showed that risks calculated ratiometrically using generic EPA risk-based vapor intrusion screening values are comparable to site-specific risks calculated using the Johnson-Ettinger model adjusted for HPS-specific values for depth to groundwater and physical properties of the soil. Risks calculated using the generic EPA screening values were higher than modeled results by approximately a factor of two. The difference results from an assumed basement exposure scenario in the generic EPA screening values, whereas the modeled results were based on a slab-on-grade exposure scenario because of the shallow depth to groundwater at HPS (roughly 7 to 8 feet bgs). This difference is not considered significant for risk results, which are represented by order-of-magnitude estimates.

## **19.6 RISK ESTIMATES FOR EXPOSURE TO DIOXINS, FURANS, AND DIOXIN-LIKE POLYCHLORINATED BIPHENYLS**

The HHRA for Parcel E used TEFs for 2,3,7,8-TCDD to calculate adjusted cancer SFs for each dioxin-like compound identified as a COPC for Parcel E. Risks were estimated separately for each dioxin-like COPC, using the TEF-adjusted cancer SFs. Additionally, dioxin-like COCs were identified separately, based on the individual risk results for dioxin-like COPCs. As discussed in [Section I6.4](#), the current method for assessing risks from exposure to dioxin mixtures involves calculating a TEQ-based EPC by multiplying measured concentrations for

individual dioxin-like compounds with respective TEFs that relate the toxicity of the individual dioxin-like compound to 2,3,7,8-TCDD. The TEF-adjusted concentrations are then summed to calculate a TEQ for 2,3,7,8-TCDD, which is evaluated in risk calculations as a single dioxin compound. The primary difference between the method used in the HHRA for Parcel E and the current method for assessing exposure to dioxin-like compounds is that the HHRA method evaluated dioxin-like COPCs as individual compounds, while the current method evaluates dioxin-like COPCs as a single compound.

To address the uncertainties associated with the TEF method used in the HHRA for Parcel E, the Navy further evaluated risk results for exposure areas with dioxin-like COPCs. Detections of dioxin-like COPCs were confined to the soil exposure medium; 31 exposure areas (grids) for soil were associated with dioxin-like COPCs. Dioxin-like COCs were identified for two of these exposure areas (grid AN38 and grid BG36); remedial alternatives for dioxin-like compounds detected in these grids will be addressed in the feasibility study for Parcel E. For the remaining 29 grids with dioxin-like COPCs, it is possible that risks for dioxin-like compounds (that is, 2,3,7,8-TCDD) may have been underestimated by assessing risks for each compound individually. As part of this analysis of uncertainties, risk results for all of the dioxin-like COPCs in each the 29 remaining grids were summed to calculate a summed dioxin risk for each grid. None of the summed dioxin risks for the 29 grids exceeds  $1\text{E-}06$ , the cancer risk level at which a COPC is identified as a COC (that is, a chemical that is targeted for evaluation of remediation alternatives in the feasibility study). Therefore, although the method used to evaluate dioxin-like COPCs for Parcel E may have resulted in an overall underestimate of risk for dioxin-like compounds, the underestimate is not considered significant, relative to the identification of COCs for Parcel E.

## Section B7. Uncertainty Analysis

Any comprehensive risk analysis must also consider the effects of uncertainty on input parameters. This analysis is no different; however, rather than perform explicit uncertainty analyses, which would have required countless additional RESRAD runs, an approach was taken that minimized the need for additional modeling computations. Nuclear Regulatory Commission Regulation (NUREG)-6697 ([NRC, 2000](#)) was used as the basis for the uncertainty analysis.

One of the primary purposes of NUREG-6697 was to study the effect of various parameter distributions on the final results of RESRAD analyses. RESRAD is a mathematical model that simplifies complex physical, ecological, dosimetric, and human processes. RESRAD requires finite input parameters that represent current and future site conditions. However, most site characteristics (such as hydrogeological and geochemical properties) are not accurately represented by a single input value; most physical characteristics vary across a site. In addition, it is difficult to obtain sufficient data to completely characterize site-specific radionuclide transport and exposure processes and to predict future site conditions and human occupancy factors. Therefore, many of the RESRAD input parameters selected during the modeling process are averages, estimates, or default values.

Because the accuracy of modeled results depends upon the accuracy of the input parameters, risk results derived from RESRAD will contain inherent uncertainties based on the assumptions used in choosing the input parameters. Where default or estimated values are used, the modeled results may not accurately represent the actual physical conditions of the site or the future land use scenarios. To limit this uncertainty and ensure health protective results for the Parcel E radiological risk assessment, input parameters for physical processes and occupancy were chosen based on conservative assumptions; these parameters are discussed in [Section B2.1](#). The uncertainty associated with some of the significant inputs to RESRAD is discussed below.

The RESRAD modeling is based on the radiological data collected during the Phase I and Phase V investigations. The data collected during those investigations were analyzed to meet acceptance criteria (such as minimum detectable activities) that were based on the release criteria current at the time the investigations were performed; however, the current release criteria for certain ROCs are more conservative. The most notable example is  $^{226}\text{Ra}$ , for which the release criterion at the time of the Phase V investigation was 5 pCi/g. The current release criterion for  $^{226}\text{Ra}$  is 1 pCi/g above background

(the background  $^{226}\text{Ra}$  level for the Phase V investigation was 0.82 pCi/g). Because of the differences in release criteria, the accuracy of the data for certain ROCs may not meet current acceptance criteria and results in some degree of uncertainty for the risk screening analysis. However, the degree of uncertainty is acceptable for the risk screening analysis because the analysis was only intended to provide a general estimate of radiological risks for ROCs that, in the case of  $^{226}\text{Ra}$ , were known to consistently exceed current release criteria and warrant analysis of remedial alternatives in the FS.

The RESRAD default cover material density was used for all analyses performed. The default was designed to be representative of the body of soil types. In reality, existing asphalt and concrete covers would have a greater density than the default soil value. The specific density is dependent upon the asphalt-laying process. By underestimating the density of asphalt, a certain measure of conservatism has been built into the results presented in this appendix. It is therefore reasonable to assume that any uncertainty associated with the cover material density is minimal and a full uncertainty analysis for a range of cover material densities is not necessary.

Construction worker exposure to the A-aquifer includes exposure to both volatile and nonvolatile chemicals. Although the risk plumes delineated in the A-aquifer were based on volatile chemicals, all detected chemicals (volatile and nonvolatile) within the delineated boundaries of the risk plume were included for evaluation of construction worker exposure. Chemical concentrations detected at some groundwater sampling locations at Parcel E were not associated with risk plumes; as a result, these nonplume-based locations were evaluated on a grid-basis, using the same grid system that was used in the HHRA to evaluate soil exposures as an efficient mechanism to locate each nonplume exposure area for the HHRA.

Chemical plumes are not present in the B-aquifer at Parcel E; however, risk plume boundaries delineated for the A-aquifer were extrapolated vertically and applied to the B-aquifer as part of this HHRA. Since the delineated A-aquifer risk plumes represent worst-case scenarios of groundwater contamination, and since contaminant plumes have not been identified in the B-aquifer at Parcel E, the extrapolated boundaries of the B-aquifer are conservative and likely represent larger areas than present-day conditions warrant. Extrapolation of the boundaries of the A-aquifer risk plumes to the B-aquifer was based on meetings between with EPA, DTSC, and the Navy in 2003 and 2004. The extrapolated plume boundaries were used to represent exposure areas for the B-aquifer for the residential domestic use evaluation. Of the eight risk plumes delineated for the A-aquifer, boundaries for three of the risk plumes (IR-02, IR-03, and Building 406) were extrapolated to the B-aquifer. The boundaries for the remaining risk plumes in the A-aquifer were not extrapolated to the B-aquifer because the B-aquifer is not present in those risk plume areas. Similar to the approach used for the A-aquifer, chemical concentrations detected at groundwater sampling locations in the B-aquifer at Parcel E that fell outside of the extrapolated plume boundaries were evaluated as non-plume exposure areas, using the exposure area grids established for soil.

The risk plumes reflect a worst-case scenario of groundwater contamination because the methodology used to delineate risk plumes includes historical data over 10 years old. [Figures 4-3 through 4-6](#) show the 2004 plume boundaries for metals, VOCs, pesticides, and PCBs and TPH. The lateral extent of 2004 plumes at Parcel E is smaller than the extent of the risk plumes evaluated in the HHRA; likewise, concentrations of volatile chemicals are less than the concentrations evaluated in the HHRA (see [Section 4.1.2.3](#)).

### 5.1.2 Total and Incremental Risks for Soil Exposure

Both total and incremental risks were evaluated for exposure to soil at Parcel E. For the total risk evaluation, all detected chemicals were included as COPCs regardless of concentration, except for the essential nutrients calcium, magnesium, potassium, and sodium. The total risk evaluation provides an estimate of the risks posed by all chemicals at Parcel E, including those present at concentrations at or below ambient levels. For the incremental risk evaluation, the above essential nutrients and metals with maximum detected concentrations below HPALs were excluded as COPCs. The incremental risk evaluation provides an estimate of risks posed by all chemicals at Parcel E, except those that do not exceed ambient levels.

No toxicity criteria are currently available for evaluating health risks from exposure to lead. Therefore, specific cancer risk or noncancer hazard results for lead were assessed by comparing exposure point concentrations (EPC) for lead with (1) a HPS-specific risk-based concentration for lead (155 mg/kg) for residential and recreational receptors and (2) the EPA Region 9 industrial preliminary remediation goal for lead (800 mg/kg) for industrial and construction worker receptors.

### **5.1.3 Soil Risk Summary**

This section summarizes the results of the total and incremental risk evaluations for soil based on planned reuse.

#### **5.1.3.1 Total Risk Evaluation**

For the total risk evaluation, risks from residential and industrial exposure to COPCs in soil were assessed for both surface soil (0 to 2 feet bgs) and subsurface soil (0 to 10 feet bgs). The evaluation of recreational and construction worker exposures to COPCs in soil were limited to surface and subsurface soil, respectively. [Figures 5-2 and 5-3](#) summarize the total risk results for surface and subsurface soil, respectively, at each risk grid based on the planned reuse of the redevelopment block associated with each grid. [Figure 5-4](#) summarizes the total risk results for construction worker exposure to soil at each risk grid. Results for each grid are shown relative to the cancer risk threshold of 1E-06, the highest segregated noncancer hazard index (HI) of 1.0, and the HPS risk-based concentration for lead (155 mg/kg for residential and recreational receptors, and 800 mg/kg for industrial and construction worker receptors). [Tables 5-2, 5-3, and 5-4](#) present the specific calculated total cancer risk and noncancer HI results for each grid.

The risk results shown in the above-referenced figures and tables represent total risk; that is, all detected chemicals not considered to be essential human nutrients were included in the total risk evaluation. Risks were assessed for 141 grids in the industrial reuse areas, 103 grids in the residential reuse areas, and 46 grids in the open space reuse areas. Results of the total risk evaluation showed that of these grids, 134 grids in the industrial reuse areas, 99 grids in the residential reuse areas, and 44 grids in the open space reuse areas exceeded the cancer risk threshold of 1E-06 or the noncancer threshold HI of 1.0. For the construction worker exposure scenario, risks were assessed for 227 grids; 207 of these grids exceeded the cancer risk threshold of 1E-06 or the noncancer threshold HI of 1.0.

[Tables 5-5, 5-6, and 5-7](#) present a risk characterization analysis for each grid for which the total cancer risk or segregated noncancer HI exceeds thresholds. For each of these grids, the tables identify the COCs (that is, the chemicals for which the chemical-specific cancer risk exceeds 1E-06 or the highest segregated HI exceeds 1.0) and show the percent contribution of the COCs to the calculated total risks and hazards for each exposure pathway evaluated.

The following chemicals are identified as COCs in at least one grid based on planned reuse and results of the total risk evaluation for soil.

| Exposure Scenario         | Chemicals of Concern in Surface Soil (0 to 2 feet bgs), Total Risk                                                                                                                                       |                                                                                                                                           | Chemicals of Concern in Subsurface Soil (0 to 10 feet bgs), Total Risk                                                                                                                                                                                                    |                                                                                                                                                                                                                        |

Notes:

a COCs identified for this exposure scenario are based on the planned reuse for Parcel E.

b The construction worker exposure scenario is not associated with a specific planned reuse for Parcel E. Based on agreement with the BCT, evaluation of construction worker exposure to soil was based on subsurface soil from 0 to 10 feet bgs; this depth range includes surface soil (0 to 2 feet bgs) exposure.

HPCDD Heptachlorodibenzo-p-dioxin

HXCDF Hexachlorodibenzofuran

PECDD Pentachlorodibenzo-p-dioxin

Of these chemicals, the following most frequently occur as COCs for each exposure scenario for the total risk evaluation:

- For industrial exposure (industrial and maritime industrial reuse areas), arsenic and PAHs (primarily benzo[a]pyrene) were the most frequently occurring COCs. Arsenic was a COC in 93 percent of the grids evaluated, and the PAH benzo(a)pyrene was a COC in 33 percent the grids evaluated.
- For residential exposure (mixed-use and research and development reuse areas), metals (arsenic, iron, manganese, nickel, and vanadium) were identified as COCs in most of the grids evaluated. Arsenic was identified as a COC in 73 percent of the grids evaluated, iron in 93 percent, manganese in 63 percent, nickel in 86 percent, and vanadium in 58 percent.
- For recreational exposure (open space reuse areas), arsenic, benzo(a)pyrene, lead, and Aroclor-1260 were COCs in over 40 percent of the grids evaluated.
- For construction worker exposure (evaluated parcel-wide), arsenic was identified as a COC in 93 percent of the grids evaluated. Lead, PAHs, and PCBs were also identified as COCs in approximately 10 to 15 percent of the grids evaluated.

#### **5.1.3.2 Incremental Risk Evaluation**

For the incremental risk evaluation, risks from residential and industrial exposure to COCs in soil were assessed for both surface soil (0 to 2 feet bgs) and subsurface soil (0 to 10 feet bgs). The evaluation of recreational and construction worker exposures to COCs in soil was limited to surface and subsurface soil, respectively. [Figures 5-5 and 5-6](#) summarize the incremental risk results for surface and subsurface soil, respectively, at each grid based on the planned reuse of the redevelopment block associated with each grid. [Figure 5-7](#) summarizes the incremental risk results for construction worker exposure to soil at each grid. [Tables 5-8, 5-9, and 5-10](#) list the incremental cancer risk and noncancer HI results calculated for each grid.

The risk results shown in the above-referenced figures and tables represent incremental risk; that is, all detected chemicals except essential human nutrients and metals below HPALs were included in the risk evaluation. Risks were assessed for 141 grids in the industrial reuse areas, 103 grids in the residential reuse areas, and 46 grids in the open space reuse areas. Results of the incremental risk evaluation showed that of these grids, 71 grids in the industrial reuse areas, 53 grids in the residential reuse areas, and 37 grids in the open space reuse areas exceeded the cancer risk threshold of 1E-06 or the noncancer threshold HI of 1.0. For the construction worker exposure scenario, risks were assessed for 227 grids; of these grids, 108 exceeded the cancer risk threshold of 1E-06 or the noncancer threshold HI of 1.0. Compared to the total risk evaluation for soil, under the incremental risk evaluation, there is on average a 43 percent reduction in the number of exposure areas at Parcel E that exceed the cancer risk threshold of 1E-06 or the noncancer threshold HI of 1.0 (based on highest segregated HI) for the planned reuses of Parcel E.

Tables 5-11, 5-12, and 5-13 present a risk characterization analysis for those grids for which the total cancer risk or segregated noncancer HI exceeded thresholds. For each of these grids, the tables identify the COCs and present their contribution to the calculated incremental risks and hazards for each potentially complete exposure pathway.

The following chemicals were identified as COCs in at least one grid based on planned reuse and results of the incremental risk evaluation for soil.

| Exposure Scenario         | Chemicals of Concern in Surface Soil (0 to 2 feet bgs), Incremental Risk                                                                                                                       |                                                                                                                                           | Chemicals of Concern in Subsurface Soil (0 to 10 feet bgs), Incremental Risk                                                                                                                                                                            |                                                                                                                                                                                                                                        |

Notes:

a COCs identified for this exposure scenario are based on the planned reuse for Parcel E.

b The construction worker exposure scenario is not associated with a specific planned reuse for Parcel E. Based on discussion with the BCT, evaluation of construction worker exposure to soil was based on subsurface soil from 0 to 10 feet bgs; this depth range includes surface soil (0 to 2 feet bgs) exposure.

Of these chemicals, the following most frequently occur as COCs for each exposure scenario for the incremental risk evaluation:

- For industrial exposure (industrial and maritime industrial reuse areas), arsenic and PAHs (primarily benzo[a]pyrene) occur as COCs in approximately 33 percent of the grids evaluated.
- For residential exposure (mixed-use and research and development reuse areas), arsenic is a COC in 15 percent of the grids evaluated and manganese is a COC in 29 percent of the grids evaluated.
- For recreational exposure (open space reuse areas), arsenic, lead, and benzo(a)pyrene, were COCs in over 30 percent of the grids evaluated.
- For construction worker exposure (evaluated parcel-wide), arsenic was identified as a COC in 40 percent of the grids evaluated. Lead, PAHs, and PCBs were also identified as COCs in approximately 10 to 15 percent of the grids evaluated.

#### 5.1.4 Groundwater Risk Summary

Risks from exposure to COPCs in groundwater were assessed for the A- and B-aquifers. [Figure 5-8](#) summarizes the risk results for industrial and residential exposure to the A-aquifer from vapor intrusion for each of the identified risk plumes and nonplume exposure, based on the planned reuse for each redevelopment block. [Figure 5-9](#) summarizes the risk results for residential domestic use of groundwater in the B-aquifer. [Figure 5-10](#) summarizes the risk results for construction worker exposure to groundwater in the A-aquifer. Results in these figures are shown relative to the cancer risk threshold of 1E-06 and highest segregated noncancer HI of 1.0.

[Tables 5-14 and 5-15](#) present a risk characterization analysis for those exposure areas in the A-aquifer for which the cancer risk exceeded 1E-06 or the highest segregated HI exceeded 1.0 for the exposure scenarios associated with planned reuse and the construction worker scenario, respectively. These tables identify the groundwater COCs associated with each Parcel E risk plume and the percent contribution of each COC to the total cancer risk and HI calculated for each plume. Exposure areas in the A-aquifer not associated with risk plumes with COCs are shown in [Tables 5-14 and 5-15](#). The following chemicals were identified as COCs in groundwater in the A-aquifer based on planned reuse.

| Exposure Scenario         | Chemicals of Concern in A-Aquifer Groundwater                                                                  |                                                                                   |

| Residential <sup>a</sup>  | 1,1-DCA<br>1,4-DCB<br>Benzene<br>Chloroform                                                                    | Isopropylbenzene<br>Naphthalene<br>PCE<br>TCE                                     |

planned for mixed use, which may include residential reuse; and the recreational receptor is evaluated for redevelopment blocks planned for open space reuse. These receptors are consistent with the 2010 redevelopment plan (SFRA, 2010b). In addition, a residential scenario was also evaluated for the entire parcel. While residential reuse of the entire parcel is not planned, the residential exposure scenario presents an upper-bound risk estimation from exposure to ROCs at the parcel.

Both direct exposure pathways (external radiation) and indirect exposure pathways (inhalation and soil ingestion) are evaluated.

The goal of the RESRAD risk modeling approach was to be as consistent as possible with assumptions and inputs used in the nonradiological HHRA in the Revised RI Report. To achieve this goal, development of representative parameters for receptor scenarios other than the RESRAD default was required. This development was achieved by following guidance from EPA; specifically, “Exposure Factors Handbook” and the “Risk Assessment Guidance for Superfund (RAGS)” (EPA, 1989 and 1997b). The guidance was also used to develop input parameters for the nonradiological HHRA in the Revised RI Report. Receptor-specific RESRAD values were selected from the guidance for industrial workers, residents, and recreational users. To achieve the best correlation with site-specific agreements, it was necessary to adjust each of the parameters based on receptor-specific information. The parameters used in the RESRAD modeling, along with the basis for each, are discussed in detail in [Appendix B](#).

### 2.5.2. Total and Incremental Dose and Risk Calculation Methodology and Results

Radiological dose and risk were estimated for each of the radiologically impacted areas for which data are available. For each area, RESRAD modeling was conducted based upon the maximum reported activity for each ROC. To estimate the incremental risk from impacted areas, background concentrations of the ROCs were subtracted from the maximum reported activity levels. If the background activity exceeded the maximum reported activity for a given ROC, the ROC was not modeled in the incremental risk calculations. To estimate the total radiological risk, the maximum activity values were used as the exposure point concentration, without subtracting the background values. The exposure point concentrations used to calculate the radiological risk are presented in [Table 5](#), along with the minimum, maximum, and mean activities for each ROC within each radiologically impacted area.

Total and incremental risk results are presented in [Table 6](#). The total and incremental risk results presented in [Table 6](#) are provided for both (1) planned reuse and (2) residential reuse across the entire parcel. The RESRAD incremental risk estimates for planned reuse are summarized as follows:

- For the residential exposure scenario, incremental radiological risk estimates ranged from 2E-05 (Building 529 Site) to 7E-03 (Building 707 Triangle Area)
- For the recreational user exposure scenario, incremental radiological risk estimates ranged from 5E-08 (Building 509 Site) to 7E-03 (IR-02 Southeast).

The RESRAD total risk estimates for planned reuse are summarized as follows:

- For the residential exposure scenario, total radiological risk estimates ranged from 2E-04 (Building 508 Site) to 7E-03 (Building 707 Triangle Area)
- For the recreational user exposure scenario, total radiological risk estimates ranged from 2E-07 (Building 509 Site) to 7E-03 (IR-02 Southeast).

### 2.5.3. Combined Chemical and Radiological Risk

Estimates of the lifetime risk of cancer to exposed individuals resulting from radiological and chemical risk assessments may be summed to determine the overall potential human health hazard associated with a site (EPA, 1989). To combine the chemical risk and radiological risk, the same approach used in the Parcel E Revised RI Report to calculate chemical risk must be taken; namely, calculating total risk from ROCs inclusive of background and calculating incremental risk from the ROCs present at activity levels that do not include background.

Table 6 presents the combined chemical and radiological risk at the site. To estimate the combined chemical and radiological risk, the incremental risk was derived by reviewing the RI and locating grid points close to the impacted soil areas and adding it to the estimated risk from the radiological ROCs. In some instances (such as the Building 701 Site), chemical risk is not available because no soil samples were collected in the vicinity and chemical risk was subsequently not assessed.

With some exceptions, such as the Building 707 Triangle Area and IR-02, the estimated risks are of a comparable order of magnitude to incremental risks for nonradioactive chemicals. The results indicate that concentrations of radioactive and nonradioactive chemicals in soil pose a potential unacceptable risk to future site users and remedial alternatives should be evaluated to address the potential risks. Although the extent of radioactive contamination in subsurface soil has not been defined, this radiological addendum conservatively assumes, consistent with the findings of the HRA, that potential radioactive chemicals may be present in subsurface soil at Parcel E and will therefore require remedial option analysis.

### 2.5.4. Uncertainty Analysis for Critical Assumptions

Appendix B provides a discussion of the input parameters and modeling results for the radiological dose and risk for each radiologically impacted site. The results were compared against the EPA-increased lifetime cancer risk of 1E-06 and the NRC dose limit of 25 millirems per year. EPA does not believe this NRC dose limit is protective of human health and the environment, and recommends a maximum dose limit of 15 millirems per year (EPA, 1997a). The remedial option analysis (in Sections 3, 4, and 5) will consider both risk-based RGs and the 15 millirems per year dose limit in developing remedial alternatives that are protective of human health and the environment.

Notes: All concentrations shown in milligrams per kilogram (mg/kg).

- <1
- Less than 1
- 
- Not applicable or chemical is not a COC for this endpoint
- %
- Percent
- bgs
- Below ground surface
- C
- Cancer effect
- COC
- Chemical of concern
- EPC
- Exposure point concentration
- HHRA
- Human health risk assessment
- HI
- Hazard index
- IND
- Industrial (industrial exposure scenario)
- MI
- Maritime industrial (industrial exposure scenario)
- MU
- Mixed use (residential exposure scenario)
- NC
- Noncancer effect
- PAH
- Polynuclear aromatic hydrocarbon
- Pest/PCB
- Pesticide/polychlorinated biphenyl
- RD
- Research and development (residential exposure scenario)
- RME
- Reasonable maximum exposure
- SVOC
- Semivolatile organic compound
- VOC
- Volatile organic compound

TABLE 5-13: INCREMENTAL RISK - RISK CHARACTERIZATION ANALYSIS FOR SUBSURFACE SOIL (0 TO 10 FEET BGS), CONSTRUCTION WORKER SCENARIO
