2 Executive Summary

Introduction

Pursuant to Colorado Public Utilities Commission (Commission) Decision No. C20-0304, in Proceeding No. 19R-0408E and Rule 3605 (a)(I) of the Commission's Rules regulating Electric Utilities, Tri-State Generation and Transmission Association, Inc. (Tri-State) presents its Integrated Resource Plan/Electric Resource Plan ("Resource Plan"). This Resource Plan is also developed to meet the Integrated Resource Planning requirements of the Western Area Power Administration (WAPA) as described in the Energy Planning and Management Program (10 CFR part 905).

This Resource Plan also covers the following WAPA preference allocation recipients:

Pueblo of Laguna, Pueblo of Zuni, Ramah Navajo Chapter, Canoncito Band of Navajos, Ute Mountain Ute Tribe, Wind River Reservation, Nambe Pueblo, Pueblo of Jemez, Pueblo of Pojoaque, Pueblo of San Ildefonso, Pueblo of San Juan, Pueblo of Santa Clara, Pueblo of Zia, Southern Ute Indian Tribe, Mescalero Apache Tribe, Alamo Navajo Chapter, Colorado, the City of Truth or Consequences, New Mexico and Schriever Air Force Base.

Tri-State is a wholesale cooperative electric generation and transmission association consisting of 42 Utility Member Systems located across Colorado, Nebraska, New Mexico and Wyoming. As directed by Colorado Decision CO 10-0101, Tri-State has previously filed Resource Plans in the state of Colorado in 2010 and 2015 as well as Annual Progress Reports (APR). With the passage of Senate Bill 19-236 in Colorado in May 2019, Tri-State as a wholesale generation and transmission electric cooperative operating in the state of Colorado became subject to resource planning regulation by the Commission. Rules guiding this process are per C20-0304 and were finalized in late April 2020, with an effective date of July 15, 2020. As directed by Commission Decision No. C20-0304, Tri-State filed a June 1, 2020 informational filing which was an Assessment of Existing Resources per 3605(c). On August 3, 2020, Tri-State revised the filing to include additional information and in order to be responsive to motions filed by interveners. While participating in an extensive discovery process related to these filings, Tri-State gathered necessary data, developed and analyzed scenarios and prepared this Resource Plan to be filed by December 1, 2020 as required. As required by the Commission, this Resource Plan is inclusive of Tri-State's Assessment of Resources as filed on August 3, 2020 along with an itemized list of updates. Tri-State also included additional information to address comments related to Proceeding No. 20M-0218E as well as Commission guidance as interpreted from the November 12, 2020 Commission's weekly meeting . This assessment can be found in Volume II Section 3 Assessment of Resources of this report.

Resource Need

Tri-State has selected a 20-year period from 2021 through 2040 for its Resource Planning Period (RPP). Per rule 3605(a)(IV)(A) Tri-State has set the Resource Acquisition Period (RAP) for this Resource Plan as 2021 through 2030.

Tri-State's system-wide base load forecast for the RAP shows an average annual load growth rate of ~1.6%. The system load forecast was developed using a bottom up approach based on historical Utility Member System load data, separated into nine classes and applying relevant statistical models by class.

Utility Member System forecasts were combined to arrive at regional forecasts that were used for production cost modeling and the Tri-State system-wide forecast. Many factors can potentially influence Tri-State's load forecast and projected growth. These factors include potential Utility Member System exits, potential transition of some Utility Member Systems from all requirements contracts to partial requirements contracts, increased levels of member distributed generation, long-term impacts of COVID, long-term impacts of environmental regulations on the oil and gas industries and beneficial electrification. To account for potential deviation in load growth Tri-State develops a low and high load forecast. These forecasts are described in more detail in Volume II Section 1 Electric Energy and Demand Forecast of this report.

In early 2020, Tri-State announced the Responsible Energy Plan (REP), which includes among other initiatives, the announced retirements of Escalante Generating Station in 2020 and the retirement of all three units comprising the Craig Generating Station by 2030, as well as the addition of 1 GW of renewables by 2024. These are key Tri-State actions to supply affordable, responsible, reliable energy to Tri-State Utility Member Systems.

For this Resource Planning process, Tri-State included these announced retirements in its base assumptions. Tri-State also reviewed emerging technologies and updated its generic resource dataset to reflect proven technologies, including various types of wind, solar and gas resources, as well as energy storage. Four-hour Lithium-Ion (Li-Ion) batteries of varying sizes were used in the generic resource data set. Tri-State projected that battery prices would decline by approximately 6% per year over the RAP, compared to current pricing. Renewable generation pricing is projected to rise slightly by the mid-2020s due to the scheduled expiration of tax credits, and then is forecast to decline gradually over the RPP as a result of projected technological improvements.

As illustrated in Figure 1, Tri-State forecasts a capacity need in 2029 based on planned retirements, existing owned resources and supply contracts, and the base load forecast.

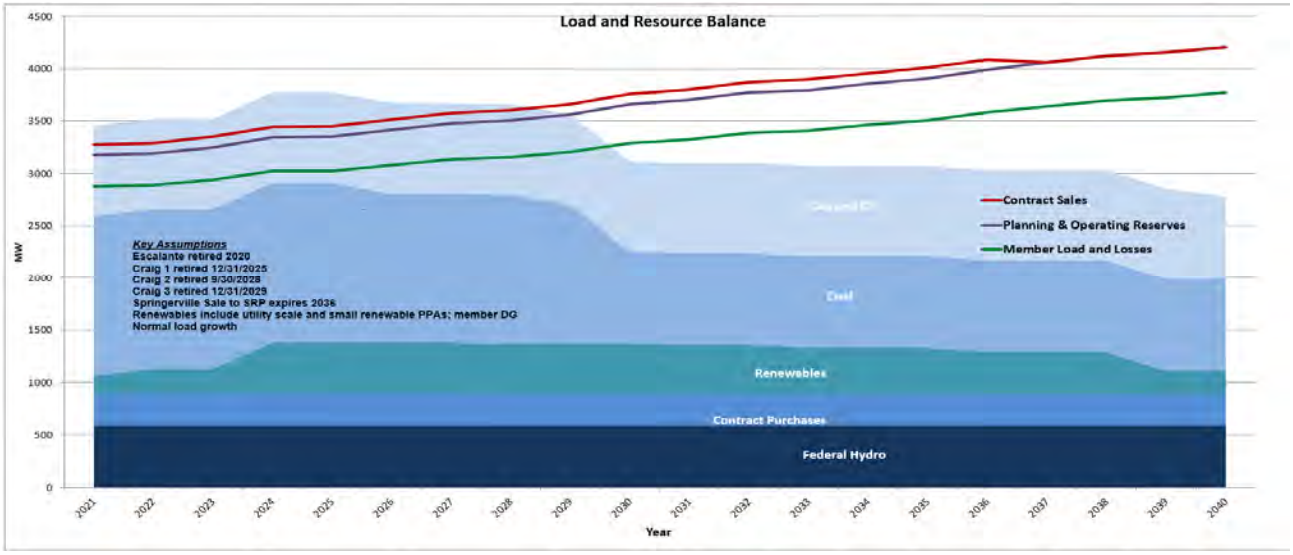

Figure 1: Tri-State Load and Resource Balance (Projected)

Industry & Regulatory Factors

Key external factors influencing this Resource Plan include potential new environmental regulation, the regional development of organized markets and state targets for Greenhouse Gases (GHG)/Carbon Dioxide ($CO_{2)}$ reductions. Tri-State is scheduled to begin operation with the California Independent System Operator's (CAISO) Western Energy Imbalance Market (WEIM) with its load and resources located in Public Service New Mexico's Balancing Authority (PNM-BA) in April 2021. Tri-State is also scheduled to begin operation in Southwest Power Pool's (SPP) Western Energy Imbalance Service (WEIS) in February 2021 for its Colorado, Wyoming and Western Nebraska loads and resources located in the Western Area Power Authority Balancing Authority (WAPA-BA). Tri-State developed modeling treatment for the intra hour effects of imbalance markets as described in Volume II Section 5 Phase I Modeling Details of this report. Tri-State also made adjustments to market depth in models beginning in 2025 to represent a forecast of the development of a "day-2" Regional Transmission Organization (RTO) organized market. Differences between imbalance markets and "day-2" organized markets are explained in more detail in Section 6 Assessment of Resource Needs under the Imbalance Markets, Regional Transmission Organizations and Independent System Operators subsection of this report.

Colorado GHG/CO_2 reduction targets are a key factor that heavily influence scenarios in this Resource Plan. Tri-State's alternative scenarios evaluated reductions in CO_2 emissions based on forecast and historic wholesale electricity sales in the state of Colorado and through the application of a Social Cost of Carbon (SCoC) across Tri-State's system. Details can be found in Section 7 Alternative Scenario Analysis of this report.

Preferred Resource Plan

In assessing the Base Case and Alternative Scenarios, Tri-State has selected the 80% Carbon Reduction (CR) V4 scenario as its preferred plan. Primary reasons for this selection include:

- Generation locations and technology diversity, as illustrated in Figure 2, are sufficient to fully utilize interconnection capability made available from announced retirements.
- Forecast additional thermal retirements projected to occur after the RAP and in addition to announced retirements during the RAP, allow a manageable transition to zero carbon resources while maintaining reliability and affordable rates.
- Transmission system network upgrade costs are minimized during the RAP compared to the base case.
- The PVRR for the RPP is ~$400M higher than the Base Case while achieving the state of Colorado GHG/CO_2 reduction target of 80% GHG/CO_2 reduction by 2030 from a 2005 baseline.
- Overall emissions and water usage are significantly reduced by 2030 from current levels and are significantly lower than in the Base Case.
- The scenario uses a glide path from 2025 to 2030, as illustrated in Figure 3, for CO_2 reduction goals in the state of Colorado to achieve meaningful reductions in the near term.

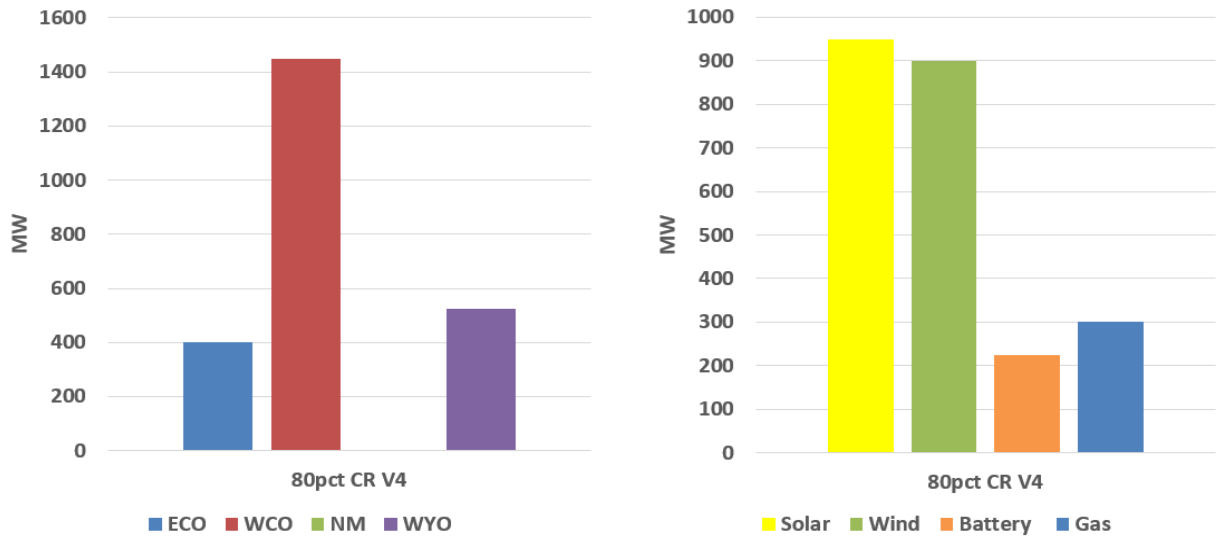

Figure 2: Preferred Plan Resource Additions over the RAP by Geographic Location and Technology

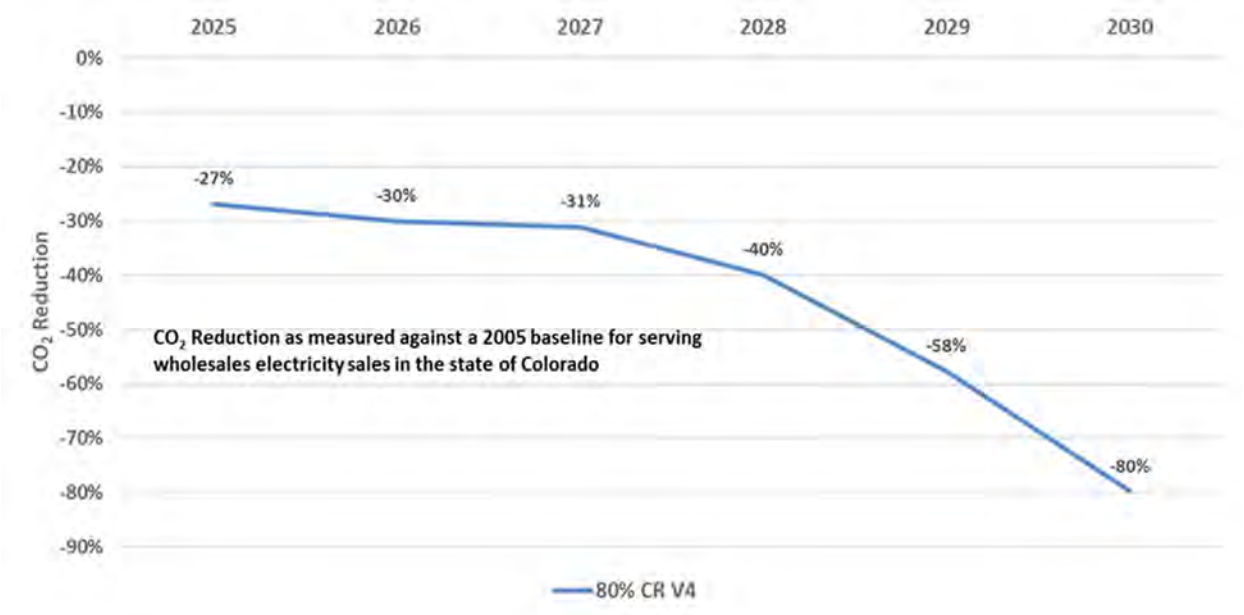

Figure 3: Preferred Plan Glide Path to CO_2 Reduction in Colorado

Action Plan

RAP – Phase II:

Tri-State's base case scenario indicates a capacity need in 2029. In order to meet near term emissions reductions additional renewable resources are forecast for deployment in the preferred plan during the RAP. Table 4 identifies resources by location, nameplate capacity, technology and year, as determined in the preferred plan

Table 4: Preferred Plan Resources during RAP

Location	Capacity (MW)	Technology	Year
East Colorado	100	Wind	2025
Wyoming	100	Wind	2025
West Colorado	200	Solar	2026
Wyoming	100	Wind	2026
West Colorado	100	Solar	2027
West Colorado	200	Solar	2028
Wyoming	100	Wind	2028
West Colorado	200	Standalone Battery	2029
West Colorado	200	Solar	2029
East Colorado	100	Wind	2029
Wyoming	100	Wind	2029
Wyoming	25	Standalone Battery	2030
West Colorado	300	Natural Gas - Combined Cycle	2030
West Colorado	250	Solar	2030
East Colorado	200	Wind	2030
Wyoming	100	Wind	2030

Given the uncertainty related to Tri-State's Utility Member System load in the near term, Tri-State anticipates that its initial Phase II process will focus on resource needs by 2025, as indicated by the shading in Table 4. We anticipate that resources needed for the period from 2026 to 2030 will be addressed in the June 1, 2023 ERP or subsequent ERPs.

By 2023, we will have better information regarding potential load reductions that could reduce capacity needs after 2025. In addition, while the RAP extends from 2021 to 2030, Tri-State is reluctant to engage in activities to add conventional thermal resources (300 MW natural gas combined cycle in 2030) without allowing time for emerging technologies that provide equally reliable capacity, but with lower emissions, to become competitive.

Utility Member System Programs:

Tri-State plans to use the following studies as guides to work with Utility Member Systems to develop relevant programs that may be beneficial to Tri-State and its membership.

- Attachment Vol II 5-1 Demand Side Management & Energy Efficiency Potential Study
- Attachment Vol II 5-7 Beneficial Electrification Potential Study

Retirement Requirements & Impacts:

With the announced retirement dates of Springerville Unit 1 and Springerville Unit 2, Tri-State plans to engage in discussions with Salt River Project (SRP), the owner of Springerville Unit 4, as well as other parties necessary to determine the impacts on Springerville Unit 3 (SPV3) for future resource planning.

While the preferred plan indicates a retirement of Laramie River Station (LRS) Unit 3 by 2033, we note that there is no agreement in place that would be required to implement this retirement with the co-owners of the Missouri Basin Power Project. Modeling performed under the preferred plan showed that the continued operation of both (LRS) Unit 2 and Unit 3 at levels needed to satisfy and maintain an 80% CO_2 reduction in Colorado would not be economic, which is why the preferred plan reflects a retirement of LRS Unit 3.

Modeling Improvements:

Tri-State plans to modify its current modeling software or replace if necessary, in order to improve modeling items prior to the June 1, 2023 ERP. Key items slated for modeling improvement include but are not limited to: the ability to handle emission reductions on a state-by-state basis in a robust manner, the ability to model sub-hourly effects, more robust modeling of intermittent resources, streamlined management of transmission capex impacts, and improved treatment of intermittent resource curtailments.

3 Introduction & Background

Purpose of Filing

The purpose of this Resource Plan is to meet the requirements of Proceeding No. 19R-0408E and Rule 3605 (a)(i) of the Commission's Rules regulating Electric Utilities and to meet the Integrated Resource Planning requirements of the Western Area Power Administration (WAPA) as described in its Energy Planning and Management Program (10 CFR part 905).

Tri-State's approach to developing a Resource Plan takes into consideration internal and external factors. Internal factors include being responsive to Utility Member System needs for affordable, responsible power while maintaining a reliable system. For purposes of this Resource Plan, Tri-State also focuses on the potential impacts to Tri-State's resource planning process due to Utility Member System interest in items such as wholesale electric service contract buyouts, transitioning from all requirements contracts to partial requirements contracts, and the increased deployment of distributed generation. These impacts will be discussed further in the Utility Member Sales Forecast subsection found in Volume II Section 1 Electric Energy and Demand Forecast of this report. External factors include requirements driven by legislation in any state within Tri-State's footprint. Recent legislative actions impacting this Resource Plan include CO_2 and GHG reduction requirements in Colorado and updates to the Renewable Portfolio Standard requirements in New Mexico. These impacts are discussed in more detail in Section 6 Assessment of Resource Needs of this report. While developing its Resource Plan, Tri-State must monitor

internal and external factors and ensure that the Resource Plan meets Utility Member System needs while adhering to applicable laws and regulations across a diverse footprint.

Additionally, Tri-State faces unique challenges given its diverse footprint, which include participation in joint owned generating units and wholesale electric market environments. While Tri-State's system crosses multiple states, Tri-State is only regulated for purposes of resource planning in the state of Colorado. Tri-State must meet individual state regulatory and legislative requirements while developing system-wide solutions. Tri-State has several resources that are jointly owned, which increases the difficulty and complexity of possible resource retirement decisions. Tri-State also faces resource planning challenges associated with the evolving nature of energy imbalance markets, and the possible future deployment of full "day-2" RTO markets, layered upon operations spanning multiple balancing authorities, utilizing extensive third-party transmission rights associated with long term network and point-to-point agreements. To illustrate, Tri-State's load in the PacifiCorp (PAC) BA has been part of the WEIM operated by CAISO since 2014. Tri-State is scheduled to enter the WEIS market operated by SPP in February 2021 with load and resources physically located or pseudo-tied into the WAPA-BA and is scheduled to join the WEIM in April 2021 with load and resources physically located or pseudo-tied into the PNM-BA. These challenges are discussed further throughout this report.

Finally, one key input to the Resource Plan is the Responsible Energy Plan (REP) as announced by Tri-State in January 2020. The following REP items influence Tri-State resource planning in general, and the preferred plan.

- Eliminating 100% of Tri-State emissions from coal in New Mexico by the end of 2030
- Eliminating 100% of Tri-State emissions from coal in Colorado by the end of 2030
- Achieving a 90% reduction in CO_2 emissions across the generation facilities Tri-State owns or operates in Colorado
- Achieving a 70% reduction in CO_2 emissions associated with Colorado wholesale electric sales
- Adding 1 GW of renewable resources by 2024
- Increasing Utility Member System contract flexibility and options to deliver more local renewable generation
- Promoting participation in a RTO
- Extending the benefits of a clean grid

Tri-State's base case and alternative scenarios in the Resource Plan include the retirement of coal in New Mexico (Escalante Generating Station in November 2020), and the retirement of coal resources in Colorado as identified in the REP, which includes the retirement of all three units comprising the Craig Generating Station[3] by 2030. Tri-State's expansion plan portfolios in all alternative scenarios exceed the REP goal of a 70% reduction in CO_2 emissions associated with Colorado wholesale electric sales.

The 1 GW of renewable resources by 2024 as identified in the REP includes resources obtained through RFP processes conducted in 2018 and 2019. These now under contract resources include Crossing Trails, Spanish Peaks, Niyol, Coyote Gulch, Dolores Canyon, Axial Basin, Escalante, and Spanish Peaks II. More

[3] The retirement of the Craig Generating Station is subject to a regulatory approval process with the Commission.

information on these resources is available in Volume II Section 3 Assessment of Existing Resources under the subsection of Overview of Purchases.

Tri-State has a long-standing Board policy allowing for member-distributed generation, which allows members to meet a portion of their energy needs with local renewable generation. Member distributed generation is included in the modeling in this Resource Plan, and more information on this modeling is located in Volume II section 5 Phase I Modeling Details.

Additionally, Tri-State's Board has approved a partial requirements contract option for Utility Member Systems. The methodology for the buy down payment to transition from an all requirements contract to a partial requirements contract is currently moving through the necessary Federal Energy Regulatory Commission (FERC) process. In 2021, Tri-State will conduct an Open Season process with its Utility Member Systems who are interested in this option. While the Low Load forecast used into two alternative scenarios is somewhat representative of potential load declines, partial requirements was not specifically modeled in this Resource Plan. Tri-State expects to have specific partial requirements driven contract changes impacting load forecasts available for its June 1, 2023 ERP process.

Tri-State is actively promoting the need for an RTO in the western interconnection to reliably interconnect more renewable resources while keeping power affordable. While full modeling for an organized market is not undertaken in the scenario analysis of this Resource Plan, starting in 2025 a market depth adjustment is made in order to simulate greater market accessibility. Further detail on modeling setup is available in Volume II Section 5 Phase 1 Modeling Details.

Tri-State engaged Mesa Point Energy to conduct a beneficial electrification potential study for Tri-State's system. This study is included as Attachment Vol II 5-7 Beneficial Electrification Potential Study. Due to the timing of the completion of this study (October 2020), this information was not included in an alternative scenario. Tri-State does expect to include beneficial electrification potential relevant to Tri-State's Utility Member System in its June 1, 2023 ERP filing.

This assessment of load and resource requirements leading to a Resource Plan is intended to meet Tri-State's obligation to provide reliable, affordable and responsible power to its Utility Member Systems and to develop options to meet resource needs in an evolving industry.

Contents and Organization of the 2020 Resource Plan

This Resource Plan is organized into two volumes with relevant sections identified as follows:

Volume I:

- Executive Summary
- Introduction and Background
- 2020 Resource Planning Process
- Landscape
    - System Energy Mix
    - External Market Dynamics
    - RPP & RAP
    - Planning Reserve Margin and Contingency Plan

  - Environmental Regulation
- Assessment of Resource Needs
- Alternative Scenario Analysis, Results and Comparison
- Preferred Plan
- Action Plan & Phase II Requirements
- Confidential and Highly Confidential Information

Volume II Technical Appendix:

- Energy and Demand Load Forecasts
- Commodity Pricing
- Assessment of Resources
- Transmission Overview
- Phase I Modeling Details
- Attachments of third party studies, scenario detail and RFP related items

4 2020 Resource Planning Process

Data and System Preparation

Tri-State's process for developing the Resource Plan includes data verification, third party reviews and related updates, development of assumptions, and scenario analysis. Regular updates of financial and energy data occur throughout the year and are used for short-term and long-term analyses and forecasting processes. Tri-State freezes base assumptions at the beginning of any scenario evaluation process, such as an ERP, to maintain the ability to reasonably compare among scenarios. Tri-State's software systems for this analysis include Hitachi ABB E7 Capacity Expansion (CE), Hitachi ABB E7 Portfolio Optimization (PO), Hyperion, and Utilities International Planner (UIPlanner). These systems, as well as their use in the resource planning process, are discussed in Volume II Section 5 Phase I Modeling Details of this report.

Tri-State engaged three outside consultants to assist in preparing material for this Resource Plan. Black & Veatch (B&V) supported review of key data including commodity pricing and unit characteristics and costs for existing and expansion plan resources. Additionally, B&V performed a Loss of Load Probability (LOLP) Study and a modified Effective Load Carrying Capability (ELCC) study. Ascend Analytics (Ascend) provided ramping analysis and a stochastic review of Tri-State's renewable resource hourly profiles. CDG Engineering provided technical system support. Various results from consultants' work products are included and incorporated into this report, and studies or results in their entirety can be found as Attachments to Volume II 5-1 to 5-7.

Upon completion of data setup and verification, scenario analyses was conducted to develop forecasts of capacity and resource needs to maintain planning reserve margins, support affordable supply to Utility Member Systems, and provide for compliance with applicable environmental regulations. The base case

and alternative scenario analysis results are discussed beginning in Section 7 Alternative Scenario Analysis of this report.

Scenario Analysis Overview

Tri-State analyzed various scenarios for this Resource Plan, by first modeling an expansion plan in CE, then running an hourly dispatch for the 20-year planning period in PO, followed by incorporation of the this dispatch and expansion plan information into Hyperion and finally transitioning Hyperion data into UIPlanner to develop a forecast of companywide expenses and revenue requirements. Transmission capital expenditures were also determined for each scenario and passed to UIPlanner. Final analysis of all scenario data in UIPlanner led to the development of a Present Value Revenue Requirement (PVRR) for each scenario. Details of these processes are discussed further in Volume II Section 5 Phase I Modeling Details of this report. Figure 4 illustrates the sequential steps of this process and the associated primary software systems:

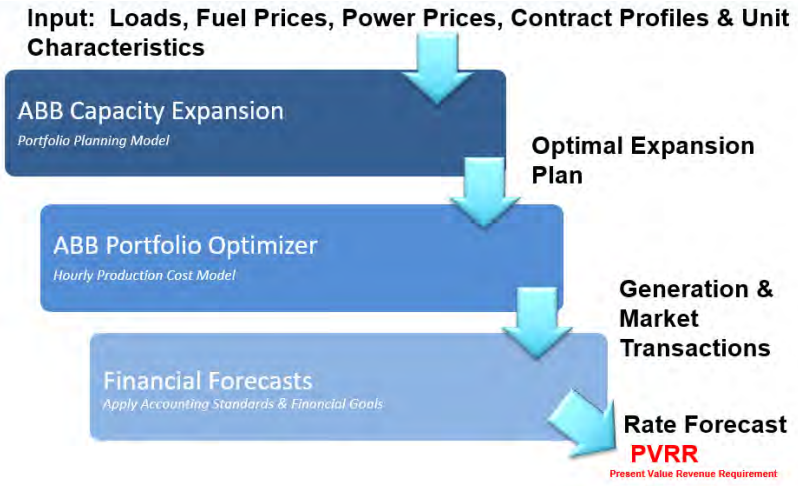

Figure 4: Scenario Modeling Flowchart

Stakeholder Outreach

Per 10 CFR part 905.11(b)(4) related to WAPA's Integrated Resource Plan (IRP) requirement, Tri-State has historically held public workshops to engage the public in the IRP process. However, due to COVID19 and related concerns for public welfare, Tri-Stated posted on its website in May 2020 that such meeting(s) would be postponed. In late July Tri-State determined that establishing a communication route for the WAPA IRP with the public that did not involve face-to-face contact would be necessary due to the continued COVID19 threat. At that time, Tri-State posted on its website in the Stakeholder Outreach and in Resource Planning pages that Tri-State was actively working on the IRP and would take comments from the public via its resourceplanning@tristategt.org email address. Additionally, Tri-State posted that it would post any such comments in the same section of the Tri-State website along with responses. Tri-State used this communication protocol to solicit concerns and input from the public as part of its WAPA IRP public process. Tri-State did not receive any comments or input through this process. Additionally, as part of the Colorado Electric Resource Plan (ERP) process under Proceeding 20M-0218E, Tri-State engaged in an extensive and far-reaching discovery processes from late July 2020 through late September 2020

with various parties. This discovery process resulted from Tri-State's June 1, 2020 informational filing, which was an Assessment of Resources per Rule 3605(c). A comment period related to this proceeding occurred in late September and early October. Tri-State's response included plans to address specific items identified as items of concerns in its December 1, 2020 Resource Plan filing. Comments from participating parties as well as Tri-State's response to those comments are available on the Commission's website.

Summary and Update of 2015 Colorado ERP

Tri-State's Action Plan from the 2015 ERP included several elements and was updated via APRs, the most recent of which was filed in December 2019. An update to the elements of this Action Plan is summarized below:

Affordable Clean Energy Rule and State Plans Review and Evaluation:

Since the 2015 ERP filing, the U.S. Environmental Protection Agency (EPA) repealed the Clean Power Plan. On July 8, 2019, the EPA finalized the Affordable Clean Energy (ACE) rule. State plans implementing the ACE rule will be due in July 2022, with initial compliance to be achieved by designated facilities no later than 24 months after State plan submittal, except if a State determines a longer period is appropriate and includes legally enforceable increments of progress. Colorado is expected to take initial steps in 2021 to implement the ACE rule. The legality of the ACE rule has been argued before the District of Columbia Court of Appeals.

Generation Planning and Development:

Since the 2015 ERP filing, Tri-State has both expanded its renewable resource portfolio and announced coal retirements. An additional 51 MW of capacity in the Missouri Basin Power Project was also acquired, which includes LRS generation rights, water rights and critical TOT 3 transmission. Tri-State past and announced retirements of coal-fired generation are as follows:

- San Juan 3 (40 MW share) retired in 2017
- Nucla Generating Station retired in 2019 (ahead of 2022 regional haze requirement)
- Escalante Generating Station retired November 2020
- Craig 1 to be retired by 12/31/2025
- Craig 2 to be retired by 9/30/2028
- Craig 3 to be retired by 12/31/2029

Renewable resource additions since 2015 are addressed in the Expansion of Renewable Portfolio subsection below. Tri-State is also moving forward with plans to participate in both the WEIM and the WEIS with expected market entry dates in 2021. It is anticipated that Tri-State load and resources located in the PNM BA and PSCO BA (in 2022) will participate in the WEIM, and load and resources located in WAPA will participate in the WEIS market.

Transmission Planning and Development:

Tri-State provides wholesale electric transmission service and makes wholesale sales of electric energy to 42 Utility Members in four states (using facilities located across five states), including the approximately 5,665 miles of high-voltage transmission lines over which Tri-State has ownership or capacity interests, as

well as the approximately 409 substations and switchyards that Tri-State owns or has a major equipment ownership interest. Tri-State's interstate transmission facilities are interconnected with those of other utilities, including WAPA, Nebraska Public Power District (NPPD), Black Hills Colorado Electric, Inc. (BHCE), PAC, PSCO, Platte River Power Authority (PRPA), Colorado Springs Utilities (CSU), Basin Electric Power Cooperative (BEPC), Tucson Electric Power (TEP), PNM, and Deseret Generation & Transmission Cooperative. The majority of Tri-State's transmission facilities operate as part of the Western Interconnection. A small portion of Tri-State's facilities supports its load centers in the Eastern Interconnection and is under the functional control of SPP.

Delivery to Tri-State Utility Member Systems also requires that Tri-State contract for transmission service from multiple third parties including PSCO, PNM, WAPA, PAC, PRPA, BHCE and others.

Tri-State continues to support regional transmission study efforts, primarily through its participation at WestConnect and the Colorado Coordinated Planning Group. Tri-State is continuing to make transmission investments to serve growing loads, increase reliability, ensure system stability, and support additional generation interconnections.

Expansion of Renewable Energy Portfolio:

Renewable energy has always been an important part of Tri-State's resource portfolio through purchases of Federal hydropower from the Colorado River Storage Projects (CRSP) and the Loveland Area Projects (LAP). The CRSP and LAP hydro contracts provide approximately 580 MW of firm capacity, and are contracted to Tri-State through 2054 and 2057 respectively. Since 2010 Tri-State has significantly increased the amount of renewable generation in its supply portfolio, via power purchase agreements (PPAs) with the addition of approximately 27 MW of small hydro, 85 MW of solar and 367 MW of wind currently operating and providing energy to Tri-State under long term purchase contracts.

In 2018, Tri-State issued a Request for Proposal (RFP) for renewables resources that resulted in a competitive bidding process and PPAs for the output of the following facilities:

- 104 MW Crossing Trails Wind (COD expected late 2020 or early 2021)
- 100 MW Spanish Peaks I Solar (COD expected 2023)

In 2019, Tri-State issued another RFP that resulted in a competitive bidding process and PPAs for the output of the following facilities:

- 200 MW Niyol Wind (expected 2021)
- 200 MW Escalante Solar (expected 2023)
- 145 MW Axial Basin Solar (expected 2023)
- 120 MW Coyote Gulch Solar (expected 2023)
- 110 MW Dolores Canyon Solar (expected 2023)
- 40 MW Spanish Peaks II Solar (expected 2023)

In addition, Tri-State Utility Member Systems' local renewable and distributed generation projects that are operating or under development has grown to 131 MW.

Tri-State has over 2,000 MW of renewable generating capacity in its resource portfolio, including CRSP and LAP hydropower, existing renewable resources and additional contracted renewable resources scheduled to be on line by 2024. Tri-State continues to engage in efforts to reduce CO_2, monitor impacts to reliability and look for opportunities to increase its renewable portfolio.

Refinement and Development of new EE and DR Products & Services:

An ongoing part of Tri-State's Action Plan, Tri-State has continued to implement Energy Efficiency (EE) programs and continues to evaluate Demand Response (DR) programs. Options that have been evaluated include residential/small commercial, irrigation, large commercial and industrial programs. These offerings are annually evaluated and refined based on industry trends, effectiveness and member feedback. For demand response, the Tri-State Utility Member System rate design, effective January 1, 2016, contains a peak demand signal, which allows member systems to control or shift their peak load, and provides a strong economic incentive to do so. This has resulted in Utility Member Systems establishing successful programs around irrigation, commercial and industrial, and residential technology load control and peak load management. Tri-State's program offerings were recently expanded to include incentives for beneficial electrification, including an on-going heat pump and heat pump water heater incentive, electric vehicle (EV) charging infrastructure incentives, and non-road EV incentives. The EE program has led to cumulative energy savings of over 212 GWh in 2019. Additionally, Tri-State completed a Demand Side Management (DSM) and Energy Efficiency Potential study with an outside consultant to further evaluate the achievable potential and cost savings for use in this resource planning process. The final study can be found in Attachment Vol II 5-1 Demand Side Management and Energy Efficiency Potential Study. An additional study for Beneficial Electrification (BE) Potential was commissioned and can be found in Attachment Vol II 5-7 Beneficial Electrification Study.

Research & Development (R&D) Programs and Projects:

Tri-State keeps informed of research, development and advanced technology initiatives through its membership in Electric Power Research Institute (EPRI) and through its participation in the National Rural Electric Cooperative Association (NRECA) Cooperative Research Network (CRN).

Some examples of Tri-State's past or present involvement in R&D projects include:

- Use of unmanned aerial vehicles to improve transmission, distribution, and generation maintenance.
- Dynamic load shaping to integrate renewable energy more cost-effectively.
- Beneficial Electrification to reduce emissions, increase energy efficiency, and improve customer's lives and businesses.
- Decarbonized hydrogen/ammonia production for season scale energy storage, grid balancing, and de-carbonization of energy uses that are hard to electrify.
- Energy storage to reduce the cost of integrating renewable energy and as an alternative to transmission and distribution upgrades.
- Incorporating DERs into resource planning to account for the effects of rooftop solar and electric vehicles on load and peak forecasting.

5 Landscape

System Energy Mix

Figure 5 shows a representation of Tri-State's 2019 Resource mix. The capacity values are based on summer nameplate ratings of Tri-State's owned, leased and long-term contracted resources. The energy values are based on gross sales to both Utility Member Systems and nonmember sales, including transmission losses. The 2019 portion of JM Shafer sold to PSCo under a tolling agreement is included in both the energy and capacity representations. Renewable energy includes WAPA hydro, existing and contracted utility scale renewables, member distributed generation and the percentage of the Basin contracts for which Renewable Energy Credits (RECs) were received from BEPC (~25% of Basin West and Electrically East contract energy).

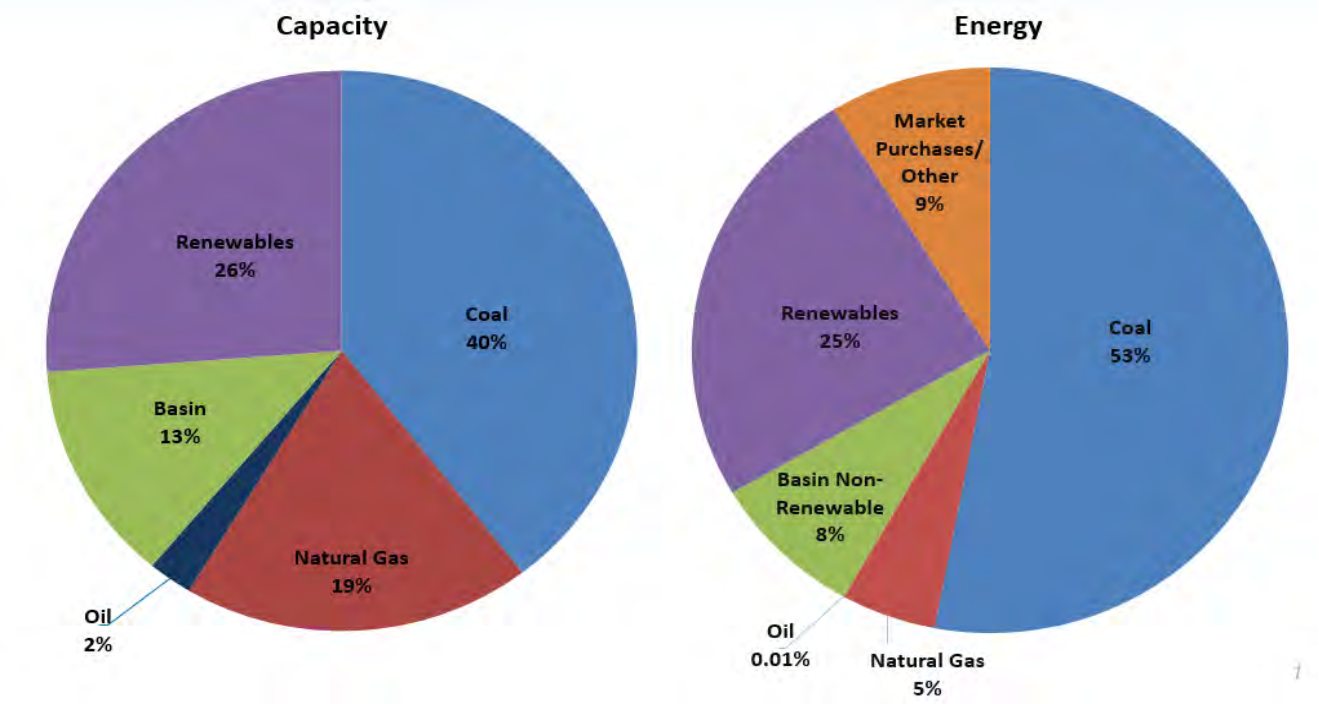

Figure 5: Tri-State 2019 Total System Resource Mix

Figure 6 shows a representation of Tri-State's forecast 2030 Resource Mix based on the preferred plan (80pct CR V4). Capacity values are based on summer nameplate ratings of owned, leased, long-term contracted resources and expansion plan resources. Energy values are based on forecast gross sales to both Utility Member Systems and nonmember sales as well as charging load for energy storage including transmission losses. Renewable energy forecasts includes WAPA hydro, existing and expansion plan utility scale renewables, member distributed generation and the percentage of the Basin contracts for which RECs are forecast to be received.

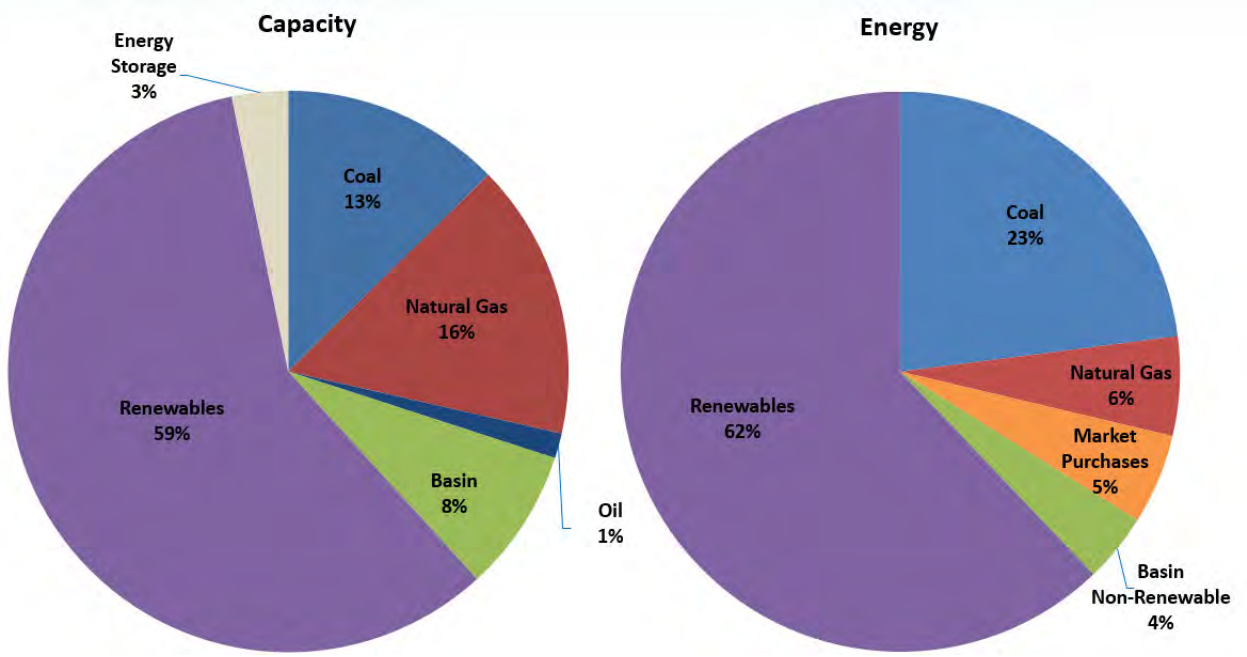

Figure 6: Tri-State Projected 2030 Resource Mix – Preferred Plan

Tri-State's preferred plan increases renewable generation on a capacity and energy basis from ~25% of system mix in 2019 to ~60% of system mix in 2030. This occurs along with a significant reduction in the capacity and energy contribution of coal fired generation. Coal capacity is forecast to decrease from ~40% in 2019 to ~13% in 2030, based on capacity and from ~53% in 2019 to ~23% in 2030 based on energy. Gas is forecast to remain reasonably constant on an energy basis from 2019 to 2030 and is forecast to be slightly reduced on a capacity basis. Along with the addition of energy storage by 2030, gas provides a reliability backstop for the integration of intermittent renewable resources.

Energy Market Dynamics and External Factors

Changing wholesale electricity market environments and external factors were considered in the development of this Resource Plan. The following factors are significant:

- Fuel Pricing
- Organized Market Development Timelines
- Possible Future Environmental Regulations
- Shift to Renewables & Increased Deployment of Distributed Energy Resources (DER)

Fuel pricing has an impact on the development of the load forecast as described below, and influences the selection of resources in the expansion plan to meet system capacity and energy needs, and the dispatch order of resources. In some instances, electricity that Tri-State Utility Member Systems offers to retail customers competes with propane, natural gas and fuel oil as an energy source. Historical price data for these alternative energy sources is obtained annually from the Department of Energy's (DOE) Energy Information Administration (EIA) State Energy Data System, Petroleum Marketing Monthly and Annual Energy Outlook. This data is used in the evaluation of the potential competition for purposes of load forecasting. Separately Tri-State's expansion planning and hourly dispatch models are populated with coal and natural gas forward price curves to forecast resource dispatch costs as they compare to other resources and forward wholesale electricity market power pricing.

Tri-State is currently planning entry, as a market participant, into the WEIM and WEIS in 2021. Entry into the WEIM is planned for Tri-State's load and resources located in the PNM-BA in April 2021. Additionally, Tri-State has a small portion of load that has been in the WEIM in PAC's BA since PAC's entry in 2014. PSCo has announced its intent to enter WEIM in 2022. Tri-State's load in the PSCo BA will enter the WEIM at that time and relevant resource participation remains under evaluation. Separately, Tri-State is planning to enter the WEIS market as a market participant in February 2021 for those load and resources located within the WAPA-BA.

In 2019, New Mexico passed legislation increasing the Renewable Portfolio Standard (RPS) percentages in New Mexico to 40% by 2025 and 50% by 2030. In Colorado, SB 19-236 and HB 19-1261 were also passed, addressing GHG and CO_2 reduction targets for all sectors including electricity sales. Specific rules addressing these emission targets are under development by the Colorado Air Quality Control Commission (AQCC). With uncertainty around final rules, Tri-State made reasonable efforts to meet and verify emission reductions based on known proposed methodologies. Both higher RPS standards and emission reduction targets impact the resource planning process in regards to resource mix. The latter has an impact both on the type of supply resources Tri-State can consider as well as the potential impact to forecast load as some of Tri-State's Utility Member Systems have load driven by industries that will also be impacted by GHG/CO_2 emission regulations.

As Utility Member Systems and their customers continue to deploy more DERs, the long-term potential effect on Tri-State's load forecast and overall Resource Plan continues to be evaluated.

The treatment of these evolving market environments and external factors are described in more detail in Section 6 Assessment of Resource Needs of this report.

Resource Planning Period

Tri-State's resource planning process uses a 20-year planning period. Tri-State selected a 20-year planning period from 2021 through 2040. For resource planning purposes Tri-State believes that this planning period appropriately maintains a focus on nearer term impacts, and properly addresses forecasts for commodity pricing, load growth rates and emerging technologies. The selection of a 20-year planning period allows the opportunity to evaluate and respond to changes in markets, technology, load and environmental and regulatory impacts over time.

Resource Acquisition Period

The RAP represents the timeframe during which detailed implementation plans are outlined. As required by Rule 3605(a)(IV)(A), the RAP must encompass the years through 2030, representing an initial 10-year RAP. The 10-year RAP provides sufficient time to allow for selection and implementation of various demand-side and supply-side actions, as well as supporting activities including permitting, RFPs, contract negotiations, and transmission interconnection. This will also provide adequate time to complete competitive market assessments of resource expansion opportunities. By not extending the RAP beyond the 10-year period, risks due to uncertainties with the bidding process, load forecasts, and commodity and labor prices are reduced.

While the Resource Acquisition Period spans from 2021 through 2030, Tri-State's next Colorado ERP filing defined by rule 3605(a)(II) is due by June 1, 2023 and every four years thereafter. Due to the timing of the next ERP, as well as the substantial uncertainty related to Tri-State's load forecast Tri-State generally would prefer to delay irreversible resource decisions as long as possible, particularly related to capital intensive options. The next 12 to 24 months will be particularly informative in regards to Tri-State's projected system load. Additionally, Tri-State would prefer to allow additional time for technology to advance non-CO_2 emitting dispatchable options that will potentially be more cost-competitive with thermal resources in the future.

Planning Reserve Margin

Tri-State has historically used a fixed 15 percent minimum planning reserve margin in its planning process. This minimum level of desired planning reserve margin is calculated as 15 percent of net load. Net load is calculated as firm load, minus firm purchases, plus firm sales. Firm purchases include Tri-States' WAPA hydro power and BEPC Western Interconnection[4], which together provide approximately 850 MW of firm capacity during peak load periods. After subtracting the capacity of firm purchases from firm load, the reserve requirement is reduced by approximately 130 MW. Tri-State's operating reserve requirements, which are inclusive of contingency reserve obligations in the Southwest Reserve Sharing Group (SRSG), and via sub-entity agreements with PSCO and WAPA who are members of the Northwest Power Pool, are

[4] Basin Electrically East contract is a full requirements contract served by BEPC and the contract and associated load are excluded from the planning reserve margin calculation.

included as part of the planning reserve margin. A 15 percent minimum planning reserve margin is a conservative measure and is comparable to industry standards. Tri-State uses the minimum planning reserve margin in the base case and all alternative scenarios.

In 2020, Tri-State engaged B&V to conduct a probabilistic LOLP study to analyze the adequacy of the current planning reserve margin and the viability of expansion plans under different scenarios including a base case, a CO_2 reduction scenario and two versions of low load scenarios. This analysis began in late spring 2020 in order to provide Tri-State input into the ERP base case and alternative scenarios. One key takeaway from the study is the value of dispatchable or semi-dispatchable resources when integrating renewables in relation to avoiding unserved energy. In the LOLP study B&V used 4-hour Lithium ion (Li-ion) batteries as needed to satisfy planning reserve margins. Tri-State's ERP scenarios follow this methodology and include standalone batteries as selected by the models in the base case and alternative scenarios evaluated in this Resource Plan. The conclusion of this B&V study is that the current planning reserve margin is adequate to continue to provide reliable service to Tri-State's Utility Member Systems. The results of the study can be found in Attachment Vol II 5-2 B&V Loss of Load Probability study.

Contingency Plan

Tri-State recognizes the need to be flexible in regards to changing demands. Forecast electric generation and customer demand will not actualize exactly as planned, and transmission or generation projects could be unexpectedly delayed for many reasons. This section attempts to identify contingencies that could occur during the RAP and to develop alternatives to address them.

Potential Contingency Events:

- Failed contract negotiations with selected bidders or proposal withdrawal
- Project development delays or cancellation
- Transmission development delays
- Higher than anticipated electric demand
- Extended outages of transmission or generation facilities

Contingency Plan options available to Tri-State include:

- Purchase of short-term capacity via an RFP process to cover anticipated shortfalls.
- Initiation of negotiations with replacement bidder(s)
- Issuance of additional RFPs
- Acceleration of the in-service dates of projects

Depending on the need and severity of the contingency, any combination of the options listed above could be implemented. In the event Tri-State forecasts a near-term capacity shortage, the appropriate course of action would depend upon several factors including magnitude of shortage, timing and length of shortage, market conditions, and projects currently in progress.

Environmental Regulation

Regional Haze Rule and Retirement of Coal-Fired Electric Generating Units:

The Regional Haze Rule establishes requirements for states to periodically create State Implementation Plans ("SIPs") to protect visibility in national parks and wilderness areas throughout the United States, with a visibility goal of returning to natural visibility conditions by 2064. The Regional Haze Rule could require additional controls for particulate matter, SO2 and NOx emissions from any source with such emissions, including certain utility sources. The Regional Haze Rule requires that states revise their SIPs every ten years.

Under the existing, approved Colorado SIP, Tri-State committed to NOx emissions rates that resulted in the installation of selective catalytic reduction on Craig Station Unit 2 and the owners of Craig Station Unit 1 will retire Craig Station Unit 1 by December 31, 2025.

The APCD is now developing its second SIPs, which are due to the EPA by July 2021. The AQCC on November 20, 2020 took preliminary final action to adopt a regional haze regulation and SIP that, if finally approved, would incorporate the voluntarily announced retirement of Craig Station Unit 2 no later than September 30, 2028 and would require accelerated retirement of Craig Station Unit 3 no later than December 31, 2028. The AQCC anticipates taking final action in December 2020.

See Mr. Berger's testimony for more detail on environmental regulations applicable to Tri-State.

6 Assessment of Resource Needs

Resource Capacity & Energy

Traditional utility resource planning requires that a comparison of demand forecasts, existing generation, and purchase and sale commitments be developed in order to forecast the need for additional resources to maintain appropriate reserve margins.

The assumptions for the load and resource balance are as follows:

- Total obligations are defined as firm load, losses, firm contract sales, operating reserves, and planning reserves.
    - 2020 long term load forecast data
- All existing purchase and sales contracts are assumed to expire on their terms, with the exception of distributed generation under Tri-State Board Policy 115 and Board Policy 119, which are continued through the entire planning period.
- Craig 1 station will be retired by 12/31/2025.
- Craig 2 station will be retired 9/30/2028.
- Craig 3 station will be retired 12/31/2029.
- No spot purchases or sales are included.

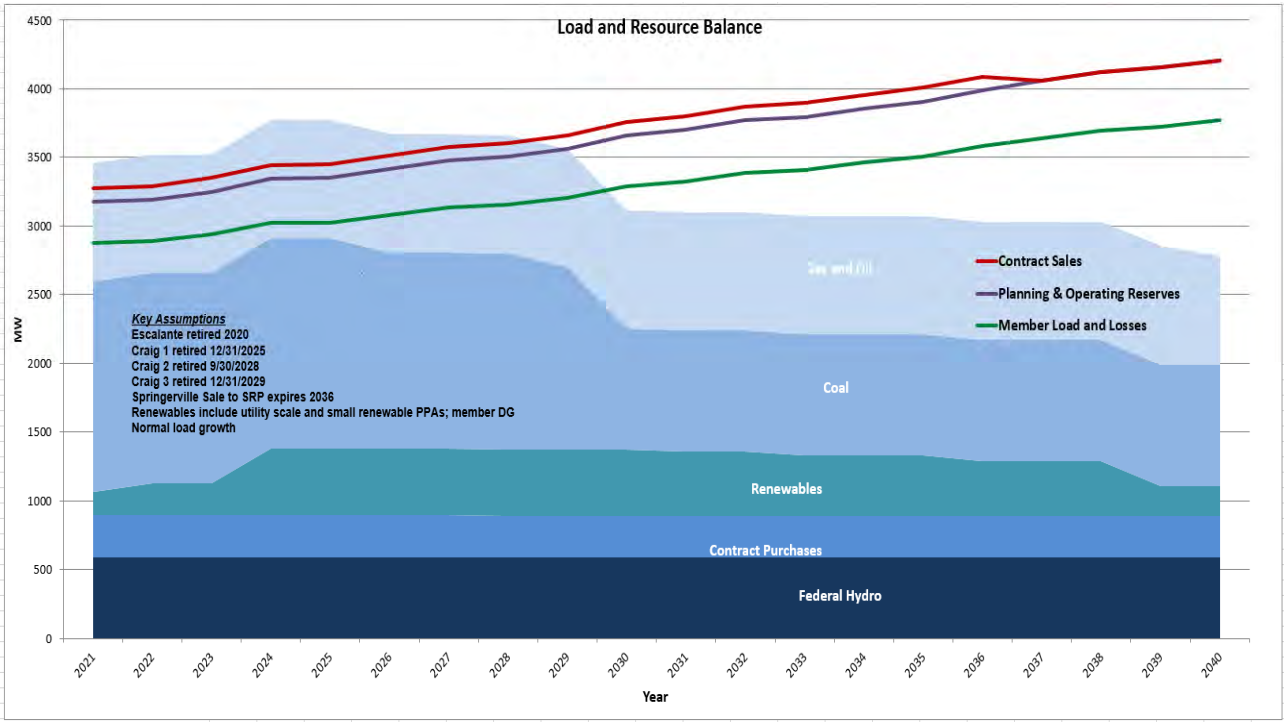

Figure 7: Tri-State Load and Resource Balance (Projected)

The above graph indicates a capacity resource need in 2029, which is later than the 2019 APR assessment. It is important to note that other factors may drive the need for additional generation beyond the scope of the above standard assessment. The scenarios described in Section 7 Alternative Scenario Analysis of this report are designed to demonstrate the potential impact that various load growth and legislative and environmentally driven conditions have on resource planning. In the evaluation of each scenario, the overall environmental impact and costs are considered in addition to resource diversity, dispatchability and reliability.

The capacity credit for existing and expansion plan resources is determined by technology. Capacity credit for dispatchable resources or semi-dispatchable resources is 100% of the summer rating. The contribution of renewables to system peak is based on B&V's modified ELCC Study as identified in Attachment Vol II 5-3 B&V Modified Effective Load Carrying Capability Study. This study takes into account the impact of additional renewables to the timing of the system peak. For example, as more solar is added to the system, the peak is pushed further into evening hours where solar is not capable of fully contributing to the peak, thus resulting in a decline in capacity credit. Final capacity credit values by technology are shown in Table 5.

Table 5: Modeled Capacity Credits by Technology

Resource Technology	**Capacity Credit** *(% of Nameplate)*
Thermal – Existing and Generic Resources	100%
Standalone Batteries	100%
Existing Solar (Commercial & Under Contract)	35%
Existing Wind (Commercial & Under Contract) & Wind Generic Resources	30%
Solar Generic Resources	15%
Solar + 25 MW Battery Generic Resources	15% Solar; 100% for Battery
Wind + 25 MW Battery Generic Resources	30% for Wind; 100% for Battery

Renewable Portfolio/Energy Standards

Overview:

The purpose of this analysis is to document Tri-State's forecasted compliance with the Colorado Renewable Energy Standard (RES) and the New Mexico Renewable Portfolio Standard (RPS), as well as any future compliance obligations for specific amounts of renewable and carbon free energy resources that may be enacted on the state or federal level affecting Tri-State or its member systems. Currently only Colorado and New Mexico have regulations requiring renewable, recycled or carbon neutral energy sources.

Compliance Obligations:

A RES/RPS requires a utility to generate, or cause to be generated, electricity from certain eligible renewable energy resources, at a percentage of retail electricity sales or as a percentage of energy provided to members. The definition of a renewable energy resource varies slightly depending on the state, but generally includes solar, wind, biomass, geothermal and small hydro resources. The Colorado statute also allows the application of recycled energy or waste heat energy and greenhouse gas neutral resources to count toward the total compliance requirement. The combination of these resources, together with renewable energy, is termed eligible energy.

The Colorado General Assembly left the RES unchanged in 2019, and the focus has shifted to GHG/CO_2 reduction requirements for which rules are still to be promulgated. It remains uncertain how this legislation applies to Tri-State. For the RES, Tri-State, as a Qualifying Wholesale Utility (QWU) under Colorado statute must meet a 20% Renewable Energy Standard (RES) by 2020. The Colorado RES also imposes a requirement on Tri-State's Utility Member Systems, as Qualifying Retail Utilities (QRU) under Colorado statute, increasing renewable energy at various levels until reaching 10% in 2020. The 20% Tri-State obligation may include Utility Member System-located renewable projects used towards satisfaction of the 10% requirement on cooperative electric associations by 2020.

In New Mexico, SB 489, also known as the Energy Transition Act, was signed into law in 2019. It leaves in place the RPS requirement through 2024 and increases renewable requirements starting in 2025. Tri-State Utility Member Systems are still required to meet a 5% RPS by 2015, which then escalates 1% per year to 10% in 2020 through 2024. The RPS requirement then rises to 40% for 2025 through 2029 and to 50%

beginning in 2030 through 2049. In 2050, the legislation sets a target of serving all retail sales with 100% zero carbon resources, composed of at least 80% renewable energy. This target is conditioned upon compliance solutions being technically feasible, and not having negative impacts to reliability or affordability. Another significant change to the NM RPS is that for co-ops, "hydropower facilities supplying no greater than the amount of energy from hydropower facilities that were part of an energy supply portfolio prior to July 1, 2007" (§ 62-15-37) can now be applied toward compliance. This category of renewable energy for Tri-State's New Mexico Utility Member Systems is essentially the CRSP allocation from the Western Area Power Administration's SLCA/IP projects that are assigned to New Mexico.

The current Colorado RES and New Mexico RPS requirements by year through 2020 are shown in Table 6.

Table 6: RES/RPS Requirements in Colorado and New Mexico

	Colorado		New Mexico
Year	**Co-ops**	**Tri-State**	**Co-ops**
2008-2010	1%		
2011-2014	3%		
2015	6%		5%
2016	6%		6%
2017	6%		7%
2018	6%		8%
2019	6%		9%
2020 – 2024	10%	20%	10%
2025-2029	10%	20%	40%
2030-2050	10%	20%	50%
2050 - beyond	10%	20%	80%

The Colorado RES includes a distributed generation (DG) requirement applicable to cooperative electric associations in an amount of 1% of total retail electricity sales starting in 2020. For cooperative electric associations with fewer than ten thousand (10,000) meters, the DG requirement is three quarters of 1% or 0.0075.

Only renewable energy resources count toward the DG requirement and of this requirement, one-half must come from wholesale DG and the other half from retail DG. Wholesale DG is defined as a renewable energy resource with a nameplate rating of ≤ 30 MW. Retail DG is defined as a renewable energy resource that is located on the customer's side of the utility meter and supplies no more than 120% percent of the average annual consumption. The most common example of retail DG is rooftop solar. Colorado statute allows subscription-based renewable energy facilities (ex., community solar) ≤ 5 MW to count towards meeting retail DG requirements. Cooperative electric associations may subtract industrial retail sales from total retail sales in calculating its retail DG requirement.

Compliance Reporting

Tri-State and its Utility Member Systems must submit a written report to the state utility regulatory bodies each spring documenting its compliance with state RES/RPS requirements for the preceding calendar year.

Tri-State documents its own as well as its Utility Member Systems' compliance with the Colorado RES and the New Mexico RPS through the retirement of Renewable Energy Certificates (REC). A REC represents the environmental attributes from one (1) megawatt-hour (MWh) of electricity generated from a renewable energy source. Both Colorado and New Mexico statutes provided for the use of multipliers depending on the technology and location of the project, whereby one MWh of energy could result in more than one REC being produced. All multipliers have been phased out since the RPS requirements were first developed; however many of the projects Tri-State uses for compliance achieved commercial operation before the expiration of the multipliers, and continue to benefit from grandfathered REC multipliers.

Most RECs used for state compliance are registered with the Western Renewable Energy Generation Information System (WREGIS) or in some cases, (BEPC non-hydro RECs) with the Midwest Renewable Energy Tracking System (M-RETS). RECs which are not used for compliance, sold or otherwise transferred in the year in which the associated renewable energy was generated may be carried forward for up to 5 years in Colorado and 4 years in New Mexico.

Tri-State's Compliance Analysis Methodology

Compliance with the Colorado RES and the New Mexico RPS is based on actual retail sales, although it should be noted that not all energy provided by Tri-State to its members translates into retail sales. This is due to system losses and members' own sales for resale. In order to forecast retail sales and determine projected RES and RPS compliance, the year-over-year growth rates for Colorado and New Mexico sales are calculated from the long-term financial forecast (LTFF) provided by the Load Forecasting Group and are applied to the actual retail sales values reported in previous years' Compliance Reports. Then using the RPS requirement levels shown in Table 6, the required number of RECs (corresponding to GWhs) by year to achieve RPS/RES compliance is calculated for Colorado and New Mexico.

Beginning in 2020, Tri-State's Colorado RES compliance obligation as a Qualified Wholesale Utility will be based on the amount of energy Tri-State provides to its Colorado Utility Member Systems. Therefore, the most current long-term load forecast for the energy Tri-State expects to provide its Colorado Utility Member Systems (excluding member generation) is used together with Table 6 to calculate the Colorado compliance obligation.

For both load and resources, forecast values are replaced with actual values at the beginning of each year for the preceding year. The forecasts for existing large utility scale projects, WAPA hydro and small hydro projects assume a continuation of past performance; although solar generation forecasts reflect a 0.5% degradation factor. In addition, any new projects with Tri-State Board approved PPAs are included using the forecasts provided by the developer. Forecasts reflect projected energy through the term of the PPAs.

The actual and forecast requirements are plotted graphically against the actual and forecast supply of RECs to depict Tri-State's compliance progress.

Results

The chart in Figure 8 is a graphical representation of Tri-State and its Utility Member Systems' progress towards meeting Colorado and New Mexico compliance obligations through 2040 on a yearly basis. Based on current progress, Tri-State and its member systems are exceeding the RES and RPS requirements.

The chart does not reflect banking effects of RECs that are provided for in each of the Colorado and New Mexico renewable energy statutes. During years when Tri-State and its Utility Member Systems are exceeding compliance levels, these entities may bank their unused RECs and apply them toward future years' obligations. Additionally, the figure represents only Tri-State's current renewable resource portfolio and respective PPA durations, without the inclusion of additional resources or expansion plan scenarios. It also does not reflect REC sales, or Tri-State-owned WAPA RECs not applicable toward compliance or Basin REC allocations from previous years (ex., in addition to the current year allocations, WAPA and BASIN may provide additional RECs with a prior year's vintage that it or other members/customers cannot use).

Considering the actual and forecast data in Figure 8 below and those factors not reflected in the chart, Tri-State remains confident in its ability to meet both its own and its Utility Member Systems' compliance obligations over the long term.

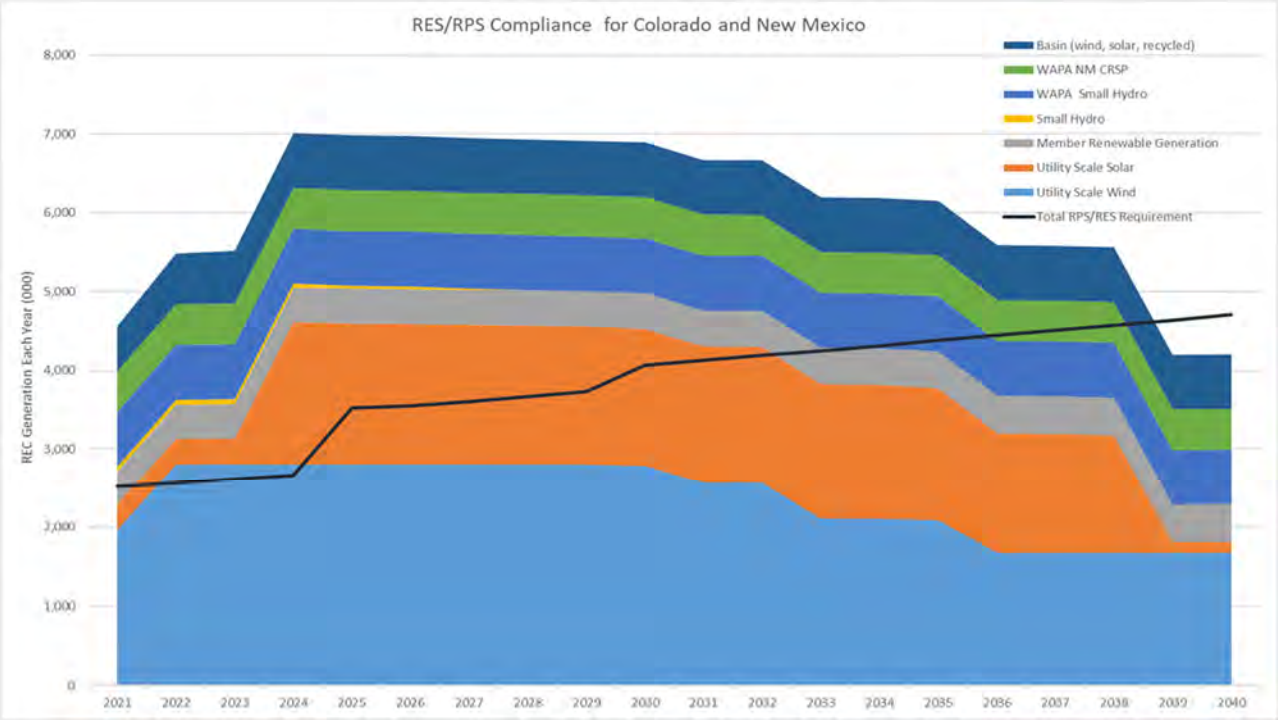

Figure 8: RES/RPS Compliance for Colorado and New Mexico

Demand Side Management and Energy Efficiency

As stated in Tri-State's 2019 APR, an important and ongoing part of Tri-State's Action Plan is the on-going implementation of Demand Side Management (DSM) measures. Options that have been evaluated include programs related to residential, small commercial, irrigation, large commercial and industrial programs. These offerings are continually refined based on effectiveness and Utility Member System feedback. As a generation and transmission provider, Tri-State does not have retail load and is reliant upon Utility Member System participation in DSM program implementations.

Demand Response:

Tri-State's current A-40 rate design provides Tri-State's Utility Member Systems an incentive to control load during Tri-State's defined peak period. Tri-State's A-40 rate consists of energy, generation demand and transmission demand rates. Some Tri-State Utility Member Systems successfully use active load control methods during Tri-State's defined peak period to reduce their monthly demand usage and related demand charges. Tri-State provides tools such as a real time load graph to help inform our members on when it may be optimal for them to control. Demand Response programs that have been developed at the Utility Member System level include:

- Irrigation Demand Response
- Commercial and Industrial Peak Load Management
- Water Heater and Air Conditioning Demand Response

Energy Efficiency:

Tri-State's electric energy efficiency program has been in place since 1985, and many of our current measures have been a strong part of our offerings for the past several years. However, with naturally evolving markets and consumer interest, these programs are continually monitored and discussed with our member system staff to ensure that they are creating value for their consumers. As we conduct our resource planning efforts, Tri-State is evaluating energy efficiency programs and offerings in order to achieve value and energy savings for our members and their consumers. Considerations in our program design include the diverse and small distribution coop staff, and historical and current membership feedback on program needs and focus. Current offerings include, but are not limited to, the following:

- Residential and commercial heating and cooling, including air source and ground source heat pumps and energy star air conditioners
- Residential LED lighting as a post-purchase rebate; Tri-State is evaluating alternative implementation pathways for this measure for the future.
- Commercial retrofit and new construction LED lighting, including refrigerated case doors, occupancy sensors, and other efficient LED lighting measures
- Heat pump water heaters
- Low-income weatherization
- Premium efficiency electric motors and variable speed drives
- Energy Star appliances

Pilot projects are available to all Utility Member Systems and can lead to DSM products.

In addition to these incentives, Tri-State offers a multitude of other programs to promote energy efficiency and the sharing of information around such programs. These include:

- R&D projects, such as the cold climate heat pump and irrigation efficiency projects done in partnership with the Electric Power Research Institute (EPRI) and our Utility Member Systems.
- Rebates on member system staff education, such as energy audit training.

- Working partnerships with external stakeholders such as state energy offices, efficiency groups, and others to promote their available programs to our membership and collaboration strengthening the market availability for energy efficient measures and contractors.
- Consumer education material on EE measures, including newsletter pieces, blog posts, educational webinars, social media pieces and others.

Table 7: 2019 Year-End Cumulative Energy Efficiency Results

Category	Typical Measures	kW Savings	kWh Savings
Agricultural	Irrigation Motors Variable Speed Drive Retrofits	13,446	22,513,016
C&I HVAC	Air Source and Ground Source Heat Pumps	4,858	5,312,892
C&I Lighting	LED Lighting Street & Parking Lot Lighting Refrigerated Case Doors	37,055	133,388,834
C&I Motors	Variable Speed Drive Retrofits	4,207	8,577,080
Residential HVAC	Air Conditioners Air Source and Ground Source Heat Pumps	83,924	56,681,586
Residential - Other	LED Lamps, Energy Star Appliances Electric Water Heaters Low Income Weatherization	52,531	26,080,067
Total		**196,020**	**252,553,476**

Energy Efficiency Historical Results:

- 2016 - $2,078,582
- 2017 - $2,349,835
- 2018 - $3,338,435
- 2019 - $3,327,027
- 2020 Budget - $6,697,353

Additionally, in late 2019, Tri-State initiated a DSM & EE Potential study through an outside consultant with the goal of receiving updated information in regards to achievable potential and cost savings in the areas of energy efficiency, demand response, and distributed energy resources for use in Tri-State's 2020 ERP process. Tri-State intends to leverage this study along with Utility Member Systems' input to evolve and expand products and service offerings in a manner beneficial to Tri-State and its member systems. Key findings from this study include:

- Identifies significant cost effective opportunities for energy and demand savings for energy efficiency programs.

- Identifies limited opportunities for DR programs; long-term operation is key for cost effectiveness.
- Distributed Energy Resource (DER) programs are not cost effective except for larger systems in specific regions.

The complete study is included as Attachment Vol II 5-1 Demand Side Management & Energy Efficiency Potential Study.

GHG & CO_2 Regulation

Tri-State continually evaluates current and proposed legislation while identifying appropriate strategies for its resource portfolio. The following legislation passed in 2019 by the state of Colorado significantly affects Tri-State's assessment of existing and future resources and is incorporated into this resource planning process:

- Colorado HB 19-1261 GHG statewide reduction goals and targets
- Colorado SB 19-096 GHG reporting
- Colorado SB 19-236 Clean Energy Plan and CO_2 Reduction

Tri-State has actively participated in Colorado AQCC working groups and sessions related to this legislation. Through this process, Tri-State has gathered insight and information from related regulations and guidance document processes and forms to create a GHG/CO_2 reduction spreadsheet to apply to each scenario that uses Colorado AQCC methodologies and expected calculations while trying to reflect Tri-State's unique position as a utility serving load in multiple states on a wholesale basis only. Some key components of Tri-State approach to addressing these emission reductions include:

- Addressing CO_2 reduction in relation to all wholesale electricity sales in Colorado whether to Tri-State's Utility Member Systems or non-members.
- Removing Tri-State Utility Member Systems in Colorado who have exited Tri-State (baseline and forecast).
- Addressing GHG reduction at a retail level based on retail sales of Tri-State Utility Member Systems.
- Incorporating all emissions produced by Tri-State owned generation located in Colorado.
- Applying emissions to out of state resources or purchases that are forecast to serve Colorado load or sales.

Tri-State's methodology for CO_2 and GHG emission reductions is based on a mass based comparison of 2030 forecast emissions to a 2005 emissions baseline. Some scenarios include a glide path to CO_2 reduction beginning in 2025. Details of the GHG/ CO_2 calculations can be found in Volume II Section 5 Phase I Modeling Details of this report and results can be found in Section 8 Base Case and Alternative Scenario Results of this report.

Beneficial Electrification

In addition to energy efficiency and demand response, Tri-State has identified Beneficial Electrification (BE) as a key goal in its on-going action plan. Tri-State has long standing electrification programs such as incentives for air source and ground source heat pumps, electric outdoor power equipment such as lawn mowers, and has established several electric vehicle programs, including funding to assist members in expanding public charging infrastructure.

In early 2020, Tri-State commissioned a BE potential study to evaluate measures and their potential to be impactful in Tri-State's service area. The primary objective of this study is to assess the technical, beneficial, and achievable electrification potential from a variety of measures over the planning horizon. This study was designed to measure achievable potential, not program potential, and is intended to assist Tri-State in developing future ERPs. The achievable potential focuses on what *could be*, but does not account for limitations that could come from program portfolio structure or organization limitations.

The study evaluated measures in the residential, irrigation, commercial, and industrial sectors. Measures must meet one of the following criteria without adversely impacting the other three:

- Saves the member-consumer money
- Reduces emissions
- Improves quality of life
- Fosters grid resiliency

The complete study can be found in Attachment Vol II 5-7 Tri-State Beneficial Electrification Potential Study. Key findings from this study include:

- Technologies assessed include electric building heating measures, electric vehicles and non-road electric vehicles, cooking measures, and electric equipment such as lawn and garden equipment.
- The achievable-moderate scenario would result in approximately 2.5 GWh of load growth in year 1, rising to 653 GWh of cumulative growth through the planning study.
- BE provides for emissions reductions.
- The irrigation sector carries significant potential from electrification of motors currently powered by natural gas, propane, or diesel.
- The commercial sector includes a large portion of potential emissions reductions from off-road EV measures such as electric forklifts.
- The top 7 most impactful measures are:
    - Small, light duty battery electric vehicles
    - Irrigation pump motors
    - Heat pump water heaters
    - Electric forklifts (class V and IV)
    - Air source heat pumps
    - Electric buses
- Customer adoption will be a hurdle to overall beneficial electrification uptake.

Due to the timing of the completion of this study, along with the additional necessary work to establish programs and implement the potential, the BE load growth is not included in any alternative scenario.

Tri-State expects to have a clearer picture of an overall BE program and related Utility Member System customer acceptance for use in preparation for the June 1, 2023 Colorado ERP filing.

Imbalance Markets, Regional Transmission Organizations and Independent System Operators (ISO)

Tri-State has the following current and expected activity in relation to imbalance markets:

- Tri-State's load located in PAC has been in the CAISO WEIM since 2014.
- Tri-State's load and resources in WAPA-BA will enter SPP's WEIS in February 2021 or such date as the Western Markets Executive Committee determines.
- Tri-State's load and resources in PNM will enter CAISO WEIM in April 2021.
- PSCo has announced entry into CAISO WEIM in 2022. Tri-State's load in PSCo will move into the WEIM at that time and prior to PSCo's entry date Tri-State will assess whether to participate in the WEIM with resources in PSCo.

To represent this market entry in the Resource Plan Tri-State modeled two imbalance markets, WEIS and WEIM, in addition to existing modeled markets of Craig, Ault, LRS, and Four Corners. The WEIS and WEIM are tied to the Colorado East power curve and Palo Verde power curve, respectively as described in Volume II Section 2 Commodity Pricing of this report. After entry into the market, Tri-State will begin to use appropriate locational marginal pricing as it becomes available to improve forward curve predictors for these markets and will adjust market depths to reflect imbalance activity. The WEIS and WEIM markets are modeled from their entry dates in 2021 through 2024, at which time Tri-State takes these markets to zero in the model and expands the depths of Craig, Ault, LRS, and Four Corners markets to reflect potential formation of an RTO across Tri-State's system footprint in which Tri-State can fully participate.

Expected benefits of the WEIM and WEIS include:

- accessibility to a wider market for Tri-State resources,
- lower power purchase prices,
- potential for development of a "day-2" market, and
- additional ability to integrate renewables.

Tri-State believes entry into imbalance markets will improve reliability and help to reduce the cost of serving Utility Member System load. Additionally, the formation of a full RTO or ISO will further increase the ability to integrate renewables, while maintaining reliability and reducing costs as both day ahead and real time functions related to unit commitment and economic dispatch of both energy and ancillary services will be under the umbrella of one market operator over an extended footprint.

7 Alternative Scenario Analysis

Overview

Tri-State uses scenario analysis for resource planning. The process is designed to measure the effect of changes to key assumptions and the impact of sensitivities on key inputs. For the 2020 IRP/ERP process, Tri-State established a base case using inputs known as of June 2020. This case does not include changes

from normal assumptions or any regulatory impacts. The purpose of the base case is for use as a standard against which other scenarios can be measured. Each alternative scenario is analyzed for financial, reliability and environmental impact. Financial impacts include transmission capital expenditures, resource build costs, and resulting PVRR for the RPP. Reliability impacts include dispatchability, diversity and reliability assessment. Environmental impacts include system-wide emissions rates and water usage for hourly dispatch, as well as required GHG/CO_2 reduction in the state of Colorado. Compliance with RES in Colorado and RPS in New Mexico is also assessed for each scenario.

Tri-State used base inputs as well as scenario-specific assumptions, and employed an iterative process to reach an optimal expansion plan for a given study. The expansion plan was then analyzed for transmission capital expenses, run through the production cost hourly dispatch model, and analyzed in financial forecasting software to arrive at a final PVRR.

In the Section 9 Base Case & Alternative Scenario Comparison of this report, comparisons of PVRR, GHG/CO_2 reduction in Colorado, transmission capital expense, SCoC, and emissions and water usage can be found. A qualitative comparison of reliability impacts is also included. Scenarios are given rankings for diversity, dispatchability and reliability with scores ranging from one to three, where one is lowest and three is highest.

- High diversity is determined by having variability in fuel supply and location in resource mix.
- High dispatchability is determined as the operational ease of increasing or curtailing the resource mix, as well as financial impact.
- High reliability is determined as a resource mix with strong ability to support the grid and flexibility in providing ancillary services.

Alternative Scenario Process

Method for Developing Alternative Scenarios:

The CE model optimized alternative scenario expansion plans by selecting the plan with the lowest costs while adhering to various constraints. Some constraints include 1) minimum levels of planning / operating reserve margins, 2) limits on CO_2 and nitrous oxides (NO_x) emissions to specified levels, and 3) limits on new resources in a given location, so as not to exceed transmission link capacities.

For scenarios with a CO_2 emission constraint applied, CE was unable to completely model the constraint. CE accounts for CO_2 emissions associated with thermal units located within Colorado. However, for thermal generation located outside of Colorado serving loads both in Colorado and in other states, the CO_2 emissions cannot be included in the CE constraint. Therefore, the resulting CE expansions plans did not fully meet the targeted emission limits. In order to meet the carbon emission targets, the CE expansion plans for each scenario were modified outside of CE through additional analysis. Adjustments included adding more renewable resources and/or changing the installation dates of resources identified in the expansion plan. Some considerations for making adjustments were locating resources to minimize transmission network upgrades, the feasibility of wind or solar in any given transmission area, maximizing the use of transmission made available through resource retirements, ensuring the minimum reserve requirement is met and balancing the mix of technologies.

Scenarios:

In an effort to develop alternative plans, Tri-State first developed the base case. As previously stated, the base case serves as a standard against which other scenarios can be measured. The base excludes GHG/CO_2 reductions in Colorado. It was developed using the following main inputs:

- Load forecast – 2020 annual long term forecast
- Electric price forecast – May 2020 spring reset long term forecast
- Gas price curves - May 2020 spring reset long term forecast
- Coal price forecast – 2020 forecast
- Announced coal unit retirements
- A set of generic resources as listed in Volume II Section 5 Phase I Plan Modeling Details of this report.

Note that in all scenarios, 2021 preliminary budget data was used as it represented the best available data on Tri-State's expected 2021 budget. These resource planning processes will not drive a change in the 2021 budget.

For a more complete summary of the remaining inputs, see Volume II Section 5 Phase I Plan Modeling Details under the Modeling Assumptions subsection in this report.

Two primary metrics against which alternative plans were evaluated were PVRR and reduction in GHG/CO_2 emissions in the state of Colorado. Each alternative scenario was required to meet minimum reserve requirements, serve Utility Member System loads, and not exceed the capacities of the transmission links serving the various modeling regions.

Tri-State developed the following alternative scenarios:

- 80pct CR Version 1
- 80pct CR Version 2
- 80pct CR Version 3
- 80pct CR Version 4
- Low Load 80pct CR Version 1
- Low load 80pct CR Version 2
- Social Cost of Carbon (SCC)

The 80pct CR Version 1 scenario was developed by calculating an emissions constraint of 20% of the Colorado 2005 Baseline emissions. The resulting mass-based emissions quantity was then applied as a restriction within the expansion plan and dispatch models to the extent technically feasible for the year 2030. This resulted in CO_2 emissions being reduced in 2030 by 80% from 2005 levels, in regards to emissions from wholesale electricity sales in Colorado. Additionally, this scenario includes a glide path beginning in 2025 for further reducing emissions annually until arriving at the requirement of 80% reduction in CO_2 emissions in Colorado for 2030 relative to the 2005 Colorado Baseline. This scenario also included forced aggressive level EE and low level DR in Colorado.

The 80pct CR Version 2 scenario is similar to the 80pct CR Version 1 scenario but with the removal of generic DR& EE resources as supply-side options. The scenario was analyzed to see how the PVRR and overall costs would be impacted by the removal of aggressive energy efficiency in Eastern Colorado and Western Colorado, which were present in Version 1.

The 80pct CR Version 3 scenario is similar to the 80pct CR Version 2 scenario but includes an additional wind resource to improve CO_2 reduction and enhance reliability.

The 80pct CR Version 4 scenario is similar to the 80pct CR Version 2 scenario but includes an additional solar resource to improve carbon reduction and enhance reliability.

The Low Load 80pct CR Version 1 uses the low load forecast. The load forecast used is the lower end of a 90% prediction interval estimated for the expected load. This scenario also achieves an 80% reduction in CO_2 emissions related to emissions from wholesale electricity sales in Colorado in 2030, using the year 2005 as a baseline.

The Low Load 80pct CR Version 2 is similar to the Low Load 80pct CR Version 1 but with the removal of generic DR & EE resources as supply-side options.

The SCC scenario uses the technical support document under *Executive Order 12866 – Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis,* to determine the social cost of carbon. Values were converted from metric to short tons and escalated from 2007 to 2020 dollars. Tri-State used revised values for real and nominal prices per PUC Staff's comments[5] in Proceeding No. 20M–0218E and as interpreted from guidance in Commission's November 12, 2020 weekly meeting. The social cost of carbon per ton for each existing and generic resource was calculated by multiplying in each year the social cost of carbon per short ton (in real dollars) times the CO_2 emission rate of each resource. Social Cost of Carbon was applied to both in state and out of state resources. This value was added to the variable operating & maintenance (VOM) cost for each resource in each year of the RPP. Only the CE expansion plan model used these escalated VOMs. Market purchases are not used in expansion planning. SCC was not applied to the Basin contracts, as the expansion plan tool is not set up to evaluate retiring contracts.

The nominal social cost of carbon for the final dispatch of the SCC scenario including existing and generic resources, market purchases, energy imbalance purchases and the Basin contracts were passed to UIPlanner for calculation of the PVRR. The social cost of carbon specific to each resource for each year in both real and nominal dollars can be found in Volume II Section 5 Phase I Modeling Details under the subsection of Social Cost of Carbon of this report.

8 Base Case & Alternative Scenario Results

This section identifies key data assumptions and results related to expansion plan, capacity factors of thermal resources, annual emissions by owned or contracted resource, CO_2 reduction in Colorado by 2030 from a 2005 Colorado Baseline and social cost of carbon.

[5] See Volume II Section 5 Phase I Modeling Details under subsection of Social Cost of Carbon for values used.

Tri-State transmission areas that represent modeling regions are as follows:

- Eastern Colorado (ECO)
- Western Colorado (WCO)
- Wyoming (WYO)
- New Mexico (NM)
- Nebraska (NE)
- Springerville (SPV)
- Mt Elbert
- Wyoming Green

Load, resources and markets are assigned to these transmission areas. More detail on these transmission areas can be found in Volume II Section 5 Phase I Modeling Details under the subsection of CE and PO of this report.

Base Case

Base Case assumptions are as listed in Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report.

Assumptions Unique to this Case:

- No additional assumptions unique to this case.

Results:

Table 8: Expansion Plan (Base Case)

Location	MW	Technology	Year

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$400M in New Mexico in 2030
- ~$300M in Eastern Colorado in 2031
- ~$300M in Eastern Colorado in 2039

Detailed transmission expenses related to generic resources are shown in the following table.

Table 15: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (Base Case)

Year	**Size** *(MW)*	**Type**	**Interconnection Cost** *($M)*	**Network Upgrade at POI Cost** *($M)*	**Network Upgrade for Size** *($M)*

80pct CR Version 1

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 16: Unique Assumptions (80pct CR V1)

Assumption Item	Description
Additional Retirements	Allowed – coal retirements after 2025; SPV3 not allowed to retire until after end of Salt River Project (SRP) contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV 3 **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV 3 **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• Max Study – ECO 2000 • Max Study – NM 400 • Max Study – Storage 1200 • Max Study – Thermal 300

Assumption Item	Description
	• Max Study – WY 650 • Max Annual – Renewable 1000
DSM & EE Level	Aggressive EE and Low DR forced for ECO and WCO
CO_2 Reduction	80% CO_2 in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Mt. Elbert	Off
Transmission Links	See Table 17 for detail
Market Depths	See Tables 18 & 19 for detail

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2030
- ~$150M in Western Colorado in 2030
- ~$300M in Eastern Colorado in 2034
- ~$400M in New Mexico in 2037
- ~$300M in Eastern Colorado in 2040

Detailed transmission expenses related to generic resources are shown in the following table.

Table 28: Transmission Interconnection & Network Upgrade Expenses(2020 Real Dollars) (80pct CR V1)

80pct CR Version 2

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 29: Unique Assumptions (80pct CR V2)

Assumption Item	Description
Additional Retirements	Allowed – coal retirements after 2025; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• Max Study – ECO 2000 • Max Study – NM 400 • Max Study – Storage 1200 • Max Study – Thermal 300 • Max Study – WYO 650 • Max Annual – Renewable 1000
DSM & EE Level	Existing DSM EE only
CO_2 Reduction	80% CO_2 reduction in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Mt Elbert	Off
Transmission Links	See Table 30 for details
Market Depth	See Tables 31 & 32 for details

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$150M in Western Colorado in 2030
- ~$300M in Eastern Colorado in 2032
- ~$400M in New Mexico in 2037
- ~$300M in Eastern Colorado in 2039

Detailed transmission expenses related to generic resources are shown in the following table.

Table 41: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (80pct CR V2)

80pct CR Version 3

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 42: Unique Assumptions (80pct CR V3)

Assumption Item	Description
Additional Retirements	Allowed – coal retirements after 2025; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• Max Study – ECO 2000 • Max Study – NM 400 • Max Study – Storage 1200 • Max Study – Thermal 300 • Max Study – WY 650 • Max Annual – Renewable 1000
DSM & EE Level	Existing DSM EE only
CO_2 Reduction	80% CO_2 reduction in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Mt. Elbert	Off
Transmission Links	See Table 43 for detail
Market Depth	See Tables 44 & 45 for detail

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$150M in Western Colorado in 2030
- ~$300M in Eastern Colorado in 2030
- ~$400M in New Mexico in 2037
- ~$300M in Eastern Colorado in 2039

Detailed transmission expenses related to generic resources are shown in the following table.

Table 54: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (80pct CR V3)

80pct CR Version 4

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 55: Unique Assumptions (80pct CR V4)

Assumption Item	Description
Additional Retirements	Allowed – coal retirements after 2025; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• Max Study – ECO 2000 • Max Study – NM 400 • Max Study – Storage 1200 • Max Study – Thermal 300 • Max Study – WY 650 • Max Annual – Renewable 1000
DSM & EE Level	Existing DSM EE only
CO_2 Reduction	80% CO_2 reduction in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Mt. Elbert	Off
Transmission Links	See Table 56 for details
Market Depths	See Tables 57 & 58 for details

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$150M in Western Colorado in 2030
- ~$300M in Eastern Colorado in 2032
- ~$400M in New Mexico in 2037
- ~$300M in Eastern Colorado in 2039

Detailed transmission expenses related to generic resources are shown in the following table.

Table 67: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (80pct CR V4)

Low Load 80pct CR Version 1

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 68: Unique Assumptions (Low Load 80pct CR V1)

Assumption Item	Description
Load Forecast	2020 Annual Load Forecast – LCL 90
Additional Retirements	Allowed – coal retirements in 2026; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• ECO 2021 to 2023 Annual Max: 0 • ECO 2024 to 2027 Annual Max: 100 • ECO 2028 to 2040 Annual Max: 10000 • Max Annual – Renewable: 1000 • Max Study – ECO: 2000 • Max Study – NM: 400 • Max Study – Storage: 1200 • Max Study – Thermal: 300 • Max Study – WY: 650
CO_2 Reduction	80% CO_2 reduction in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Transmission Links	See Table 69 for detail
Market Depths	See Table 70 & 71 for details

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$150M in Western Colorado in 2033
- ~$300M in Eastern Colorado in 2036
- ~$400M in New Mexico in 2037

Detailed transmission expenses related to generic resources are shown in the following table.

Table 80 : Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (Low Load 80pct CR V1)

Low Load 80pct CR Version 2

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 81: Unique Assumptions (Low Load 80pct CR V2)

Assumption Item	Description
Load Forecast	2020 Annual Load Forecast – LCL 90
Additional Retirements	Allowed – coal retirements in 2026; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2024 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2025 - 2040:** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• ECO 2021 to 2023 Annual Max: 0 • ECO 2024 to 2027 Annual Max: 100 • ECO 2028 to 2040 Annual Max: 10000 • Max Annual – Renewable: 1000 • Max Study – ECO: 2000 • Max Study – NM: 400 • Max Study – Storage: 1200 • Max Study – Thermal: 300 • Max Study – WY: 650
DSM & EE Level	Existing DSM/EE only
CO_2 Reduction	80% CO_2 reduction in 2030 from 2005 baseline in relation to electricity sales in Colorado; Glide path from 2025 to 2030
Transmission Links	See Table 82 for details
Market Depths	See Table 83 & 84 for details

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2029
- ~$150M in Western Colorado in 2034
- ~$300M in Eastern Colorado in 2036
- ~$400M in New Mexico in 2037

Detailed transmission expenses related to generic resources are shown in the following table.

Table 93: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (Low Load 80pct CR Version 2)

Social Cost of Carbon

Assumptions Unique to this Scenario:

Modeling assumptions are per Volume II Section 5 Phase I Plan Modeling Details under the subsection of Modeling Assumptions of this report with the following exceptions:

Table 94: Unique Assumptions (Social Cost of Carbon)

Assumption Item	Description
Additional Retirements	Allowed – Coal and Gas retirements after 2025; SPV3 not allowed to retire until after end of SRP contract (first year 2037)
Social Cost of Carbon	Used Social Cost of Carbon adder for all thermal resources
Thermal Resource Status: **Econ** - Model can choose to turn resource on and off but resource has a 168 hour on line min. **Must Run** - Model can choose what level to run the resource at but resource cannot go lower than min.	**Must Run 2021 - 2040 :** Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV **Econ 2021 - 2040:** Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and Shafer
Build Limits	• Max Study – Eco 2000 • Max Study – NM 400 • Max Study – Storage 1200 • Max Study – Thermal 1000 • Max Study - Wyo: 650 • Max Annual – Renewable 1000
EE & DR DSM Level	Aggressive EE and Low DR forced for ECO and WCO
CO_2 Reduction	RestrictedCO_2 levels on Colorado thermal resources
Transmission Links	See Table 95 for detail

Table 95: Applied Transmission Link Capacities (Social Cost of Carbon)

Transmission Impact

Beyond normal interconnection transmission expenses, significant additional network upgrades for size in this plan (Costs are in 2020 dollars) were incurred as follows:

- ~$400M in Eastern Colorado in 2028
- ~$400M in New Mexico in 2028
- ~$150M in Western Colorado in 2030
- ~$300M in Eastern Colorado in 2030
- ~$300M in Eastern Colorado in 2037

Detailed transmission expenses related to generic resources are shown in the following table.

Table 104: Transmission Interconnection & Network Upgrade Expenses (2020 Real Dollars) (Social Cost of Carbon)

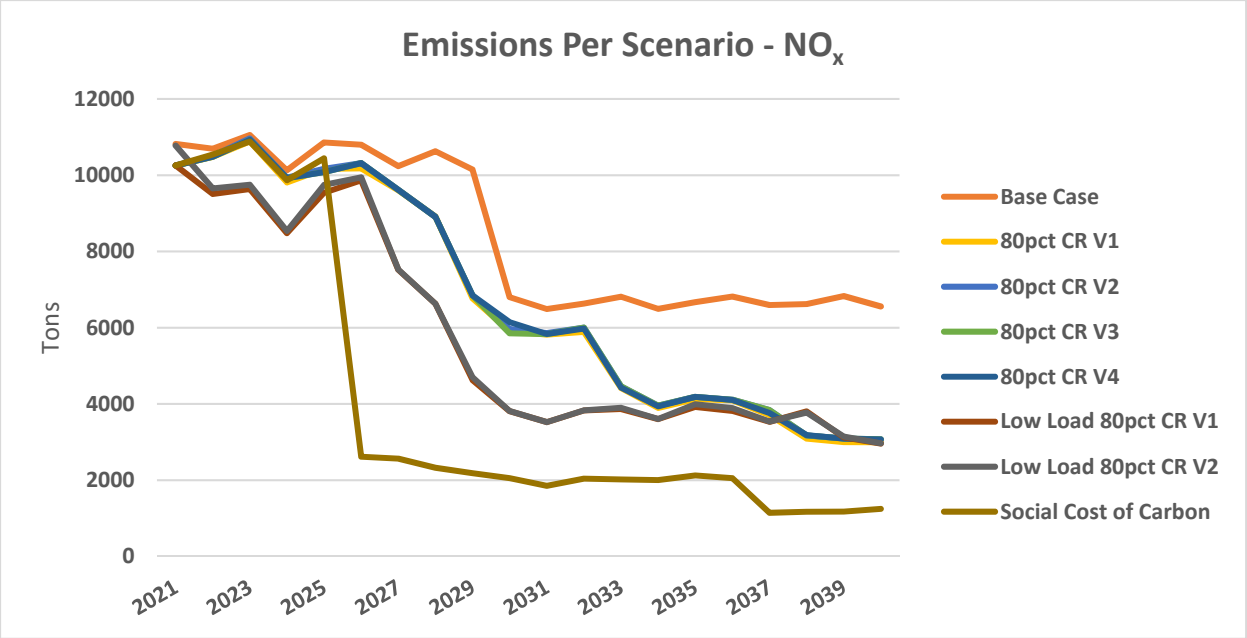

Figure 29: Comparison of NO_x Emissions per Scenario

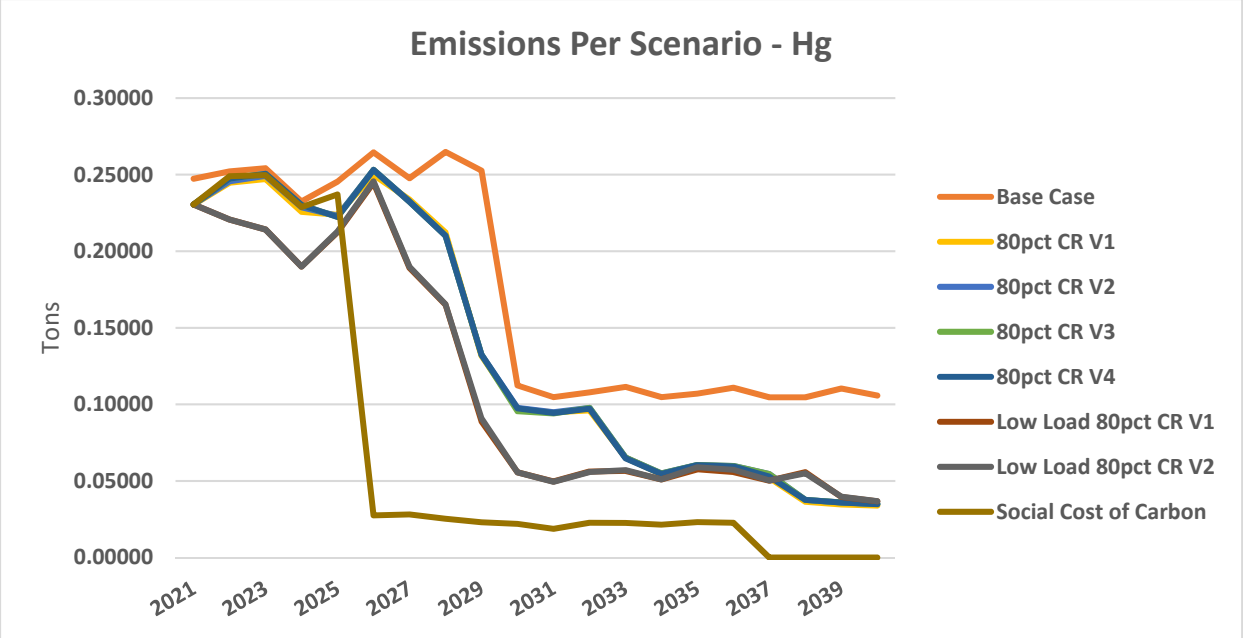

Figure 30: Comparison of Hg Emissions per Scenario

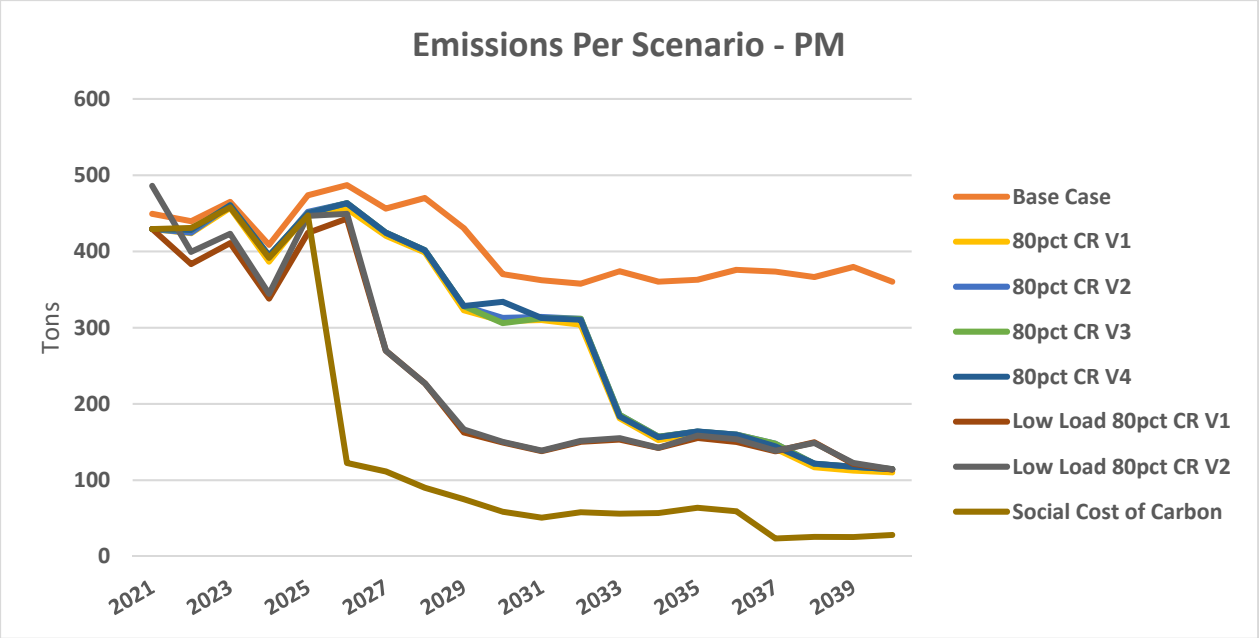

Figure 31: Comparison of PM Emissions per Scenario

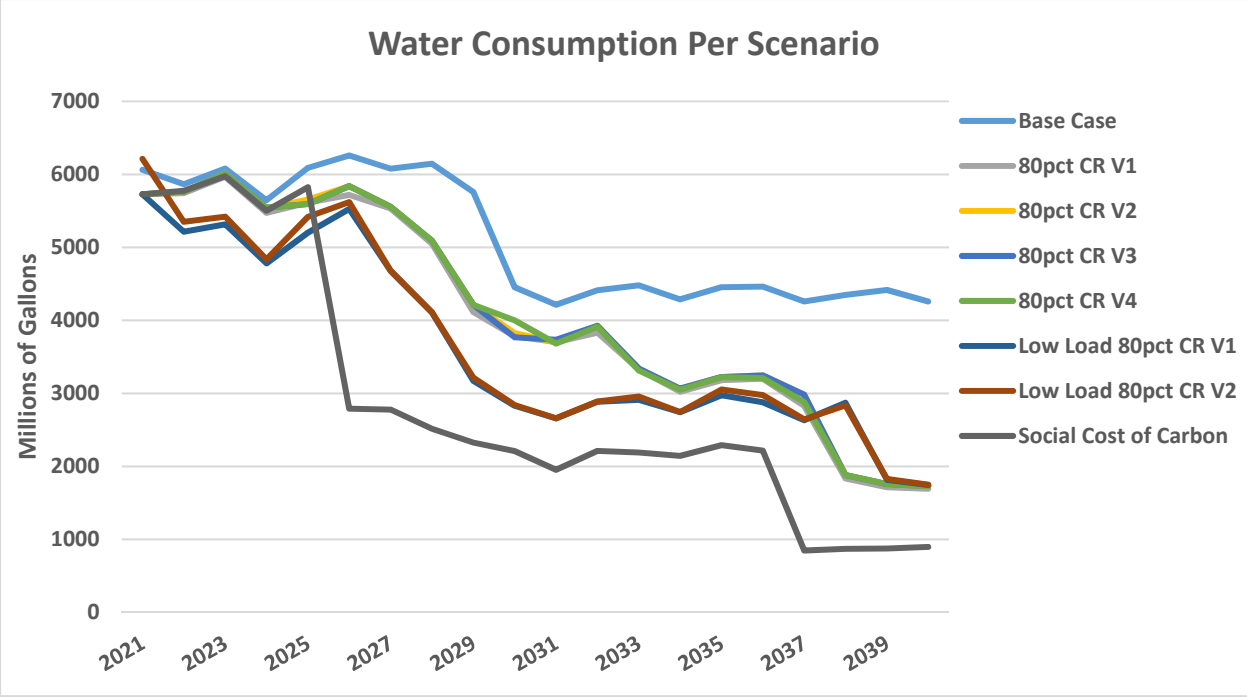

Figure 32: Comparison of Water Consumption per Scenario

RES/RPS Comparison

All scenarios fully meet Colorado RES and New Mexico RPS over the RAP. Data was checked both with contract energy profiles for existing and under contract, resources as stored in Hyperion for financial analysis and with the variable (intermittent) energy resource profiles as developed and used for dispatch in PO. Key drivers for meeting renewable energy or portfolio standards include retirement of thermal resources, significant planned addition of renewables and a focus on carbon reduction targets in the state of Colorado. See Attachment Vol II 6-2 RES/RPS for renewable standard evaluation of each scenario.

Diversity, Dispatchability, & Reliability Comparison

Tri-State applied a qualitative analysis to each scenario based on diversity, dispatchability and reliability defined as follows:

- Diversity is determined as having variability in fuel supply and location in resource mix.
- Dispatchability is determined as the operational ease of increasing or curtailing the resource mix as well as financial impact.
- Reliability is determined as a resource mix with strong ability to support the grid and flexibility in providing ancillary services

A score of 1 = Low, 2 = Medium and 3 = High.

Each alternative scenario scored high on diversity for both technology and location. All scenarios include varying levels of solar, wind, energy storage and gas resources and such resources are dispersed across the eastern Colorado, western Colorado, New Mexico and Wyoming regions within the model. The base case scores at a medium level on diversity due to a high quantity of thermal resources, both existing and generic. There are technical or economic feasibility limitations to the location of particular technologies within Tri-State's footprint. For instance, solar is technically feasible in western Colorado, but wind is not. Conversely, in Wyoming wind is more feasible than solar. The generic resource data set used for all scenarios reflected these feasibilities.

Dispatchability is highest in the base case as the expansion plan has a higher level of dispatchable resources allowing more ramping flexibility to handle the integration of intermittent resources. However, all GHG/CO_2 reductions scenarios have a reasonable level of dispatchability, as a significant portion of existing thermal resources, primarily gas, are retained in the plan along with the addition of a combined cycle gas resource and adequate amounts of energy storage. The SCC scenario retires significantly more thermal resources, but does add a larger quantity of expansion plan gas resources.

Reliability is the highest in the base case as the expansion plan includes a higher quantity of thermal resources, which historically have a greater capacity to support the grid in regards to reserves, regulation and voltage support. However, all GHG/CO_2 reduction scenarios have a reasonable level of retention of existing thermal resources along with addition of energy storage that will be used to help integrate renewables in a transitioning grid.

Table 106 illustrates the base case and scenario ranking in all three of these areas.

Table 106: Diversity, Dispatchability & Reliability Scoring

Scenario	Diversity	Dispatchability	Reliability	Total Score
Base	2	3	3	8
80% CR V1	3	2	2	7
80% CR V2	3	2	2	7
80% CR V3	3	2	2	7
80% CR V4	3	2	2	7
Low Load 80% Carbon Reduction V1	3	2	2	7
Low Load 80% Carbon Reduction V2	3	2	2	7
Social Cost of Carbon	3	2	2	7

Comparison Summary

The Base Case and seven alternative scenarios all share assumptions such as the same generic resource data set, commodity pricing, and announced coal retirements. Assumptions varied between scenarios in regards to DSM/EE, allowable thermal retirements, build limits by technology and location, transmission links and GHG/CO_2 reduction levels and/or costs.

All scenarios had a reasonable mix of solar, wind, energy storage and gas. The Base Case and SCC scenario had the most gas additions, but this is primarily due to a restriction on all other scenarios to meet GHG/CO_2 reduction goals in the state of Colorado. The SCC scenario also had significantly higher quantities of thermal resource retirements resulting in additional expansion plan gas resources. Energy Storage becomes increasingly more competitive across the RPP. Renewables begin and remain competitive throughout the RPP.

All scenarios to some extent utilize transmission interconnection capacity made available by thermal retirements. All plans show considerable resource additions in WCO due to the transmission capacity that will become available through the retirement of the Craig facility. Tri-State's primary transmission constraints resulting in a need for network upgrades occur in ECO. The ECO load area represents a significant portion of Tri-State's system load and most long-term load growth is focused in this area.

Retirement of existing thermal resources vary by scenario with SCC showing the highest volume of retirements. Announced retirement dates are included in all scenarios, and all scenarios except for the Base Case allow additional coal retirements starting in either 2025 or 2026. This timing limit allows for a reasonable timeframe for replacement decisions and acquisition of replacement resources. The SCC scenario also allows gas retirements.

Planning Reserve Margins (PRM) primarily run high between ~15% to ~25% during the RAP. Spikes are seen when thermal retirements occur and additional resources are brought on. The elevated PRM is due to the low energy cost of renewables coupled with lower capacity credits for renewables than their thermal counterparts as well as the semi-dispatchable nature of energy storage.

The Base Case shows GHG/CO_2 reduction of 31% in the state of Colorado as measured against a 2005 baseline. All other scenarios have GHG/CO_2 reductions in the state of Colorado as measured against a 2005 baseline of ~80%. System wide emissions and water usage are significantly reduced for all scenarios over the RAP. The calculated SCoC is the lowest in the SCC scenario but is also substantially reduced from

the base case in all 80% CR (base and low load) scenarios. The overall environmental impact of GHG/CO_2 reduction in all alternative scenarios is significant.

All scenarios easily meet Colorado and New Mexico RPS/RES requirements. This is driven by both the competitiveness of renewable resources as well as the GHG/CO_2 restrictions to meet state of Colorado goals.

As more thermal retirements result in fewer dispatchable resources on the bulk electric system. Tri-State has concerns about potential financial impacts driven by Balancing Authority alternative steps to continue to secure the reliability of the grid. While all of these scenarios have a reasonable diversity, dispatchability, and reliability mix from a planning perspective, it is critical for Tri-State to be aware of resource mix changes occurring in relation to the actions of other utilities in the Rocky Mountain and Southwest regions and to step into changes to resource mix in a responsible manner to ensure reliability and financial stability for Tri-State's Utility Member Systems. A representation of this regional impact can be seen in Figure 33.

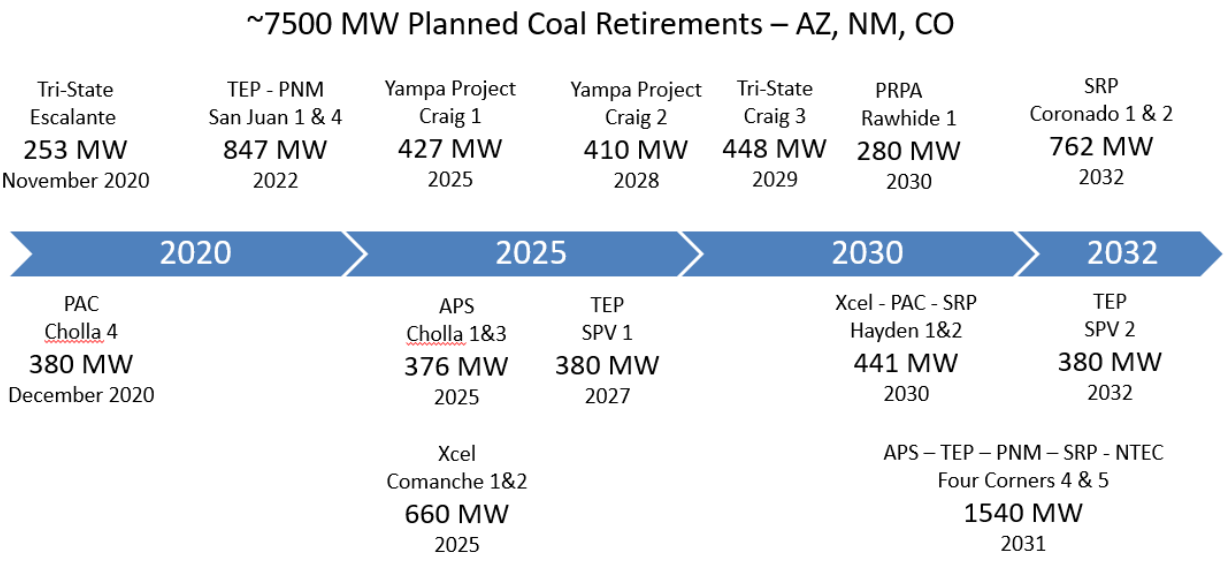

Figure 33: Planned Coal Retirements in Arizona, New Mexico and Colorado

10 Summary of Preferred Plan

In assessing the Base Case and Alternative Scenarios, Tri-State has selected the 80% CR V4 scenario as its preferred plan. Primary reasons for this selection include:

- Generation locations and technology diversity, as illustrated in Figure 34 are sufficient to fully utilize interconnection capability made available from announced retirements.
- Forecast additional thermal retirements projected to occur after the RAP as shown in Figure 35 and in addition to announced retirements during the RAP, allow a manageable transition to zero carbon resources while maintaining reliability and affordable rates.
- Transmission system network upgrade costs are minimized during the RAP compared to the base case.
- The PVRR for the RPP is ~$400M higher than the Base Case while achieving the state of Colorado GHG/CO_2 reduction target of 80% GHG/CO_2 reduction by 2030 from a 2005 baseline.
- Overall emissions and water usage are significantly reduced by 2030 from current levels and are significantly lower than in the Base Case.
- The scenario uses a glide path from 2025 to 2030, as illustrated in Figure 36, for carbon reduction goals in the state of Colorado to achieve meaningful reductions in the near term.

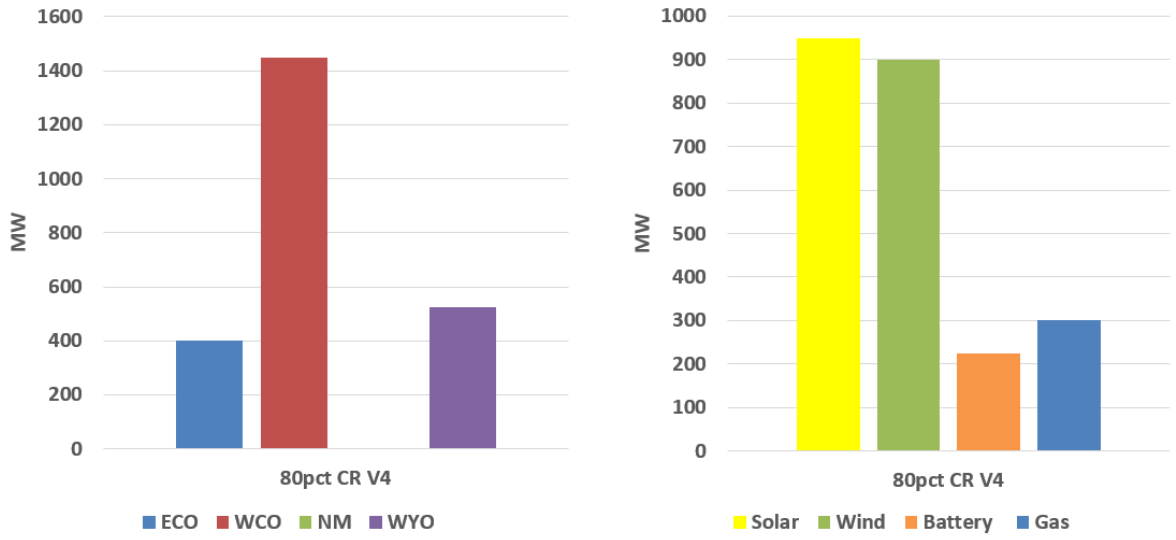

Figure 34: Preferred Plan Resource Additions over the RAP

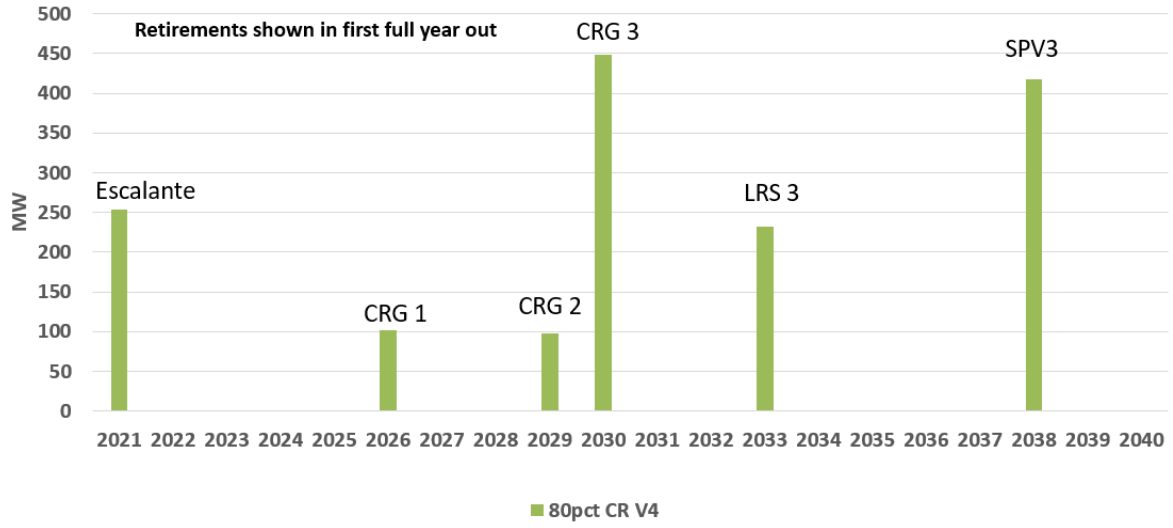

Figure 35: Preferred Plan Announced & Proposed Retirements

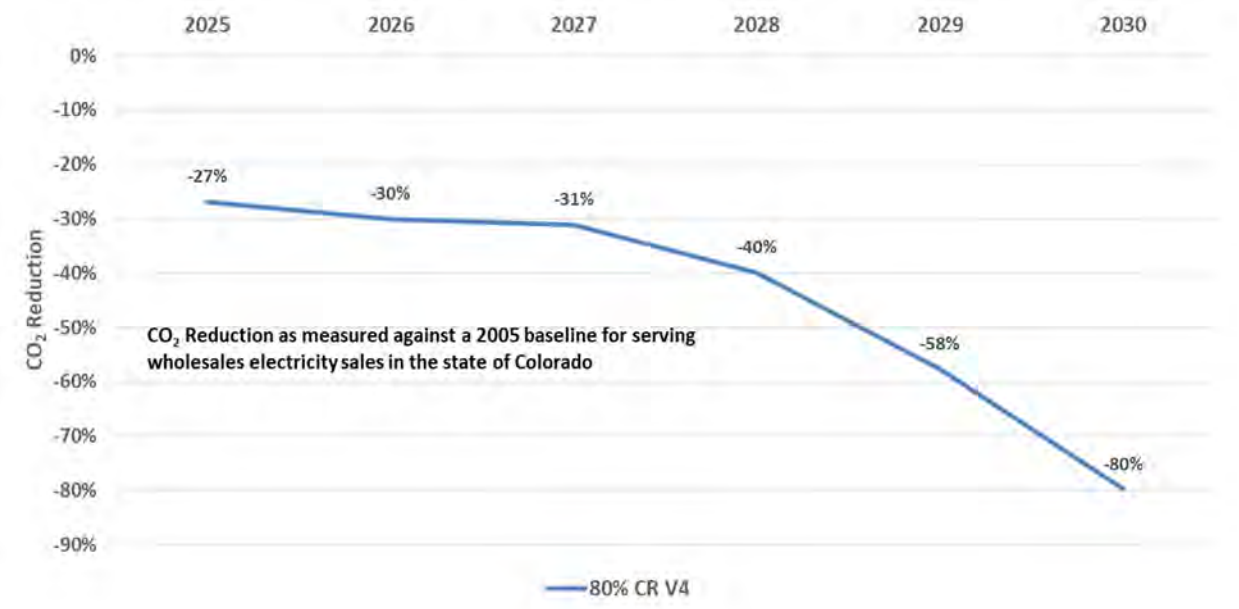

Figure 36: Glide Path to 80% CO_2 Reduction in 2030 from 2005 Base (Serving electricity sales in Colorado)

While this particular scenario does not include increases in DSM as an expansion plan resource, Tri-State is actively working on expanding DSM and EE programs to the extent Utility Member Systems are interested. As these programs are developed and expanded the resulting decrease to capacity needs in relevant years may affect future expansion plans. This scenario like all scenarios has a significant transmission capital expense component. As future resource plans are developed through the Commission ERP and WAPA IRP processes, Tri-State will continue to investigate ways to incorporate higher quantities of renewable resources while limiting transmission expense including the need for

network upgrades. DSM and EE as well as the expected move of some Utility Member Systems from all requirements contracts to partial requirements contracts driven by the desire to serve retail load with more distributed generation will help this effort and will continue to be explored in Tri-State's 2023 ERP.

This scenario retires thermal generation and replaces it primarily with renewables along with some energy storage and one 300 MW gas resource. The evolution of the grid away from thermal dispatchable resources to intermittent resources creates the potential for reliability and financial uncertainty, but the preferred plan takes a measured approach to minimize this risk.

11 Resource Acquisition Period - Action Plan

Action Plan Items

Tri-State's Action Plan covers the period of 2021 to 2030 (RAP). Items will be addressed as necessary between the Phase I final ruling and the next Colorado ERP filing, which is June 1, 2023. Tri-State will file annual updates to this Resource Plan and related Action Plan items with the Commission and WAPA.

Phase II Capacity Need:

Tri-State's base case scenario indicates a capacity need in 2029. In order to meet near term emissions reductions additional renewable resources are forecast for deployment in the preferred plan during the RAP. Table 107 identifies resources by location, nameplate capacity, technology and year, as determined in the preferred plan.

Table 107: Preferred Plan Resources during RAP

Location	Capacity (MW)	Technology	Year
East Colorado	100	Wind	2025
Wyoming	100	Wind	2025
West Colorado	200	Solar	2026
Wyoming	100	Wind	2026
West Colorado	100	Solar	2027
West Colorado	200	Solar	2028
Wyoming	100	Wind	2028
West Colorado	200	Standalone Battery	2029
West Colorado	200	Solar	2029
East Colorado	100	Wind	2029
Wyoming	100	Wind	2029
Wyoming	25	Standalone Battery	2030
West Colorado	300	Natural Gas - Combined Cycle	2030
West Colorado	250	Solar	2030
East Colorado	200	Wind	2030
Wyoming	100	Wind	2030

Given the uncertainty related to Tri-State load in the near term, Tri-State anticipates that its initial Phase II process will focus on resource needs by 2025, as indicated by the shading in Table 107. We anticipate that resources needed for the period from 2026 to 2030 will be addressed in the June 1, 2023 ERP or subsequent ERPs.

By 2023, we will have better information regarding potential load reductions that could reduce capacity needs after 2025. In addition, while the RAP extends from 2021 to 2030, Tri-State is reluctant to engage in activities to add conventional thermal resources (300 MW natural gas combined cycle in 2030) without allowing time for emerging technologies that provide equally reliable capacity, but with lower emissions, to become competitive.

Milestone – Tri-State intends to procure all resources in the preferred plan through 2025 as part of a competitive bidding process in Phase II. The start of Phase II will be dependent upon the timing of Phase I and the overall direction or the Commission. Tri-State plans to update progress on this item each year in its required IRP and ERP APR process.

Utility Member System Programs:

Tri-State plans to use the DSM EE Potential study produced by Mesa Point Energy and included as Attachment Vol II 5-1 Demand Side Management & Energy Efficiency Potential Study as a starting point from which to work with Utility Member Systems to establish additional DSM and EE programs over the RAP.

Tri-State plans to use the BE study produced by Mesa Point Energy and included as Attachment Vol II 5-7 Beneficial Electrification Potential Study as a guide from which to work with Utility Member Systems to establish BE programs over the RAP.

Milestone – Tri-State plans to update progress on this item each year in its required IRP and ERP APR process. Established programs with forecast growth will be utilized in the modeling for the June 1, 2023 IRP/ERP process.

Retirement Analysis:

With the announced retirement dates of Springerville Unit 1 and Springerville Unit 2, Tri-State plans to engage in discussions with SRP, the owner of Springerville Unit 4, as well as other parties necessary to determine the impacts on Springerville Unit 3 for future resource planning.

While the preferred plan indicates a retirement of LRS Unit 3 by 2033, we note that there is no agreement in place to that would be required to implement this retirement with the co-owners of the Missouri Basin Power Project. Modeling performed under the preferred plan showed that the continued operation of both LRS Unit 2 and Unit 3 at levels needed to satisfy and maintain an 80% CO_2 reduction in Colorado would not be economic, which is why the preferred plan reflects a retirement of LRS Unit 3.

Milestone – Tri-State plans to update progress on this item each year in its required IRP and ERP APR process. Tri-State will incorporate relevant changes in its modeling for the June 1, 2023 IRP/ERP process.

Model Improvements:

Tri-State plans to modify its current modeling software or replace if necessary, in order to improve modeling items prior to June 1, 2023 ERP. Key items slated for modeling improvement include but are not limited to: ability to handle emission reductions on a state-by-state basis in a robust manner, ability to model sub-hourly effects, more robust modeling of intermittent resources, streamlined management of transmission capex impacts, and improved treatment of intermittent resource curtailments.

Milestone – Tri-State plans to begin efforts for modeling software replacement or improvements in 2021 with completion in 2022 in time to begin the modeling for the Jun 1, 2023 IRP/ERP process.

Phase II Competitive Bidding Process & Criteria

A Request for Proposals (RFP) will be released soon after the issuance of the Commission's final Phase I decision approving and/or modifying Tri-State's ERP application. In support of this RFP, Tri-State has prepared competitive bidding documents organized as a single, all-source RFP seeking proposals for three different resource types. The RFP focuses on Power Purchase Agreements (PPA) as the likely transactional structure and does not contemplate any utility build or ownership options at this time.

The Phase I decision will define the scope of the RFP. As a result, this competitive bidding process description and RFP documents may be modified or supplemented as necessary to conform to the Commission's Phase I decision.

The RFP currently identifies three distinct categories of resources Tri-State will consider for resource additions.

1. Renewable Resources - All intermittent renewable and carbon-free resources without co-located storage whose pricing will be offered on an annual energy-only price. This includes, but is not limited to, wind and solar, hydroelectric, geothermal, biomass, and in Colorado, recycled energy or eligible coal-mine methane.

2. Semi-Dispatchable Resources - All stand-alone energy storage systems or resources coupled with storage systems that are limited in the amount of energy delivered during a particular cycle. This includes, but is not limited to, stand-alone battery systems, pumped hydro, compressed air energy storage systems as well as renewable resources with co-located thermal or battery storage.

3. Firm Capacity Resources - New or existing gas generation or any other resource that can be dispatched by Tri-State for a reasonable amount of time without any restriction on duration at the rated maximum capacity threshold. Renewable or carbon-free resources such as hydroelectric, biomass, and geothermal capable of this requirement may be bid into this resource type. Resources that include carbon capture technologies may be considered under this category as well.

RFP Documents

The RFP documents will be posted on the Tri-State website when the RFP is released. Any confidential or highly confidential information will be made available in accordance with a nondisclosure agreement as directed by Rule 3605(g)(II)(G)(iv) and which form is filed in an appendix to this ERP.

1. **RFP** – Announces the solicitation for resources. Provides a general description of Tri-State's system, outlines proposal submittal deadlines and other key dates in the evaluation schedule, identifies the required contents of a proposal, provides evaluation criteria, describes the resource types, contract terms, and minimum project size Tri-State is seeking. The RFP also includes contact information for submitting questions about the process.
2. **Model Contracts** - Developed for each of the resource type categories and that reflect Tri-State's expected PPA terms and conditions.
3. **Form Nondisclosure Agreement (NDA) -** Rule 3605(g)(II)(G)(iv) requires that bidders be provided with an NDA necessary for gaining access to confidential and highly confidential modeling inputs and assumptions filed in the Docket.
4. **Voluntary Consent Agreement** - Requests that entities proposing projects interconnecting with the Tri-State transmission system provide consent to allow the merchant function to communicate with the interconnection administrator (Tri-State Transmission function) regarding the project or projects submitted into the RFP.
5. **Bidder Response Forms** - These forms are in Microsoft Excel format with multiple tabs that request key data related to each proposal to allow Tri-State to evaluate each project and option offered.

Bid Fee

A non-refundable bid fee of $5,000 will be required. The bid fee is applicable to a single project location and single project technology. A bidder may propose up to three different combinations of pricing, contract term, size or commercial operation date options for a single project without having to submit an additional fee. Projects that are proposed with additional technology options (i.e., wind + solar or solar + battery storage) or different interconnection points will be considered different projects requiring an additional bid fee. Failure to submit the required bid fee will result in a proposal being disqualified from further evaluation.

RFP Release through Receipt of Bids

Pursuant to Rule 3605(g)(III)(D), the Phase I Decision will establish the deadline for the submittal of the ERP Implementation Report that will detail the cost-effective resource portfolios to be presented to the Commission. Given this deadline and the necessary time to fully evaluate the proposals submitted into the RFP and model various resource portfolios, the RFP will be issued to allow bidders approximately six weeks to submit their proposals to Tri-State.

Tri-State will send an email to all developers who have submitted proposals to past Tri-State RFPs to notify them when the RFP is released, as well as sending an email to developers or other entities that have contacted Tri-State since the last RFP and requested notification of future RFPs. Tri-State will announce the RFP release on its corporate website, as well as maintain a dedicated area on its website where the RFP, Commission Orders and other related documents will be posted.

Tri-State will ask bidders to submit a Notice of Intent to Bid (NOI) form (which will be located on the RFP website) within two weeks of the RFP being issued. This is not a mandatory step for bidders to participate in the RFP, but bidders will be encouraged to submit the NOI by the deadline.

Tri-State will answer questions from prospective bidders by posting and regularly updating a Q&A on the RFP website during the period after the RFP is released and before the proposal submittal deadline. This Q&A is intended to benefit all potential bidders and provide for efficient use of Tri-State staff time in providing answers to bidders that may have similar questions. In answering questions, care will be taken not to include identifying information about the bidder or project.

On or prior to the proposal due date, bidders will submit their proposals, bidder response forms, model contract comments, NDAs, and, if applicable, a voluntary form of consent electronically by email through the dedicated RFP email address, as well as ensure that a hard copy of the proposal has also been delivered. Bid fees are to be sent to Tri-State via check or wire transfer.

Upon receipt, Tri-State will ensure that proposals are complete. This includes having received both a hard and electronic copy of the proposals and associated documents, and the appropriate amount of bid fees. If any initial oversight or discrepancy is found, the bidder will be promptly notified and will be given the opportunity to immediately correct the issue.

Bid data will be imported and verified utilizing the bidder response forms. Each proposal and project option will be given the same attention and evaluated individually. The bid data will then be reviewed for completeness to identify any apparent bad data or misunderstandings. If any corrections or additional data are required, Tri-State will notify the bidder within 14 days of the receipt of the proposals.

Analysis of Bids

An initial economic analysis will be conducted where the Levelized Cost of Energy (LCoE) for each project option is calculated using the discount rate approved by the Commission in its Phase I decision. The LCoE will be calculated by determining the “all in” Net Present Value (NPV) of the average annual costs divided by the NPV of the average annual energy.

Projects will be categorized by technology within each resource type, commercial operation date, contract term, size, and location in order to ensure a meaningful comparison and analysis.

Projects will then be reviewed with respect to non-price factors. These will include the following:

- Best Value Employment Metrics
- Contribution to meeting GHG reduction goals of Colorado
- Location in a Tri-State utility member system service territory
- Financial viability of the bidder, including its parent or any other guarantor of services under the bidder's proposal

- Bidder's prior experience with project development
- Certainty of outside funding sources (i.e. tax credits or government subsidies)
- Compliance with all applicable local, state and federal laws, rules and orders
- Renewal and purchase options at the end of PPA
- Project retirement / decommissioning plan
- Legal, engineering and other costs required to implement the proposed project
- Forecasting capability

Tri-State may consider other factors that it deems to be relevant to its supply portfolio needs.

Following the initial analysis of projects on price and non-price factors, projects will then be evaluated with respect to transmission interconnection and network upgrade costs. Bidders are expected to clearly identify projected interconnection and transmission costs in their proposals as well as reflect these costs in the prices associated with each bid.

Following the analysis noted above, Tri-State may contact bidders with questions and requests for clarifying information, including a request to update or refresh pricing.

Short List, Modeling, Portfolio Analysis

Following the interconnection and transmission costs review, certain projects will be advanced to the Resource Planning Modeling group for development of resource portfolios utilizing a capacity expansion planning model, a production cost model, and financial models. The expansion planning and production cost modeling will take advantage of the detailed project data provided by bidders to better determine an overall system dispatch cost in the context of serving forecast load on the Tri-State system and the financial models will incorporate additional corporate data to determine the Net Present Value Revenue Requirement of each portfolio.

The modeling process will culminate in various resource portfolios, which together with a discussion of the non-price factors, will be included in an ERP Implementation Report to be filed as directed by the Phase I decision. The report will present various cost-effective portfolios comprised of projects bid into the RFP.

Project Agreement Negotiations and RFP Conclusion

Based on a final Commission Phase II Decision giving approval of a portfolio and potential back-up bids, Tri-State will complete its contract negotiations to implement the approved plan. Contingent on the final Phase II Decision, Tri-State may choose to commence contract negotiations after submitting its ERP Implementation Report.

Once agreement is reached on key terms, a contract will be signed if all terms are within the scope of the approval granted by the Commission and the Tri-State Board of Directors.

Once all contracts are finalized and the RFP has concluded, Tri-State will provide feedback to any bidder whose projects were not selected in the RFP process that has requested such feedback. This usually takes place on a phone call, but could occur in person or by email. Further, pursuant to 3605(h)(III) and (IV) Tri-

State will file a proposal to refile all confidential and highly confidential information related to the bids as well as post this information to the website.

ERP Implementation Report Plan

Tri-State proposes to include the following information in its Phase II ERP Implementation Report:

Proposed Resource Information

- Name of Bidder
- Project Name
- Location of Resource
- Resource Technology
- Nameplate Rating of Resource
- In-Service Year
- Contract Term
- Interconnection Point
- Interconnection Costs
- Levelized Cost of Energy
- Storage Capacity (if applicable)
- Storage Duration (if applicable)

Proposed Portfolio Information

- PVRR with and without SCoC
- Generation and Transmission CapEx
- Timing and location of network upgrades if applicable
- CO_2 reduction in Colorado in 2030 from a 2005 baseline
- SCoC totals by portfolios (Total emissions times SCoC)
- Planning Reserve Margin
- Emissions and Water Usage

12 Confidential and Highly Confidential Information

Confidential Information

Pursuant to Commission Rule 3605(a)(IV)(K), the following is a list of information included in this ERP Filing and which Tri-State has designated as confidential information:

- Scheduled Outage Plan (Maintenance)

Highly Confidential Information

Tri-State believes the following information requires extraordinary protection as highly confidential information:

- Fixed O&M expenses
- Variable O&M expenses
- Coal contract pricing and forward curve
- Unit specific capital balances, depreciation, amortization, impairment and decommissioning
- Contract/PPA energy rate, except in regards to Tri-State's LAP and CRSP hydropower purchase contracts with WAPA.
- Contract/PPA capacity rate, except in regards to Tri-State's LAP and CRSP hydropower purchase contracts with WAPA.
- Performance or operating output guarantees and any associated pricing adjustments included in Tri-State' Renewable PPAs
- Any information protected by a confidentiality clause in a PPA.
- Load forecast information at the Utility Member System level
- Renewable PPA and build transfer pricing for generic resources based on B&V proprietary model.

1 Electric Energy and Demand Forecast

Description of Process 3605(b)(IV)

The base long-term load forecast is prepared with each of Tri-State's Utility Member Systems every year. Tri-State has a four state service territory, with 42 Utility Member Systems and each consists of up to nine retail classes in which a bottom-up forecast methodology is employed.

Inputs:

The primary source for historical retail data by each class of consumers is Rural Utilities Service (RUS) Form 7. Information on the number of accounts, energy use per account, total energy and the average price of electricity is collected monthly from each Member. In addition, data on large commercial accounts is gathered on RUS Form 345. Wholesale Utility Member System billing data is obtained from Tri-State monthly bills to Utility Member Systems.

Weather data from 20 weather stations within Tri-State's region is supplied through DTN Meteorlogix. Tri-State's database includes temperature, heating and cooling degree-days, and precipitation. Weather normalizations of this data are used in forecast models (defined as 10-year average values).

Tri-State obtains economic and demographic data for each Utility Member System from Woods & Poole Economics, Inc. (W&P). The vast majority of data from W&P originates with the Department of Commerce and Bureau of Economic Analysis (BEA). All projections of the economic and demographic data have been performed by W&P. Tri-State uses more than 20 measures of employment and income activity by sector from the W&P data.

The electricity that Tri-State Utility Member Systems provides to its retail customers often competes with propane, natural gas and fuel oil as an energy source. Historical price data for these alternative energy sources is obtained annually from the Department of Energy's (DOE) Energy Information Administration (EIA) State Energy Data System, Petroleum Marketing Monthly and Annual Energy Outlook. Tri-State based its price projections for each of these alternative fuels on information from the EIA.

The statistical models are estimated using annual historical data from 2000 through 2019.

Forecasting Process:

The nine retail classes include residential, seasonal, irrigation, small commercial, large commercial, public authorities, streetlights, resales to RUS, and resales to others. Each retail class, with the exception of large commercial, is broken into the number of customers and use-per-customer, which are then modeled separately and aggregated to arrive at forecast energy. By separating the demand forecast into the use-per-customer and customer components, Tri-State is able to better distinguish between the trends driving growth in the number of customers versus technology or weather impacts on customer-level usage.

Customer forecasts are generated using a combination of econometric techniques, time series regressions and simple trend analyses. Time Series processes typically utilize Auto Regressive Integrated Moving Average (ARIMA) modeling. Econometric models for customers consist of a multiple regression with explanatory variables including, but not limited to, population, employment and income.

Use-per-customer is also modeled using econometric models or simple trend analysis. Multiple regressions on use-per-customer typically consider weather, fuel prices and electric prices; however, in the event that there is not a good model fit, a five-year average is used. The residential use forecast is an exception and utilizes an end-use model when possible.

Additional detail on the forecast modeling by retail class can be found in Ms. Tiffin's direct testimony. Once the forecasts are completed for each Utility Member System, the final step is forecast aggregation to arrive at the Tri-State system forecast.

Demand Forecast:

The projected values of the Member Coincident Peak (MCP) demands are based upon an hourly load forecast. Hourly loads are generated for each calendar month by applying the projected purchased energy requirement to a corresponding normalized historical load duration curve. The resultant hourly loads are dispatched chronologically based upon known historical loads appearing in a typical month. Once individual members' hourly demand forecasts have been determined, they are summed to arrive at a total Tri-State hourly load forecast (using a bottom-up approach), allowing the coincident peak demand to be established.

The peak period used for billing is defined as the period between 12:00 (noon) and 10:00 PM, Monday through Saturday, except certain holidays. The Tri-State aggregate billing peak is the sum of the individual member coincident peaks from the hourly demand forecasts, which occur within the defined peak period. The Tri-State Coincident Peak for capacity planning is the highest hourly sum of Utility Member System hourly demand forecasts in July, as Tri-State is a summer peaking system.

Range of Forecasts 3605(b)(II):

Tri-State developed a range of forecasts including the base, low and high forecasts. To develop the low and high forecasts, Tri-State established prediction intervals to express uncertainty around the expected value forecast. The total variance includes both economic and weather related uncertainty. Intervals are generated for one standard deviation (68.27%) and 90%, meaning that the actual value should be within the given interval with a probability of 68.27% or 90% respectively. The lower limit of the 90% prediction interval was used as the Low Load forecast for Low Load scenarios. Many potential factors exist which could significantly reduce Tri-State's load, including:

- Potential Utility Member System buy-outs
- Transition of some Utility Member Systems from all to partial requirements wholesale electric service contracts
- Increased Utility Member System distributed generation
- Increased demand side management and energy efficiency
- Load reduction due to COVID impacts
- Load loss related to environmental and regulatory impacts to the oil and gas industries

The Low Load forecast represents the potential load reduction that could result from any combination or subset of these items. Figure 1 illustrates the deviation from the base load forecast for the Low load (TS LCL 90^{tH}) forecast as well as other potential load reductions such as Partial Requirements (PR), increased community solar subscription under Board Policy 119, increased distributed generation deployment under Board Policy 115, or the exit of a Utility Member System such as United Power. The figure indicates that the Low Load forecast is comparable during the early years of the RAP to the combination of low load drivers with the exception of a United Power Withdrawal (Total Drivers w/o UP out).

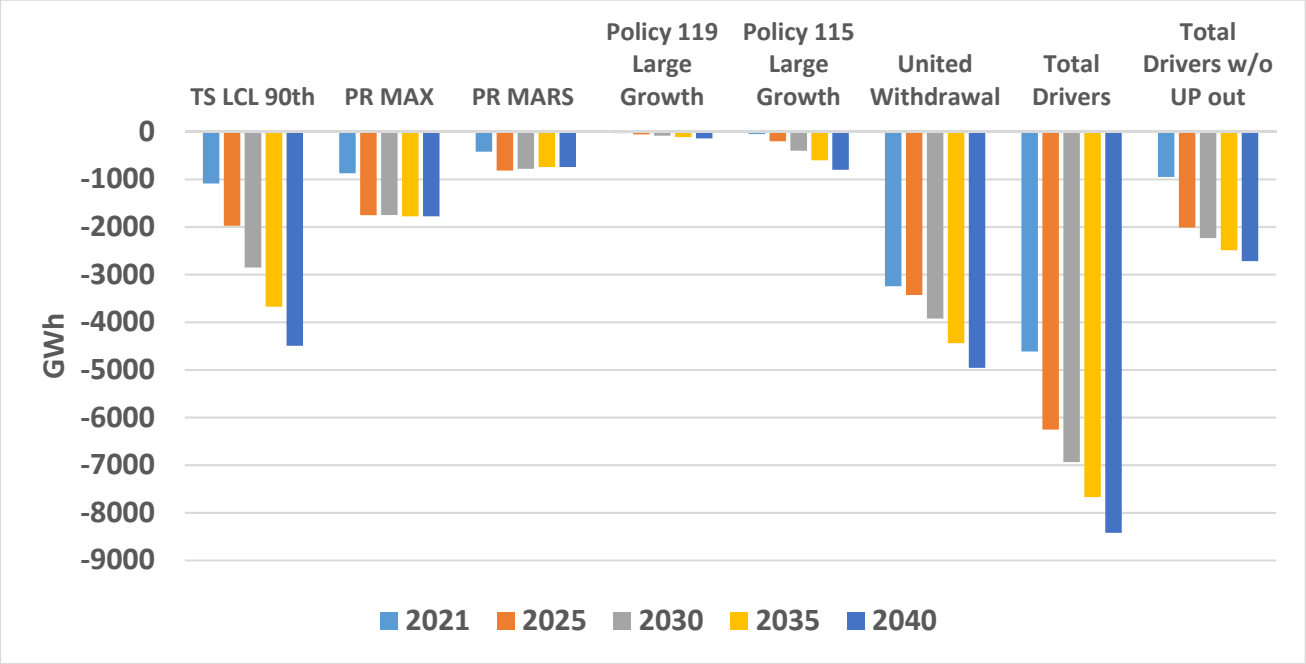

Figure 1: Comparison of Low Load Forecast to Potential Load Reductions - Energy

Tri-State did not conduct an alternative scenario for purposes of this Resource Plan in regards to UCL 90th (High) load forecast due to the number of potential risks that could result in significant reductions to Tri-State's system load. However, both the High Load forecast and Low Load forecast are presented in the following subsection, as well as in "Attachment Vol II 1-1 Tri-State Load Forecasts by Member and State".

Utility Member Sales Forecasts 3650(b)(I)(A)

The following graphs show Tri-State's load forecasts for the RPP for the Tri-State System. Tri-State's annual system energy average growth over the RPP is 1.55%, while summer coincident system demand has an annual average growth rate of 1.44%.

Where appropriate, data is presented for a range of forecasts, including Base, High and Low Load forecasts. Base, High and Low Load forecasts are marked with the following identifiers on all graphs:

- Base Load Forecast Scenario – PRS20 Expected Value
- High Load Forecast Scenario – UCL90_00
- Low Load Forecast Scenario – LCL90_00

Tri-State System Annual Energy Sales, Summer Peak & Winter Peak*:*

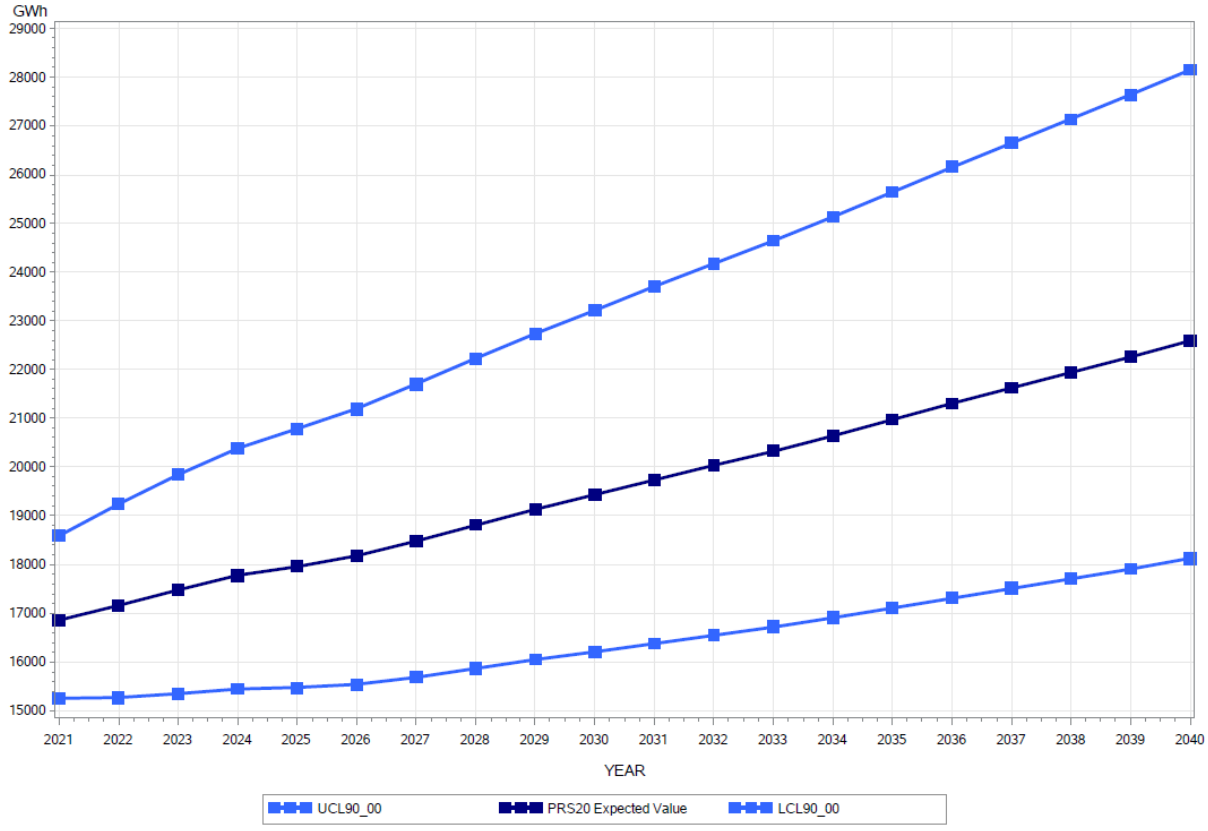

Figure 2: Tri-State System Annual Energy Sales to Utility Member Systems

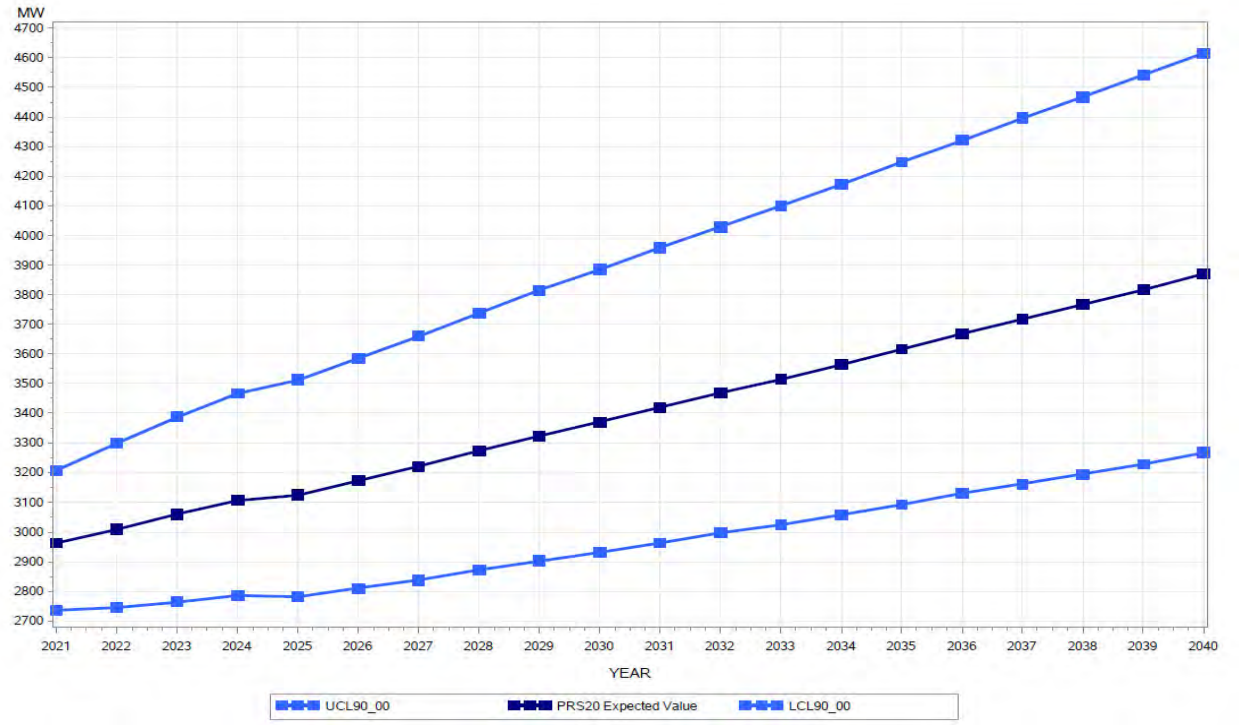

Figure 3: Tri-State System Annual Coincident Summer Peak

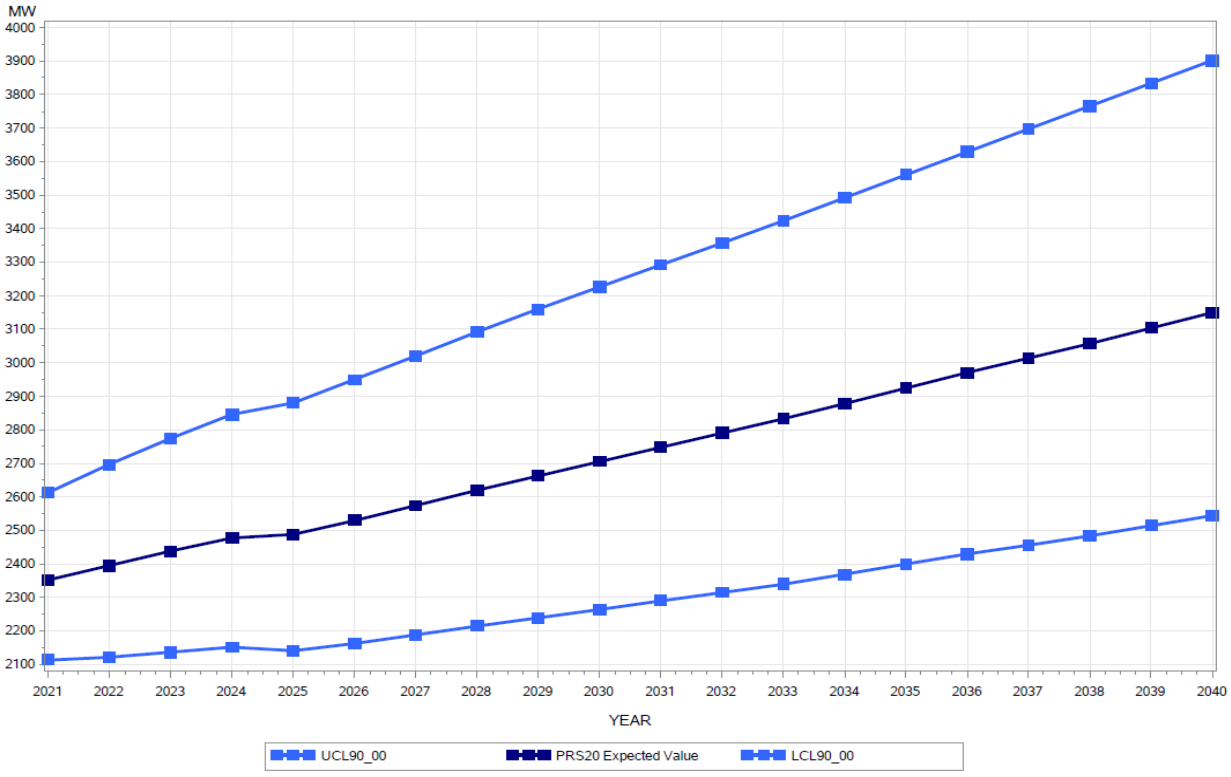

Figure 4: Tri-State System Annual Coincident Winter Peak

Tri-State's load forecasts for the RPP by State and Utility Member System are located in Attachment Volume II 1-1 Tri-State Load Forecasts by State and Member.

Table 1: Reference Guide for Attachment Vol II 1-1 State and Utility Member System Data

Rule	Item	Granularity	Page(s)
3605(b)(I)(A)	Annual Energy Sales	States	1-4
3605(b)(I)(A)	Annual Coincident Summer Peak	States	47-50
3605(b)(I)(A)	Annual Coincident Winter Peak	States	93-96
3605(b)(I)(A)	Annual Energy Sales	Utility Member System	5-46
3605(b)(I)(A)	Annual Coincident Summer Peak	Utility Member System	51-92
3605(b)(I)(A)	Annual Coincident Winter Peak	Utility Member System	97-138
3605(b)(I)(E)	Hourly Peak Day By Calendar Month	States	139-186
3605(b)(I)(E)	Hourly Off Peak Day by Calendar Month	States	691-738
3605(b)(I)(E)	Hourly Average Day by Calendar Month	States	1243-1290
3605(b)(I)(E)	Hourly Peak Day By Calendar Month	Utility Member System	187-690
3605(b)(I)(E)	Hourly Off Peak Day by Calendar Month	Utility Member System	739-1242
3605(b)(I)(E)	Hourly Average Day by Calendar Month	Utility Member System	1290-1794

Comparison of Load Forecasts (3605)(b)(III):

Comparison of 2015 ERP to 2020 ERP Load Forecast:

Tri-State has experienced changes in base load between the release of the 2015 ERP and the 2020 ERP. In 2015, Tri-State had 44 Utility Member Systems; however, 2020 reflects the departure of both Kit Carson and Delta Montrose Electric Association (DMEA). Another key difference is an improvement in the methodology used to forecast the large commercial class. Most individual large commercial and industrial accounts exhibit random walk behavior making it difficult to generate a forecast. The 2020 forecast combines the accounts and generates a forecast for energy using the growth exhibited in the previous 20 years resulting in a large commercial forecast for Tri-State system that better reflects historical patterns.

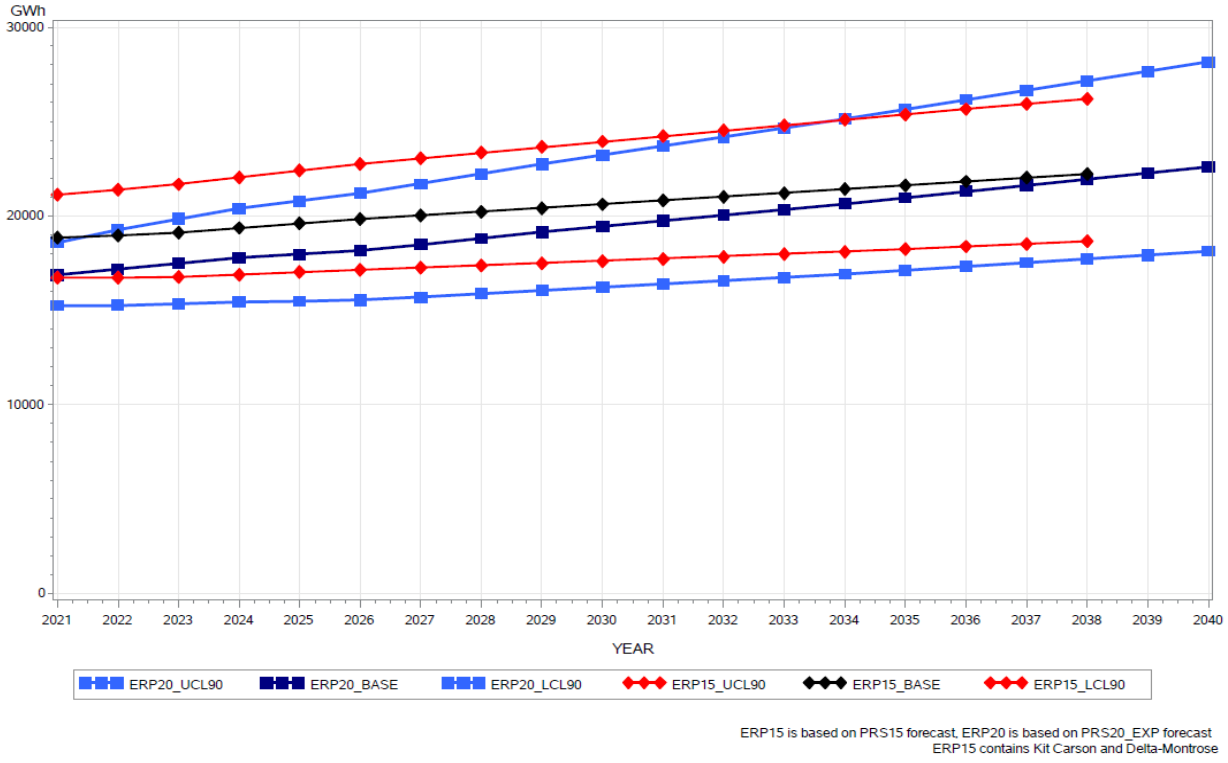

Figure 5: Tri-State System Annual Energy Sales to Utility Member Systems

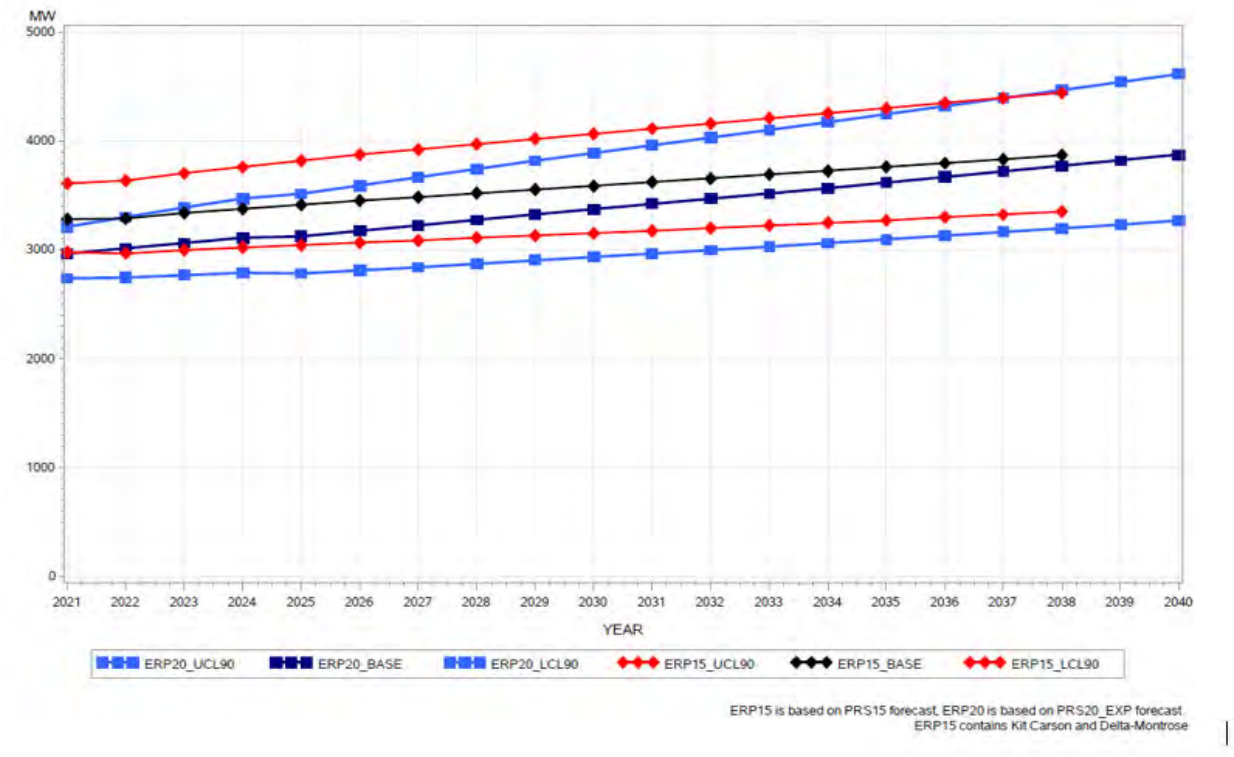

Figure 6: Tri-State System Annual Summer Coincident Peak

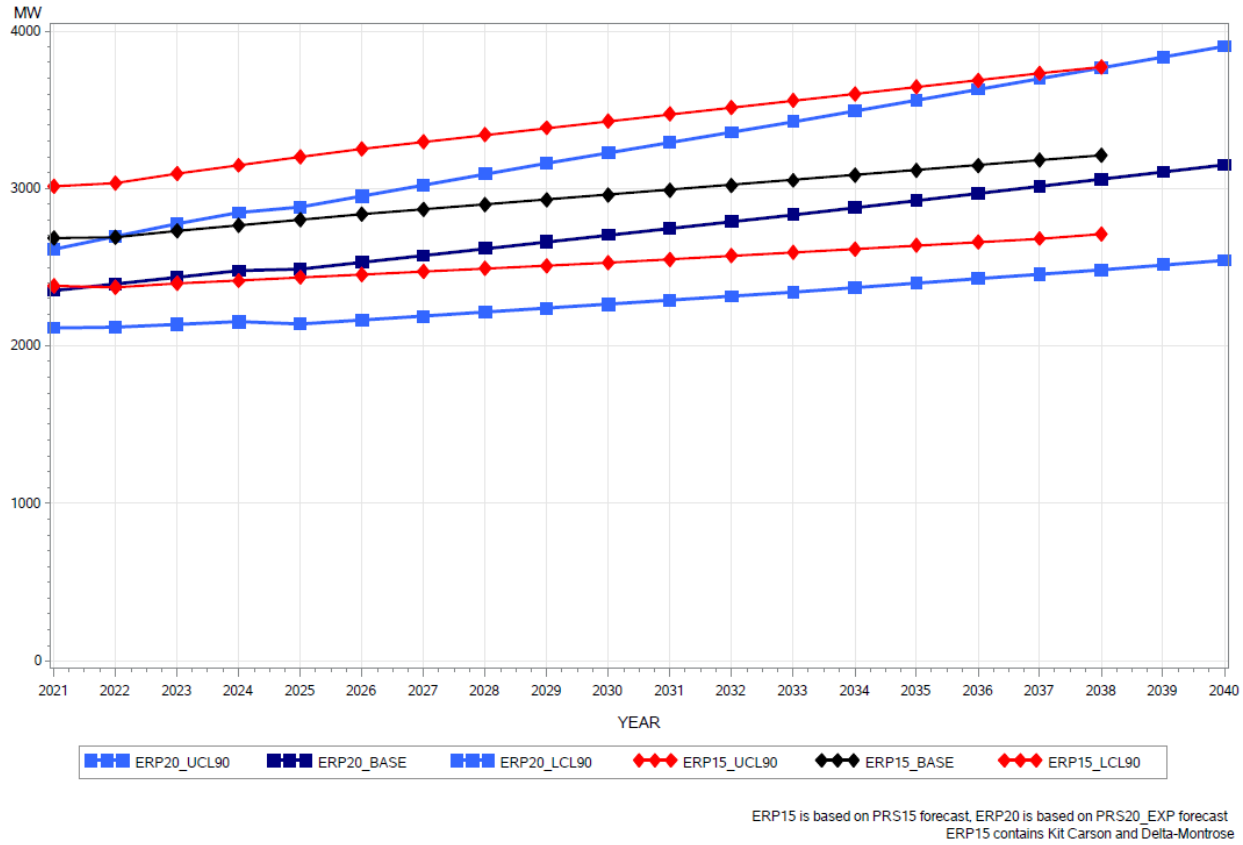

Figure 7: Tri-State System Annual Winter Coincident Peak

Comparison of Historical Forecasts & Actuals:

For the following tables Kit Carson is included in actuals and forecasts for 2015-2016 and DMEA is included in actuals and forecasts for 2015-2019. "PRS" and the corresponding year represents the forecast value.

Losses 3605(b)(I)(D):

Tri-State adds a 5% transmission loss factor to load across Tri-State's system in the Western Interconnection for modeling purposes. Tri-State load in the Western Interconnection is located in multiple BA and TP systems. The 5% transmission loss factor is meant to represent an average of expected transmission losses. Tri-State's load in the Eastern Interconnection is covered by a full requirements contract.

Energy and Capacity Sales to Other Utilities (3605)(b)(I)(B)

Annual contract energy and capacity sales to other utilities and counterparties are described below:

SRP Sale: SPV 3 Facility located in Arizona, 100MW (Maximum Capacity) ~375 GWh/year. Effective Date 10/20/2003; Contract Expires 8/31/2036.

PNM Unit Contingent Sale: 100MW unit contingent sale at SJ345. 100 MW (Maximum Capacity) ~876 GWh/year. Effective Date 06/01/2017; Contract Expires 05/31/2022. This is the sale side of a swap that reduces spinning reserve obligations.

WAPA Regulation Sale: Rate Schedule L-AS3 Partial Self Supply Utilizing Craig Station Unit 3: As the BA operator, WAPA provides Regulation and Frequency Response under Rate Schedule L-AS3. Tri-State currently purchases these services from WAPA. Historically, WAPA has provided this service by adjusting its Federal hydropower resources to balance load, generation, and interchange. This contract allows WAPA to diversify its availability of regulation and frequency response resources by utilizing 30MW of capacity of Craig Unit 3. Effective Date 07/01/2020. Contract Expires 10/01/2021. Either party may choose to discontinue service under this contract by providing sixty (60) days advance written notice to the other party.

Municipal Energy Agency of Nebraska (MEAN) Reserve Sale[1]: Tri-State provides operating reserves to Northwest Power Pool on behalf of MEAN under the terms of the MEAN sub-entity agreement. Effective Date 09/30/2020. Contract Expires 09/30/2021. Contract is evergreen unless terminated by either party via 180 day advanced written notice.

For all sales for purposes of resource planning, contract capacity at the time of peak is considered to be at maximum. This approach is based on conservative business practices. Dispatch energy is based on contract or forecast values.

Intra-utility Energy and Capacity Use (3605)(b)(I)(C)

Tri-State intra-utility loads consist of a number of service centers and the headquarters building. For these loads, Tri-State takes retail service from the local provider. Accordingly, Tri-State has no intra-utility loads that contribute to energy and capacity requirements for purposes of Tri-State resource planning.

[1] This sale was finalized after the start of the ERP process and was not included in the modeling.

2 Commodity Pricing

Electric Forward Curve

Tri-State models six markets to forecast purchase and sale activity across its Western Interconnection footprint, including four transaction points where trading activity currently occurs and two entities representing the real time energy imbalance markets of WEIS and WEIM:

- LRS – located in Wyoming
- AU – Ault in Eastern Colorado
- CRG – Craig in Western Colorado
- 4C – Four Corners in New Mexico
- WEIS – imbalance market in Colorado and Wyoming (WAPA BA)
- WEIM – imbalance market in New Mexico (PNM BA)

Tri-State employs a four-step approach to obtain its electric price forecast. First, a long-term Palo Verde price is derived from third-party data including Bloomberg energy future prices ("Market" prices) and Hitachi ABB & Wood Mackenzie forecasts ("Fundamental" prices). The Market prices are taken at the Palo Verde trading hub at a monthly temporal resolution for on-peak, off-peak, and composite periods. The Fundamental prices are determined from production cost modelling for the Palo Verde hub. For the near-term period (the first three years), Market prices are used, whereas in the long-term (years 11 to 20) Fundamental prices are used. For the mid-term (years four to ten), Market and Fundamental prices are blended to facilitate a smooth transition. Second, the blended Palo Verde prices are then used to derive regional (Colorado East, Colorado West, and New Mexico) prices using a basis adder[2]. Third, a system-wide price is then derived by taking a 30%, 30%, and 40% weighting of the Colorado East, Colorado West, and New Mexico regional prices, respectively creating a blended curve. Finally, Fundamental-based hourly scalars are used to calculate "8760" (all-hours) price streams for Palo Verde, Colorado East, Colorado West, New Mexico and Blended.

For modeling purposes, the 8760 price stream is applied as follows:

- Blended curve is applied to LRS, AU, CRG and NM markets
- Colorado East (COE) curve is applied to WEIS market
- Palo Verde (PV) curve is applied to WEIM market

Additionally, different multipliers are applied to the curves for purchase and sales as follow:

- Blended curve – purchases 95% and sales 85%
- COE curve – purchases 110% and sales 85%
- PV Curve – purchases 105% and sales 95%

The WEIS and WEIM markets are in effect in the model from 2021 to 2024. In 2025, Tri-State opens up market depth to reflect participation in a RTO for its entire footprint. At that point, only the four transaction point markets (LRS, AU, CRG and 4c) remain in use in the model. For more information on

[2] Basis adder is provided by Hitachi ABB.

market depths see Section 5 Phase 1 Modeling Details under the Modeling Assumptions subsection of this report.

Figure 8 represents the power forward curve data in real (2020) dollars for the RPP:

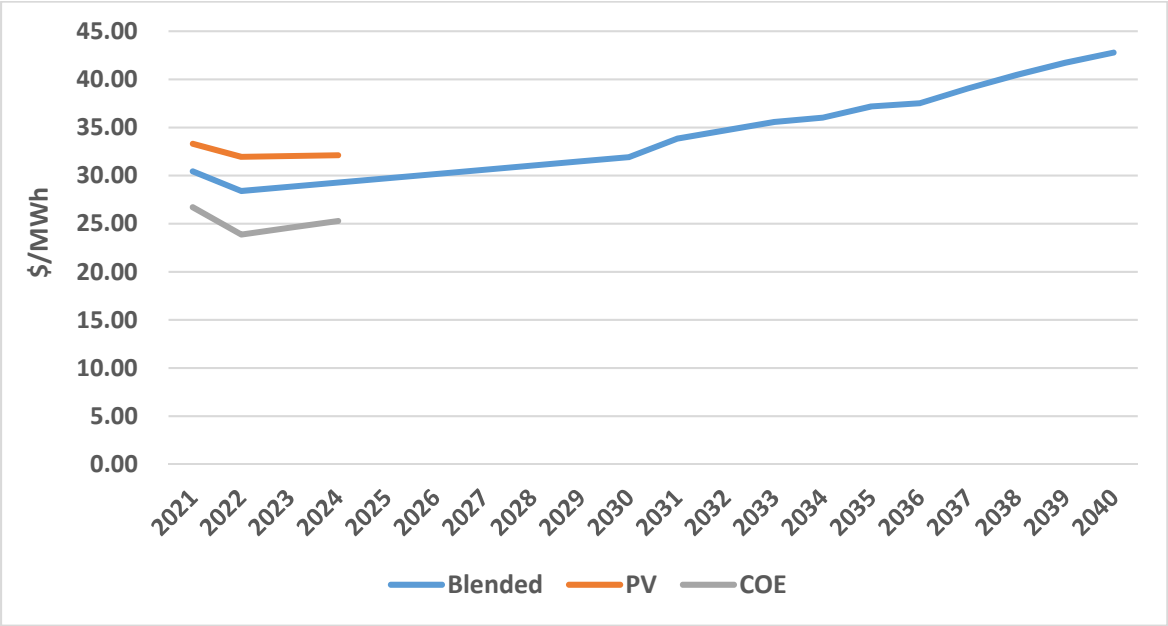

Figure 8: Electric Forward Curve

Gas Forward Curve

Tri-State uses a similar approach for gas forward pricing. First, prices are derived from a combination of third-party data including Bloomberg energy future prices ("Market" prices) and Hitachi ABB & Wood Mackenzie forecasts ("Fundamental" prices). The Market prices are taken at CIG hub and Waha hub at a monthly granularity. The Fundamental prices are derived from a production cost modelling approach for the Palo Verde hub. In the near-term (first five years) the Market prices are used, whereas in the long-term (years 11 to 20) the Fundamental prices are used. For the mid-term (years six to ten) the Market prices are blended with the Fundamental prices for a smooth transition. The monthly values are applied to all applicable days within the model.

For modeling purposes, the daily price stream is applied as follows:

- CIG curve is applied to JM Shafer, Rifle, Limon, Knutson and generic gas resources in Wyoming and Colorado.
- Waha curve is applied to Pyramid units and generic gas resources in New Mexico.

Figure 9 represents the gas forward curve in real (2020) dollars. Additional transport costs apply.

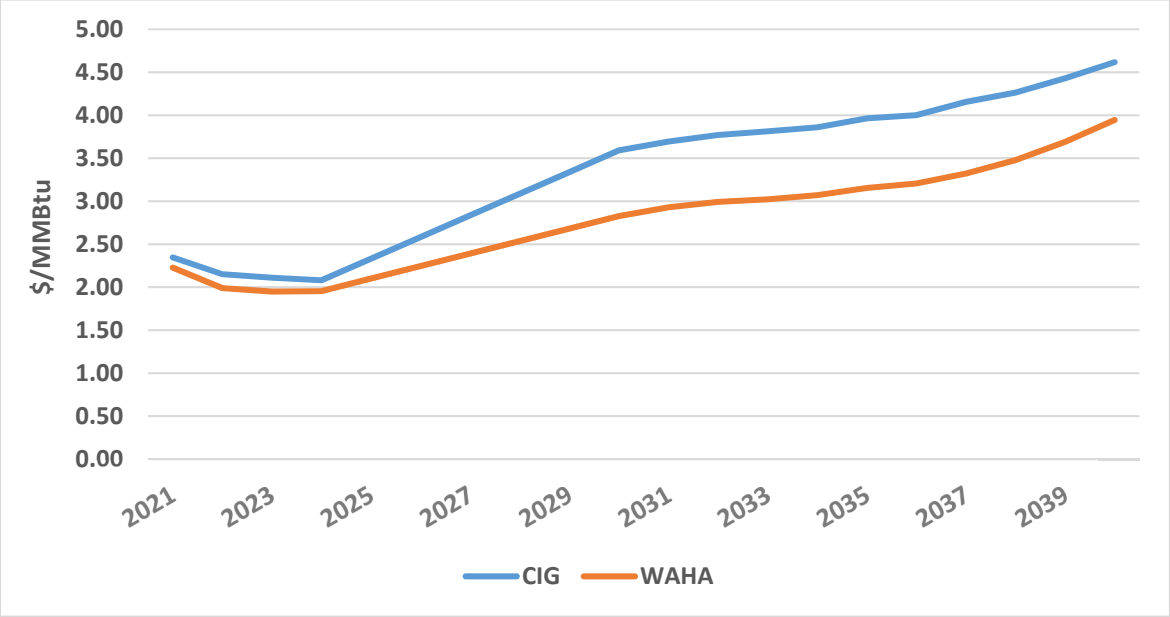

Figure 9: Gas Forward Curve

Table 11 summarizes the additional transport costs and forward curves associated with each gas generating unit:

Table 11: Transportation Costs & Fuel Forward Curve for Gas Resources

Existing Gas Plant	**Transport Adder** *($/MMBtu)*	**Forward Curve**
Limon	$0.31	CIG
Knutson	$0.31	CIG
Pyramid	$0.90	Waha
Rifle	$0.42	CIG
JM Shafer	$0.17	CIG
Generic Gas Resources – CO & WY	$0.31	CIG
Generic Gas Resources - NM	$0.70	Waha

Tri-State uses interruptible gas transport service except for a portion of service for JM Shafer. Tri-State has contractual rights to 14,697 Decatherm (Dth) of firm CIG transportation, (8,000 Dth from King to Lakin, 2,000 Dth from Lost Cabin to Lakin, and another 4,697 Dth from Beaver to Milton). For modeling purposes Tri-State assumes JM Shafer uses the firm transport at a sunk cost and then the additional potentially needed interruptible transport cost is considered and prorated. Therefore, JM Shafer has a lower transport adder than other units.

Coal Forward Curve

Tri-State forward coal prices change annually. Figure 10 shows the coal forward curve in real (2020) dollars. LRS and SPV3 values are all inclusive costs of fuel. CRG (Inc.) is the Craig coal cost as an incremental value. These values are used in CE and PO. Figure 11 shows the coal forward curve in nominal dollars, and all values are all inclusive costs of fuel. These values are used in the final PVRR analysis in UIPlanner.

Figure 10: Coal Forward Curve for CE & PO (2020 Dollars)

The Craig coal forward curve is based on the actual mine plan as forecast by Colowyo. The SPV 3 coal forward curve is based on an estimation of 2% annual escalation rate of the total delivered price (coal + freight). The LRS coal forward curve is provided by Basin and is an estimation of escalation occurring at the rate of 3% per year. Historical coal prices for these resources are located in Section 3 Assessment of Existing Resources.

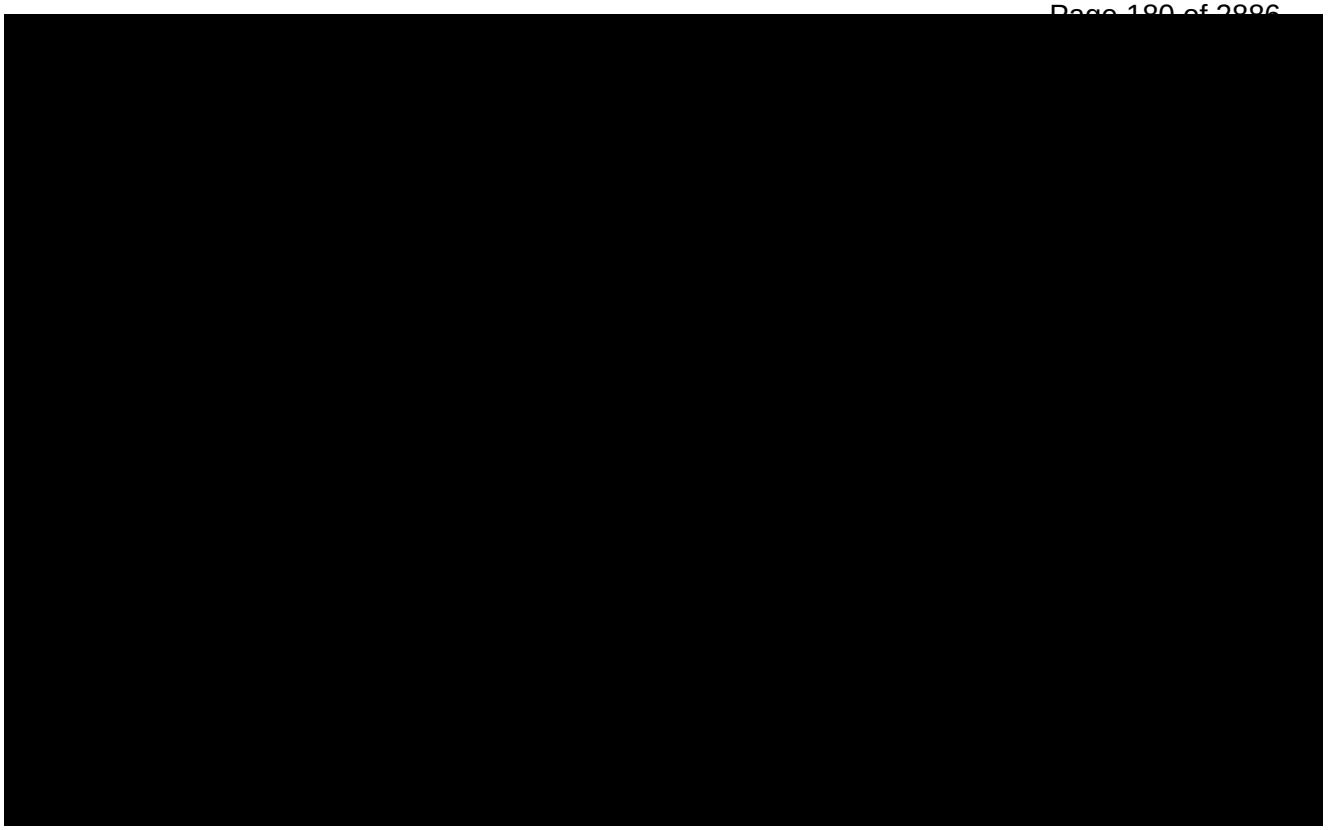

Figure 11: Coal Forward Curve for UIPlanner (Nominal dollars)

3 Assessment of Resources

Overview of Thermal Resources

The following is a description of Tri-State-owned and leased resources in terms of unit characteristics, emission rates and revenue requirements. The assessment excludes the following items, as Tri-State does not have any applicable resources in these categories:

- Thermal resources under contract (3605(c)(I)(A))
- Utility-owned energy storage resources (3605(c)(I)(A))
- Utility-owned thermal resources that are not in service at this time (3605(c)(I)(D))

The following assumptions and interpretations apply:

- The Springerville 3 minimum operating level was lowered from 251 MW to 109 MW in the fall of 2019 as a result of modifications to the coal mills and related logic. The modifications allow pulverizers to operate in a 4-burner operation per pulverizer vs the normal 6-burner operation. This allows velocity to be maintained through the mills at lower fuel throughput.
- NOx limits for Craig 1 are in place to comply with the Colorado State Implementation Plan related to the Regional Haze rule.
- Capacity credits values were updated. See Section 5 Phase I Modeling Details “Table 56: Capacity Credit Values”.

- Tri-State has transitioned to the use of random hourly profiles for renewable resources instead of average hourly profiles.
- Escalante is excluded, as it was retired November 2020.
- Craig units 1, 2, and 3 useful life dates are identified as their respective announced retirement date.
- Net Dependable Capacity for coal resources is the same MW value as Maximum Capacity. (3605(c)(I)(B))
- Net Dependable Capacity for gas resources varies by season and is identified by Summer and Winter Capacity MW values. Gas resources reach their maximum capacity level in the winter. (3605(c)(I)(B))
- Marginal heat rate is calculated as the average heat rate over the RAP, which is identified as 2021 to 2030, for a typical dispatch.
- Fuel cost can be derived from provided heat rates for each resource and forward fuel curves for each fuel type. Tri-State does not utilize a forward fuel curve for oil, as its oil units are used for reliability events rather than economic dispatch and planning.
- Emissions rates are based on 2018 actuals data as provided by Tri-State Environmental.
- For Revenue Requirements where Tri-State has partial ownership in a resource, costs represent Tri-State's prorata share.
- There are no planned significant new investment or maintenance expenses. O&M and Capex costs are representative of necessary maintenance and improvements to maintain reliability of the resources. (3605(c)(I)(E))
- Annual capital expenses[3] are an average of annual expenses over the RPP of 2021 to 2040 for the life of each resource as determined by useful life or planned retirement date.
- Operating and Maintenance costs (fixed and variable) are held constant over the planning period in planning and dispatch models (2020 dollars). UIPlanner (financial model) escalates costs for inflation.
- Costs associated with the use of emissions control systems are not separately forecast, but are instead included in overall operating and maintenance costs.
- Although not a unit level revenue requirement, SCoC is included in the revenue requirement tables for thermal resources as Tri-State is aware of the requirement to consider this value in its assessment of resources and resulting dispatches in relation to the ERP process. The SCoC is calculated as the resource CO_2 emission rate of each unit in tons per MWh times $46.60/ton SCoC for 2021. SCoC annual costs and calculated cost by resource can be found in Section 5 Phase I Modeling Details under the Social Cost of Carbon subsection of this report.

[3] Tri-State's Generation Engineering Department works with generating station engineering personnel as well as station management and corporate finance, to develop and recommend the annual capital budget request for generation. The engineering staff also develops a list of future capital expenditures needed to maintain availability and reliability of the generation stations along with maintaining regulatory and environmental compliance. These future capital expenditures make up the long-term capital forecast for Tri-State resources.

- Tri-State's gas fleet consists of intermediate and peaking units, which are designed for cycling; therefore, no cycling or integration costs are identified for those resources. (3605(c)(I)(J))
- Forecast values for model inputs are based on a combination of historical data and known or upcoming changes that will impact model input values.

Data Updates since August 3, 2030 Revision:

- Tri-States entitlement of LRS was re-rated at 461MW.
- Rifle minimum operating level was updated to 65MW.
- Craig 1, Craig 2, and Craig 3 VOMs were updated to $1.93, $1.78, & $2.45 respectively.
- Scheduled Outages for 2021 to 2030 updated from filing.
- Tri-State is using May 2020 versus March 2020 gas and power forwards curves
- Updated SCoC costs based on Commission Staff feedback

Coal-Fueled Generation Resources:

Craig Generating Station: Craig Station is a three-unit, 1,285 MW coal-fired electric generating facility located near Craig, Colorado. Tri-State owns a 24% interest in Craig Units 1 and 2 (Yampa Project)[4], which have nameplate ratings of 427 MW and 410 MW, respectively; a 100% interest in Craig Unit 3, which has a capacity of 448 MW; and a 49% interest in the common facilities, which serve all three units. Tri-State is the operating agent for all three units and is responsible for the daily management, administration and maintenance of the facility. The non-fuel costs associated with operating Craig units 1 and 2 are divided on a pro-rata basis among all the participants[5]. Tri-State's total share of Craig Station is 648 MW. In 2016, Tri-State announced an agreement with regulators and environmental groups to retire Craig Unit 1 by December 31, 2025 as part of revisions to the Colorado regional haze State Implementation Plan. Tri-State has also announced that Craig Units 2 and 3 will be retired by 2030.

Laramie River Generating Station: The Laramie River Station (LRS) is a three-unit, 1,700 MW coal-fired electric generating facility located near Wheatland, Wyoming. As a participant in the Missouri Basin Power Project[6], Tri-State has a 27.1% interest (461 MW) in LRS. For operational purposes, Tri-State receives energy only from LRS 2 and 3 due to their location in the Western Interconnection. LRS 1 is scheduled solely to the Eastern Interconnection, and Tri-State does not receive energy from this resource. LRS is operated by BEPC.

Springerville Unit 3: Springerville Unit 3 is a 417 MW coal-fired electric generating unit that is part of the four-unit generation station located near Springerville, Arizona. One hundred percent of Unit 3 is leased by Tri-State. Tucson Electric Power (TEP) is the plant operator for the Springerville Generating Station.

[4] Yampa Project includes Craig 1 and Craig 2 and related common facilities.
[5] Yampa Project participants include Tri-State, Platte River Power Authority, PacifiCorp, Salt River Project and Public Service Company of Colorado.
[6] The Missouri Basin Power Project is the Laramie River Electric Generating Station and Transmission System located in Wyoming. Its participants include Tri-State, BEPC, the Western Minnesota Municipal Power Agency (Missouri River Energy Services), the Lincoln Electric System, and the Wyoming Municipal Power Agency (WMPA).

SPV3	2139	0.838	0.787	0.031	0.00001600	546

CO2, SO2, and NOx are lbs. per net MWh; PM and HG are lbs. per Gross MWh

Table 14: Revenue Requirements for Coal Resources (Real $)

	Fixed O&M[11] **Annual** *($000s)*	**Variable O&M** *($/MWh)*	**CapEx Costs Annual** *($000s)*	**Social Cost of Carbon** *($/MWh)*	**Integration & Cycling Costs** *($/MWh)*	**Fuel Curve**
Craig 1	[redacted]		~$800	$54.03	$0.129	CRG (Inc)
Craig 2			~$500	$54.76	$0.131	CRG (Inc)
Craig 3			~$3,000	$48.70	$0.124	CRG (Inc)
LRS 2			~$1,500	$51.33	$0.111	LRSG
LRS 3			~$1,500	$56.08	$0.108	LRSG
SPV3			~$6,500	$48.94	$0.138	SPV3

[7] Useful Life is determined by Tri-State's 2017 Generation Depreciation study unless otherwise identified.
[8] This date is the announced retirement date per the YAMPA participants
[9] This date is the announced retirement date per the YAMPA participants
[10] This date has been modified from 12/31/2044 per Tri-State's 2017 Generation Depreciation Study and reflects Tri-State's announcement to retire all of Craig station by 2030.
[11] Fixed O&M forecasts are arrived at on a resource specific basis by taking the VOM provided by TS generation engineering and multiply the value times recent historical annual generation and subtracting the production from total O&M expense for the same year. This value divided by total O&M of the historical year provides a percentage for fixed costs. The percentage is then applied to forecasted O&M to arrive at the fixed portion.

Tri-State forward coal prices change annually. Figure 10 in Section 2 Commodity Pricing of this report shows the Coal Forward Curve in real (2020) dollars as used in CE and PO for the ERP scenario modeling.

Gas & Oil-Fueled Generation Resources:

JM Shafer Generating Station: JM Shafer is a 272 MW natural gas-fueled, combined-cycle power plant located north of Fort Lupton, Colorado. The facility is wholly-owned by Tri-State subsidiary, Thermo Cogeneration Partnership, L.P., and operated by Tri-State.

Rifle Generating Station: Rifle Station is an 81 MW, natural gas-fueled combined-cycle power plant located near Rifle, Colorado. The facility is wholly-owned and operated by Tri-State.

Limon Generating Station: Limon Station is a two-unit, 140 MW, natural gas and oil-fired simple cycle combustion turbine facility located near Limon, Colorado. It is wholly-owned and operated by Tri-State.

Knutson Generating Station: Knutson Station is a two-unit, 140 MW, natural gas and oil-fired simple cycle combustion turbine facility located near Brighton, Colorado. It is wholly-owned and operated by Tri-State.

Pyramid Generating Station: Pyramid Station is a four-unit, 160 MW, natural gas and oil-fired simple cycle combustion turbine facility located near Lordsburg, New Mexico. It is wholly-owned and operated by Tri-State.

Burlington Generating Station: Burlington Station is a two-unit, 110 MW, oil-fired simple cycle combustion turbine facility located in Burlington, Colorado. It is wholly-owned and operated by Tri-State.

Table 15: Unit Characteristics for Gas Resources

	Summer Capacity *(MW)*	**Winter Capacity** *(MW)*	**Fuel Type**	**Average Heat Rate** *(btu/kWh)*	**Marginal Heat Rate** *(btu/kWh)*	**Quick Start Capable** *(Yes/No)*	**Minimum Operating Level** *(MW)*	**Useful Life**[12]
JM Shafer	272	272	NG	9,322	9,254	No	41	12/31/2047

Table 17: Revenue Requirements for Gas Resources

	Fixed O&M Annual *($000s)*	Variable O&M *($/MWh)*	CapEx Costs Annual *($000s)*	Social Cost of Carbon *($/MWh)*	Fuel Curve
JM Shafer	[redacted]		~$1,500	$22.86	CIG
Rifle			~$200	$28.10	CIG
Limon			~$275	$34.83	CIG
Knutson			~$400	$35.00	CIG
Pyramid			~$300	$28.90	Waha
Burlington			~$450	$50.07	N/A

Tri-State forward gas prices change monthly. Figure 9 in Section 2 Commodity Pricing of this report shows the gas forward curve used in the ERP scenario modeling in real (2020) dollars. Additional transport costs apply.

Depreciation, Capital Balance, Amortization and Impairment:

Table 18 shows resource depreciation as of 4th Quarter 2019. Table 19 shows the capital balance, amortization and impairment of early retirements as identified in the preferred plan. It is important to note that Tri-State does not have project financing. Tri-State finances its assets as a portfolio; therefore, debt is not tied to specific units. In addition, annual fixed O&M and capital expenses are the only avoidable costs upon early retirement of a resource.

Table 18: Resource Depreciation as of 4th Quarter 2019

FACDESC	LAND_COST	FAS_COST	106_COST	CURRENT CAPITAL INVESTMENTS	TOTAL COST EXCLUDING LAND	DEPR_RESERVE	DEPRECIATION RATE	ESTIMATED ANNUAL DEPRECIATION
[redacted]								

Table 19: Capital Balance, Amortization and Impairment of Resources per Preferred Plan[14]

Facility Description	Additional Capital Expenditures 2020 to Retirement	Early Retirement Date	Impaired Amount at Retirement	Annual amortization Early Retirement Date to Original Accounting Date (includes amortization of	Decommissioning (Including dismantling, severance, community assistance)
[redacted]					

[14] The retirement of LRS 3 and SPV3 as identified in the preferred plan are subject to further study. Any retirement of an LRS facility will be determined by the MBPP participants.

Tri-State proactively works to reduce and eliminate capital expenses related to early retirement of resources as can be seen by the historical capital expense for the Nucla facility. Nucla was set to retire by December 31, 2022 as part of an agreement in 2016, which resulted in revisions to the Colorado Visibility and Regional Haze State Implementation Plan. Tri-State retired Nucla even earlier, in September 2019. Table 20 below shows that Nucla capital expenses were reduced to zero beginning in 2017.

Table 20: Nucla Historical Capital Expenses

	2015	2016	2017	2018	2019
NUCLA	$1,573,481	$1,334,631	$0	-	$0

Tri-State eliminated capital expenses for Nucla in the years leading up to the early retirement of the facility.

Projected Availability Factors:

For modeling purposes, availability factors are a result of modeled forced outage factors as well as planned outage hours. Tri-State assumes a 4% forced outage factor for all coal-fired generation. Historically, gas and oil resources are not assigned a forced outage factor due to their limited annual capacity factors. Tri-State updated its models to reflect recommended forced outage factors as provided by B&V in Attachment Vol II 5-4 B&V Report on Review of Existing Resources.

Any required Phase 1 modeling work will include forced outage factors by unit. These factors were developed using 5 years of historical data from MicroGADS (2015-2019). Table 21 shows the forced outage factors for each thermal unit for the 5-year historical period.

Table 21: Historical MicroGADS Forced Outage Factors for Tri-State Thermal Units

Resource	2015	2016	2017	2018	2019
Craig 1	4.85	1.59	2.11	5.53	1.21
Craig 2	2.31	1.19	7.03	0.27	2.18
Craig 3	6.71	6.42	5.35	45.24[15]	3.39

Pyramid 1	0.01	0.53	0.15	0.27	0.35

[15] The Craig 3 steam turbine generator experienced a failure in 2018 resulting in a significant forced outage for repair. Due to the low probability of this type of event, Tri-State only considered 4 years of historical data to determine the forced outage factor for this thermal unit.

Resource	2015	2016	2017	2018	2019

Third Party Assessment:

In preparation for Tri-State's 2020 Resource Plan processes, Tri-State engaged B&V to assist Tri-State with this assessment of existing resources. The above data reflects the outcome of that assessment where applicable. Specific areas of recommended change were as follows:

Table 24: Summary of Third-Party Recommendations

B&V Recommendation	Conclusion
Increase Burlington Heat Rate	Adjustment made to heat rate curve
Change Availability Factor of Combined Cycle resources to 90%	Capacity factors are relatively low on Combined Cycle resources and remain so in CO_2 reduced cases, so Tri-State did not make this change at this time
Change Availability Factor of Combustion Turbine dual fuel resources to 96%	Capacity factors are relatively low on Combustion Turbine dual fuel resources and remain so in CO_2 reduced cases, so Tri-State did not make this change at this time
Change Availability Factor of Combustion Turbine oil resources to 98%	Capacity factors are relatively low on Combustion Turbine oil resources and remain so in CO_2 reduced cases, so Tri-State did not make this change at this time
Reduction in Rifle Fixed Costs	Rifle fixed costs are based on historical data. Tri-State will continue to monitor Rifle fixed costs and adjust as necessary.
Reduction to Burlington and Rifle NOx emission rate	Burlington and Rifle NOx emissions are based on historical data. There are conditions specific to these units that make their emissions rates higher than industry averages, so this will remain at the higher level for modeling purposes so as not to under represent potential emissions.
Increase to Rifle and JM Shafer SO_2 emission rates	Rifle and JM Shafer SO_2 emission rates are based on historical data. Tri-State will continue to monitor SO_2 for these units and update as needed.
Decrease of availability factor and related increase in equivalent forced outage factor for all gas units	JM Shafer and Rifle were modeled with the recommended 3% forced outage factor. Because capacity factors are relatively low on the remaining Combustion Turbine oil and

B&V Recommendation	Conclusion
	natural gas resources and remain so in CO_2 reduced cases, they were modeled at their winter and summer capacities.

The B&V evaluation of resources detail can be found in Attachment Vol II 5-4 B&V Report on Review of Existing Resources.

* Based on historical data 2015 -2019

Resource Historical Data:

Historical data for key modeling inputs are located in this subsection. Forecasts of modeling inputs are based on a combination of historical data and known present or upcoming changes that might impact forecasts. Explanations of deviations in historical data are included in this section.

Table 26 shows actual O&M expenses from 2015 to 2019 by resource or facility as available. Source of the data is Tri-State financials.

Table 26: Annual Historical O&M by Resource ($000s)[17]

[17] Note that until June 30, 2019, a portion of JM Shafer was under a tolling contract to PSCO, and therefore history of resource operation and resulting costs is not necessarily reflective of future use.

Capital expenditures fluctuate to reflect ongoing needs that have been determined by site personnel, guidelines by equipment manufacturers and regulations for environmental, safety and regulatory compliance. The timing of larger capital upgrades is planned with major maintenance work when feasible. Table 28 explains larger capital expenditures by facility in recent history.

Table 28: Explanation of Historical Capital Expenses

Facility	Explanation of Historical Capital Expenses
CRAIG 1&2	Primary capex driver in 2015 and 2017 were environmental upgrades. Primary capex drivers in 2016 were environmental upgrades and controls upgrades.
CRAIG 3	Primary capex drivers in 2015 were environmental upgrades, controls upgrades and water purchases. Primary capex driver in 2016 was the continuation of the environmental upgrades.
BURLINGTON 1&2	Primary capex driver in 2018 was replacing various protective relaying.
LIMON 1&2	Primary capex driver in 2018 upgrading/replacing the inlet silencers for both engines.
KNUTSON 1&2	Primary capex driver in 2018 upgrading/replacing the inlet silencers for both engines.
PYRAMID 1,2,3&4	Primary capex driver in 2018 replacing various protective relaying.
RIFLE	Tri-State has been actively trying to decrease capital expenses at Rifle other than what is necessary for compliance.
JM SHAFER	Primary capex drivers for 2015 and 2018 were water purchases and water infrastructure for operations. Primary capex drivers for 2019 were large maintenance projects including a complete engine overhaul/rebuild.
LRS 2&3	Primary capex drivers in 2017 and 2018 were environmental compliance projects. (Selective Catalytic Reduction and Selective Noncatalytic Reduction).
SPV3	Primary capex driver in 2019 was the superheater reheater pendant replacement.

Table 29: Annual Historical Fuel Price by Pipeline ($/MMBtu)

Hub	2015	2016	2017	2018	2019
CIG	$2.39	$2.25	$2.63	$2.58	$2.06
WAHA	$2.46	$2.33	$2.68	$2.01	$0.86

The average of the last 5 years (2015-2019) of CIG prices is $2.38/MMBtu while WAHA's 5 year average is $2.07/MMBtu. In Section 2 - Commodity Pricing - Gas Forward Curve Tri-State describes the methodology for developing its forward gas curves. The 1st five years (2021 – 2025) of forward curve pricing show CIG's average to be $2.20/MMBtu and WAHA is at $2.07/MMBtu. Following those years, the forecast shows gas prices increasing based upon blended midterm and fundamental pricing.

Overview of Purchases

The following list provides summary information regarding current firm purchase power agreements in regards to capacity, energy and demand side resources. Tri-State does not have any wheeling or coordination agreements that provide capacity and energy.

Contract Purchases and Renewable PPAs differ from thermal resources in regards to applicable characteristics and costs. The format used below is intended to present the applicable data for these agreements as required in Rule 3605(c).

Summer capacities are representative of contract demand available to serve July peak.

Net Dependable Capacities (Capacity Credit) for renewable resources are identified in Section 5 Phase I Modeling Details under the Modeling Assumptions subsection of this report.

Contract Purchases:

Basin CROD Western Interconnection BEPC: Colorado & Wyoming: 268 MW summer capacity, ~1580 GWh/year[18]. Effective Date 1/16/1975; Restructured Date 10/1/2017; Contract Expires 12/31/2050.

- If either party wishes to terminate this agreement on its expiration date of 12/31/2050, notice must be given to the other party by January 1, 2045 in writing. Otherwise, this contract will remain in effect beyond its expiration date of 12/31/2050 until such time that either party gives to the other party not less than five years written notice of intent to terminate.

[18] Profile detail is shown in the Contract Profile Information subsection.

Basin Electrically East BEPC: All Requirements Purchase Contract for Electrically East Loads[19], Effective Date 1/16/1975; Restructured Date 10/1/2017; Contract Expires 12/31/2050.

- If either party wishes to terminate this agreement on its expiration date of 12/31/2050, notice must be given to the other party by January 1, 2045 in writing. Otherwise, this contract will remain in effect beyond its expiration date of 12/31/2050 until such time that either party gives to the other party not less than five years written notice of intent to terminate.

CRSP WAPA: 231 MW summer capacity ~1424 GWh/year. Seasonal Contract Rate of Delivery, specified monthly capacity and energy, and multiple delivery points apply to this contract. Effective Date 10/1/1989; Renewed Date 10/1/2017; Contract Expires 9/30/2057.

- Contracts TS-89-0005 and PL-89-0002 expire end of day, 9/30/2024. Contract TS-17-0128 is currently effective and commences delivery of Firm Electric Service beginning of day, 10/1/2024 through end of day 9/30/2057.

LAP WAPA: 353 MW summer capacity, ~900 GWh/year. Seasonal Contract Rate of Delivery, specified monthly capacity and energy, and multiple delivery points apply to this contract, Effective Date 10/1/1989; Contract Expiration 9/30/2054.

- Contract TS-89-0002 expires end of day, 9/30/2024. Contract TS-14-0238 is currently effective and commences delivery of Firm Electric Service beginning of day, 10/01/2024 through end of day, 9/30/2054.
- LAP contract includes rights to Mt. Elbert pump back storage 176 MW summer capacity with a 68% efficiency and prescribed generating and pumping hours. The Mt. Elbert contract capacity shares transmission with the LAP contract and the combination of usage cannot exceed the LAP contract max capacity in any hour.

Native American WAPA Allocations: Monthly (fixed schedule peaking) at 5 MW annually, ~28 GWh/year. Effective Date 10/1/2004; Expires 10/1/2024.

Central Valley Electric: ~1 MW capacity, ~5 GWh/year. Effective Date 12/05/1996; Contract Expires Evergreen

Public Service Company of New Mexico Unit Contingent Purchase: 100MW unit contingent purchase from PNM at SJ345. 100 MW (Maximum Capacity) ~876 GWh/year. Effective Date 06/01/2017; Contract Expires 05/31/2022. This is the purchase side of a swap that reduces spinning reserve obligations.

Additionally, Tri-State has several contracts under WSPP agreements that serve Utility Member system load associated with wind and solar facility station service for generators that are under contract and deliver energy to third party utilities but are located in a Tri-State Utility Member's service territory. These contracts are de minimis in nature (i.e., under 1 GWh in annual energy; 2 MW maximum demand).

- PRPA – Rawhide Solar Station Service (SS): Contract commenced 9/1/2016; contract expires 9/1/2021 – Expected to renew making the new contract expiration 9/1/2026
- PRPA – Prairie Solar SS: Contract commenced 5/1/2020; contract expires 5/1/2025

[19] Profile detail is shown in the Contract Profile Information subsection.

- PRPA – Roundhouse Wind SS: Contract commenced 6/3/2020; contract expires 6/1/2025
- CSU – Palmer Solar SS: Contract commenced 4/1/2020; contract expires 4/1/2025

Contract Profile Information:

Projected Basin Contract Energy & Demand

Basin CROD Western Interconnection contract energy profile is a set hourly profile identified by point of delivery. Stegall West 230KV Bus is located in Nebraska. AU 230KV and Story 230KV busses are located in Colorado. Figures 12 and 13 show the hourly profiles by point of delivery for each month:

POINT OF DELIVERY: STEGALL WEST 230KV BUS

Amounts shown in MW, hours shown are Hour-Ending and in Mountain Standard Time

Figure 13: Basin CROD Western Interconnection AU 230KV and STORY 230KV Busses Hourly Profile

Basin Electrically East contract has an energy and demand profile based on forecast Electrically East (Nebraska and Colorado) load, as this is a full requirements contract. The load served by this full requirements contract is located in the Eastern Interconnection primarily in the state of Nebraska with a small amount of Colorado load in the far northeastern portion of Colorado. On an average annual basis, ~15% of this purchase serves Colorado. The balance of this purchase serves load in Nebraska.

Hourly Profiles for the Basin Electrically East contract vary by season and are heavily impacted by irrigation. Figure 14 shows a typical hourly profile in a given day for the Irrigation and Non-Irrigation seasons. As shown by the orange line in the graph the hourly load during non-irrigation season barely exceeds 50 MW with a sharp morning peak, while the hourly load during irrigation season (yellow line) has a sustained daytime peak closer to ~280MW.

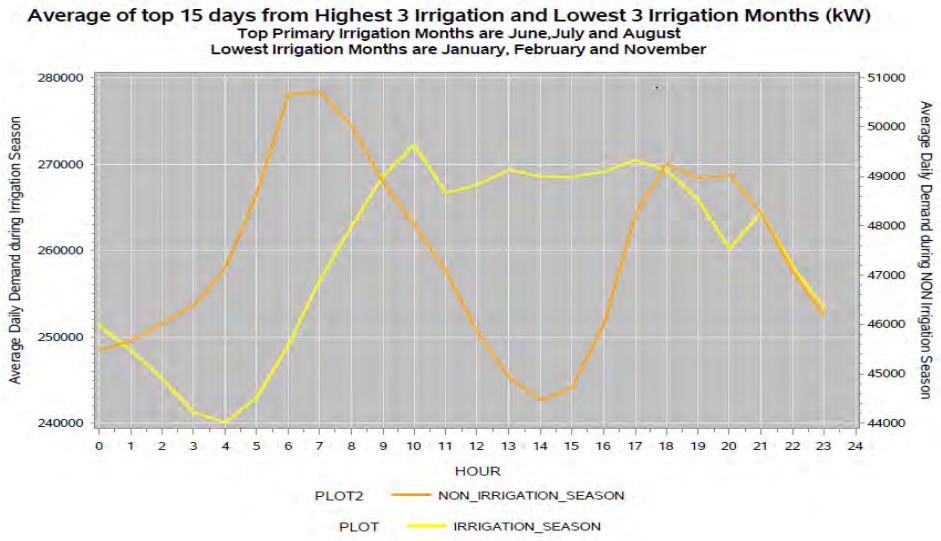

Figure 14: Basin Electrically East Irrigation and Non-Irrigation Seasons Demand Profiles

Below is a snapshot of historical energy and demand for the Basin Electrically East contract by month:

Table 38: Historical Energy and Demand for Basin Electrically East

Year	Data/UOM	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2018	Energy *(GWh)*	38	35	36	37	38	72	129	138	59	28	28	30
2018	Demand *(MW-Mo)*	76	76	62	64	88	191	335	269	126	55	49	53
2019	Energy *(GWh)*	29	29	27	23	35	45	137	117	60	24	29	29
2019	Demand *(MW-Mo)*	52	54	57	55	73	155	305	255	208	48	51	47

Below summarizes the annual projected energy and demand for each Basin contract.

Projected WAPA Contracts – LAP & CRSP Energy & Demand

LAP and CRSP contracts provide a set amount of energy delivered to each sub region by month. Additionally, an hourly minimum and maximum MW take is provided for each sub region by month. Tri-State is required to schedule on a two-day ahead basis the hydro in each sub region by "dispatching" the energy within the hourly minimum and maximum ranges.

Table 41 below summarizes the annual projected energy and demand for the WAPA CRSP and LAP contracts.

Table 41: Annual Projected Energy by Contract

Energy *(GWh)*	**2021**	**2022**	**2023**	**2024**	**2025**	**2026**	**2027**	**2028**	**2029**	**2030**
CRSP Total	1424	1424	1424	1424	1424	1424	1424	1424	1424	1424
Colorado Deliveries	930	930	930	930	930	930	930	930	930	930

Renewable Power Purchase Agreements:

Cimarron (First Solar) Purchase: Facility located in northeastern New Mexico, 30 MW (Maximum Capacity), ~64 GWh/year. Effective Date 2/23/2009; COD 11/25/2010; Contract Expires 11/24/2035.

Kit Carson Wind Purchase: Facility located in eastern Colorado, 51 MW (Maximum Capacity), ~185 GWh/year. Effective Date 6/30/2009; COD 11/19/2010; Contract Expires 11/30/2030.

Colorado Highlands Wind Purchase: Facility located in northeastern Colorado, 94 MW (Maximum Capacity) 91 MW (Nameplate Capacity), ~369 GWh/year. Effective Date 2/28/2012; COD 12/6/2012; Contract Expires 12/31/2032.

Carousel Wind Purchase: Facility located in eastern Colorado, 150 MW (Maximum Capacity), ~665 GWh/year. Effective Date 12/27/2013; COD 07/07/2016; Contract Expires 7/31/2041.

San Isabel Solar Purchase: Facility located in southern Colorado, 30 MW (Maximum Capacity), ~77 GWh/year. Effective Date 8/19/2015; COD 12/5/2016; Contract Expires 12/31/2041.

Alta Luna Solar Purchase: Facility located in southern New Mexico, 25 MW (Maximum Capacity), ~77 GWh/year. Effective Date 9/24/2015; COD 1/12/2017; Contract Expires 01/31/2042.

Twin Buttes II Wind Purchase: Facility located in southeastern Colorado, 75 MW (Maximum Capacity), ~302 GWh/year. Effective Date 6/1/2015; COD 12/28/2017, Contract Expires 12/31/2042.

Spanish Peaks Solar Purchase: Facility located in southern Colorado, 100 MW (Maximum Capacity), ~267 GWh/year. Effective Date 12/12/2018; Expected COD 11/01/2023, Contract Expires 11/30/2038*.Crossing Trails Wind Purchase: Facility located in eastern Colorado, 104 MW (Maximum Capacity), ~439 GWh/year. Effective Date 2/5/2019; Expected COD 12/18/2020, Contract Expires 12/31/2035*.

Niyol Wind Purchase: Facility located in northeastern Colorado, 200 MW (Maximum Capacity), ~843 GWh/Year. Effective Date 12/18/2019; Expected COD 12/31/2021, Contract Expires 12/31/2041*.

Escalante Solar Purchase: Facility located in western New Mexico, 200 MW (Maximum Capacity), ~566 GWh/Year. Effective Date 12/10/2019; Expected COD 11/30/2023, Contract Expires 11/30/2040*.

Axial Basin Solar Purchase: Facility located in northwestern Colorado, 145 MW (Maximum Capacity), ~370 GWh/Year. Effective Date 12/10/2019; Expected COD 12/31/2023, Contract Expires 12/31/2038*.

Dolores Canyon Solar Purchase: Facility located in southwestern Colorado, 110 MW (Maximum Capacity), ~297 GWh/Year. Effective Date 12/10/2019; Expected COD 12/31/2023, Contract Expires 12/31/2038*.

Spanish Peaks II Solar Purchase: Facility located in southern Colorado, 40 MW (Maximum Capacity), ~107 GWh/Year. Effective Date 12/10/2019; Expected COD 12/31/2023, Contract Expires 12/31/2038*.

Coyote Gulch Solar Purchase: Facility located in southwestern Colorado, 120 MW (Maximum Capacity), ~331 GWh/Year. Effective Date 1/13/2020; Expected COD 12/31/2023, Contract Expires 12/31/2038*.

All solar power purchase agreements are assumed to have declining annual energy at approximately 0.5% per year to reflect solar panel degradation

*Contract expiration calculated from expected COD

Small Power Producers (Hydropower) Contracts:

Table 45: Summary of Small Power Producers (Hydro) Contracts

Facility Name (Maximum Capacity)	Effective Date	Expiration	Location
Boulder Hydro (5MW) & Other Facilities (1.27 MW)	6/1/2018	5/31/2028	Colorado
Denver Water/Williams Fork (3.5 MW)	1/1/2007	12/31/2026	Colorado
Mancos/Jackson Gulch (0.26 MW)	9/1/1995	2/8/2035	Colorado
Vallecito/Ptarmigan (5.6 MW)	6/25/2004	6/24/2024	Colorado
Garland Canal (2.9 MW)	12/10/2014	12/31/2024	Wyoming
Tri-County Water/Ridgway (8 MW)	8/22/2012	9/30/2023	Colorado

Energy Payments for Renewable Power Purchase Agreements:

The following rates are averaged over the RAP. Capacity rates are not applicable to our Renewable Power Purchase Agreements:

Contract Provisions – Modification of Capacity and Energy Purchased:

The above contract purchases and renewable purchase power agreements are a combination of must take energy or take or pay energy. Limited ability to modify capacity or energy purchased under these contracts exists. The few exceptions are listed below:

- Annually LAP contract capacity and energy is adjusted by WAPA per the contract formula. Additionally, WAPA can adjust capacity and energy due to changes in hydrology and river operations or the addition of new resources.
- At predetermined dates in the CRSP contract, WAPA will adjust capacity and energy as necessary up to the maximum 1% withdrawal limit for the resource pool. Additionally, WAPA can adjust capacity and energy due to changes in hydrology and river operations or the addition of new resources.
- All utility scale renewable projects have a right of first refusal option with regard to facility expansion and exercise of such option when made available could result in additional capacity and energy.
- All utility scale renewable projects allow for Tri-State to take excess energy produced over and above expected contract energy as defined by each contract
- The majority of Tri-State's utility scale renewable contracts have a provision to curtail energy production without penalty under certain conditions through an allowable curtailment option. The allowable curtailment amount varies by contract but does not exceed 1% of annual contract energy.

[25] Low pricing in 2015 for Carousel and 2017 for Twin Buttes is a result of test energy.

Note:

- The Basin CROD Western Interconnection contract does not expressly allow for the modification of capacity or energy amounts purchased. The contract exhibit identifies a set hourly energy profile that supplier will deliver and Tri-State will receive.
- The Basin Electrically East contract does not expressly allow for the modification of capacity or energy amounts purchased. The Basin Electrically East contract is a full requirements contract, and supplier is obligated to serve Tri-State Utility Member System load located in the Eastern Interconnection in its entirety at delivery points as identified in the contract including changes to Utility Member System load as a result of natural cycles of load growth or decline.

Emissions & RECs Associated with Contract Purchases and Renewable Purchase Power Agreements:

Tri-State receives Renewable Energy Credits (RECs) associated with its Renewable Purchase Power Agreements. Tri-State's renewable PPAs are non-CO_2 emitting resources.

The WAPA LAP contract energy is generally sourced from power generated at federal dams in the Pick-Sloan Missouri Basin Program – Western Division and the Frying pan-Arkansas Project, collectively Loveland Area Projects. The WAPA CRSP Contract energy is generally sourced from power generated by the Salt Lake Area Integrated Projects. WAPA purchases energy from other sources as needed to meet the marketing plan obligations of its federal electric service customers including the LAP and CRSP contracts with Tri-State. Primarily these deliveries are from hydro. Annually, Tri-State receives RECs for prior year deliveries, which are recorded in WREGIS. These contracts are considered non-CO_2 emitting resources.

The Basin CROD Western Interconnection contract and the Basin Electrically East contract do not specify a source within the contract. Basin has the sole ability to determine the source of the energy for these contracts on a daily and hourly basis. Both contracts do require the energy to be delivered to specific delivery points. Based on this, the energy provided by these contracts are "unspecified energy" as identified in the Colorado AQCC Regulation 22. In order to estimate emissions of these contracts for the purpose of this Resource Plan, Tri-State considered the following:

Basin CROD Western Interconnection Contract: while historically this contract has been primarily served by LRS, future supply of this contract is in no way limited to a source of LRS. Organized market development, changing environmental landscape in the Western Interconnection, changing market or business conditions for BEPC or other factors can potentially influence BEPC's choice for hourly sourcing of this contract energy.

Basin Electrically East: This load in its entirety is within the Southwest Power Pool (SPP) footprint and BEPC supplies this load through the SPP market process.

Actual CO_2 emission rates used for the Basin contracts are discussed further in Section 5 Phase I Modeling Details under the GHG & CO_2 Reduction Methodology subsection of this report.

Additionally, it is noted that Tri-State receives RECs related to both of the Basin contracts as a Class A member of BEPC under an associated board policy, Renewable Resource Obligations Policy. The allocation process is similar to Basin's capital credit allocation process for Class A members. Allocation of RECs is determined annually for prior year. Recent historical allocations have been equal to ~25% of energy delivered under the Basin Western Interconnection and Basin Electrically East contracts.

Utility Member System Distributed Generation:

Tri-State's wholesale power contract with each of its Utility Member systems and applicable Tri-State Board policies allow for and facilitate the development of local distributed generation projects in Tri-State Utility Members' service territories, including community solar projects. These renewable and distributed projects help to fulfill both Colorado and New Mexico RES/RPS requirements, as well as satisfy Utility Members' and consumers' interest in purchasing renewable power from locally-sited projects.

As of October 2020, over 60 renewable or distribution generation projects, totaling 131 MW of capacity and capable of producing ~370 GWh/year are operating or under development. Approximately 85% of Utility Member System distributed generation is located in Colorado, and on a capacity basis, approximately 80% of the distributed generation in Colorado and New Mexico is solar. It is expected that the number of these projects will continue to grow as pricing for renewable resources continues to be attractive and Utility Member Systems continue to show interest in supporting local renewable projects. These numbers are also expected to grow as a result of Tri-State's Board of Directors approving a new policy in 2019 that will facilitate the development of community solar projects throughout its Utility Member Systems' service territories.

These resources are neither owned by nor contracted to Tri-State, but instead serve Utility Member system load directly. Tri-State has not attempted to provide a detailed assessment of these generation projects.

Forced Outage Assistance Agreements

TEP Hazard Agreement[26]: Upon any full forced outage of Springerville Unit 2, Tri-State shall deliver 100 MW per hour to TEP. TEP will deliver 100 MW per hour for any full forced Springerville Unit 3 loss. Hazard supply is limited to 168 hours of delivery. Contract energy is optional. Expected Effective Date 12/01/2020; Contract Expires 03/31/2022. Contract is evergreen unless Parties submit notice of greater than 150 days or designated unit retires.

PRPA Hazard Agreement: Upon any full forced outage of Craig Unit 3, PRPA will deliver 100MW per hour to Tri-State. Upon any full forced outage of Rawhide Unit 1, Tri-State will deliver 100MWper hour to PRPA. Hazard supply is limited to 168 hours of delivery. Contract energy is must take. Effective Date 04/01/2014. Contract expires 03/31/2024. Contract can be terminated by either party on two years written notice.

[26] Replaces prior agreement.

Table 48: Forced Outage Assistance Agreements Historical Pricing

Average Energy Rate	2016	2017	2018	2019	2020
TEP Hazard Agreement					
PRPA Hazard Agreement					

Scheduling Agent Agreements

WMPA Contract: Tri-State acts as WMPA's scheduling agent for its WAPA Network Integrated Transmission Service Agreement, Federal hydropower, generation resources, sales of available energy, and purchases of replacement energy. Effective Date 09/26/2017; Commencement Date 10/01/2017; Contract Expires 6/30/2021.

- WMPA sells Tri-State ~125 GWh of excess energy/year in instances where WMPA's resources are in excess of its load requirements.
- Tri-State sells WMPA ~6 GWh of energy to serve WMPA's load/year when WMPA's resources are not sufficient to serve its load.
- Additionally, Tri-State provides WMPA's spinning and operating reserves in the amount of WMPA's Pro Rata Reserve Share as determined in accordance with the WMPA Sub-Entity Agreement with WAPA for participation in NWPP.

Overview of Merchant Transmission

Tri-State is a wholesale cooperative electric generation and transmission association consisting of 42 Utility Member systems located across four states, operating within multiple Balancing Authorities and served by multiple Transmission Providers. Additionally, Tri-State's load is dispersed in multiple states and in both the Eastern Interconnection grid and the Western Interconnection grid. Tri-State's load in the Eastern Interconnection, which primarily includes loads in Nebraska along with a small amount of northeastern Colorado load, is served by an all requirements contract with BEPC. Resources for serving Tri-State load in the Western Interconnection, which includes loads in Wyoming, Nebraska, Colorado and New Mexico, are a combination of company owned resources and PPAs.

Figure 15 below illustrates the geographic diversity of Tri-State's load and resources along with Tri-State Merchant[27] owned transmission capacity and related transmission constraints. In the Western Interconnection, Tri-State Merchant is a network transmission customer of the following Transmission Providers:

- Tri-State Generation & Transmission Association (Tri-State Transmission)
- PSCo
- PNM
- PRPA
- WAPA Rocky Mountain Region Loveland Area Projects (LAPT)
- BHCT

[27] Tri-State Merchant is the marketing arm of Tri-State Generation and Transmission Association that is responsible for planning and resource acquisitions in regards to energy, capacity and transmission necessary to serve Utility Member system load along with related dispatch, scheduling and settlements activity.

- PAC

Additionally, Tri-State Merchant is a Point-to-Point (PTP) transmission customer of many TPs in the Western Interconnection. Tri-State Merchant uses these network and PTP transmission rights within Western Electricity Coordinating Council (WECC) TOT[28] capacity limits and other system constraints to schedule power from resources to loads on a day ahead and hourly basis to serve Utility Member System loads. The "Tri-State owned capacity" arrows in Figure 15 represent Tri-State transmission rights between modeling regions.

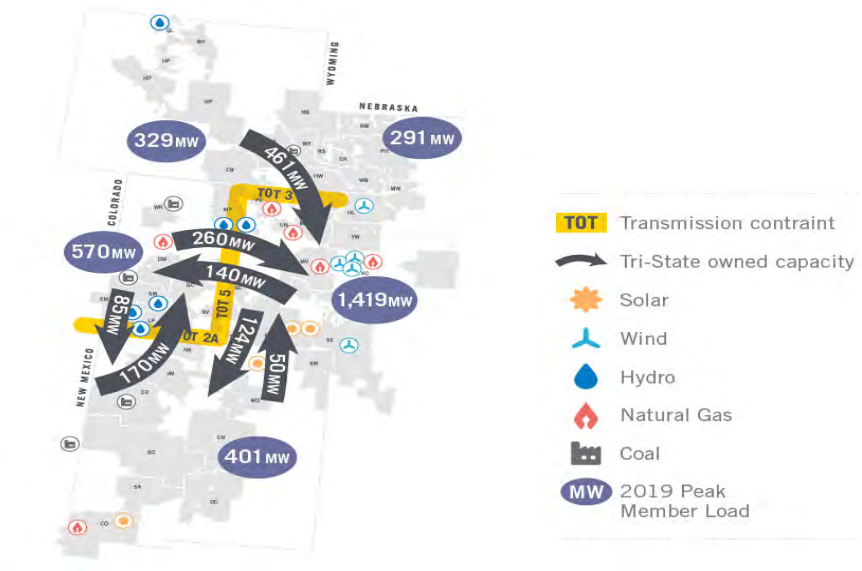

Figure 15: Tri-State System Major Transmission Paths

Table 49 represents Tri-State's major transmission reservations for moving power between regions across Tri-State's system. This is a reflection of the transmission modeling within the modeling systems for resource planning but does not represent a complete list of transmission rights including those within regions necessary to tag load in day-to-day operations.

Table 49: Tri-State's Major Transmission Network Paths

Transmission Capacity *(MW)*	**TOT**	**Path Flow Direction**	**TP/Type**	**Comments**
85	2a	NM to CO	TSGT Network	Path is often significantly reduced.
100	2a	NM to CO	CRCM PTP	
70	2a	CO to NM	TSGT Network	Path is often significantly reduced.
124	-	CO to NM	TSGT Network	Requires additional PTP leg to serve TS network load in PNM.

[28] A collection of transmission paths with a total operating limit that is often lower than the total of the underlying path reservations.

Transmission Capacity *(MW)*	**TOT**	**Path Flow Direction**	**TP/Type**	**Comments**
50	-	NM to CO	TSGT Network	Requires additional PTP leg to serve TS network load in PSCO.
461	3	WY to CO/CO to WY	TSGT MBPP[29]	Multiple reservation paths but total scheduled cannot exceed TOT limit.
260	5	West CO to East CO	TSGT Network	Additional PTP rights exist related to WAPA federal hydro contracts and other long-term firm PTP reservations.
140	5	East CO to West CO	TSGT Network	Additional 3rd party PTP transmission is available along this path at an additional cost.

In the Western Interconnection, Tri-State is required to deliver and tag power to sinks as configured in the North American Reliability Electric Corporation (NERC) webRegistry and as required by NERC Reliability Standards. Below is a breakdown of major load sinks:

- Nebraska West and Wyoming
  - 2 network sinks[30] in LAPT[31] TP – Western Area Colorado Missouri (WACM) BA and 1 ancillary[32] only sink in WACM BA
  - 3 network sinks in PAC TP and BA
- Colorado
  - 1 network sink in PSCO TP and BA and 3 ancillary only sinks in PSCO BA
  - 1 network sink in BHCT TP - PSCO BA
  - 1 network sink in LAPT TP and WACM BA
  - 3 ancillary only sinks in WACM BA
- New Mexico
  - 1 network sink in PNM TP and BA

There are specific Points of Delivery (POD) within each sink to which power can be delivered in order to supply Tri-State Utility Member System load. These PODs are similar to transaction points where purchases and sales occur. Tri-State may purchase power or move owned or contracted resources to these points, within applicable transmission rights, to serve load at the specific sinks.

WEIS/WEIM Transmission Impact:

[29] Transmission rights related to MBPP. However, use of this transmission is not limited to LRS.
[30] A network sink represents a subset of network delivery points with a third party TP where Tri-State has a network transmission integrated service agreement. Tri-State pays for network transmission on a prorata share basis each month based on load levels during the TP's peak.
[31] LAPT represents the transmission lines associated with the Loveland Area Projects federal hydropower
[32] An ancillary sink is a registered load within a Balancing Authority where only Tri-State Transmission is required to serve load.

Upon entry into energy imbalance markets in 2021, transmission and tagging for day ahead and real time activities will mostly remain as-is for load and resources located within WEIS and WEIM. However, the energy imbalance market will also introduce new intra-hour activity driven by the market operator. Intra-hour use of transmission by resources at the market operator's direction will be on a non-firm basis with no related tagging or charges.

RTO Transmission Impact:

Entry into an RTO consists of a common Open Access Transmission Tariff (OATT) and typically a market operator taking on BA responsibilities for the RTO footprint. The following are key changes related to or impacting transmission rights and usage in an RTO:

- One common OATT exists for the market and transmission billing is facilitated through the market operator.
- Congestion and losses are included as components of the Locational Marginal Price (LMP).
    - Resources are offered in at their location and awarded the LMP
    - Load is bid in at its location and pays the associated LMP
- Mitigation of congestion costs is handled through a financial congestion right that is to some extent correlated to transmission reservation rights.
- No tagging occurs within the market footprint; only imports, exports and wheel-thrus are tagged.

Overview of Merchant Ancillary Services

Tri-State meets its ancillary service requirements through Network Integration Transmission Service Agreements and Balancing Authority Ancillary Service Agreements. In the Western Interconnection, Tri-State receives ancillary services from PAC, PSCo, PNM and WAPA. As mentioned previously in this report, Tri-State's electrically east load is served via a full requirements contract with BEPC, which includes ancillary services.

Tri-State currently operates in bilateral energy and ancillary trading markets, and in 2021 will move additional load and resources into energy imbalance markets (WEIS and WEIM). Tri-State does not have load or resources in a full "day-2" organized market (an RTO or ISO) which would allow for both an energy and ancillary market.

Primary Ancillary Services:

The following is a list of primary ancillary services required via applicable TP OATTs and how Tri-State acquires these services, including applicability to any Tri-State resources:

Schedule 1 - Scheduling, System Control & Dispatch: Tri-State pays for this service monthly from appropriate TPs or BAs. Tri-State resources do not have any impact on or relation to this service.

Schedule 2 - Reactive Supply & Voltage Control: Tri-State pays for this service monthly from appropriate TPs or BAs. Tri-State's generating resources do not have any impact on or relation to this service. Tri-State does, however, have several applicable agreements with entities to partially self-supply reactive support via transmission system equipment in exchange for a reduced cost in service. Separately, Tri-

State generation resources are required via NERC Reliability Standards to follow reactive power instructions from Transmission Operators and operate in automatic voltage control mode.

Schedule 3 - Regulation and Frequency Response (includes load following capabilities): Tri-State pays for this service monthly from appropriate TPs or BAs. Applicable Tri-State-owned or contracted resources and Utility Member system distributed resources nameplate capacity are, at times, a factor in determining regulation cost, but Tri-State does not have any obligation to regulate for its own load or resources. Tri-State does, however, have generating resources that have the capability to operate in Automatic Generation Control (AGC) mode and thereby provide regulation as a service for a cost or partially self-supply regulation[33].

Tri-State generating resources that are AGC capable include:

- Craig 1,2,3
- LRS 2
- SPV 3
- JM Shafer
- Knutson 1,2
- Limon 1,2
- Pyramid 1,2,3,4
- Burlington 1,2

Schedule 4 - Energy Imbalance Service: Tri-State currently pays for this service monthly from appropriate TPs or BAs. Beginning in 2021, a significant portion of Tri-State's load and resources will be in two energy imbalance markets – the WEIS and WEIM. Upon entry, Tri-State will be able to participate with its resources located within the respective market's footprint. Financial settlements will occur with the appropriate Market Operator.

Schedule 5 - Operating Reserve Spinning Service: Tri-State self-provides spinning reserves through Southwest Reserve Sharing Group membership and via two sub-entity Reserve Sharing Group Agreements[34]. Tri-State generating resources typically online and capable of carrying spinning reserves include:

- Craig 1
- Craig 2
- Craig 3
- LRS2
- LRS3
- SPV 3
- JM Shafer

[33] See WAPA Regulation Contract for partial self-supply in Section 1 Electric Energy and Demand Forecast under the Energy and Capacity Sales to Other Utilities subsection for an example.

[34] The two sub entity Reserve Sharing Group Agreements are with PSCO and WAPA. PSCO and WAPA are participants of the Northwest Power Pool for reserve sharing as of the fall of 2019. Prior to that time PSCO, WAPA and Tri-State participated in the Rocky Mountain Reserve group for resources in these BAs.

Due to recent changes in operating standards in the Western Interconnection, operating reserves may be fully served via non-spinning supplemental service rather than the previous requirement that operating reserves must include of a minimum of 50% spinning reserves.

Schedule 6 - Operating Reserve Supplemental Service:

Tri-State self-supplies spinning reserves through Southwest Reserve Sharing Group member agreement and two sub-entity Reserve Sharing Group agreements. Tri-State's generating resources with quick start capability, which qualify for supplemental services, include:

- Burlington 1,2
- Limon 1,2
- Pyramid 1,2,3,4

Schedule 9 - Generator Imbalance Service: Tri-State currently receives and pays for this service monthly from appropriate TPs or BAs. Beginning in 2021, a portion of Tri-State's load and resources will be in two energy imbalance markets – the WEIS and the WEIM. Upon entry, Tri-State will be able to participate with its resources located within each respective market's footprint. Financial settlements will occur with the appropriate Market Operator.

Schedule 16 - Flex Reserve Service[35]: Tri-State currently takes and pays for this service monthly from appropriate TPs or BAs. This service is calculated based on proportional wind capacity contribution within the footprint as is used by the Balancing Authority to cover the costs of ramping requirements related to wind intermittency. There is no current option to self-supply.

Loss Supply Service: Tri-State either pays for this service monthly from appropriate TPs or BAs or provides physical loss requirement depending on specific contractual arrangements.

Self-Supply Discussion:

Tri-State has the ability to potentially self-supply all or a portion of the following ancillary services as allowed under TP OATTs and related contractual agreements:

- Reactive Supply and Voltage Control
- Regulation and Frequency Response
- Operating Reserves (Spinning or Supplemental)
- Loss Supply

With the transition of Tri-State's load and resources in the PNM-BA and WAPA-BA into WEIM and WEIS respectively Tri-State will also be able to offer in resources to meet intra-hour energy imbalance in these markets.

[35] Currently this ancillary service is only applicable to resources in PSCo.

Forecasting Ancillary Service Charges:

Table 50 provides a description of Tri-State's forecasting methodology for each ancillary service.

Table 50: Forecasting Methodology by Ancillary Service

Ancillary Service	Forecast Method
Scheduling, System Control & Dispatch	Current charges with adjustments for any known upcoming rate changes are used along with the appropriate forecast quantity (load or tags) to arrive at a forecast.
Reactive Supply & Voltage Control	Current charges with adjustments for any known upcoming rate changes are used along with the appropriate forecast quantity (load) to arrive at a forecast.
Regulation and Frequency Response	Current charges with adjustments for any known upcoming rate changes are used along with the appropriate forecast quantity (load, generation by type) to arrive at a forecast.
Energy Imbalance	Historical data is used to arrive at a forecast. The operational goal is always to minimize imbalance.
Operating Reserve Service (Spinning and Supplemental)	Tri-State models for self-supply of operating reserves on Pyramid and Burlington resources. Potential sales or purchases related to Reserve Sharing Group are forecast based on recent history. Contracts for specific sale of operating reserves as a service are forecast separately.
Generator Imbalance	Historical data is used to arrive at a forecast.
Flex Reserve Service	Financial forecast based on applicable resources and OATT rate. Included in Regulation forecast.
Loss Supply Service	Average of TP Provider's loss rate (5%) is applied to forecast load. Losses are included as load in the dispatch model.

Historical Ancillary Service Charges:

The following are average historical ancillary service charges from recent years as used to serve load across the Tri-State system in the Western Interconnection.

- Schedule 1 & 2 are recorded for accounting purposes with Network Transmission and Point-to-Point Transmission charges. The history detail for these charges is not readily available.
- Schedule 3 and Schedule 16 average annual regulation total charges for load and resources was $5 Million.
- Schedule 4 Energy Imbalance and Schedule 9 Generator Imbalance average annual purchase price was ~$25/MWh and the average annual sale price was ~$20/MWh.

- Schedule 5 & 6 Operating Reserves[36] average annual purchase price for receiving reserve activation assistance as part of a reserve sharing group or sub entity agreement was ~$40/MWh and average annual sale price was $80/MWh.

Current Ancillary Service Charges:

Table 51 shows current ancillary service rates for network and long-term firm PTP transmission.

[36] Reserve activation transactions occur upon the loss of a resource. The owner of the resource self-supplies replacement power to some extent and then purchases the additional assistance from reserve sharing counterparties.

Table 51 Ancillary Service Charges

NOTES: Settlements
PAC - Schedule 5 & 6 are included in Regulation
PNM - Attachment R is Wheeling Expense
PSCO - Schedule 9 is included in Energy Imbalance
Schedule 16 is Regulation Expense
Schedule 1 & 2 are included as Wheeling Expense
Schedule 3 is Regulation and is Purchase Power Expense
Schedule 4 is Energy Imbalance and is PP Expense/NMS Revenue

Schedule 1 - Scheduling System control and dispatch services
Schedule 2 - Reactive Supply and Voltage Control service
Schedule 3 - Regulation and Frequency response service
Schedule 4 - Energy Imbalance Service
Schedule 5 - Operation Reserve (Spinning Reserve Service)
Schedule 6 - Operating Reserve (Supplemental Reserve Service)
Schedule 9 - Generator Imbalance Service
Schedule 16 - Flex Reserve Service

Note 1:	To the extent the Control Area operator performs this service for the Transmission Provider, charges to the Transmission Customer are to reflect only a pass-through of the costs charged to the Transmission Provider by that Control Area operator
Note 2:	Pass Through (purchase price, energy activation, plus administrative fee)
Note 3:	TSGT's Network Load with PRPA - A/S 3 and 4 services supplied by WAPA
Note 4:	Platte River is not a balancing authority, and does not offer this service. Upon written request, Platte River will assist in arranging for the local balancing authority operator
Note 5:	Joint Dispatch Transmission Service ($0.00/MW-month)
Note 6:	A/S is not a required service for LTFPTP transmission service
Note 7:	Reliability Redispatch Costs and Methodology (details in PNM's OATT)
Note 8:	A/S Schedules 1 and 2 are not applicable with pre-OATT FPTP transmission service

Benchmarking

For the purposes of the Rule 3605(c)(II) Benchmarking requirement, Tri-State engaged Black & Veatch to perform an analysis of cost and performance of existing owned and contracted resources as compared to generic resources. The scope of this benchmarking analysis was limited to the following:

- Thermal and renewable utility scale resources that are:
  - Commercially operational, and
  - Located in the state of Colorado, or
  - Located outside of the state of Colorado but capable of serving Colorado load at any time.
- Basin Western Interconnection and Basin Electrically East contracts

Alta Luna and Cimarron renewable resources located in New Mexico are included in the benchmarking process but have never been scheduled to Colorado load.

Resources excluded from the benchmarking process include:

- Federal hydro contracts of LAP and CRSP as these long term, cost-based contracts for delivery of firm, renewable, quasi-dispatchable power with certain transmission and ancillary service benefits do not have a reasonable comparison within the generic resource pool.
- Other small contract purchases, small hydro power producer contracts

The full methodology, results and insights from the B&V benchmarking process are located in Attachment Vol II 5-5 B&V Benchmarking Study. This attachment was filed previously in the August 3, 2020 revised filing.

UPDATE: Tri-State is waiting for the Commission Order related to guidance in Proceeding No. 20M-0218E. Once this order is published, Tri-State will reengage B&V to revise this benchmarking study to meet Commission expectations. The revised study will be provided as soon as is reasonably possible.

The benchmarking process is informative to the overall resource planning process but does not take the place of scenario modeling required to arrive at least cost, reliable resources plans within transmission and environmental constraints.

Retirement Analysis

Tri-State allowed the expansion plan model to retire resources in the following scenarios:

- 80pct CR V1, V2, V3 and V4 – coal resources allowed to retire in 2025 except SPV3 which was allowed to retire after the end of the SRP sales contract (mid-year 2036)
  - Results: LRS 3 retires early 2030s; SPV3 retires late 2030s
- Low Load 80 pct CR V1 and V2 – coal resources allowed to retire in 2026 except SPV3 which was allowed to retire after the end of the SRP sales contract (mid-year 2036)
  - Results: LRS 3 retires late 2020s; SPV3 retires late 2030s
- Social Cost of Carbon – coal and gas resources allowed to retire in 2025 except SPV3 which was allowed to retire after the end of the SRP sales contract (mid-year 2036)

- Results: Craig 3, LRS 2 and LRS 3 retire in 2026; SPV3 retires in late 2030s; Various gas resources retired in late 2020s or early 2030s

In the 80pct CR V1, V2, V3 and V4 scenarios and Low Load CR V1, and V2 scenarios the expansion plan model chose to keep Craig 2 and 3 online until announced retirement dates. SPV3 was not allowed to retire prior to the end of the SRP contract associated with this resource in any scenario, because the current expansion plan model setup cannot appropriately consider the lost revenue of the SRP contract associated with SPV3 when making a retirement decision.

While the CE model is retiring LRS3 and SPV3 at varying times during the scenarios including in the preferred plan, Tri-State will need to work with the MBPP joint owners of Laramie River Station to determine the best retirement schedule for either LRS resource for all participants. In regards to SPV3 Tri-State will need to resolve the modeling issue mentioned above and work with other joint owners of common facilities at the Springerville station to arrive at the best retirement schedule for SPV3.

4 Transmission System & Planning

Overview – Transmission System

Tri-State owns (wholly or jointly) more than 5,500 miles of transmission lines in Colorado, Nebraska, New Mexico and Wyoming. Tri-State continues to support regional transmission study efforts. Tri-State continues to make transmission investments to serve growing loads, increase reliability, ensure system stability, and support additional generation development.

Transmission Planning

Tri-State transfer capability limitations on its transmission network are generally based on facility ratings. Tri-State's facility ratings equal the most limiting applicable Equipment Rating of the individual equipment associated with that facility. An overall transmission line rating factors in both the conductor rating and the associated terminal equipment ratings. Facility ratings commonly limit and affect the future siting of resources. See Attachment Vol II 4-1 Tri-State Facility Rating Report for additional detail.

The following Tri-State transmission projects have been identified in Tri-State's 10-year transmission plan filed pursuant to Rule 3627 included as Attachment Vol II 4-2 Tri-State 10-year Transmission Plan. Note, while these transmission projects were categorized as Planned in the filing, most are still in the developing stages. In Tri-State's experience, many of the planned transmission projects in the Rule 3627 report are ultimately modified or cancelled as the result of changing drivers and future needs.

- Burlington-Burlington (KCEA) 115kV Line Re-build
  - Tri-State will re-build the existing Burlington-Burlington KCEA line to increase the thermal rating of the line.
- Del Camino-Slater 115kV Line Uprate
  - This project will replace all the remaining spans of 397.5 ACSR conductor on the Del-Camino Slater line with 477 ACSR conductor.
- Falcon-Midway 115kV Line Uprate
  - This project involves raising, moving, or rebuilding structures along the Falcon-Midway 115kV line to increase the overall line rating to 145 MVA.

- Falcon-Paddock-Calhan 115kV Line
  - The current Falcon-Paddock-Calhan 69 kV transmission line will be rebuilt to create a 115 kV loop.
- Lost Canyon – Main Switch 115kV Line
  - This project will add a new 115kV line between Lost Canyon and Main Switch.
- Sisson Delivery Point Project
  - This project will add approximately 20 miles of new 115 kV transmission to radially serve the new Sisson substation radially north from the existing Keota substation.
- Vollmer Delivery Point Project
  - This project will tap the existing Jackson Fuller-Black Squirrel 115kV line and add approximately 2 miles of 115 kV transmission to serve the new Vollmer substation.
- Western Colorado Transmission Upgrade Project (re-build of Montrose-Nucla-Cahone 115kV line)
  - This project will rebuild the existing Montrose-Nucla-Cahone 115kV with 1272 ACSR conductor and be capable of future 230kV operation. Additionally, the line will be sectionalized at the new Maverick substation, rather than Nucla, which is located between Nucla and Norwood substations.

Project information for each transmission line or facility identified in 3605 (d)(II) can be found in Appendix E of the most recent Rule 3627 Report. See Attachment Vol II 4-3 Tri-State Transmission Project Information for a reduced copy of Appendix E showing the requested information for the identified projects.

Response to C20-0661-I Related to Transmission Impacts on the ERP Process

In the November 12, 2020 Commission weekly meeting the Commission gave guidance in regards to Proceeding No. 20M-0218E. Tri-State interpreted this guidance as the Commission requiring Tri-State to respond to the joint transmission proposal submitted by participants in Proceeding No. 19R-0096E. Tri-State first notes that it submitted comments in that proceeding pursuant to Decision No. C20-0661-I (the "Interim Decision") regarding the transmission-related rule proposals (the "Rule Proposals"). Tri-State's present position with respect to those proposals is the same as what it described in those earlier comments. Namely, while Tri-State agrees that some of the Rule Proposals have merit, there simply was not enough time remaining before Tri-State's ERP filing was due for Tri-State to incorporate any new requirements coming out of the 19R-0096E rulemaking process. Tri- State explains its position in more detail below, consistent with its earlier comments.

The rules governing this ERP filing were finalized in Proceeding No. 19R-0408E and became effective on July 15, 2020. These rules include Rule 3605(d), requiring Tri-State to submit an assessment of transmission resources, which will require Tri-State to provide extensive information regarding its current and planned transmission systems. This information includes Tri-State's transmission capabilities and future needs during the planning period for facilities of 115 kilovolts and above, the location and extent of transfer capability limitations on Tri-State's transmission network that may affect the future siting of resources, and a description of the transmission lines and facilities appearing in Tri-State's 2020 Rule 3627 Report that, as identified in that report, could reasonably be placed into service during the RAP. For each transmission line or facility that could reasonably be placed into service during the RAP, Tri-State must

include the following information detailing assumptions to be used for resource planning and bid evaluation purposes:

- length and location;
- estimated in-service date;
- injection capacity;
- estimated costs;
- terminal points; and
- voltage and megawatt rating.

In addition to providing this information, Tri-State must consider the transmission costs required by, or imposed on the system by, and the transmission benefits provided by a particular resource as part of the bid evaluation criteria. And it also must describe and shall estimate the cost of all new transmission facilities associated with any specific resources proposed for acquisition other than through a competitive acquisition process.

Tri-State has included this required information in Section 4 Transmission System & Planning and in other sections throughout this report as identified in the Transmission Summary subsection of Section 4.

The Rule Proposals in the Interim Decision would modify Commission Rules 3608, 3614, and 3615. These rules do not apply to Tri-State, nor should they be extended to do so. As was explained in Decision No. C20-0155 in Proceeding No. 19R-0408E, "given the structure and contents of Rule 3605 . . . the following ERP Rules being reviewed in Proceeding No. 19R-0096E are not intended to apply to Tri-State: . . . Existing/Proposed Rule 3608 Transmission Resources . . . Proposed Rule 3614. Phase I; and Proposed Rule 3615. Phase II." It would be contrary to this clear statement if the Rule Proposals in this proceeding were extended to modify the final rules adopted in Proceeding No. 19R-0408E.

Although Tri-State has not expressly incorporated any of the Rule Proposals into this ERP, it does agree in principle with some of the Initial Comments and Rule Proposals in the 19R-0096E proceeding. At a high level, Tri-State believes it will be important for the ERP process to account for transmission projects that are likely to come online during the resource acquisition period and recognizes that new transmission will be needed to meet Colorado's emissions-reduction goals. As such, Tri-State provides the following comments on some of the Rule Proposals or comments submitted in this proceeding.

Rule 3627 Information

Tri-State has no objection to the Commission taking administrative notice of the 2020 Rule 3627 filings in this ERP. While not all of the Rule 3627 information will be relevant to Tri-State's ERP, these filings nevertheless provide useful context regarding the transmission system and Tri-State believes they are appropriate to include in the ERP process. Indeed, under Rule 3605(d), Tri-State has already included information on those transmission resources in its Rule 3627 filing that could reasonably be placed into service during the resource acquisition period.

Planned Transmission Facilities

Tri-State agrees with the principle that transmission facilities under construction or for which a CPCN has been filed with the Commission at the time this ERP is being filed are in most cases facilities "that could

reasonably be placed into service during the resource acquisition period" under Rule 3605(d)(II). Tri-State has included such facilities in this ERP and intends to accept bids into these facilities as appropriate.

More generally, Tri-State notes that the RFP process for this ERP allows bidders to bid into developing transmission projects that are not yet in service, even where those facilities are not yet under construction and may be altered significantly or even cancelled. In general, this includes transmission projects that have been identified in Tri-State's 10-year transmission plan filed pursuant to Rule 3627.

While Tri-State intends to continue to accept such bids going forward, it urges the Commission to be cautious about adopting future rules that would encourage bids into projects that are still in the developing stages. In Tri-State's experience, many of the planned transmission projects in the Rule 3627 report are modified significantly or cancelled as the result of changing future needs. As an example, of the 16 new transmission line projects included in Tri-State's 3627 filings since 2014, only 2 have been constructed (the Burlington – Wray 230 kV line, and the Southwest Weld Expansion Project). This reflects the reality that Tri-State's long-term transmission planning reports are snapshots in time that rely heavily on forecasts of future drivers (oil and gas loads, for example) that change based on factors largely outside of Tri-State's control.

Tri-State further notes that it has network load that is served via other utilities' transmission systems and that it must coordinate with these utilities and conduct joint studies in some instances in order to accommodate new generation projects. This required coordination can add another layer of complexity and uncertainty with respect to some projects.

While bidders can bid into future, uncertain transmission projects, such bids are contingent on the continued need for the project. Where, as is often the case, the transmission project becomes unnecessary or dramatically changes, the economics of the bids relying on the project often become untenable.

Transmission Related Costs in Portfolios

Tri-State also agrees in principle with OCC that all transmission-related costs related to a particular generator bid should be included for purposes of bid evaluation.

Tri-State's ERP generally seeks to account for all such costs in order to ensure that it is securing the most cost effective generation for its Members. Tri-State notes that it is currently in the process of seeking FERC approval of certain reforms to its generator interconnection queue process that will allow it to better account for transmission costs associated with new generation through a cluster study process, rather than the sequential process it currently uses pursuant to the FERC Pro Forma Large Generator Interconnection Procedures.

Tri-State appreciates the Commission's consideration of these important transmission-related issues. Although the Commission should not adopt new requirements for Tri-State, Tri-State agrees with some of the Rule Proposals and comments in principle as discussed above. Tri-State recognizes the importance of these transmission-related items and is addressing some of them in this ERP filing.

Transmission Summary

In addition to the Transmission System & Planning section of this report transmission information related to Tri-State's system is available as follow:

- Volume I Section 8 Base case and Alternative Scenario Results contains specific transmission assumptions and transmission capital expenses by scenario.
- Volume I Section 11 Resource Acquisition Period – Action Plan contains transmission information related to the Phase II process.
- Volume II Section 3 Assessment of Resources contains a section on merchant transmission.
- Volume II Section 5 Phase 1 Modeling Details contains modeling constraints and assumptions related to transmission modeling.

5 Phase I Modeling Details

Model Description

Overview

Tri-State uses various industry standard software to perform resource planning including the following:

Table 52: Summary of Software Used in Tri-State Resource Planning

System	Purpose
SAS	Load forecasting by region for use in CE & PO and by member for use in Hyperion and UIPlanner.
Hitachi ABB Capacity Expansion (CE)	Develops expansion plans including resource acquisitions and retirements.
Hitachi ABB Portfolio Optimization (PO)	Hourly least cost dispatch within environmental and transmission constraints.
Transmission Siemens PSEE (PSEE)	Evaluates interconnection and network upgrade costs for new resources.
Hyperion	Receives load data from SAS and dispatch data from PO and incorporates this data along with capacity, energy, wheeling, transport and related expenses and revenues for transfer to UIPlanner.
Utilities International Planner (UIPlanner)	Financial model used to calculate PVRR for scenarios incorporating all expense and revenue data while adhering to Tri-State financial goals.

Tri-State's process for scenario analysis includes determining an expansion plan using CE, running an hourly dispatch for the 20-year planning period in PO, and gathering dispatch, plan and load data along with other capacity, energy and wheeling expenses and revenue in Hyperion. The CE plan for each scenario is sent to Tri-State's Transmission Planning group for an evaluation of transmission capital expenditures based on resource additions and retirements in each scenario. All analysis in CE, PO, Hyperion and Transmission are performed in real (2020) dollars without inflation. Final data is sent to UIPlanner for PVRR analysis for each scenario. UIPlanner inflates expense and revenues into nominal dollars.

The diagram below shows the succession through the primary software systems:

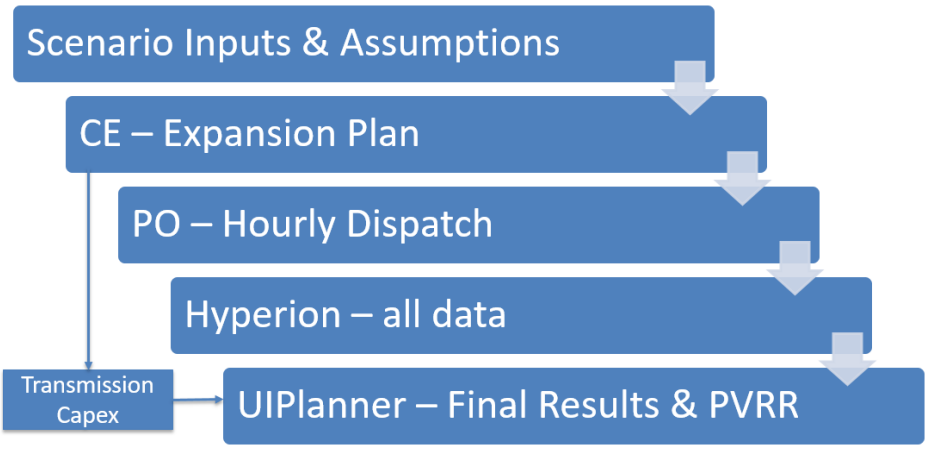

Figure 16: Scenario Modeling Process Overview

CE and PO

CE is a resource expansion planning model used to deliver an optimal expansion plan including timing, technology and size of potential resources. The plan respects a set planning reserve margin and adheres to transmission and emission constraints. For expansion planning, technologies are identified for use in the generic resource dataset. Emerging technologies are evaluated in regards to maturity and availability of reliable pricing and are included or excluded accordingly. Generic resources are set up as build, build transfers or power purchase agreements within the model. Characteristics and pricing of technologies included in the generic resource dataset can be found in the Section 5 Phase 1 Modeling Details under the Generic Resource Cost, Performance Emissions data subsection of this report.

CE uses a number of key inputs necessary for determining an ideal expansion plan from the perspective of cost, technology and timing within the planning horizon. Figure 17 lists inputs required for the system to define the expansion plan.

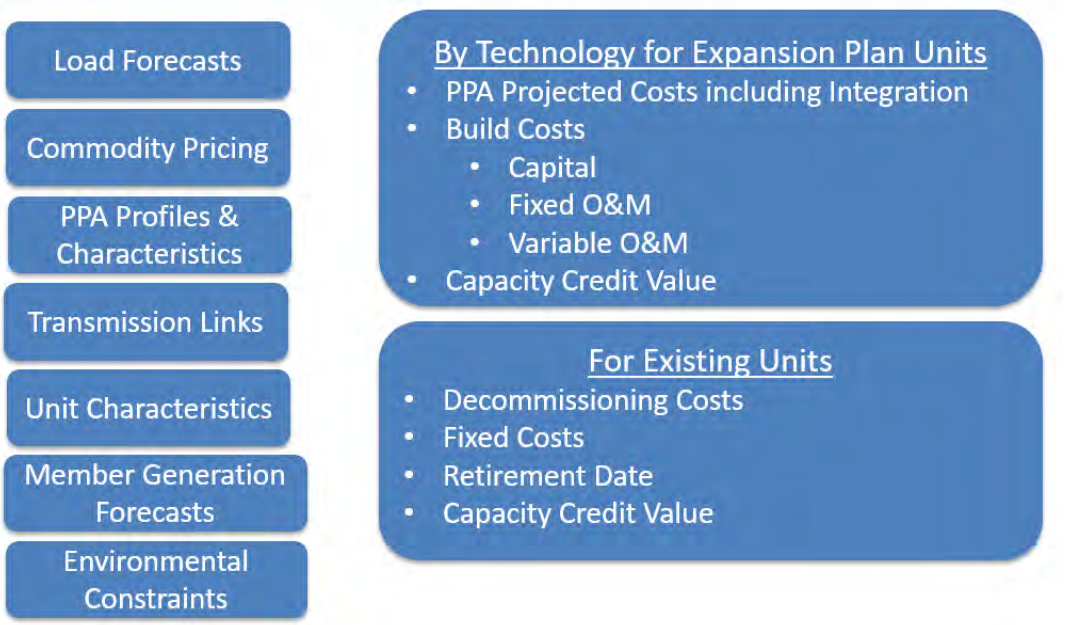

Figure 17: System Inputs for Expansion Plan Scenario Modeling

CE results include the size, timing, location, technology, and characteristics of each new unit.

Figure 18: Capacity Expansion (CE) Plan Results

The final expansion plan is then moved into the hourly dispatch model, PO.

PO is a production cost model used to determine a least-cost hourly dispatch plan based on unit operating characteristics, market prices, transmission constraints, regional load forecasts, and Power Purchase Agreements. Existing resources including any early retirements and generic resources additions identified in the expansion plan are modeled in PO for each scenario. Resources include thermals, renewables, energy storage, distributed generation, and demand-side-management, as

well as contracts with hourly and monthly energy limits. Final PO hourly output for the planning period is reviewed to ensure that all contract, environmental and dispatch limits are followed.

Dump Energy and Energy not Served:

As PO is modeling a dispatch over a 20-year period on an hourly basis, PO uses two methods to allow the model to complete within a reasonable timeframe. These methods are "dump energy" and "energy not served". "Dump energy" allows for an additional market outside of normal market depth limits where energy can be sold at an extremely low price. It is also a reasonable reference to potential curtailments in the plan driven by excess energy. "Energy not served" allows energy in a given hour that cannot be served by the existing and generic resources or existing market to be served at an extremely high market price. If the PO algorithm is having difficulty solving in a particular hour of the 20-year planning period with too much or too little energy, it can fall back on one of these methods to complete the overall dispatch. For each scenario, annual "dump energy" and "energy not served" are reviewed and kept within reasonable bounds. During the RAP, the threshold for "dump energy" is less than 25GWh in any given year, and the threshold for "energy not served" is less than .5GWh in any given year of a study.

Modeling Region/Transmission Area Setup:

PO and CE are setup with up to eight different Transmission Areas (TA) depending on the scenario. These are modeling regions that represent high-level operations of the Tri-State system footprint and allow for the modeling of known transmission limitations via links with set transmission capacity. TAs are not specific to any one TP. Load, resources and markets are assigned to these TAs for modeling purposes.

Table 53: Transmission Areas for CE and PO

TA	Geographical Location	BAs	Transmission Location
WACM_Eastern Colorado	Eastern Colorado	WACM, PSCo	East of TOT 5; South of TOT 3
WACM Wyoming	Wyoming & Nebraska West	WACM, PAC	North of TOT 3
WACM Wyoming Green[37]	Wyoming & Nebraska West	WACM	North of TOT 3
West_Colorado	Western Colorado	WACM	West of TOT 5
New Mexico	New Mexico	PNM	South of TOT 2
Springerville	Arizona	PNM[38]	PTP transmission to PNM
Mt. Elbert	Colorado	WACM	Shares LAP Hydro transmission
Nebraska	Nebraska East and Northeast Colorado	SPP	Eastern Interconnection

[37] This TA is used to allow TOT 3 transmission capacity to be assigned to renewable generic resources located in Wyoming while restricting the use of TOT 3 transmission capacity by thermal resources in the WACM Wyoming TA. The result is to allow more green power to flow from Wyoming to Colorado for CO_2 reduction.

[38] This resource transitioned to a pseudo-tie into PNM instead of WACM in 2020 due to planned entry into WEIM in 2021.

In the model, the Nebraska TA is setup so that load is met entirely by the Basin Electrically East purchase and no flow is allowed from Nebraska into any of the other TA's.

For the other TA's links are used to simulate transmission flow or the ability to flow from one TA to another. Maximum capacities are used to set the boundaries of the amount of energy that can flow from one TA to another. These link capacities are found in Section 5 Phase 1 Modeling Details under the Modeling Assumptions subsection of this report.

Transmission Capex Process

Planning level cost estimates for transmission facilities associated with generation expansion plan resources were developed by Tri-State's Transmission Planning department for the base case and each alternative scenario. For each resource in the expansion plan, a specific Point of Interconnection (POI) on Tri-State's transmission system was assumed within the given region (Eastern Colorado, Western Colorado, Wyoming, and New Mexico). These locations were chosen based on previous requests received as part of Tri-State's Large Generation Interconnection Process (LGIP) Queue, neighboring entities' LGIP studies, and/or locations known to be able to accommodate generation injection from coordinated planning efforts. Each unit was then assigned required upgrades at the POI, which typically consisted of a new switching station or additional breaker bays at an existing substation needed to tie in the generator.

For units assumed to be owned by Tri-State an additional interconnection facilities cost was assigned, which includes costs for generator tie line termination equipment and metering. These interconnection facilities costs were not included for generators assumed to be included in the expansion plan via a PPA as those costs would be borne by the generator owner, consistent with Tri-State's LGIP.

The bulk of the transmission costs are associated with additional Network Upgrades (beyond the POI facilities) that would be required to accommodate the aggregate levels of injection and maintain the reliability of the transmission system. These costs do not include costs for projects in Tri-State's 10-year transmission plan. Similarly, the expansion plan was only evaluated for transmission reliability impacts and transmission service for the additional resources was not in the scope of this analysis. The reliability impacts and necessary upgrades were identified by powerflow contingency analysis using Siemens' PSSE software and WECC approved powerflow models. In general, the costs were primarily associated with new transmission lines and/or transformers needed to mitigate thermal overloads associated with single contingencies.

To the extent possible, results from previous studies were leveraged to determine injection limits and identify Network Upgrades. Primarily, results from the Colorado Coordinated Planning Group's (CCPG) Lamar Front Range Task Force studies, Tri-State's LGIP System Impact Studies, and other internal Tri-State studies were utilized. Where needed, additional powerflow contingency analysis was performed by heavily dispatching the local existing resources consistent with LGIP study methodology. Due to the highly interconnected nature of Tri-State's transmission system, future changes made by other entities can greatly affect the results. As such, the provided cost estimates have a higher degree of uncertainty than is associated with typical planning level cost estimates. This is especially true for resources added beyond the ten-year horizon, as WECC does not build base cases beyond this

timeframe. Additionally, since it was assumed that a regional transmission organization (RTO) will be needed beyond the ten- year horizon, impacts to WECC Rated Paths were not considered.

Financial Analysis Process

Hyperion:

Data from the PO dispatch including the CE expansion plan resources and retirements along with hourly dispatch for resources, markets and contracts is loaded into Hyperion. Additionally, load forecasts and member distributed generation forecasts from SAS are loaded into Hyperion. Finally, manual forecast inputs including wheeling expense and revenue, ancillary service expense and revenue, capacity expense and revenue and fixed charges are entered into Hyperion. This data is compiled and sent to UIPlanner for final financial analysis.

UIPlanner:

Financial forecasting is completed within UIPlanner, resulting in a final value for PVRR for each scenario. UIPlanner is a financial forecasting model specifically designed for, and widely utilized in, the utility industry. Tri-State continuously maintains the functionality of the model, and on a periodic basis throughout the year, updates inputs and assumptions. Key rates used in ERP analysis include:

- Inflation rate of 1.7% in 2021 and 2022 and 2.0% 2023 to 2040
- Discount rate of 4.15%
- A discount rate of 3.00% per Commission guidance was also used for separate analysis of the SCC scenario

The model provides long-term financial forecast results such as Class A member rates, pro forma financial statements and financial ratios.

The expansion plan and hourly dispatch data from the CE and PO, along with the load forecast are extracted by Hyperion and files are prepared for import into UIPlanner. Transmission capital expenditures related to the expansion plan are prepared by Transmission Planning and imported into UI Planner. Along with Near-term operating and capital budgets and forecasts, UIPlanner forecasts capital expenditures, and operating and non-operating revenues and expenses. Financial assumptions and Board approved financial goals, including minimum equity to total capitalization ratios, debt service requirements, liquidity levels and net margins, are also input into UIPlanner. Given those parameters, UIPlanner solves for the minimum Class A revenue requirement to achieve those financial goals for each year of the study period. UIPlanner calculates the PVRR from the monthly revenue requirement over the study period.

For purposes of the base case and alternative scenarios, thermal retirements were handled as follows:

- Net book values impaired and amortized over original accounting life.
- Severance, community assistance and decommissioning cost estimates deferred and amortized over original accounting lives.
- Colowyo depletion accelerated to early retirement date.
- 50% of allocated G&A expense eliminated after an entity's retirement.

Modeling Constraints

As Tri-State progressed through its 2020 ERP process, some modeling issues were identified. The following identifies these issues, their impact to scenarios and plans for resolution.

Tri-State upgraded to its current version of CE and PO in early 2019. Despite robust functionality within the models themselves, some limitations were observed given new modeling requirements and workarounds were used to meet scenario requirements. These issues included the following items:

- The model does not allow a limit on emissions for transmission links. This created difficulties in limiting emissions within a particular state while considering imports. To work around this, Tri-State used an iterative process, which included placing emissions limits on resources where possible, manually checking emissions of final dispatch results and adjusting emission limits and re-running the dispatch as necessary to achieve appropriate emissions limits in a given state inclusive of imports.
- Tri-State's contractual share of Mt. Elbert, a pump storage resource associated with the LAP federal hydro contract, was modeled and functioning properly in initial scenarios. However, a software issue related to Mt. Elbert was encountered during successive scenario modeling which was unable to be resolved for a significant period of time. For impacted scenarios, Tri-State turned Mt. Elbert off and marked assumptions accordingly.
- Transmission capital expenditure analysis related to interconnection costs and network upgrade costs occur outside of CE and PO and typically occur after a CE plan for a given scenario is complete. It is difficult to incorporate into CE the cost of potential network upgrades. Tri-State works around this issue in the current model through the following methods:
    - Restricted early years of the model (prior to 2028) to allow limited generic resources from which the model could select. These restrictions were based on technology type and region depending upon available transmission interconnection and timing to accommodate network upgrades. For example, 200 MW of Wyoming and 100 MW of ECO interconnection capacity are available prior to 2028 without requiring additional significant network upgrades. Tri-State could not reasonably construct additional significant network upgrades in those regions prior to 2028. In such cases, priority for the interconnection capacity was given to renewable resources.
    - Applied a $600/KW transmission adder to the build cost of gas resources in eastern Colorado, where network upgrades are more likely to occur upon the addition of generic resources.
- DSM and EE were modeled as supply-side resources to compete with utility scale resources in CE and PO. While program costs were accounted for within CE, the lost member revenue from reduced load was not. This component of the analysis occurred in the financial models, Hyperion and UIPlanner.
- In scenarios where SPV3 was allowed to retire, the potential retirement date of the resource was limited to any time after the end of the related SRP contract (midyear 2036), as the model setup does not account for the impact of the revenue loss from the SRP contract.
- PO is an hourly least-cost dispatch tool and is unable to perform sub-hourly modeling in the current setup.

In 2021 Tri-State plans to revisit its current modeling setup, assess the current modeling tools, investigate other potential modeling tools and takes steps to close the above gaps from a system perspective without workarounds.

Modeling Assumptions

Table 54 identifies base modeling assumptions used in the 2020 ERP process.

Table 54: Modeling Assumptions used in 2020 ERP Base Case

Assumption Item	Description
Load Forecast	2020 Annual Long Term Forecast
Electric Price Forecast	May 2020 Spring Reset Long Term Forecast
Gas Price Forecast	May 2020 Spring Reset Long Term Forecast
Coal Price Forecast	May 2020
Announced Coal Retirements	• Escalante by 12/31/2020 • Craig 1 12/31/2025 • Craig 2 9/30/2028 • Craig 3 12/31/2029
Forced Outage Factors	• All Coal = 4% • Existing CC's = 3% • Existing CT's = 0% • Proposed CC's = 0% • Proposed CT's 0%
Thermal Resource Status: **Econ** - Model can turn resource on and off but resource has a 168-hour on-line minimum. **Must Run** - Model can choose the level at which resource is run but cannot dispatch lower than the resource minimum operating level.	• *Must Run 2021 - 2040*[39] : Craig 1, Craig 2, Craig 3, LRS 2, LRS 3, and SPV • *Econ 2021 - 2040*: Burlington 1, Burlington 2, Knutson 1&2, Limon 1&2, Pyramid 1-4, Rifle, and JM Shafer
Build Limits – represents the capacity allowed to be built by Transmission Area/Modeling Region or technology.	• Max RPP – East Colorado 1200 MW • Max RPP – New Mexico 400 MW • Max RPP – Storage 400 MW • Max RPP – Thermal 300 MW • Max RPP – Wyoming 600 MW • Max Annual – Renewable 500 MW
Water limits	JM Shafer capacity factor limited to 47% due to current water contracts. Ability to purchase additional water exists.
Emission limits[40]	NOX Limits: • Craig 1 annual capacity factor limited to 80% or less

[39] Through 2040 or announced retirement data as applicable.

[40] A modeling error in 80pct CR V1 and 80pct CR V2 caused Craig 1 to run slightly above the allowed 80% capacity factor set by the Regional Haze agreement. Based on the correction in similar scenarios, the correction of the capacity factor to 80% results in movement of the dispatch generation to Craig 3 and Colorado gas resources. Tri-State did not rerun these two scenarios with this correction.

Assumption Item	Description
	• Pyramid annual capacity factor limited to 30%
EE & DR DSM Level	Low and Aggressive Energy Efficiency (EE) Allowed Low Demand Response (DR) allowed for all Regions.
RES/RPS Levels	Must meet or exceed current RES for Colorado and RPS for New Mexico.
CO_2 Reduction in Colorado	No forced CO_2 reductions or restrictions applied in base assumptions.
Contracts/Power Purchase Agreements	Allowed to expire on terms.
Mt Elbert	On and available to dispatch within contract parameters.
Member Distributed Generation	Treated as renewed upon contract expiration at a proxy price by technology: $25/MWh Wind, $44/MWh Solar, $55/MWh Biomass, hydro and other.
Transmission Links	See Table 55 for detail.
Capacity Credits	See Table 56 for detail.
Market Depths	See Table 57-58 for detail.

Transmission Constraints:

The following constraints were implemented from 2021 to 2027 in the model due to current interconnection limitations and time needed to accomplish significant network upgrades. It was assumed additional significant network upgrades are possible by 2028.

- From 2025 to 2027: New Mexico 0 MW, Wyoming 200 MW, Eastern Colorado 100 MW
- Until 2026 Western Colorado 0 MW interconnection, afterwards interconnection MW amount equal to Craig 1 capacity

Transmission Links:

Table 55: Transmission Links in Base Case

Link Name	From Transmission Area	To Transmission Area	Forward Capacity *(MW)*	Backward Capacity *(MW)*	Dates
LK-E_CO>NM	WACM_Eastern_Colorado	New Mexico	124	0	2021 - 2040
LK-LAP>E_CO	Mt_ Elbert	WACM_Eastern_Colorado	107	139	2021 - 2040
LK-SPRV>NM	Springerville	New Mexico	317	0	2021 - 2040
LK-W_CO>E_CO	West_Colorado	WACM_Eastern_Colorado	457	150	2021 - 2040

Link Name	From Transmission Area	To Transmission Area	Forward Capacity *(MW)*	Backward Capacity *(MW)*	Dates
LK-W_CO>NM	West_Colorado	New Mexico	0	170	2021 - 2024
LK-W_CO>NM	West_Colorado	New Mexico	50	170	2025 - 2040
LK-WY>E_CO	WACM_Wyoming	WACM_Eastern_Colorado	400	400	2021
LK-WY>E_CO	WACM_Wyoming	WACM_Eastern_Colorado	550	400	2022 - 2040

Capacity Credit Values:

For both solar and wind resources, an analysis was performed to determine an appropriate capacity credit value using a modified ELCC method[41]. In later years as more solar resources are added, the time of net system peak load is shifted to later in the day when the sun is setting (or has already set). Therefore, solar capacity credit is decreased. The capacity credit for wind is relatively consistent across all years of the various scenarios. Below are capacity credit values applied to base case scenario modeling.

Table 56: Capacity Credit Values

Resource Technology	Capacity Credit *(% of Nameplate)*
Thermal – existing and generic resources	100%
Standalone Batteries	100%
Existing Solar (Commercial & Under Contract)	35%
Existing Wind (Commercial & Under Contract) & Wind Generic Resources	30%
Solar Generic Resources	15%
Solar + 25 MW Battery Generic Resources	15% Solar; 100% for Battery
Wind + 25 MW Battery Generic Resources	30% for Wind; 100% for battery

Market Depths:

Tri-State has modeled several markets that represent typical locations of power transactions.

Sales Markets

- MS-4 Corner-N_NM – New Mexico
- MS-WEIM – New Mexico
- MS-Ault-E_CO – Eastern Colorado
- MS-Craig-NW_CO – Western Colorado
- MS-LRS-WY - Wyoming
- MS-WEIS - Eastern Colorado

[41] See Attachment Vol II 5-2 B&V Modified Effective Load Carrying Capability Study.

Purchase Markets

- MP-4 Corner-N_NM – New Mexico
- MP-WEIM – New Mexico
- MP-Ault-E_CO – Eastern Colorado
- MP-Craig-NW_CO – Western Colorado
- MP-LRS-WY - Wyoming
- MP-WEIS – Eastern Colorado

Tables 57 and 58 show the hourly market depths associated with each market for sales and purchases respectively, as applied to base case modeling. Market Depths are adjusted from base in alternative scenarios as necessary to accommodate for an evolving grid with higher quantities of intermittent resources and reducing levels of dispatchable resources. This is representative of the long-term need for an organized market to facilitate the addition of intermittent renewables. Changes to assumptions are identified in Volume I Section 8 Base Case and Alternative Scenario Results of this report.

Table 57: Market Sales (Hourly Capacity)

Dates	**MS-4 Corner-N_NM** *(MW)* [42]	**MS-WEIM** *(MW)*
Jan 2021 - Mar 2021	20-OFF / 75-ON	0
Apr 2021 - 2024	0-OFF / 20-ON	25-OFF / 60-ON
2025-2040	150	0

Dates	**MS-Ault-E_CO** *(MW)*	**MS-Craig-NW_CO** *(MW)*	**MS-LRS-WY** *(MW)*	**MS-WEIS** *(MW)*
Jan 2021	0-OFF / 50-ON	15-OFF / 100-ON	0	0
Feb 2021 - 2024	0-OFF / 25-ON	0-OFF / 25-ON	0	25-OFF / 125-ON
2025-2029	150	150	0	0
2030-2040	50	50	200	0

Table 58: Market Purchases (Hourly Capacity)

Dates	**MP-4 Corner-N_NM** *(MW)*	**MP-WEIM** *(MW)*
Jan 2021 - Mar 2021	100	0
Apr 2021 - 2024	85	15
2025-2040	200	0

[42] "OFF" and "ON" references off peak and on peak hours respectively.

Dates	MP-Ault-E_CO *(MW)*	MP-Craig-NW_CO *(MW)*	MP-LRS-WY *(MW)*	MP-WEIS *(MW)*
Jan 2021	200	125	75	0
Feb 2021 - 2024	150	100	75	75
2025-2040	200	200	200	0

Generic Resource Cost, Performance and Emissions Data

Cost and technology characteristics for generic resources including renewables, gas resources, and energy storage were verified by B&V. Below highlights key aspects of this review by resource type:

Thermal Resources: Working from Tri-State's original generic resource data set, which primarily consisted of gas resource cost and characteristics data from EPRI TAGWeb Version 3.52 software, B&V utilized in house subject matter experts to compare existing data for generic resources to B&V's independent check-estimates developed using a combination of past project estimates, Thermoflow's GTPRO/GTMASTER modeling software, and Original Equipment Manufacturer (OEM) online performance tools. Key data assessed included capital cost, net heat rate, ability to cycle and load follow, availability, emissions and operation and maintenance expense. Resulting recommended changes included additions or removal of existing gas generic resources in the data set as well as changes to underlying cost and performance data.

Renewable (including renewable plus batteries) Build Transfers: Tri-State was relying on National Renewable Energy Laboratories (NREL), EIA, EPRI and other industry resources to develop costs and characteristics for renewables modeled as build transfers. B&V in house subject matter experts reviewed capital expenses, O&M expenses and net capacity factors for build transfer renewables and provided recommendations.

Renewable (including renewable plus batteries) PPAs*:* B&V utilized its power project data for capital costs, O&M costs and expected production, and its in-house subject matter expertise to forecast PPA prices for generic renewable energy resources, including solar, solar + storage, wind, and wind + storage resources, within the Tri-State operating area. The renewable resources were assumed to have a 35-year life. Net energy output was calculated as follows:

Table 59: Renewable Resource Capacity and Energy Calculations

Resource Type	Net Capacity Factor *(%)*	Year 1 Net Energy Production *(MWh)*
Solar PV	30.0%	262,800
Solar PV + Storage	28.0%	245,192
Wind	43.0%	376,680
Wind + Storage	40.1%	351,442

Solar energy output was assumed to degrade at a rate of .32% per year.

The expiration of tax credits were taken into consideration, and prices were forecast by technology type and region.

Storage Builds: Tri-State was relying on NREL, EIA, EPRI and other industry resources to develop costs and characteristics for standalone energy storage, specifically Li-ion 4 hour batteries. B&V in house subject matter experts reviewed capital expenses, O&M expenses and efficiencies for energy storage builds and provided recommendations. Additionally, Tri-State utilized a proposed pumped storage project in New Mexico as the basis for pumped storage costs and characteristics.

Final costs and characteristics for generic resources as modeled in Tri-State's 2020 ERP process based on recommendations by B&V are as follows. All costs are in real (2020) dollars.

Table 60: Costs for Thermal Build Resources

Resource	Technology	Location[43]	Build Cost *($/kW)*	Fixed Cost *($ Annual)*	VOM *($/MWh)*	Startup Costs *($ per start)*
112_18x6RICE_eco	Recip Engine	Eastern CO	$1,881	$2,332,224	$7.42	$50
112_18x6RICE_nnm	Recip Engine	New Mexico	$1,281	$2,332,224	$7.42	$50
300_1x1_7FA05_eco	Combined Cycle	Eastern CO	$2,163	$4,000,000	$3.00	$500
300_1x1_7FA05_nnm	Combined Cycle	New Mexico	$1,563	$4,000,000	$3.00	$500

300 MW Pumped Storage	Pumped Storage	New Mexico	$2,200	$5,100,000	n/a	n/a

[44] For solar resources build costs decline over time at an average of ~4% per year during the RAP and remain steady thereafter. For wind resources build costs decline over time at an average of ~1.75% per year over the RPP.
[45] Battery build costs are projected to decline by 6% per year through the RAP.

[46] These resources were not modeled to provide ancillary services (i.e. regulation up, regulation down or contingency reserves).

[47] For wind plus battery and solar plus battery resources, the batteries are modeled as charged from the related renewable resource.

Table 68: Storage Emissions & Water Usage (pounds per MWh)[48]

Resource	CO_2	SO_2	NOx	HG	PM	Water
100MW Li-Ion Battery_eco	1280	0.40	0.70	-	-	-
100MW Li-Ion Battery_wco	1280	0.40	0.70	-	-	-
100MW Li-Ion Battery_nnm	1280	0.40	0.70	-	-	-
25MW Li-Ion Battery_eco	1280	0.40	0.70	-	-	-
25MW Li-Ion Battery_nnm	1280	0.40	0.70	-	-	-
25MW Li-Ion Battery_wco	1280	0.40	0.70	-	-	-
25MW Li-Ion Battery_wyo	1280	0.40	0.70	-	-	-
300 MW Pumped Storage	1280	0.40	0.70	-	-	-

Modeled life of resources are as follows:

- Wind, Solar, Wind plus battery, and Solar plus battery PPA – 20 years
- Wind and Solar Build transfer – 20 years
- Energy Storage Li-Ion Batteries – 15 years
- Energy Storage Pumped Storage Hydro – 30 years
- Gas Resources – 30 years

DSM & EE Generic Resources:

DSM & EE are modeled as supply side generic resources. This modeling is discussed in Section 5 Phase I Modeling Details under the Modeling Assumptions & Analytical Methodology subsection.

Consideration for Clean Energy and Energy Efficient Technologies

Tri-State includes clean energy and energy efficient technologies in its resource mix of available technologies for expansion planning. In regards to clean energy, available technologies included in expansion planning are solar, solar plus battery, wind and wind plus battery installations. Renewable resources are available in the generic resource dataset in each modeling region/TA in sufficient quantities to influence the environmental impact of the overall resource plan for a given scenario. Additionally, energy storage options in the form of stand-alone batteries as well as batteries coupled with solar and wind installations are made available in the generic resource data set to support the addition of renewable resources within the scenarios.

Tri-State also includes in the generic resource dataset for use in expansion planning demand side resource options including energy efficiency and demand response. These represent programs that Tri-State could develop with the consensus of and for use by Tri-State's Utility Member Systems. Forecast data for energy efficiency and demand response generic resource is based on the results of the 2020 DSM & EE Potential study, which can be found in Attachment Vol II 5-1 Demand Side Management & Energy Efficiency Potential Study. Forecast energy efficiency and demand response are selectable resources in scenarios

[48] Standalone batteries are modeled as charged from market purchases. Above rates, reflect expected market purchase emission rates based on egrid RMPA values for 2018 as available.

allowing the model to consider these resources on an economic basis. In select scenarios, the energy efficiency or demand response generic resources are forced. Further detail can be found in Volume I Section 8 Base Case and Alternative Scenario Results of this report.

Including renewable resources as well as demand side management and energy efficiency helps to continue to diversify Tri-State's fleet including increasing fuel diversity, which insulates the overall cost of power from technology specific fuel price increases. Diversity also incorporates different types of technology with varying generating patterns to more reliably serve Utility Member System load. Finally, diversity in resource planning by incorporating clean energy and energy efficient technologies into scenarios allows for a clear method of measuring environmental impact while respecting reliability.

Assessment of Costs and Benefits of Integration of Intermittent Resources

Tri-State 2020 ERP scenarios include the integration of significant quantities of intermittent renewable energy. The expansion plan for the base case alone, which does not include GHG/CO_2 restrictions as an assumption within the model, has ~2500 MW of wind and solar generic resources. Alternative scenarios with CO_2 restrictions related to the state of Colorado incorporate between ~2,700 MW and ~4,100 MW of wind and solar generic resources. Tri-State currently has ~467MW of commercially operational wind and solar across its system and an additional ~1000 MW under contract and expected to be commercially operational by 2024. As Tri-State looks to integrate a substantial amount of intermittent energy over the RPP, an assessment of the costs and benefits is necessary.

Costs related to integrating larger quantity of intermittent renewable resources include impacts to dispatchable resources, economic impacts, and the need to maintain reliability within an evolving grid. Currently, Tri-State uses thermal resources, coal and gas, to handle ramping needs to meet load requirements when renewable resources are not available. Coal resources that were primarily intended for base loading incur additional cycling costs of less than ~$0.15/MWh. This cost is due to the additional wear and tear on the resource, and specific cycling costs for Tri-State coal resources are identified in Section 3 Assessment of Resources under the subsection of Overview of Thermal Resources in this report. Gas resources are built to be flexible resources, and Tri-State has not determined a similar cycling cost impact to existing gas resources in Tri-State's fleet.

Related to this cycling requirement is the potential to curtail renewable resources in the event sufficient dispatchable generation is not available to move down in a low load, high renewable situation. Tri-State's current contracted and operational renewable resources are via PPAs, and specifically, the associated tax credit for wind resources can exacerbate the economic impact of curtailments. The addition of energy storage to accommodate power that would otherwise be curtailed is a potential solution. Tri-State's scenario modeling shows the need for energy storage to accommodate the integration of renewable resources. From a cost perspective, an expected decline in energy storage build costs over the next decade is necessary to allow this resource type to be a viable part of a renewable integration solution.

As dispatchable resources are retired and more renewables are brought onto the grid for economic and regulatory compliance reasons, the ability to have sufficient capacity to meet planning reserve margins and ramping requirements is critical. Related to this, Tri-State engaged Black & Veatch to perform a modified ELCC study based on the expected significant increase of renewable resources and decrease of dispatchable resources on Tri-State's system over the RPP. Details of the impact of the modified ELCC on

capacity credits for intermittent resources can be found in Volume I Section 6 Assessment of Resource Needs of this report. Overall, an evolving grid with less dispatchable resources and an increasing quantity of intermittent resources leads to a need for more ramping capabilities from existing and expansion plan resources. The movement of load and resources into an organized market where a larger set of resources can respond on a sub hourly basis to ramping needs is critical for successful integration of large quantities of intermittent renewable resources.

Benefits related to the integration of larger quantities of intermittent renewable resources include economic impacts, supply diversity and emissions reductions. Intermittent renewable generation projects represent a low cost option for meeting energy needs, and effective, large-scale integration of this resource is necessary to drive down the cost of serving Utility Member System load.

The low cost of renewables was a key driver behind Tri-State's recent RFPs, which resulted in the planned addition of 1 GW of renewables by 2024. Adding renewable resources also brings diversity to Tri-State's resource mix and allows for locating resources in areas where the addition of thermal resources is not a viable option. Another significant benefit of renewables is the resulting reduction in fleet emissions as renewable energy displaces thermal generation. Tri-State's Responsible Energy Plan, state-specific CO2 reduction goals, and Renewable Energy or Portfolio Standards are all intended to reduce the environmental impacts associated with electric power generation.

Modeling Assumptions & Analytical Methodology

Energy Storage

In the current CE and PO models, the value of energy storage is focused on its ability to assist with the integration of intermittent resources. This value includes the ability to smooth delivery of intermittent resources and avoidance of potentially costly renewable curtailments. Tri-State's western interconnection load and resources currently do not have access to full "day-2" organized markets with ancillary service markets, so the value of energy storage as a supplier of ancillary services such as regulation up and regulation down was not evaluated at this time.

Li-Ion Batteries:

Tri-State does not have any existing battery storage facilities, but Tri-State modeled generic Li-Ion battery storage facilities as resource options for expansion planning. The Li-Ion batteries were modeled with four hours of storage and either 100MW (ECO, CO, NM) or 25MW (ECO, WCO, NM, and WY) of capacity. Discharge capability of four hours of energy storage was modeled based on demonstrated projects and proposed projects previously evaluated. The batteries are allowed to have multiple cycles per day, but a 4% annual forced outage factor is applied. Batteries were modeled with a 90% efficiency. 100% of the capacity is assumed to be available to meet planning reserve requirements at the peak hour. Given that the generation expansion planning module can build multiple units of the same generic resource it can in theory build multiple four-hour resources to simulate an eight-hour or larger resource. The model is designed to dispatch the charge and discharge to most economically serve Utility Member System load. Specific cost and modeling data can be found in Section 5 Phase I Modeling Details under the Generic Resource Cost, Performance and Emissions Data subsection of this report.

Li-Ion Batteries combined with Solar and Wind:

Hybrid renewable-battery storage plants were modeled based on the existing 100MW wind and solar profiles paired with a 25MW/100MWh lithium-ion battery system. The hybrid facilities offer advantages in pricing due to the availability of Investment Tax Credits for hybrid solar facilities as well as efficiencies related to using a single inverter to reduce balance of plant construction costs. Discharge capability of four hours of energy storage was modeled based on demonstrated projects and proposed projects previously evaluated.

The hybrid facilities are modeled such that all of the power to charge the battery is produced from the associated renewable facility. For Solar-Battery hybrid facilities this resulted in new daily shapes created to maximize load peak shaving by moving energy into the 5 peak hours of the day. For Wind-Battery hybrid facilities the shape is developed to minimize ramping spikes and provide a consistent energy resource throughout the day. Specific cost and modeling data can be found in Section 5 Phase I Modeling Details under the Generic Resource Cost, Performance and Emissions Data subsection of this report.

Pumped Storage Hydro (Mt. Elbert):

The Mt. Elbert pumped storage hydro facility is part of Tri-State's portfolio, modeled within the eastern Colorado transmission area, as a part of its LAP hydro contract purchases. Tri-State does not operate Mt. Elbert, and Tri-State's share of the facility is limited to a daily schedule for pumping and generation and a seasonal amount of the energy and capacity. Per contractual limits, return energy is scheduled between Hour Ending (HE) 23 and HE7 and generation is scheduled between HE8 and HE22. Mt. Elbert is capable of storing up to 1380MWh in the summer season and can receive or generate a capacity of 176MW in a given hour. The "roundtrip" efficiency of the Mt. Elbert facility 68% in that 1.47MWh is required to add 1MWh of energy storage. The market is the source for charging/pump back energy. The total generation capacity of the Mt. Elbert pumped storage and LAP Hydro contract is limited by the capacity of the LAP Hydro contract. Within the limits of the contract and the capability of the facility Mt. Elbert is modeled to dispatch to reduce system costs.

Pumped Storage Generic Resource:

A generic pumped storage resource was modeled as an option for all scenarios. Because of the difficulty of development and siting a pumped storage facility, a single option in Northern New Mexico was identified and modeled. Tri-State's portion of the facility would be limited to 300MW of capacity and 2400MWh of energy or eight hours of storage at full capacity. The efficiency of the facility is assumed to be 80% or 1.25MWh of energy is required to add 1MWh of energy output. The market is the source for charging/pump back energy. The cost of the facility is modeled as $2,200/kW with a 30-year operating and book life. Due to the limited options for pump storage only one unit may be added in the study period and only in 2028 or later.

Renewables

Tri-State models existing, under contract and generic renewable resources as varying 8760 profiles. The methodology to arrive at these profiles utilizes historical generation for existing facilities as recorded by Tri-State's OSIsoft PI historian system. These actual monthly profiles are randomized to create new pseudo-random hourly profiles for the duration of the PPA contract. Up to five years of historical data

was used to develop the hourly profiles and, to the extent possible, the same dates were used across resources to maintain the same daily weather patterns and demonstrate the geographical diversity of the existing generation.

For generic renewable resources, a similar method was employed to develop hourly profiles. Tri-State uses similar existing resources that are most representative of future renewable resources in each geographical area to the extent possible. Western Colorado, eastern Colorado and Wyoming wind profiles for generic resources were developed from the Colorado Highlands wind facility. New Mexico generic resource solar profiles were developed from the Alta Luna solar facility, while the Colorado solar generic resource profiles were developed from the Spanish Peaks solar facility. Table 69 shows this setup and related capacity factors. Individual generation profiles were developed by randomizing the data. This mimics the geographic diversity of the generation. For hybrid wind-battery and solar-battery generic resources, the same renewable profiles were used and a 4 hour 25MW battery is used to maximize peak shaving for solar and limit high ramping hours for wind.

Table 69: Renewable Hourly Forecast Development

Renewable Options	Location(s)	Actual Generation Source	Storage Capacity	Capacity Factor
Tracking PV (PPA)	ECO, WCO	Spanish Peaks	N/A	28%
Tracking PV (Build Transfer)	ECO, WCO	Spanish Peaks	N/A	28%
Tracking PV (PPA)	NM	Alta Luna	N/A	32%
Tracking PV (Build Transfer)	NM	Alta Luna	N/A	32%
Tracking PV with Battery	ECO, WCO, NM	Alta Luna	25MW (4 Hour)	31%
Wind (PPA)	ECO, WCO, WY	Colorado Highlands	N/A	44%
Wind (Build Transfer)	ECO, WCO, WY	Colorado Highlands	N/A	44%
Wind with Battery	ECO, WCO, WY	Colorado Highlands	25MW (4 Hour)	40%

The annual outputs for new and existing generation were compared for reasonableness to the simulated forecast for each resource as created by Ascend Analytics. The complete results of the comparison can be found in Attachment Vol II 5-6 Ascend Analytics Renewables and Ramping Analysis.

Using the method described above for existing and under contract resources, annual energy for individual PPAs may be higher or lower than the forecasted contract energy amount due to the variability of the underlying technology, but the output is representative of previously recorded actual output. While this is to be expected, in the event that the total annual renewable energy was out of the range of contracted PPA energy, the Ascend hourly profiles were used in place of the outlier profiles to better align with the contract energy.

For financial modeling purposes actual contract energy for existing and contracted renewable PPAS is used in Hyperion and forwarded to UIPlanner for calculation of PVRR. The variance between Hyperion contract energy for existing and under contract renewables and the PO randomized 8760 profile annual totals are shown in Figure 23.

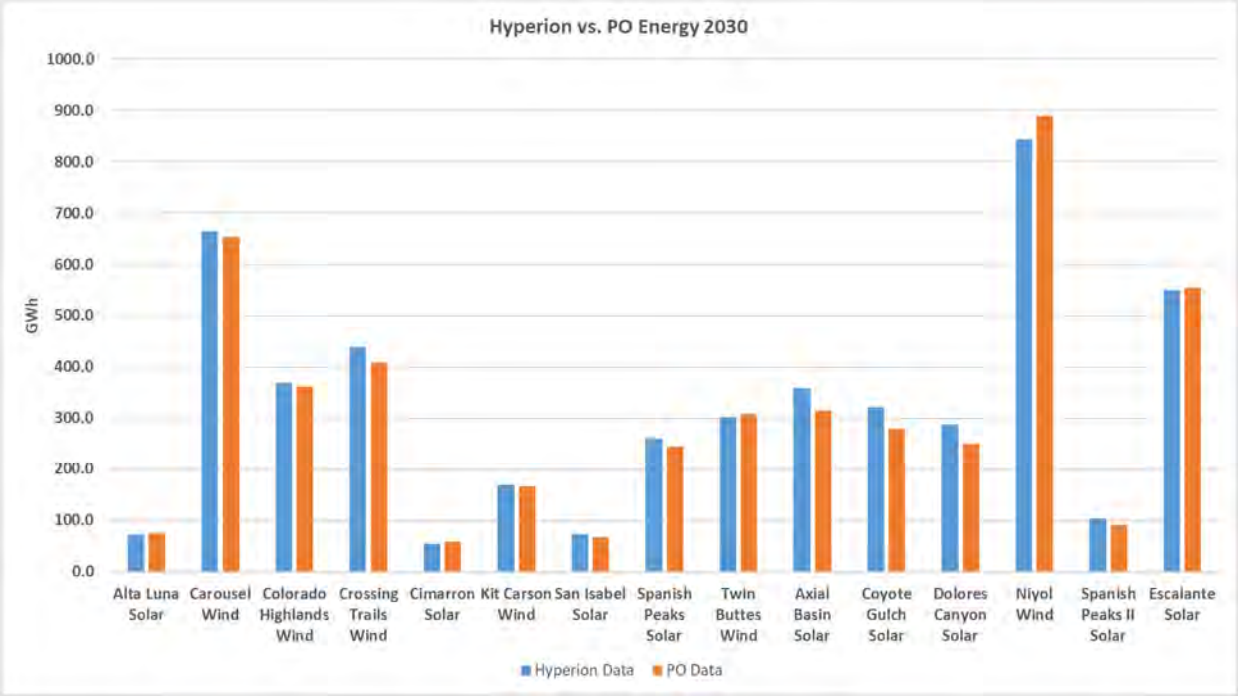

Figure 23: Hyperion versus PO Energy by PPA - Projected 2030

PO Dispatch data for renewables is used for determining GHG/CO_2 reduction.

DSM and EE

Tri-State's current demand side management and energy efficiency programs are described in Volume I Section 6 Assessment of Resource Needs under the subsection of Demand Side Management & Energy Efficiency.

In regards to potential expansion plan resources, Tri-State modeled in the generic resource dataset demand side resource options including energy efficiency and demand response by region.

Tri-State commissioned Mesa Point Energy to perform a DSM and EE potential study in 2019 that was completed in the spring of 2020. The study can be found as Attachment Vol II 5-1 Demand Side Management and Energy Efficiency Potential Study. This analysis was the basis for the modeled energy efficiency and demand response options in the generic resource dataset. The study was performed by load type (HVAC, Lighting, etc.), scenario (low achievable through max achievable), sector (Residential, Commercial, Industrial, Irrigation), and load region.

To model the resources, the individual load types, sectors, and load regions were consolidated to match the modeling regions/TAs used in CE and PO (New Mexico, West Colorado, East Colorado, Wyoming, and Nebraska). Tri-State modeled two levels of EE generic resources: Low Achievable and Aggressive Achievable and modeled one Low Achievable DR program level based on data from the study. For the EE generic resources costs were broken down to a must take $/MWh cost. For the DR generic resources, the associated study costs were represented as an annual fixed cost with a limited energy quantity representing the number of times that the demand response resource was called on as assumed by the DSM & EE Potential Study. It is important to note that the costs associated with DSM and EE are solely related to outgoing expenses related to funding the potential programs through incentives and promotion and does not include the opportunity cost associated with lost billing revenues.

Each EE or DR resource was eligible to be added during the years 2021, 2025, 2030, and 2035 with the same energy, capacity, and cost curves shifted to the start year. This was done to reduce the model size and complexity while allowing EE or DR resources to be introduced later in the study. For EE the model could select either Low or Aggressive Achievable generic resources within a region but not both. Modeled values can be found in Table 70 through Table 75.

Distributed Generation

Tri-State models member distributed generation projects, under Board Policy 115 and Board Policy 119, as resources in CE and PO. Energy forecasts of distributed generation projects are based on project history or history for similar technology types. Projects are associated with their appropriate region within the model. Hourly profiles are developed and used in PO dispatch. Projects are added to the model upon Tri-State Board and FERC approval. Additionally, a 2% annual expected growth forecast is included to represent potential future projects. In CE a capacity planning factor of 22% was applied to these resources. This percentile was derived from four years of hourly generation data during typical system peak hours in July and August and ranking them from smallest to largest. Then the generation level at the 15th percentile is selected as the estimated contribution to the system peak. This means that 85% of the time the capacity contribution will be equal to or greater than the estimate. Due to their size, these resources were not incorporated into the modified ELCC study.

GHG & $C0_2$ Reduction Methodology Used in Scenarios

The following is a description of the methodology for calculating Tri-State's CO_2 and GHG emissions baseline, calculating forecasted emissions and determining the resulting emission reductions.

GHG and CO_2 reductions are calculated on all wholesale electricity sales in the state of Colorado by Tri-State. Tri-State only sells electricity at the wholesale level. Wholesale electricity sales include sales to Tri-State's Utility Member Systems and non-member sales to counterparties (other utilities, marketers) at transaction points in Colorado. From a resource perspective, all resources in Colorado including owned thermal generators, renewable PPAs, long-term contracts with delivery points in Colorado, and forecast market purchases at Colorado transaction points are considered to supply wholesale electricity sales in Colorado. Also, Tri-State resources, thermal or renewable, located outside of Colorado that are forecast to be imported to serve wholesale Utility Member System load in Colorado are included in the total emissions calculation. GHG emissions include carbon equivalent (CO_2e) rates for CH_4, N_2O and SF_6.

GHG and CO_2 emissions are also calculated on retail load served in the state of Colorado by Tri-State's Utility Member Systems. To arrive at the forecast retail load the amount of wholesale electricity sales by Tri-State to Utility Member Systems in Colorado excluding transmission losses is reduced by representative distribution losses for a given year.

Calculation of Tri-State's 2005 Baseline of CO_2 & GHG Emission in the state of Colorado:

Colorado Electricity Sales are defined as all wholesale electricity sales including Tri-State sales to Utility Member Systems in Colorado and non-member sales from Colorado generation and/or sold at transaction points in CO. Delta Montrose Electric Association (DMEA) was a member of Tri-State in 2005 but withdrew as a member of Tri-State July 1, 2020. DMEA is included in the initial load calculation in order to arrive at total 2005 emissions, but related emissions for DMEA are then removed to arrive at the final 2005 baseload calculated emissions for Tri-State. Non-Member sales energy is based on Colorado non-member sales as identified in a Tri-State report from 2005, "All revenue by State.xls". All sales are marked up 6.1%, which is the transmission loss value identified in Tri-State's 2005 financial reports.

The following resources are considered to serve wholesale electricity sales in Colorado whether to Utility Member Systems or non-member sales:

- All thermal owned generation in Colorado
- LAP and CRSP hydro contract deliveries at transaction points in Colorado[49]
- Basin Western Interconnection at transaction points in Colorado [50]
- Small renewable contracts located in Colorado
- Any necessary balance required to meet wholesale electricity sales in Colorado was most likely imported from LRS 2 & LRS 3 with potential small contributions from Escalante Generating Station, San Juan 3, or the Pyramid facility.

CO_2 emission methodology and source for each 2005 resource are identified in Table 76:

Table 76: CO_2 Emission Rates – 2005

Resource	Emission Source	Emission Rate *(short tons/MWh)*
Craig 1 & 2[51]	Plant Rate (average of generator rates)	1.17
Craig 3	Generator Rate	1.05
Nucla	Generator Rate	1.30
Rifle	Generator Rate	0.95
Knutson 1 &2	Plant Rate (average of generator rates)	0.75
Limon 1 & 2	Plant Rate (average of generator rates)	0.75
Burlington 1 &2	Plant Rate (average of generator rates)	1.12
CRSP Colorado Deliveries	Federal Hydropower – No GHG/CO_2	0
LAP Colorado Deliveries	Federal Hydropower – No GHG/CO_2	0
Small Power Producers	Hydropower – – No GHG/CO_2	0
Basin Western Interconnect Colorado Deliveries	Plant Rate (average of LRS 2 & LRS 3 rates)	1.15
Market Purchases in Colorado	Based on average of Tri-State coal rates[52]	1.10
Imports from out of state	Plant Rate (average of generator rates)[53]	1.15

[49] Identified in 555XX Purch Pwr by State_2005.xls
[50] Identified in 555XX Purch Pwr by State_2005.xls
[51] Historical data is available as Yampa Project – Craig 1 & 2 combined
[52] No regional published rate available
[53] Average of LRS 2 & LRS 3 emission rates as LRS generation would have been the primary import source.

After determining the amount of wholesale electricity sales in Colorado and the necessary in and out of state resources that supplied those sales, emissions are calculated using rates from Table 76. Total emissions are then calculated. Next, the percentage of energy necessary to serve each of the following is calculated:

- DMEA load including losses
- Tri-State Utility Member Systems load in Colorado including losses (net of DMEA)
- Wholesale electricity sales to non-members including losses

The percentages of energy to supply Utility Member System sales including losses and wholesale electricity sales to non-members including losses are then summed and this percentage is applied to the total calculated emission. The result is Tri-State's 2005 CO_2 emissions baseline for wholesale electricity sales in Colorado, which is 9,180,383 short tons of CO_2 emissions.

GHG emissions for CH_4 and N_2O were calculated based on EPA CO_2e emission factors and fuel used for thermal generation. Additionally, SF_6 GHG emissions were provided by Tri-State's environmental department. Resulting 2005 GHG emissions baseline for wholesale electricity sales in Colorado is 9,257,365 CO_2e short tons of GHG emissions.

To determine CO_2 and GHG emissions in the state of Colorado in 2005 for Tri-State Utility Member System retail sales, Tri-State used Tri-State Utility Member System load net of DMEA and transmission losses and then further reduced the load amount by 7%[54] for distribution losses. Tri-State used two calculation options to arrive at emissions from Utility Member System retail load in Colorado:

Option 1 uses "known" resources serving Colorado load and itemizes the related MWh and emission associated with those resources. The balance of the energy required to serve Colorado Utility Member System retail load after netting the energy supplied from these resources is then given a CO_2 emission rate calculated from an average of Craig and LRS plant emissions and market purchase emissions. The CO_2 emissions from known resources and the calculated emissions for the balance energy are summed to arrive at total CO_2 emissions.

Option 2 calculates CO_2 emission by taking total 2005 CO_2 emissions (emissions caused by sales to Tri-State Utility Member Systems in Colorado including DMEA and non-member sales in Colorado) and multiplying this values times the quotient of Tri-State Utility Member System retail sales in Colorado divided by all Tri-State wholesale electricity sales in Colorado.

For both options the GHG adder (percentage), based on CH_4, N_2O and SF_6 CO_2e emissions divided by total CO_2e emissions, is applied to Utility Member System retail loadCO_2 emissions and used to arrive at total GHG emissions.

Based on option 1, Tri-State's 2005 baseline of CO_2 emissions to serve retail load in Colorado is 6,147,055 short tons. Tri-State's 2005 baseline of total GHG emissions to serve retail load in Colorado is 6,198,172 carbon equivalent short tons.

[54] Representative of average distribution losses at the Utility Member System level in 2005

Based on option 2, Tri-State's 2005 baseline of CO_2 emissions to serve retail load in Colorado is 6,244,171 short tons. Tri-State's 2005 baseline of total GHG emissions to serve retail load in Colorado is 6,296,096 carbon equivalent short tons.

Calculation of Tri-State's Forecasted CO_2 & GHG Emissions in the state of Colorado:

For forecast CO_2 and GHG emissions, the primary focus is emissions in 2030 and related reductions from the 2005 baselines. However, for some scenarios Tri-State calculated a glide path[55] beginning in 2025. Tri-State also monitored reduction levels in 2035 and 2040.

In general, the calculations for forecasted emissions are similar to the 2005 baseline method. Any differences are identified as follows:

- Transmission losses are calculated at 5% instead of 6.1% as this is more representative of current OATT loss factors.
- Distribution losses are calculated at 4%, as this is more representative of an average of Tri-State's Utility Member Systems' distributions losses today.
- Charging load that occurs, as a result of energy storage due to efficiency levels is included in the total load calculation. This includes batteries and pump back hydro serving Colorado wholesale electricity sales.
- In both 2005 and forecast emission calculations, gross load is used. Therefore, Utility Member System distributed generation forecast is used as a resource in serving electricity sales in Colorado for purposes of total emissions calculations.
- Basin Electrically East contract portion serving load in Colorado is pulled out as a separate line item due to Basin Electrically East now being served via an RTO (SPP).

CO_2 emission methodology and source for each forecasted resource are identified in Table 77:

Table 77: CO_2 Emission Rates - Forecasted

Resource	Emission Source	**CO_2 Emission Rate** *(short tons/MWh)*
Craig 1 & 2[56]	Plant Rate (average of generator rates)	1.17
Craig 3	Generator Rate	1.05
Rifle	Generator Rate	0.95
Knutson 1 &2	Plant Rate (average of generator rates)	0.75
Limon 1 & 2	Plant Rate (average of generator rates)	0.75
Burlington 1 &2	Plant Rate (average of generator rates)	1.12
JM Shafer	Generator Rate	0.49
CRSP Colorado Deliveries	Federal Hydropower – No GHG/CO_2 w RECs	0
LAP Colorado Deliveries	Federal Hydropower – No GHG/CO_2 w RECs	0
Small Power Producers	Hydro power – No GHG/CO_2 w RECs	0

[55] The glide path includes measured reductions in emissions beginning in 2025 and continually increasing to reach required emission reduction levels in 2030.
[56] Historical data is available as Yampa Project – Craig 1 & 2 combined.

Resource	Emission Source	CO_2 Emission Rate *(short tons/MWh)*
Basin Western Interconnect Colorado Deliveries	Published Regional rate – egrid RMPA[57]	0.64
Market Purchases in Colorado[58]	Published Regional rate – egrid RMPA	0.64

Imports from LRS 2&3	Plant Rate (average of generator rates)	1.15
Expansion Plan Wind	Contract Rate - Wind w RECs	0
Expansion Plan Solar	Contract Rate - Solar w RECs	0
Expansion Plan Combined Cycle	Generator Rate	0.4
Expansion Plan Combustion Turbine, RICE, Aeroderivative	Generator Rate	0.6

Basin Western Interconnection, Market Purchases in Colorado including energy imbalance and Basin Electrically East use the egrid published 2018 CO_2 emission rates for RMPA or MROW based on location. During the Colorado AQCC Clean Energy Plan Guidance process, discussion around forward emission rates for markets and contracts with unspecified sources included using region wide published numbers such as WECC and SPP. Additionally, the potential for using a trend line to 2030 was discussed. While Tri-State agrees that the market purchase and contracts with unspecified sources emission rates will likely decline between now and 2030, Tri-State has taken a conservative approach in its CO_2 reduction calculation by applying the 2018 emission rate. Also, it is important to note that there is a general movement towards organized markets in WECC, and it is likely that all of Tri-State's load and resources will be located within an RTO by 2030. In an RTO, load and resources are no longer connected in that a utility does not schedule their resource to their load, but instead bid load and offer resources into the market. At that point, the applicable RTO published emission rate may be the more suitable rate to apply to market purchases and contracts with unspecified sources.

[57] Rate is reflective of 2018 published egrid RMPA rate.
[58] Market purchases in Colorado includes energy imbalance forecast purchases.
[59] 2018 Egrid MROW rate

Calculations of total emissions are similar to 2005 method with the exception that there is no need to remove DMEA load as DMEA load is already removed from the load forecast.

CO_2 & GHG Reduction Calculations:

Following are the calculations for CO_2 reduction - forecasted vs 2005 baseline emission:

Colorado CO_2 Reduction:

- Colorado Wholesale Electricity Sales
  - 2005 CO Electricity Sales Baseline CO_2 emissions excluding DMEA minus forecasted 2030 CO Electricity Sales CO_2 emissions divided by 2005 CO Electricity Sales Baseline CO_2 emissions excluding DMEA
- Colorado Utility Member System Retail Sales
  - 2005 CO Member Retail Load Baseline CO_2 emissions excluding DMEA minus forecasted 2030 CO Member Retail Load CO_2 emissions divided by 2005 CO Member retail Load Baseline CO_2 emissions excluding DMEA

GHG Reduction:

- Calculate additional GHG emissions for CH_4, N_2O and SF_6 as CO_2e and add to CO_2 emissions for 2005 baseline and 2030 forecast. Use CO_2 reduction calculation method above to arrive at total GHG reduction

2005 Baseline:

In Table 80 column "PUC Staff Step 4" represents the values in nominal dollars for SCoC used in the calculation of PVRR for the SCC scenario. Resulting PVRR for the SCC scenario is identified in Volume I Section 9 Base Case and Alternative Scenario Comparison of this report. PVRR for this scenario is calculated both with and without the social cost of carbon with both Tri-State's discount rate of 4.15% and a discount rate of 3% per Commission guidance.

Additionally, this nominal value for SCoC for each year is applied to annual system CO_2 emissions for each scenario. Total system CO_2 emissions include emissions from energy imbalance, market purchases, thermal owned resources, and Basin contracts. Total SCoC for each scenario is identified in Volume I Section 8 Base Case and Alternative Scenario Results of this report.

Table 83 shows the Appendix 5 to Commission Staff comments from September 2020, which provided direction on values to use for SCoC and a comparison of Tri-State's original methodology.

Comparison of the Calculation of the Social Cost of Carbon for Modeling

Staff's Recommended Methodology:

Year	Step 1 Central Estimate (3% Average) ($2007/metric-ton)	Step 2 Central Estimate (3% Average) ($2007/short-ton)	Step 3 $2020/short-ton ($2007/short-ton)	Step 4 Inflation Factor	Step 4 Nominal $/Short-ton
2020	42	38	46.6	100%	46.58
2021	42	38	46.6	102%	47.51
2022	43	39	47.7	104%	49.61
2023	44	40	48.8	106%	51.78
2024	45	41	49.9	108%	54.02
2025	46	42	51.0	110%	56.32
2026	47	43	52.1	113%	58.70
2027	48	44	53.2	115%	61.15
2028	49	44	54.3	117%	63.67
2029	49	44	54.3	120%	64.94
2030	50	45	55.4	122%	67.59
2031	51	46	56.6	124%	70.32
2032	52	47	57.7	127%	73.14
2033	53	48	58.8	129%	76.03
2034	54	49	59.9	132%	79.02
2035	55	50	61.0	135%	82.09
2036	56	51	62.1	137%	85.25
2037	57	52	63.2	140%	88.51
2038	58	53	64.3	143%	91.87
2039	59	54	65.4	146%	95.32
2040	60	54	66.5	149%	98.87
2041	61	55	67.6	152%	102.53
2042	61	55	67.6	155%	104.58
2043	62	56	68.8	158%	108.42
2044	63	57	69.9	161%	112.37
2045	64	58	71.0	164%	116.44
2046	65	59	72.1	167%	120.63
2047	66	60	73.2	171%	124.93
2048	67	61	74.3	174%	129.36
2049	68	62	75.4	178%	133.92
2050	69	63	76.5	181%	138.60

Tri-State's Methodology

Year	Step 1 Central Estimate (3% Average) ($2007/metric-ton)	Step 2 Central Estimate (3% Average) ($2007/short-ton)	Step 3 Escalated ($2020/short-ton)
2020	42	38	46.0
2021	42	38	46.0
2022	43	39	47.1
2023	44	40	48.2
2024	45	41	49.3
2025	46	42	50.4
2026	47	43	51.5
2027	48	44	52.6
2028	49	44	53.7

2049	68	62	74.5
2050	69	63	75.6

Summary of Third Party Studies

The following third party studies were completed in support of Tri-State's 2020 ERP.

Table 84: Third Party Study Summaries

Third Party Study	Consultant	Attachment	Description
Demand Side Management/Energy Efficiency Potential Study	Mesa Point Energy	5-1	Evaluates Demand Side Management achievable potential in relation to energy efficiency and demand response across Tri-State's Utility Member Systems' territories.
Loss of Load Probability Study	Black & Veatch	5-2	Evaluates representative plans with varying load and CO_2 reduction statuses to determine the adequacy of the current planning reserve margin.
Modified Effective Load Carrying Capability Study	Black & Veatch	5-3	Determines reasonable capacity credits for wind and solar based on increasing renewable penetration levels.
Report on Assessment of Existing Resources	Black & Veatch	5-4	Assesses key costs and performance metrics of existing resources against industry standards.
Benchmarking Study	Black & Veatch	5-5	Compares existing resources to generic resources in regards to cost and performance.
Renewable & Ramping Analysis	Ascend Analytics	5-6	Assesses the reasonability of Tri-State's hourly renewable profiles for existing and generic resources and evaluates potential ramping needs related to integration of intermittent resources.
Beneficial Electrification Study	Mesa Point Energy	5-7	Evaluates the achievable potential to convert non-electrical load to electrical load within Tri-State's Utility Member System territories while reducing carbon emissions.

6 Scenario Results Data

Emissions & Water Usage Data

See Attachment Vol II 6-1 Annual Emissions and Water Usage for a detailed list of annual emissions and water usage data by resource for the base case and alternative scenarios.

RES/RPS Data

See Attachment Vol II 6-2 RES/RPS for a detailed annual list of RECs by resource for the base case and each alternative scenario. Renewable energy under PPAs are shown with contractual annual energy amounts from Hyperion as well as dispatched annual energy amounts from PO.

7 Phase II RFP

See Attachment Vol II 7-1 Phase II All-Source RFP.

See Attachment Vol II 7-2 Bidder Highly Confidential Non-Disclosure Agreement.

For model contracts, see the following attachments:

- Attachment Vol II 7-3 Dispatchable PPA
- Attachment Vol II 7-4 Semi-Dispatchable PPA
- Attachment Vol II 7-5 Renewable PPA

SB19-236	Colorado Senate Bill 19-236 (the PUC Sunset Bill)
Sierra	Sierra Subregional Planning Group
SLV	San Luis Valley
SOL	System Operating Limits
SPG	Sub-regional planning group
SPP	Southwest Power Pool
SWAT	Southwest Area Transmission Group
SWEP	Southwest Weld Expansion Project
TBD	To Be Determined
TCPC	Transmission Coordination and Planning Committee
TP	Transmission Provider
Tri-State	Tri-State Generation and Transmission Association, Inc.
TRMID	Transmission Reliability Margin Implementation Document
TTC	Total Transfer Capability
WECC	Western Electricity Coordinating Council
Western/WAPA	Western Area Power Administration (also WAPA)

I. Executive Summary

The purpose of transmission planning is to ensure the present and future reliability of the interconnected bulk electric transmission system. Planning is performed to meet customer needs by facilitating the timely and coordinated development of transmission infrastructure projects on a cost-effective and reliable basis. In order to promote an efficient utilization of the transmission system, planning also takes into account drivers such as public policy initiatives, environmental concerns, and stakeholder interests, which are collected via numerous meaningful input opportunities throughout the planning process.

In 2011, the Colorado Public Utilities Commission ("Commission" or "CPUC") adopted Rules 3625 through 3627, which set forth requirements for transmission planning applicable to Commission-regulated utilities. The rules require these utilities to establish a process to coordinate the planning of additional electric transmission in Colorado in a comprehensive and transparent manner. The process is to be conducted on a statewide basis and is to take into account the needs of all stakeholders. This 2020 10-Year Transmission Plan for the State of Colorado ("2020 Plan") is the result of a cooperative effort among Black Hills Colorado Electric, LLC, d/b/a Black Hills Energy ("Black Hills"), Tri-State Generation and Transmission Association, Inc. ("Tri-State"), and Public Service Company of Colorado ("Public Service") (each a "Company" and collectively the "Companies"), and is the fifth 10-Year transmission plan that the Companies have filed under Rule 3627.

Since filing the first 10-Year transmission plan in 2012, the Companies have continued to coordinate the transmission planning process with all Colorado Transmission Providers ("TPs") and interested stakeholders through active outreach efforts and coordinated planning activities in a variety of transmission planning venues. The 2020 Plan is the culmination of a collaborative process and includes transmission facilities that the Companies, individually or jointly, may construct or participate in over the next 10 years in the state of Colorado. The 2020 Plan includes two types of projects.

"Planned Projects" are projects for which the companies generally have a level of commitment such that proposed schedules for completion have been drafted, site control has been established, or the project has received budgetary approvals. These include projects that are required to meet reliability and load growth needs, planned interconnection of new generation, or to meet enacted public policy requirements. "Conceptual Projects", on the other hand, may not have specific in-service dates, and their implementation depends on numerous factors, some of which include forecasted load growth and generation needs, economic considerations, public policy initiatives, and regional transmission development.

The Companies are confident that the 2020 Plan and the individual transmission projects included in the 2020 Plan meet all applicable reliability criteria and do not negatively impact the system of any other TP or the overall transmission system in the near-term and long-term planning horizons. Projects included in the 2020 Plan do not duplicate existing or planned transmission facilities of any other transmission provider in Colorado. Finally, the Companies are confident that the coordination and stakeholder outreach processes described herein effectively have solicited and addressed the interests of stakeholders.

When possible, individual transmission projects have been designed to accommodate the collective needs of multiple TPs and stakeholders. Changes in regulatory requirements, regulatory approvals, or underlying assumptions such as load forecasts, generation or transmission expansions, economic issues, and other utilities' plans may impact this 2020 Plan and could result in changes to in-service dates or project scopes.

Public policy initiatives, such as recent and future federal and local mandates, also may impact the 2020 Plan and the transmission planning process in general. Examples of public policies and legislation potentially impacting the Companies include Colorado House Bill 19-1261, Senate Bill 19-236 (including the "Colorado Transmission Coordination Act"), Senate Bill 19-077, Executive Order B 2019 002, Colorado's

Renewable Energy Standard, Senate Bill 07-100, and the U.S. Environmental Protection Agency's ("EPA") Affordable Clean Energy Rule.

Section II provides background information about the transmission planning process—including coordinated regional and statewide efforts, as well as internal practices of each Company. Sections III and IV of this report provide additional details for these and other projects that the Companies have identified in their transmission planning processes; complete details and supporting information can be found in Appendices D-I. Sections V to VIII address compliance with specific legal, regulatory and technical requirements of Rule 3627 and Federal Energy Regulatory Commission ("FERC") Orders, with an emphasis on stakeholder outreach efforts.

This 2020 Plan identifies 74 significant transmission projects. These projects are listed in Table 1 and shown geographically in Figure 1. Figures 2 and 3 are maps depicting transmission projects in the Denver-Metro area and in Black Hills' 10-Year Transmission Plan, respectively. Larger maps of the state plan showing chronological stages of development are provided in Appendix A. Larger versions of the Denver-Metro and Black Hills maps are provided in Appendices B and C.

Table 1. Significant transmission projects included in the 2020 Plan

Map #	Project Name	In-Svc (1)	Cost (MIL)	BH	TS	PS	Other	Purpose
1	Arequa Gulch 115 kV Capacitor	2018	$0.85	√				R

2 Boyd 230/115kV Substation Expansion (PRPA)
3 Missile Site - Shortgrass 345kV Transmission (PSCo)
4 Moon Gulch 230kV Substation (PSCo)
5 Two Basins Relocation Project (PSCo)
2019
6 Bluestone Valley Substation Phase I (PSCo)
7 Cottonwood 230/115kV Autotransformer Replacement (CSU)
8 La Junta 115kV Area Upgrades (BHCE)
9 Pawnee - Daniels Park 345kV (PSCo)
10 Portland 115/69kV Transformer Replacement (BHCE)
11 Sunshine - Telluride Line Uprate (Tri-State)
12 Thornton Substation (PSCo)
13 West Station 115kV Substation Upgrade (BHCE)
2020
14 Ault 345/230kV Transformer Replacement (WAPA)
15 Boone - La Junta 115kV Rebuild (BHCE)
16 CEPP Voltage Support (New, PSCo)
17 Midway KV1A Replacement (WAPA)
18 Nixon - Kelker 230kV Transmission (CSU)
19 NREL Substation (PSCo)
20 Shortgrass - Cheyenne Ridge 345kV Transmission (New, PSCo)
21 Shortgrass Switching Station (New, PSCo)
22 Sisson Project (New, Tri-State)
23 Western Colorado Trans Upgrade (Tri-State)
24 Williams Creek 230kV Switching Station (New, CSU)
2021
25 Avery Substation (PSCo)
26 Barker Distribution Substation (PSCo)
27 Del Camino - Slater 115kV Line Uprate (New, Tri-State)
28 Desert Cove - Fountain Valley - Midway 115kV (New, BHCE)
29 Hogback Ranch 115kV Substation (New, BHCE)
30 Pueblo West 115kV Distribution Sub (New, BHCE)
31 Salt Creek 115kV Sub (New, BHCE)
32 South Fowler Substation (New, BHCE)
2022
33 Airport Memorial - Nyberg 115kV Rebuild (New, BHCE)
34 Ault - Cloverly 230/115kV Transmission Project (PSCo)
35 Avon - Gilman 115kV Transmission (PSCo)
36 Boone - South Fowler 69/115kV Conversion (New, BHCE)
37 Burlington - Burlington (KCEA) Rebuild (Tri -State)
38 CEPP Switching Station Bid S085 (New, PSCo)
39 CEPP Switching Station Bid X645 (New, PSCo)
40 CSU Flow Mitigation (PSCo/CSU)
41 Falcon - Midway 115kV Line Uprate (Tri-State)
42 Greenwood - Denver Terminal 230kV Line (New, PSCo)
43 High Point Distribution Substation (PSCo)
44 JG Kalcevik Project (New, Tri-State)
45 Mirasol Switching Station CEP Bid X647 (formerly Badger Hills Substation) (PSCo)
46 North Penrose 115kV Distribution Sub (New, BHCE)
47 Titan Distribution Substation (PSCo)
48 Vollmer Project (New, Tri-State)
49 West Station - Greenhorn 115kV Line Rebuild (New, BHCE)
50 West Station - Hogback 115kV Transmission Project (BHCE)
2023
51 Dove Valley Distribution Substation (PSCo)
52 Southwest Weld Expansion Project (Tri-State)
2024
53 Burlington - Lamar 230kV (Tri-State)
2025
54 San Luis Valley - Poncha 230kV #2 (Tri-State/PSCo)
2026
55 Stock Show Distribution Substation (PSCo)
Beyond 2026 or ISD TBD
56 Bluestone Valley Substation Phase-2 (PSCo)
57 Falcon - Paddock - Calhan 115kV (Tri-State)
58 Glenwood - Rifle 115kV (PSCo)
59 Hayden - Foidel - Gore 230kV (PSCo)
60 Lamar Front Range (Tri -State/PSCo)
61 Lamar - Vilas 230kV (Tri-State/PSCo)
62 Lime Road Delivery Point (New, Tri-State)
63 Lost Canyon - Main Switch 115kV (Tri-State)
64 New Castle Distribution Substation (PSCo)
65 Parachute - Cameo 230kV #2 (PSCo)
66 Poncha - Front Range (New, PSCo)
67 Rifle - Story Gulch 230kV (PSCo)
68 Sandy Creek Distribution Substation (PSCo)
69 Solterra Distribution Substation (PSCo)
70 Superior Distribution Substation (PSCo)
71 Weld County Expansion (PSCo)
72 Weld - Rosedale - Box Elder - Ennis 230/115kV (PSCo)
73 Wheeler - Wolf Ranch 230kV (PSCo)
74 Wilson Distribution Substation (PSCo)

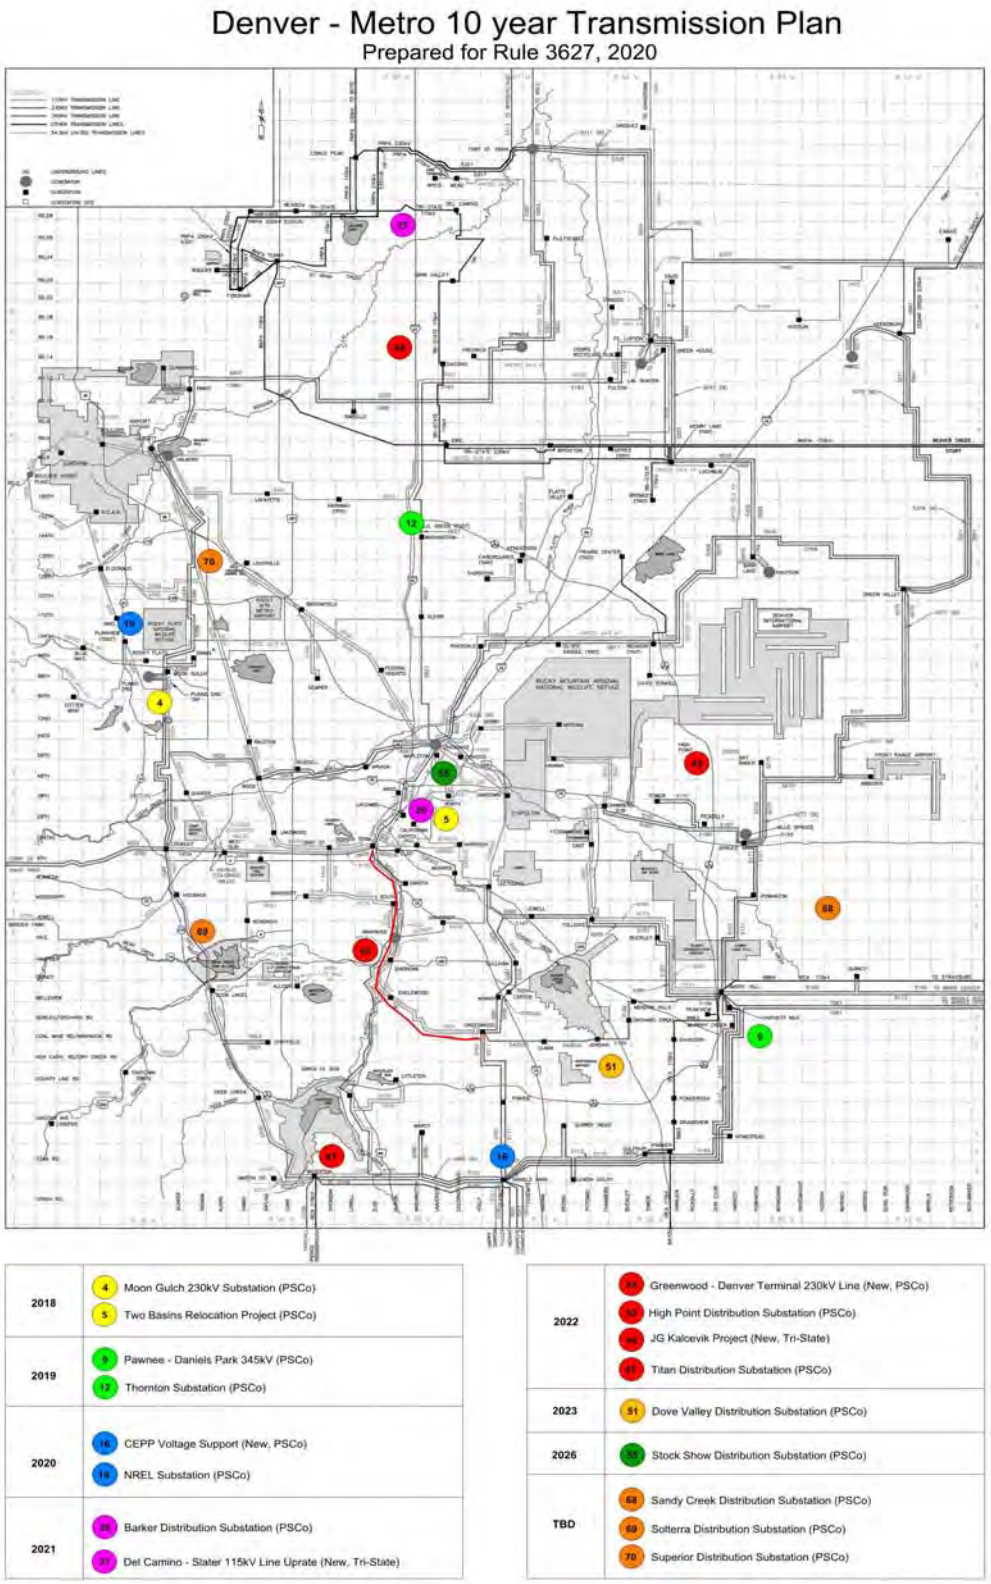

Figure 3. Pueblo area map of transmission projects in the 2020 Plan

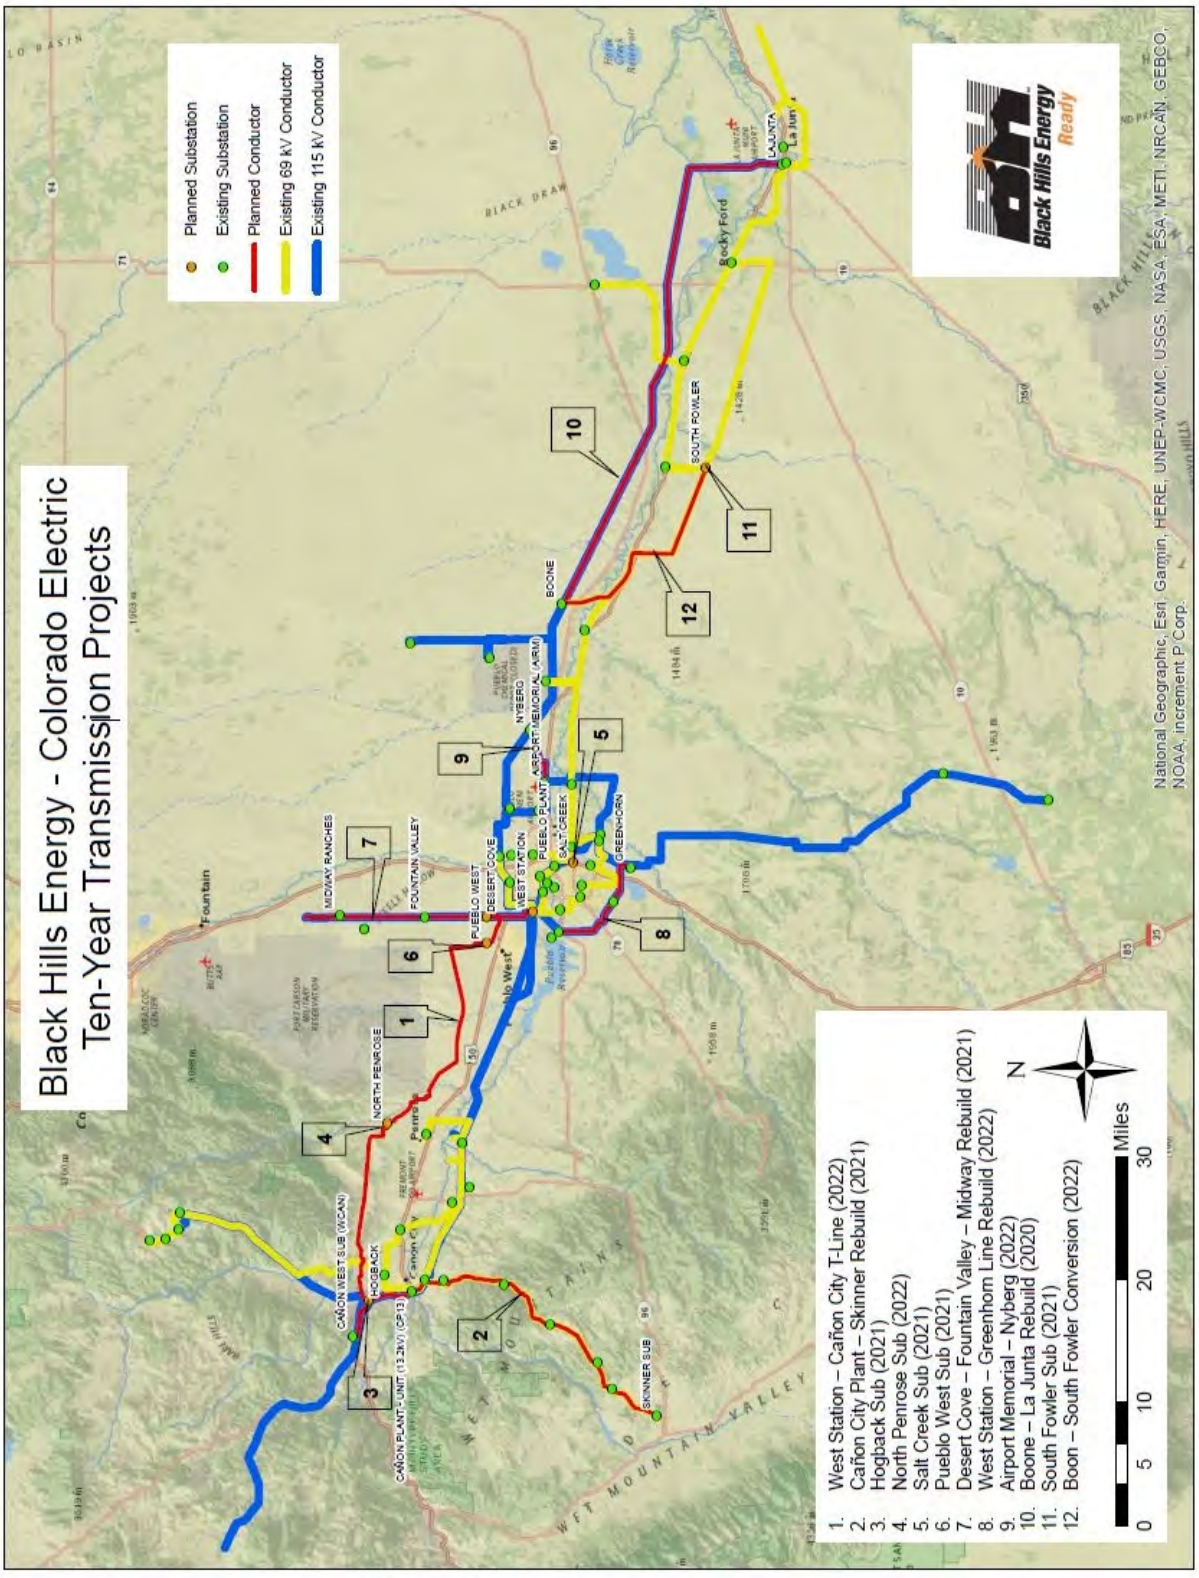


II. Transmission Planning in Colorado

A. Coordinated Planning

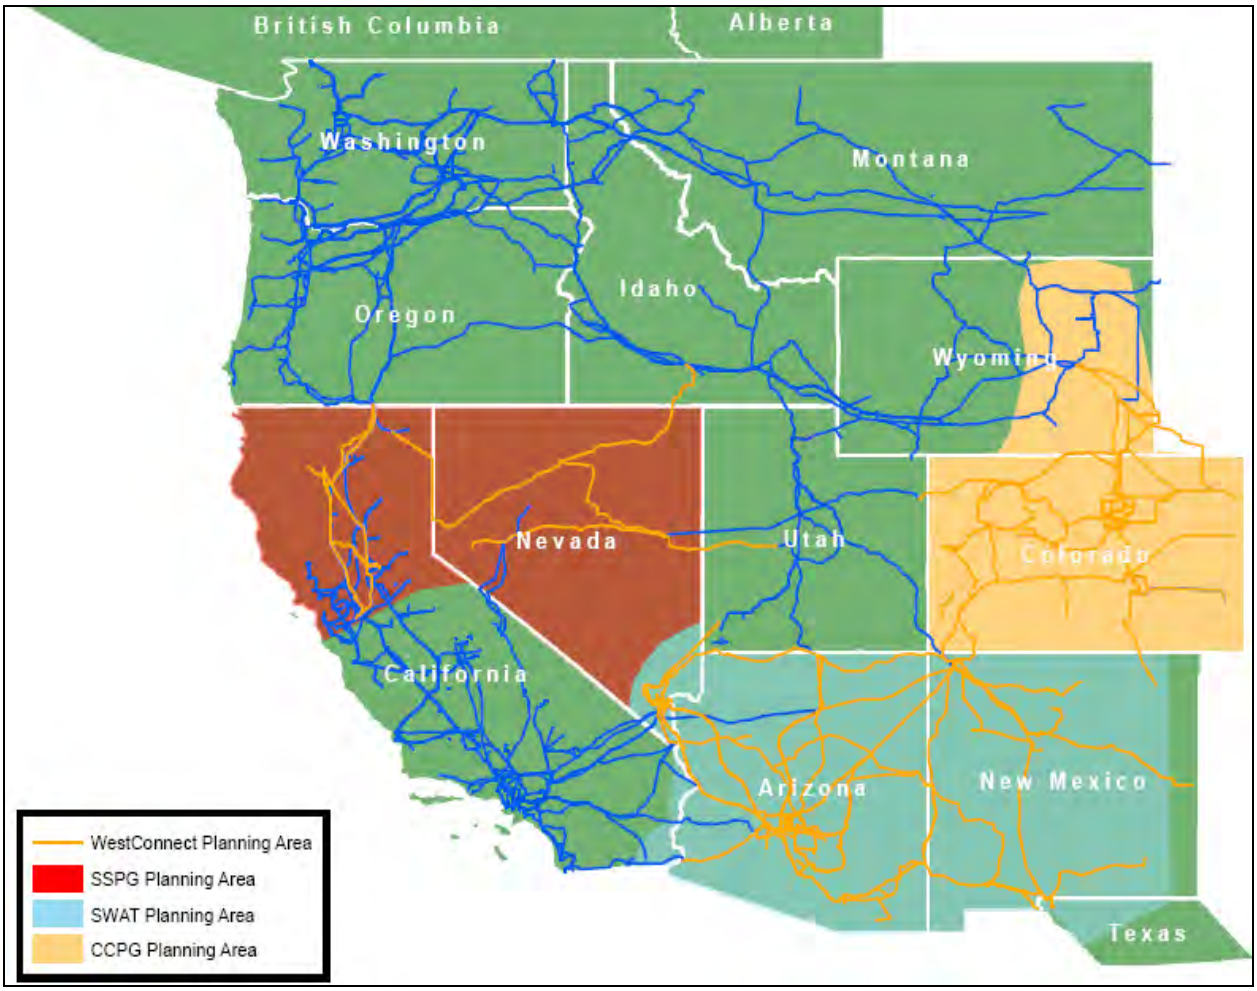
The Companies' transmission planning processes are intended to facilitate the development of electric infrastructure that maintains reliability and meets load growth. Because Colorado does not have a Regional Transmission Organization ("RTO"), each TP in the State is responsible for planning its own transmission system. To ensure that this process is as seamless and efficient as possible, the Companies participate in coordinated transmission planning at regional, sub-regional, and local levels.

The Companies are active members and participants in regional and subregional transmission planning organizations, including the WECC, WestConnect, and the Colorado Coordinated Planning Group ("CCPG"). WECC is the forum responsible for coordinating and promoting Bulk Electric System ("BES") reliability in the entire Western Interconnection.

WestConnect is one of four planning "regions"[3] within WECC established for regional transmission planning to comply with FERC Order No. 1000*, Transmission Planning and Cost Allocation by Transmission Owning and Operating Public Utilities* ("Order 1000"). WestConnect includes three sub-regional planning groups ("SPGs"): CCPG, Southwest Area Transmission Group ("SWAT"), and Sierra Subregional Planning Group ("Sierra").

[3] The other three are Columbia Grid, Northern Tier Transmission Group, and the California Independent System Operator.

Figure 4. WestConnect Planning Subregional Group Footprints



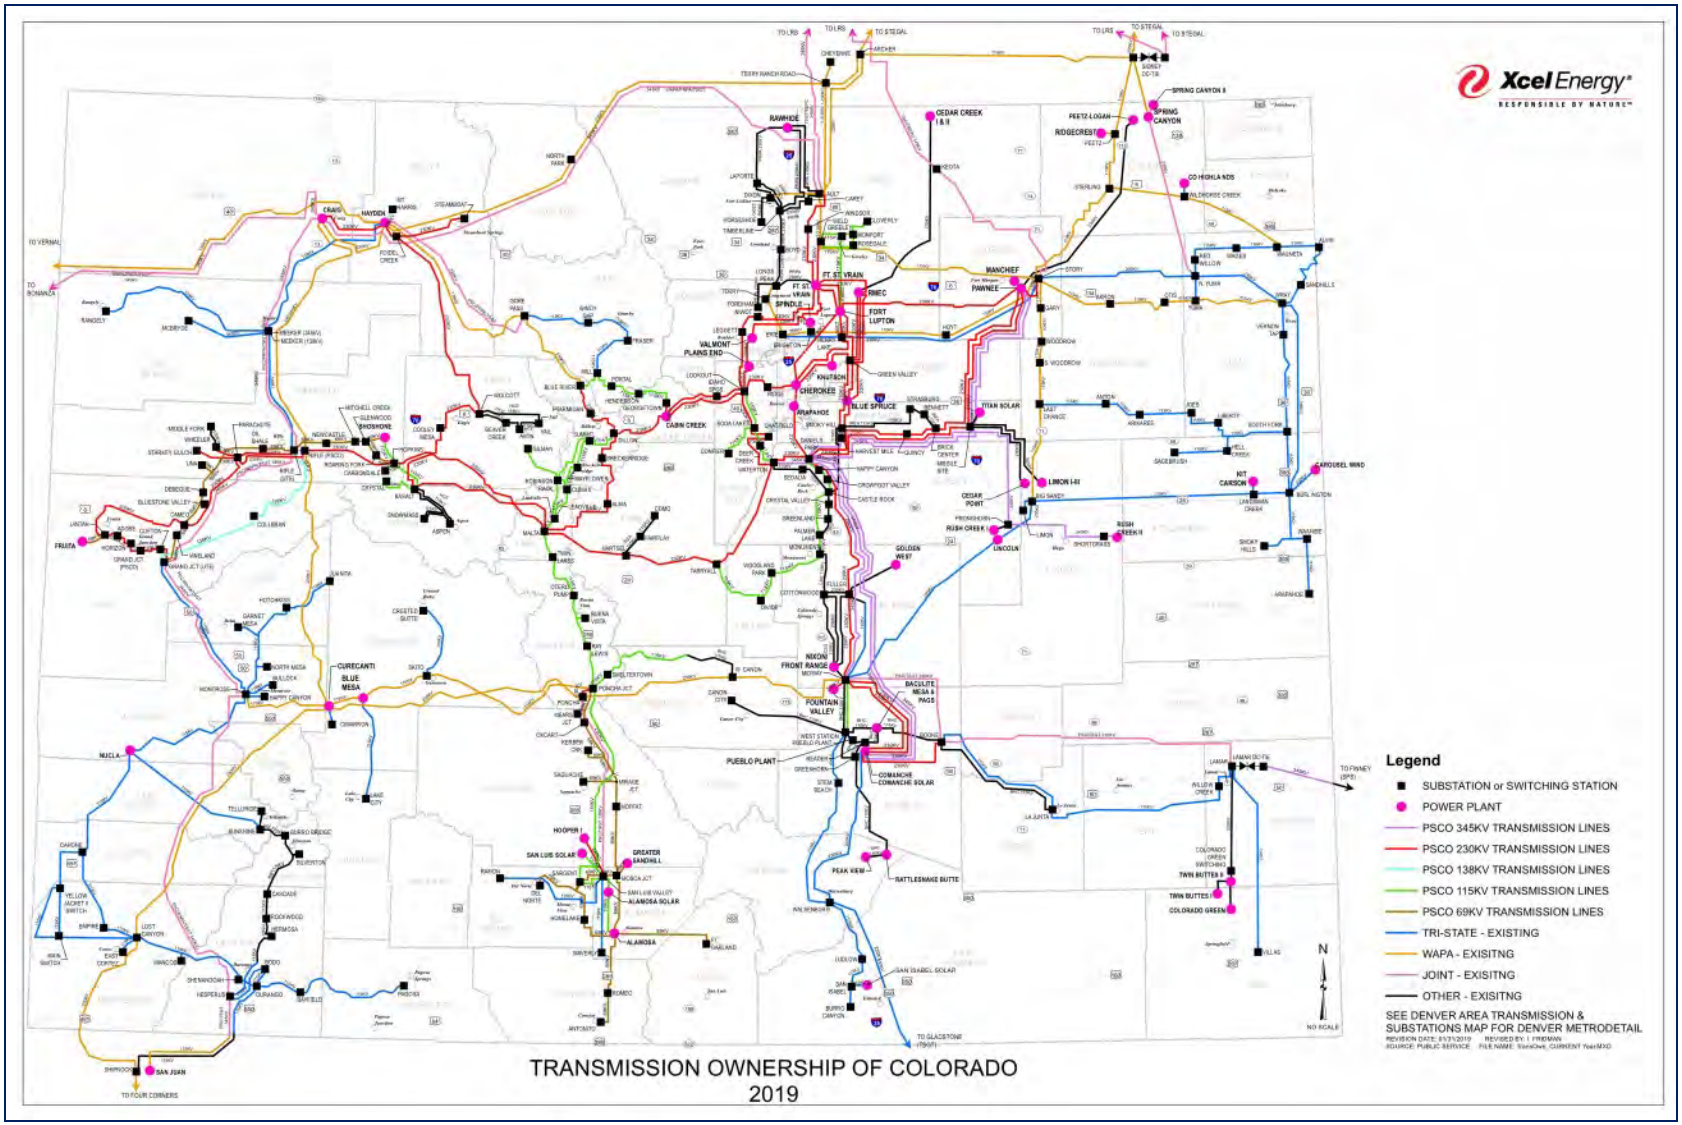
CCPG, which was formed in 1991, is a planning forum that cooperates with state and regional agencies to ensure a high degree of reliability in planning, development and operation of the transmission system in the Rocky Mountain Region. Figure 4 shows the planning areas of the CCPG and other subgroups of WestConnect.

The Companies have a long history of coordinated transmission planning with each other and other Transmission Planners in Colorado. As shown in Figure 5, the Colorado transmission system includes many jointly owned lines. Given the integrated nature and ownership of the transmission grid in Colorado, coordinated transmission

planning has been commonplace in Colorado since even before the adoption of Rule 3627.

As part of the Large Generator Interconnection Procedures ("LGIP"), the Companies often coordinate with each other as well as with other TPs in Colorado on the impacts of any proposed generation projects on the transmission system.

Figure 5. Transmission Ownership in the State of Colorado (2019)



Internally, and through WestConnect and CCPG, each Company performs annual system assessments to verify compliance with reliability standards, to determine related system improvements, and to demonstrate adherence to the standards and criteria set forth by North American Electric Reliability Corporation ("NERC") and WECC. Compliance is certified annually.

During the coordinated planning process, a wide range of factors and interests are considered by the Companies, including, but not limited to:

- The needs of network transmission service customers to integrate loads and resources;
- Transmission infrastructure upgrades necessary to interconnect new generation resources;
- The minimum reliability standard requirements promulgated by NERC and WECC;
- Bulk electric system considerations above and beyond the NERC and WECC minimum reliability standard requirements;
- Transmission system operational flexibility, which supports economic dispatch of interconnected generation resources; and
- Various regional and sub-regional transmission projects planned by other utilities and stakeholders.

This comprehensive internal, regional, and sub-regional planning process ensures that transmission plans continue to be carefully coordinated with all TPs in the State of Colorado.

B. Public Policy Issues

In addition to planning for load growth and reliability, Companies must consider proposed and enacted public policy initiatives, such as Colorado House Bill 19-1261, Senate Bill 19-236 (including the "Colorado Transmission Coordination Act"), Senate Bill

19-077, Executive Order B 2019 002, Colorado's Renewable Energy Standard, Colorado Senate Bill 07-100 ("SB07-100"), and the U.S. EPA Affordable Clean Energy Rule. Two of the Companies, Black Hills and Public Service, are subject to the requirements of SB07-100, which requires Colorado's rate-regulated electric utilities to identify areas that have a high potential for beneficial resource development. A discussion of SB07-100 and other public policy-related planning is included in Section V.

Colorado's Seventy-Second General Assembly enacted climate-action legislation in the 2019 Regular Session. The legislation will transition the state toward a clean-energy, low-carbon economy. The legislation establishes public policy requirements applicable to transmission planning for the 10- and 20-year periods of this Rule 3627 Report. We describe the applicable parts of this legislation for Colorado's transmission infrastructure, as follows:

Senate Bill 19-236 ("the PUC Sunset Bill")

The primary purpose of this bill is to reauthorize the CPUC, by appropriations, for a seven-year period to September 1, 2026. Reauthorization is required by the sunset process. Additionally, the bill carries numerous requirements for utilities and the CPUC to achieve an affordable, reliable, clean electric system. Of these requirements, four are viewed as significant drivers for transmission development in Colorado.

1. Clean Energy Plan ("CEP")

Senate Bill 19-236's CEP requirement is only mandatory for retail utilities providing electric service to more than 500,000 customers. *See* C.R.S. 40-2-125.5. While Public Service is the only public utility subject to this mandatory requirement to formulate a CEP, the legislation provides that other public utilities may "opt in" to CEP regulation upon notification to the Commission. However, the statute expressly excludes municipally owned utilities from CEP regulation. Public utilities that are

subject to the CEP requirement must include a CEP as part of the first Electric Resource Plan ("ERP") the public utility files after January 1, 2020. The PUC determines whether a CEP/ERP, as filed, is in the public interest.

A CEP seeks to reduce the qualifying retail utility's carbon dioxide emissions associated with electricity sales to the qualifying retail utility's electricity customers by 80 percent from 2005 levels by 2030. Further, a CEP seeks to achieve providing a qualifying retail utility's customers with energy generated from 100% clean energy resources by 2050.

Clean energy resources generate or store electricity without emitting carbon dioxide into the atmosphere. Clean energy resources include, without limitation, those generating resources deemed eligible energy resources under the state's Renewable Energy Standard ("RES") pursuant to C.R.S. § 40-2-124(1)(a). CEP activities that may be undertaken to meet the CEP targets under Senate Bill 19-236 include retirements of existing generation facilities, changes in system operations, or other necessary actions to achieve the reduction targets.

A CEP must ensure rate stability for customers served by the utility. Senate Bill 19-236 provides that the "Commission shall establish a maximum electric retail rate impact of 1.5 percent of the total electric bill annually for each customer for implementation of the approved additional clean energy plan activities" through at least 2030 through a CEP revenue rider to afford customers certainty of this maximum rate impact.

New transmission development for a CEP will be reviewed by the PUC under existing transmission planning processes and cost recovery, namely: Rule 3206, Rule 3627, SB07-100, and the Transmission Cost Adjustment. Senate Bill 07-100 Energy Resource Zones will apply to the beneficial resources required for CEP compliance.

In summary, a CEP will present significant drivers for transmission planning, namely:

- New interconnection facilities for clean energy resources;
- Decommissioning, or redevelopment, of existing transmission facilities associated with the potential for accelerated fossil-fuel retirements.

Transmission planning must enable a transition from plant retirements to new generating resources that ensures reliability and resiliency.

2. Cost of Carbon

Senate Bill 19-236 additionally requires public utilities to perform a "cost of carbon" analysis under certain circumstances. *See* C.R.S. §40-3.2-106. This "cost of carbon" analysis requirement applies to the following categories of proceedings: ERPs or any utility plan or application that considers or proposes the acquisition of new electric generating resources or the retirement of existing utility generation; proceedings pertaining to RES; electric demand-side management proceedings; and plans or applications for transportation electrification or other forms of beneficial electrification. The cost of carbon dioxide emissions is based on the social cost of carbon dioxide developed by the federal government. This equals $46 per short ton starting in 2020 and escalates thereafter.

In ERP proceedings, the cost of carbon dioxide emissions must apply to the evaluation of all existing electric generation resources and to any new resources evaluated or proposed as part of the resource modelling. The statute prescribes modeling and analysis steps for evaluating resource portfolios, with and without the cost of carbon dioxide.

In summary, cost-of-carbon planning will result in similar requirements as a CEP for transmission planners, namely: new interconnection facilities and accelerated

decommissioning, or redevelopment, of existing transmission facilities, which together may serve to reduce carbon intensity of the electric utility sector while ensuring reliability and resiliency of the grid.

3. Colorado Transmission Coordination Act

The Colorado Transmission Coordination Act, C.R.S. § 40-2.3-101 *et seq.*, requires the CPUC to open an investigatory proceeding on the potential costs and benefits of participation by Colorado's electric public utilities in a centralized market: specifically, an energy imbalance market, a regional transmission organization, a power pool, or a joint tariff. The statutory timeline is prescribed as follows:

(1) On or before July 1, 2021, the CPUC shall hold a public comment hearing to consider whether electric public utilities should participate in an energy imbalance market, regional transmission organization, power pool, or joint tariff.

(2) On or before December 1, 2021, the CPUC shall issue a decision determining whether participation in an energy imbalance market, regional transmission organization, power pool, or joint tariff is in the public interest.

(3) On or before July 1, 2022, if the CPUC determines that electric utility participation in an energy imbalance market, regional transmission organization, power pool, or joint tariff is in the public interest, the CPUC shall direct electric utilities to take appropriate actions and conduct proceedings the CPUC deems appropriate to pursue participation in an energy imbalance market, regional transmission organization, power pool, or joint tariff.

Adoption of a centralized market is uncertain. If adopted and implemented, a centralized market could be transformative but is highly dependent on the form and function of the determined market design. A centralized market has the potential to

change the locational mix of generating resources and provide congestion relief on the grid through market operations. While relieving congestion is a driver of transmission planning now, a centralized market also may give a market price signal at zones or nodes along the grid. These market prices are known as "Locational Marginal Price" or "LMP". An LMP is a market-clearing price that includes the energy charge, a congestion charge, and transmission system losses. High LMPs at zones/nodes mean more transmission congestion. LMPs may drive investment needs for, and locations of, new transmission facilities to relieve congestion.

4. Wholesale Electric Coops and Resource Planning

Senate Bill 19-236 additionally directs the Commission to promulgate new rules that require wholesale electric cooperatives to submit an application for approval of an integrated or ERP. *See* C.R.S. § 40-2-134. In developing such rules, the Commission must consider, among other factors determined by the Commission, whether wholesale electric cooperatives: serve a multistate operational jurisdiction; have a not-for-profit ownership structure; and have a resource plan that meets the energy policy goals of Colorado.

The Commission issued a Notice of Proposed Rulemaking on July 31, 2019, addressing this statutory requirement and proposing an electric resource planning process applicable to wholesale electric cooperatives. Final rules are pending.

Consistent with this rulemaking, Tri-State expects to continue to interconnect new renewable facilities while retiring certain legacy facilities, and anticipates making transmission improvements as appropriate to accommodate these changes.

House Bill 19-1261 ("the GHG Reduction Bill")

House Bill 19-1261 requires the Air Quality Control Commission ("AQCC") to promulgate rules and regulations for statewide greenhouse gas ("GHG") pollution abatement. *See* C.R.S. § 25-7-105.

Because these rules and regulations will target statewide GHG abatement from all sources, multiple sectors of Colorado's economy will be considered for compliance (transportation, electric generation, industrial manufacturing, etc.). The statewide goals are, at a minimum, a 26 percent reduction in statewide GHG pollution by 2025, a 50 percent reduction in GHG pollution by 2030, and a 90 percent reduction in GHG pollution by 2050 measured relative to statewide GHG pollution levels.

It is anticipated that the AQCC will consider opportunities to incentivize renewable energy resources, issues related to the beneficial use of electricity to reduce GHG, and whether program design could enhance the reliability of electric service.

For transmission planning, the GHG Reduction Bill presents the potential for new load growth and/or changing demand levels and characteristics (beneficial electrification), and shifting generation resources and locational mix (renewable energy and clean-energy adoptions).

Senate Bill 19-077 ("the Electric Vehicles Bill")

Statutory provisions enacted through Senate Bill 19-077 in C.R.S. §§40-1-103.3, 40-3-116, and 40-5-107 may expand electric vehicle infrastructure in Colorado. Charging ports and fueling stations are presently operated by third parties and as non-regulated services of public utilities. Senate Bill 19-077 authorizes utility ownership of electric vehicle charging infrastructure. The bill enables a regulatory approval process for electric utilities to invest in charging facilities and provide incentive rebates; thus, the investments and rebates may earn a return at the utility's authorized weighted-average

cost of capital. Where approved, the costs for the investments and rebates may be recovered from all customers of the electric utility similar to recovery of distribution system investments. Natural gas public utilities may provide fueling stations for alternative fuel vehicles as non-regulated services only.

The regulatory process for electric utilities will commence by May 15, 2020, and every three years thereafter, with the filing of a transportation electrification plan application by each jurisdictional utility. The application filing will request Commission authorization of a proposed transportation electrification program in the utility's certificated service territory; specifically, regulated activities and capital spending for electric vehicle charging facilities, electric vehicle make-ready infrastructure investments, and associated electrical equipment. The transportation electrification program may include community-based, multifamily charging infrastructure, car share programs, and electrification of public transit. The regulatory process will consider impacts on low-income customers, and access by low-income, moderate income, and underserved communities. The legislation provides that the retail rate impact from the development of electric vehicle infrastructure must not exceed one-half of 1 percent of the total annual revenue requirements of the utility. The legislation specifies that in evaluating the retail rate impact, the Commission "shall consider revenues from electric vehicles in the utility's service territory."

Widespread deployment of electric vehicles will represent load growth for transmission planning requirements within the 10-year period of this report. Further, adoption of electric vehicles will provide benefits to the grid. With charging electric vehicles essentially acting as energy storage, there may be an ability to integrate variable renewable resources and off-peak generation.

House Bill 18-1270 ("the Energy Storage Procurement Act")

House Bill 18-1270 directs the Commission to develop a framework to incorporate energy storage systems in utility procurement and planning processes. *See*

C.R.S. § 40-2-201, *et seq*. The legislation broadly addresses resource acquisition and resource planning, and transmission and distribution system planning functions of electric utilities. Energy storage systems may be owned by an electric utility or any other person.

House Bill 18-1270 required the Commission to adopt rules for procurement and planning by February 1, 2019, to create conditions under which the procurement or ownership of energy storage systems by an electric utility will provide systemic benefits. These benefits include increased integration of energy into the grid; improved reliability of the grid; a reduction in the need for increased generation during periods of peak demand; and, the avoidance, reduction, or deferral of investment by the electric utility.

Decision C18-1124 in Proceeding No. 18R-0623E, mailed on December 12, 2018, adopted permanent rules in 4 *Code of Colorado Regulations* (CCR) 723-3. The rule requirements on transmission planning are relevant to this 10-year planning period.

Governor Jared Polis Administration's "Roadmap to 100% Renewable Energy by 2040 and Bold Climate Action"

On May 30, 2019, Governor Polis unveiled a roadmap to 100% renewable energy by 2040 and bold climate action. The roadmap seeks to transition the state of Colorado to 100% renewable energy by 2040. Toward this end, the roadmap has seven components, namely:

1. Grow green jobs and save consumers money.
2. More zero emission vehicles and commuting options.
3. Support local commitment to 100% renewable energy.
4. Modernize the Public Utilities Commission.
5. Promote energy efficiency.
6. Move toward zero emissions buildings.
7. Ensure a just and equitable transition for all of Colorado.

A transition to 100% renewable energy would have a significant impact on transmission planning in the 10-year period with load growth. Specifically, electrification of transportation will represent load growth; notably, the Governor's plan strives for 940,000 zero emission vehicles by 2030 and $14 million of transit bus fleet conversions. Similarly, electrification of buildings will represent load growth as space heating and manufacturing needs shift from direct fossil fuels to electricity. The Governor's plan has three financing programs for residential and commercial building improvements: C-Pace, RENU, and the Colorado Clean Energy Fund. In FY2019, approximately $30 million was financed by C-Pace and RENU alone.

Executive Order B 2019 008 ("the Zero Emission Vehicle Mandate")

On January 17, 2019, Executive Order B 2019 002 – Supporting a Transition to ZEV –was issued by Governor Polis. Four areas are directed in the Executive Order to further the state toward a higher electric vehicle market share:

1. Creates a transportation electrification workgroup composed of 17 members, appointed by the Governor. The members represent state agencies and offices. The workgroup will develop, coordinate, and implement state programs and strategies for transportation electrification with annual reports to the Governor.

2. Directs the Colorado Department of Public Health and Environment ("CDPHE") to develop rules for a Colorado Zero Emission Vehicle Program pursuant to Colorado's authority under section 177 of the federal Clean Air Act, 42 U.S.C. § 7507.

3. Revises the spending for the remaining funds available in Colorado's $70 million VW Beneficiary Mitigation Plan for electrification of transportation, including transit buses, school buses, and trucks. Furthermore, if additional

settlement or lawsuit funds are received by Colorado, those funds will assist consumers' transition to ZEVs.

4. Directs the Colorado Department of Transportation to develop a department-wide ZEV and clean transportation plan.

In compliance with the Executive Order, the Air Quality Control Commission ("AQCC") adopted a ZEV rule on August 16, 2019. The rule is codified at 5 *CCR* 1001-24, Part C. For the 2023 vehicle model year, a specified percentage of vehicles *offered for sale* in Colorado must be ZEV. The percentage shall be consistent with California Code of Regulations, Title 13, Section 1962.2. The percentage is more than 5 percent zero emission vehicles by 2023 and more than 6 percent zero emission vehicles by 2025. The vehicles covered by the ZEV rule are passenger car and light-duty trucks.

The ZEV rule follows the Low Emission Vehicle ("LEV") rule adopted by AQCC on November 16, 2018. The rule is codified at 5 *CCR* 1001-24, Part B. The LEV rule complied with Executive Order B 2018 006 issued by Governor John Hickenlooper on June 18, 2018. For the 2022 vehicle model year, sales of passenger cars, light-duty trucks, medium-duty passenger vehicles or medium-duty vehicles must meet the LEV III Criteria emissions and GHG emissions codified by California Code of Regulations, Title 13, Sections 1961.2 and 1961.3, respectively. The proposed ZEV program will reduce total GHG emissions by 3.5 million short tons cumulatively by 2030.

For transmission planning, electrification of transportation as directed in the ZEV rule will represent load growth. However, in the near term, there are regulatory uncertainties. The ZEV rule is facing federal challenges by the Administration of President Donald Trump under authority of the Clean Air Act.

Senate Bill 18-009 ("the Energy Storage Rights Bill")

Senate Bill 18-009, enacted in C.R.S. § 40-2-130, protects the rights of Colorado electricity consumers to install, interconnect, and use energy storage systems on their property without the burden of unnecessary restrictions or regulations and without unfair or discriminatory rates or fees. In particular, Senate Bill 18-009 prohibits electric utilities from requiring additional customer-sited meters to monitor the energy storage system where a single net energy meter is installed (with exceptions for certain large energy systems). Moreover, Senate Bill 18-009 ensures that statutory net metering, as provided for in C.R.S. § 40-2-124, is neither altered nor superseded.

Senate Bill 18-009 requires the CPUC to adopt conforming rules. In rulemaking Proceeding No. 19R-0096E, the CPUC has proposed additions and amendments at Rule 3850 (Interconnection Procedures and Standards) to *inter alia* implement Senate Bill 18-009. Notably, a proposed definition for "distributed energy resource" has replaced the former definition for "small generating facility". Distributed energy resources, or DERs, is proposed to be defined as customers' sources of electric power, including retail renewable distributed generation, other small generation facilities, and energy storage systems. Distributed energy resources, or DERs, will be subject to PUC-approved interconnection procedures upon adoption of final rules.

C. Emerging Issues

1. Wildfire Risk Mitigation

One only needs to look to California to see the impact a wildfire can have on the electric system and community at large. Given that, the companies believe that investment in wildfire mitigation and grid resiliency is the most prudent course of action to moderate the risks associated with extreme weather events. Wildfire mitigation efforts have been and will continue to be centered on long-term investments in projects targeted at enhancing grid resiliency, expanding vegetation management, and

accelerating system hardening and equipment maintenance throughout the companies' service territories.

2. Energy Storage and Non-wires Alternatives

Non-wires alternatives to address capacity needs and reliability constraints related to load growth is an emerging topic for consideration during transmission planning. As such, an additional work group at CCPG, the Energy Storage Work Group (ESWG), has been created to analyze the benefits and challenges for energy storage and other non-wire alternative technologies. Studies may include geo-targeted energy efficiency, demand-side management, demand response, distributed generation, energy storage, and potentially other technologies. The first meeting for the ESWG was held on January 23, 2020.

3. Distributed Energy Resources (DER)

The increase of customer-sited DER may alter transmission system requirements. Most utilities have been able to model customer DER primarily on distribution systems as net load. Increasing DER penetration presents new challenges with modeling and operation of distribution and transmission systems. DERs also may present opportunities to address load growth and provide resiliency, if planned correctly. DERs tend to be more expensive than larger-scale generation options, and so cost-effectiveness will be a factor in the growth of DERs over time. It will be important to understand policies and consider investments that may be needed in the 10-year horizon.

4. Grid Resiliency with Inverter-Based Resources

The influx of inverter-based resources combined with conventional power plant closures has raised concerns of grid resiliency. The Blue Cut Fire (2016) and Canyon 2 Fire (2017) in California triggered approximately 900 MW and 1200 MW, respectively, of

solar PV generation to cease generation during transmission system faults. These events and other system observations have led NERC to develop Reliability Guidelines to assist utilities and manufacturers in maintaining a resilient grid. Recent Reliability Guidelines include the following:

- Integrating Inverter-Based Resources into Low Short Circuit Strength Systems (December 2017)
- BPS-Connected Inverter-Based Resource Performance (September 2018)
- Improvements to Interconnection Requirements for BPS-Connected Inverter-Based Resources (September 2019)

At the regional level, WECC's Studies Subcommittee has a Change to System Inertia with High Renewable Implementation Task Force (SITF) evaluating the reliability impacts on the Western Interconnection as conventional resources are retired during increased implementation of inverter-based resources. The companies believe that it will be important to understand and apply the Reliability Guidelines as they are developed, as well as participate in regional study efforts to ensure proper analysis is performed to maintain grid resiliency.

III. Company Plan Narratives

A. Black Hills 10-Year Plan Overview

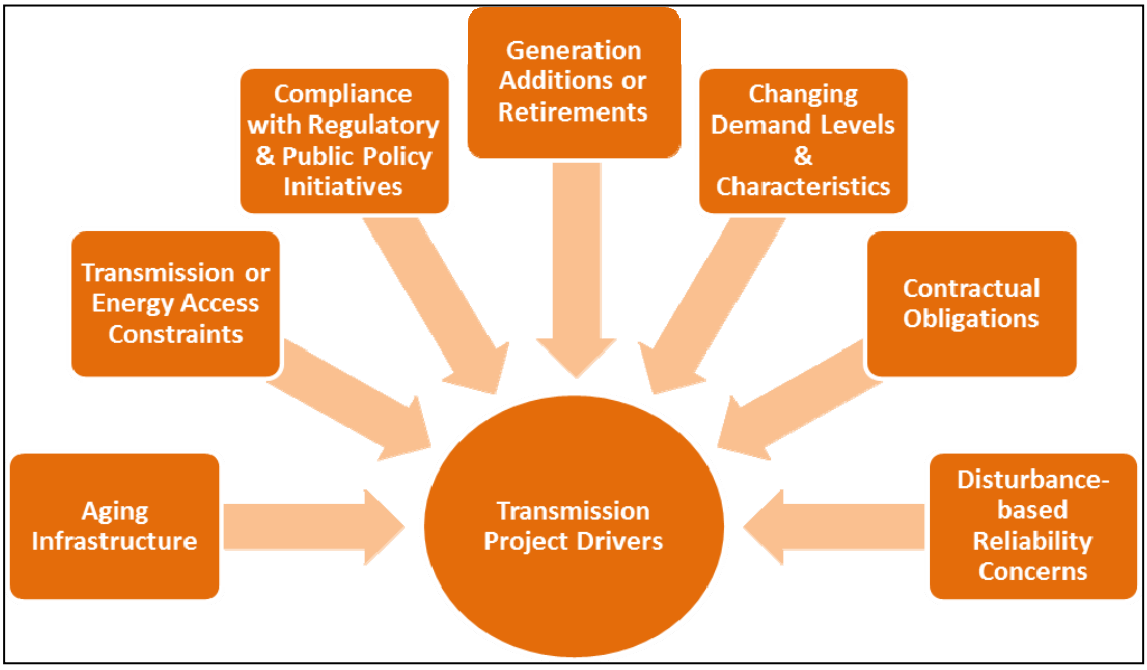
1. Black Hills Service Territory

Black Hills Colorado Electric, LLC, a division of Black Hills Corporation, serves over 98,000 customers in south-central Colorado. The counties served are parts of Crowley, Custer, El Paso, Fremont, Otero, Pueblo, and Teller. Twenty-one communities are served, and of these, the largest communities are Pueblo, Cañon City, and Rocky Ford.

The Black Hills planning process emphasizes education, participation, and coordination, with the ultimate goal of contributing to the development of an optimal long-term road map for transmission development in Colorado, consistent with Rule 3627.

Throughout its transmission planning process, Black Hills considers a number of variables and inputs, the first of which is a specific need or set of needs that drive the development of a certain project. Figure 6 shows a selection of needs that commonly give rise to projects within the Company's planning horizon.

Figure 6. Needs that Drive Transmission Development



Needs may arise from a single entity, or they may coincide with the needs of multiple entities, in which case a joint project may be appropriate. Once a need has been identified, Company planners begin searching for a solution. As solution alternatives are developed, the following considerations may come into play:

- Potential of each alternative to augment or inhibit potential future projects
- Cost of implementation and availability of project funding
- Required implementation schedule
- Environmental and societal impacts
- Project life expectancy
- Tangible benefits to customers
- Geographic and physical constraints
- Ability to integrate with existing and planned transmission projects
- Impact to telecom, transportation, and other energy-related networks

Black Hills transmission planners, through coordination with the stakeholder community, evaluate the weight of the above considerations to determine the best

overall solution to the identified need, ensuring that the solution is financially prudent, publicly acceptable and physically feasible. Often a small subset of these factors will comprise a majority of the justification for a project.

Because communication and stakeholder participation is critical at all stages of planning, Black Hills performs its planning process on an annual basis in an open, transparent, coordinated and non-discriminatory fashion to ensure the opportunity for direct participation is offered to all stakeholders. Consistent with FERC Order Nos. 890 and 1000, Black Hills promotes participation in the planning process to all interested parties, and coordinates study efforts and results with other utilities as well as regional planning organizations such as West Connect, CCPG, and various groups within WECC.

Planning reliability studies are conducted annually to satisfy NERC and WECC requirements. Additional studies are performed as necessary to address specific purposes including, but not limited to, transmission service requests, generator interconnections, transmission interconnections, load interconnections and transfer capability assessments. This process and related discussions are subject to FERC's Critical Energy Infrastructure Information ("CEII") procedures.

Black Hills planners employ software models representative of the transmission system during the timeframe of interest, including current load and resource information, existing and planned infrastructure, service commitments, facility ratings and parameters, valid disturbance events, and any operating constraints to be observed. Additionally, all guidelines, requirements and applicable criteria, as well as 10-Year load and resource projections (submitted annually by network customers), are reviewed and included in the study plan. These study models allow planners to identify conditions and timeframes during which the transmission system will or will not satisfy all reliability and economic requirements.

If a planning study identifies a deficiency in transmission system performance, various mitigation options are evaluated to determine an optimal solution to meet the long-term needs of all affected parties. Evaluation of each potential project is coordinated with interested stakeholders and neighboring transmission providers to avoid duplication, minimize impacts and the likelihood of unmet obligations, and maximize the overall benefit of a project.

Routine planning is conducted for a wide range of scenarios to evaluate the performance of the transmission system over a 10- to 20-year period. In a given study year, viable system upgrades and transmission initiatives are compiled to create the Black Hills 10-Year Local Transmission Plan, which is evaluated annually and updated as needed to reflect ongoing project needs. Potential changes in reliability requirements, planned generation, transmission, load growth, and regulations require the build-out of a flexible, robust transmission system that meets customer needs under a wide range of foreseeable circumstances within the planning horizon.

2. Black Hills Projects

A. Renewable Advantage (200 MW)

On November 22, 2019, Black Hills Colorado Electric, LLC filed an application at the Commission to amend its 2016 Electric Resource Plan with a competitive solicitation for up to 200 MW of renewable energy and energy storage. The competitive solicitation is known as Renewable Advantage. The application was docketed in Proceeding No. 19A-0660E.

The Company's expected load and resource balance was determined in Phase I of the 2016 ERP and completed in January 2017. There have been no significant changes to the load and resource balance. The Company has no material need for new capacity through December 31, 2023.

This notwithstanding, the Company's indicative analysis provides that procuring energy from renewable resources and/or energy storage, with an in-service date no later than December 31, 2023, may produce significant benefits for customers. The benefits are energy fuel cost savings and emission reductions beyond the state's Renewable Energy Standard (30% of retail electricity sales by 2020). The fuel cost savings will be implemented through the ECA rate mechanism. The procurement will have no negative impact to the RESA fund. The emission reductions could bring the Company's service territory to approximately 55-65% renewable.

The Company's indicative analysis is based, in part, on modeling of recent bid price results from PSCo's renewable competitive solicitation. The PSCo renewable competitive solicitation was held from July 1 through August 1, 2019. The median bid price was $24.00 MWh for Solar PV and $36.30 MWh for SolarPV+Storage. Black Hills Energy has modeled these median bid prices for a 200 MW generic resource, showing customers savings in every year of the life of the generic resource.

An important consideration for any procurement of renewable or storage resources under Renewable Advantage will be to minimize any transmission cost impacts to customers.

The Company has identified five existing substations where minimal or no upgrades to the broader network transmission system are expected with the addition of 200 MW. While the Company has not specifically studied these locations, there is a high degree of confidence that these five substations can accommodate the new resources with lesser amounts of upgrades and costs. The preferred locations for interconnection are:

1. West Station Substation
2. Baculite Mesa Substation
3. Nyberg Substation

4. Boone Substation
5. Midway Substation

Further, it is appropriate to limit the addition of new renewable and storage resources to 200 MW for two primary reasons. First, a contingency scenario indicates that forcing any amount beyond 200 MW on a single 222 MVA-rated line, or on a single 120 MVA- or 160 MVA-rated line, would require significant spending for line rebuilds, system improvements, and/or generation curtailment to successfully interconnect the project. Thus, 200 MW is a prudent approach for mitigating transmission cost impacts. Second, the Company's transmission planning only studies a moment in time and not real-time (minute-to-minute) operating situations that can occur when variable generation ramps quickly. As the Company's renewable penetration increases, it will be increasingly difficult to balance the Company's generation and load in real-time. The 200 MW bid amount for the Renewable Advantage is about equal to the Company's minimum system load, a prudent limit for balancing the Company's generation and load in real-time conditions.

B. Transmission Projects

Black Hills' load growth has increased over the past couple of years, driven primarily by large industrial load expansions as well as some commercial load growth. The Black Hills projects included in the 2020 Plan largely reflect the continued strategy of infrastructure upgrades of additions to enhance reliability. Since most of Black Hills' projects are reliability-driven equipment replacements or upgrades, the focus on best-cost considerations was narrowed as appropriate.

In the 2020 Plan, which was the result of an open and coordinated planning approach on regional, sub-regional and local levels, Black Hills documents a procedure to address foreseeable local reliability, integrity and load service issues. Detailed project information can be found in Appendix D.

Since the filing of the 2018 10-Year Plan, Black Hills has completed three projects: Arequa Gulch 115kV Capacitor, Portland 115/69 kV Transformer Replacement, and West Station 115 kV Substation Upgrades. Black Hills identified 11 planned projects within the upcoming 10-year planning horizon that represent $89.52 million in capital expenditures between 2020 and 2023. The projects were identified to increase reliability within Black Hills' network transmission system, to support voltage, and to meet the requirements associated with expected load growth and generation development. The reliability-driven projects are required under various NERC Reliability Standards to address anticipated system performance issues. The projects in this section were coordinated with stakeholders and neighboring entities to ensure the best solution is achieved while avoiding duplication of facilities.

Planned projects are categorized according to the three distinct geographic areas within Black Hills' Colorado service territory.

Cañon City area

Three projects, shown in Table 2, address reliability and integrity concerns in the Cañon City area. Local load growth has resulted in the need for additional capacity in the area, as well as local voltage support. A new transmission line into the area and a substation rebuild will improve load service and operational flexibility.

Table 2. Cañon City area projects included in the Black Hills 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
West Station – Hogback Transmission Line[4]	1/2022	$24.00	Not required

[4] This line also is known as the Southern Colorado Reliability Upgrade Project.

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
115/69 kV Hogback Ranch Substation Build	9/2021	$9.90	Not required
115kV North Penrose Distribution Substation	1/2022	$4.5	A planned project included in the 2018 Rule 3206 filing (Proceeding No. 18M-0005E)

The Black Hills planning process identified these projects as solutions for expected concerns regarding reliability and anticipated load growth in the Cañon City area. The primary driver of the West Station – Cañon City Transmission Line was to increase the reliability of Black Hills' transmission system feeding Cañon City and the surrounding area. Load growth in the Cañon City area has led to reliability concerns following the loss of the two transmission lines connecting that area to the Pueblo part of the Black Hills system. To mitigate these concerns, several options were considered. The West Station – Cañon City 115 kV Transmission Line build is set to rectify the burden of load growth in the area. The new connection also enables the future replacement of stressed transmission lines at a greatly reduced operational risk.

The Hogback Ranch project provides the added benefit of adding a 115/69 kV source near the existing North Cañon 69 kV substation. This will offload the existing Cañon City transformer and add operational flexibility to the local 69 kV system. The new source may provide future improved backup service to the Cripple Creek area via the normal open 69 kV line for emergency situations. The initial scope of the West Station-West Cañon project was coordinated with other entities to explore opportunities for joint participation in the project. This was done to potentially meet a wider range of system needs while minimizing the impact to the local landscape through the potential use of double circuit towers and utilization of existing transmission corridors when possible. The project was identified as an SB07-100 project in the 2015 study because it facilitates a larger resource injection from Energy Resource Zone ("ERZ") 4. Refer to

the Black Hills Corporation 2020 SB07-100 Study Report included in Appendix L for more information.

The North Penrose Distribution Substation consists of constructing a new substation to accommodate two 115/13.2kV, 25MVA transformers. Currently, the community of Penrose is served radially on a 69kV line with limited contingency backup alternatives. This addition will provide the community with another source, while also offloading the 115/69kV transformers at Portland.

Pueblo area

Five projects, shown in Table 3, address reliability and contingency concerns in the Pueblo area. There has been unanticipated significant growth in the Pueblo area that will be accommodated through these future projects.

Table 3. Pueblo area projects included in the Black Hills 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
115 kV Salt Creek Substation	Q3 2021	$6.4	Not required
115 kV Desert Cove - Fountain Valley – Midway Rebuild	11/20/2021	$5.08	Not required
115kV Pueblo West Distribution Substation	1/2021	$4.5	A planned project included in the 2018 Rule 3206 filing (Proceeding No. 18M-0005E)
115kV West Station-Greenhorn Line Rebuild	9/2022	$4.5	Not required
115kV Airport Memorial – Nyberg Rebuild	9/2022	$3.7	Not required

The 115 kV Salt Creek Substation project was determined by the planning team to be a way to rectify growth concerns for the increasing demand in Colorado. Salt Creek Substation would relieve some of the load from existing distributions systems, while also supplying contingency and maintenance switching options. The addition of this substation also allows for increased capacity and contingency with distribution systems within the same area. The project is currently in land negotiation phases; therefore, the total project cost is TBD.

The 115kV Desert Cove – Fountain Valley – Midway rebuild is a result of studies that determined inadequacies in heavy summer conditions. The potential for high power flows in the north-south direction could result in a Category P2 and P4 230kV breaker failure and loss of 230kV lines. This situation would lead to inadequate thermal ratings on the 115kV Desert Cover – Fountain Valley – Midway line. To mitigate this potential issue, the 14-mile line is to be rebuilt and replaced with a minimum rating of 1110A end to end.

The 115kV Pueblo West Distribution Substation will be built to ultimately accommodate two 115/13.2kV, 25MVA transformers. This project is required to serve new industrial and agricultural load as well as contingency back-up for existing distribution infrastructure. This substation additionally addresses low voltage concerns under peak demand conditions for the area.

The 115kV West Station – Greenhorn Line rebuild is to address the age of the infrastructure. The existing 336 ACSR conductor will be replaced to increase the capacity of the line. This project will be a 12.1-mile-long rebuild that uses the current right-of-way. The project, once completed, will increase the line ratings to accommodate current summer and winter ratings.

The 115kV Airport Memorial – Nyberg rebuild is to increase the thermal capability of the lines by replacing the 336 ACSR line with 795 ACSR. Overloads on this line were identified in previous 10-year planning assessments under a contingency of losing both

the Boone-Comanche 230kV and Nyberg-Baculite Mesa 115kV lines. By replacing this line, the thermal capacity can be increased to accommodate the load under the studied contingency.

Rocky Ford area

Three projects, as shown in Table 4, address reliability and contingency concerns in the Rocky Ford area.

Table 4. Rocky Ford area projects included in the Black Hills 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
Boone – La Junta 115 kV Rebuild	1//2020	$15.24	Not required
South Fowler Substation	10/2021	$5.10	Not required
Boone – South Fowler 69/115kV Conversion	9/2022	$6.6	Not required

The Boone-La Junta 115 kV line rebuild is a multi-year project beginning in 2018 and ending in 2020. The entire 45-mile length of the line will be rebuilt using larger conductors to address age-related integrity issues, as well as provide additional capacity on the only transmission line serving that portion of the Black Hills system. The modest load growth forecasted for the area did not necessitate the need to implement the project at a higher operating voltage.

Previously known as “La-Junta Area Upgrades”, the South Fowler Substation and Boon-South Fowler 69/115kV conversion replaces this project. Under a study that was geared to determine the integrity of the 69kV infrastructure, it was deemed that a significant number of lines needed to be rebuilt within the near-term planning horizon. The addition of the South Fowler substation proves to be beneficial for offering additional capacity to the area, along with operational flexibility when rebuilding neighboring aged 69kV lines. The Boone-South Fowler 69/115kV conversion will be

accomplished using 795 ACSR on double circuit structures to accommodate the new line, while maintaining a connection from Boone to Huerfano. This line will be a 19-mile build and is set to improve the reliability of the line regarding increased voltage.

Information concerning the specific Colorado projects included in the Black Hills 2020 10-Year Plan is contained in Appendix D. Additional general information can be found at https://www.blackhillsenergy.com/transmission-rates-and-planning/transmission-projects

B. Tri-State 10-Year Plan Overview

1. Tri-State Planning Process

Tri-State's transmission planning process is intended to facilitate the timely and coordinated development of transmission infrastructure that maintains system reliability and meets customer needs, while continuing to provide reliable, responsible, cost-based electric power to its 43 electrical cooperatives and public power districts (Member Systems). With Member Systems in four states (Colorado, Nebraska, New Mexico, and Wyoming), Tri-State is a regional power provider with only a portion of its planned transmission facilities located in Colorado and therefore included in this plan.

The primary objectives of Tri-State's transmission planning process are to meet the needs of network and point-to-point customers, maintain reliability, accommodate load growth, and coordinate interconnections. The key elements of Tri-State's transmission planning process are:

- Maintaining safe, reliable electric service to its members at the lowest possible cost;
- Improving efficiency of electric system operations;
- Providing open and non-discriminatory access to its transmission facilities; and

- Planning new transmission infrastructure in a coordinated, open, transparent and participatory manner.

Tri-State's primary planning activities center on the preparation of the 10-Year Capital Construction Plan for approval by the Tri-State Board. All projects included in Tri-State's 10-Year Capital Construction Plan adhere to NERC and WECC Standards and Criteria, FERC Order No. 890 Planning Principles, and coordinated regional planning principles, as well as the criteria outlined in Rule 3627.

Tri-State implements its transmission planning process through various studies, including:

- Reliability studies (for both bulk system infrastructure and sub-transmission);
- System impact studies;
- Transmission service requests;
- Generator interconnection studies;
- Facilities studies; and
- Economic studies.

Tri-State's Member Systems create long-range plans and other work plans that they provide periodically to Tri-State's Transmission Planning Department. When Member Systems' plans indicate the need for system upgrades or new construction, Member Systems apply to Tri-State Transmission Planning for a new or modified delivery point to be served from the Tri-State transmission system. The application contains sufficient information for Tri-State Transmission Planning to identify and consider alternatives to meet the Member Systems' requirements in a manner consistent with immediate and long-term needs in the context of the overall transmission system development.

Tri-State's contribution to the 2020 Plan was developed through an open, transparent, and participatory process that considered the needs and requirements of a wide range of stakeholders and regulatory bodies, including Tri-State's Member

Systems; transmission service customers; national and regional reliability organizations; and other transmission providers in Colorado and the region. Tri-State solicited input from a broad and diverse community of stakeholders including Member Systems, independent power producers, independent transmission companies, renewable energy advocates, environmental advocates, and federal, state, and local government agencies in the areas potentially affected by the proposed transmission projects.

The result of this coordinated and comprehensive process is a 10-Year transmission plan that includes transmission, distribution, and substation projects. Project summary information found in the following section and Appendix E focuses on the projects that involve the construction of new transmission lines in the State of Colorado. These transmission projects consist of some projects that are primarily intended to fulfill a load-serving need, some that are primarily intended to serve an identified reliability need, and some projects that are intended to provide transmission system congestion relief to better accommodate existing and future generation resources. In addition to these primary purposes, each project is a part of the bulk electric system in Colorado and therefore provides some additional benefits to the overall Colorado electric transmission system.

To understand the context and basis of Tri-State's 2020 Plan, it is important to recognize the key differences between Tri-State and other Colorado utilities. Tri-State is a generation and transmission cooperative formed and owned by its 43 member distribution cooperatives and public power systems located in four states: Colorado, Nebraska, New Mexico, and Wyoming. The territories served by Tri-State's Member Systems cover a total of approximately 200,000 square miles. This large service area results in a load density that is significantly lower than that served by urban utilities. As a cost-based cooperative, Tri-State does not operate for profit and its Board of Directors, elected by the 43 Members, sets the rates charged to Tri-State's Member Systems accordingly. Tri-State's primary mission is to provide its Member Systems reliable, affordable, and responsible wholesale electric power. Tri-State does not

engage in speculative investments or other activities that are not consistent with its mission.

2. Tri-State Projects

While Tri-State's overall 2020 Transmission Plan includes transmission, sub-station, and distribution projects throughout Wyoming, Nebraska, Colorado, and New Mexico, this summary focuses on the larger transmission projects in Colorado. Many of these projects provide multiple benefits in terms of load serving, reliability improvements, congestion relief, or the accommodation of new generation. It should be noted that the 2020 Plan includes some projects listed in the 2018 Plan.

In January 2020, Tri-State's board of directors approved and announced that Tri-State is implementing its Responsible Energy Plan ("REP"), a transition to clean energy that will provide reliable, affordable, and responsible electricity for its Member Systems. The REP commits Tri-State and its Member Systems to significant reductions in emissions of carbon dioxide attributable to Tri-State's electricity sales to its Colorado members, including early retirement of coal-fired electric generating stations in Colorado by 2030. That commitment is combined with a commitment to a precedent-setting investment in renewable energy resources to offset the loss of conventional resources. The implementation of the REP will directly impact transmission planning.

While the full extent of new renewable energy resources are not yet known, Tri-State anticipates significant transmission infrastructure needs in eastern Colorado in support of these new resources based on the region's high potential for economic wind generation. Studies completed in the CCPG Lamar Front Range Task Force have identified several viable transmission alternatives that would support increased generation in the region by building new 345 kV infrastructure between major transmission hubs, including Lamar, Burlington, and Story switching stations.

As explained in Tri-State's Responsible Energy Plan, there is a pressing need to streamline siting and permitting processes so that transmission and generation infrastructure can be constructed in time to meet Colorado's greenhouse gas emission reduction requirements and renewable energy goals. While such streamlining will not be developed through the Commission's transmission planning rules and processes, the current siting and permitting challenges will be factors considered as Tri-State identifies the transmission system improvements needed to implement the REP's clean energy transition.

Tri-State does not yet have enough information to include in this filing transmission alternatives that may be pursued in connection with the REP. Over the next year, as resource plans are further developed with stakeholder input and eventual approval of an ERP by the Commission, Tri-State will work with stakeholders to develop transmission plans to accommodate the future resource additions and retirements. Tri-State will keep the Commission informed through future Rule 3206 and Rule 3627 filings.

Table 5. Load serving projects included in the Tri-State 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
Burlington-Lamar 230 kV	2024	$58.4	Issued
Lost Canyon-Main Switch 115 kV**	TBD	$22.6	NR
Southwest Weld Expansion Project	2023	$70	Issued
Del Camino-Slater 115kV Line Uprate	2021	$1.4	NR
Sisson Project	2020	$18.8	NR
JG-Kalcevik Project	2022	$14.8	NR
Vollmer Project	2022	$7.1	NR
Lime Road Delivery Point**	TBD	$8.1	NR

*****These are conceptual projects***

Burlington-Lamar

Past studies in the Boone-Lamar area of Colorado have shown voltage collapse for the Boone-Lamar 230 kV line outage with cross-trips of all generation injected at Lamar 230 kV. In order to mitigate these violations and provide for future growth and potential new generation, Tri-State determined the best solution was to construct a new 230 kV transmission line from the existing Burlington substation to the existing Lamar substation.

Lost Canyon Main Switch 115kV

There is heavy load growth in the CO2 Loop consisting of the Yellow Jacket Switch-Main Switch-Sand Canyon-Hovenweep-Yellow Jacket 115 kV system. Constructing the new Lost Canyon-Main Switch 115 kV line will provide support to reliably meet the future load growth for the CO2 Loop in southwestern Colorado.

Southwest Weld Expansion Project

Due to large scale oil and gas development in southwest Weld County and native load growth, Tri-State is planning on constructing approximately 49 aggregate miles of 115 kV and 230 kV transmission lines to meet the forecasted demand of approximately 300 Megawatts (“MW”) within the next five years. Six potential 115 kV load-serving substations and/or line taps may be constructed by Tri-State, while new 69 kV transmission lines and substations will be constructed by United Power for the project.

Del Camino-Slater 115 kV Line Uprate

This project will replace all the remaining spans of 397.5 ACSR conductor on the Del-Camino Slater line with 477 ACSR. The increased line rating will address the limited load-serving capability of the line and allow continued area load growth.

Sisson Project

There is large oil and gas development in northwestern Colorado. This project will add approximately 20 miles of new 115 kV transmission to radially serve the new

Sisson substation radially north from the existing Keota substation. The line and substation addition will increase load-serving capability in northwestern Colorado.

JG Kalcevik Project

There is significant load growth and development north of Denver along the I-25 corridor. This project will add approximately 2 miles of 115 kV transmission to loop the existing Erie-Dacono 115kV line through the new JG Kalcevik substation. The line and substation addition will increase load-serving capability north of Denver.

Vollmer Project

There is significant load growth and development northeast of Colorado Springs. This project will tap the existing Jackson Fuller-Black Squirrel 115kV line and add approximately 2 miles of 115 kV transmission to serve the new Vollmer substation. The line and substation addition will increase load-serving capability in northeast Colorado Springs.

Lime Road Delivery Point

There is oil and gas development south of Pueblo. This project will tap the existing Stem Beach-GCC Cement Plant 115kV line and add approximately 3 miles of 115 kV transmission to serve the new Lime Road substation. The line and substation addition will increase load-serving capability in south Pueblo.

Table 6. Reliability projects included in the Tri-State 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
Western Colorado Transmission Upgrade Project	2020	$57.2	Issued
Burlington-Burlington (KCEA) Rebuild	2022	$0.7	NR
Burlington-Lamar 230 kV	2024	$58.4	Issued
Falcon-Midway 115 kV Line Uprate	2022	$3.8	NR

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
Falcon-Paddock-Calhan 115 kV Line**	TBD	$33.4	NR
Lost Canyon-Main Switch 115 kV**	TBD	$22.6	NR
San Luis Valley-Poncha 230kV #2	2025	$58	Req'd
Southwest Weld Expansion Project	2023	$70	Issued
Del Camino-Slater 115 kV Line Uprate	2021	$1.4	NR
JG Kalcevik Project	2022	$14.8	NR
Lamar Front Range**	TBD	TBD	Req'd

These are conceptual projects

Western Colorado Transmission Upgrade Project

The 40-mile long Montrose-Nucla and Nucla-Cahone 115 kV transmission lines are old, overloaded, undersized, and must be rebuilt. To ensure continued reliability of the southwest Colorado transmission system, Tri-State is replacing them with new, higher capacity lines rated for 230 kV operation. This project will increase the load-serving capability of the southwest Colorado transmission system and also eliminate the need for the existing Nucla Remedial Action Scheme, which trips the Montrose-Nucla line when it starts to overload after contingencies/outages in the area.

Burlington-Burlington (KCEA) Rebuild

Under peak loading conditions, the K.C. Electric Association ("KCEA") 69 kV system fed from Smoky Hill substation cannot be switched to the west to pick up additional load for the loss of the Limon source after the Smoky Hill transformer is replaced with a larger unit. To mitigate this limitation, Tri-State will phase-raise the existing Burlington-Burlington KCEA line to increase the thermal rating of the line. The increased capacity will also help K.C. Electric Association serve new load in the area.

Burlington-Lamar

See description in Section III.B.2, Load Serving.

Falcon-Midway Line Uprate

The current Falcon-Midway 115 kV transmission line has a thermal rating of 95 MVA, which leads to forecasted overloads from an outage on Tri-State's 115 kV Falcon-Fuller line. In order to mitigate this problem, Tri-State is raising, moving, or rebuilding structures along the line to increase the overall line rating to 145 MVA. The increased capacity will help serve Mountain View Electric Association's ("MVEA") customer load in the area.

Falcon-Paddock-Calhan 115 kV Line

The current Falcon-Paddock-Calhan 69 kV transmission line will be rebuilt to create a 115 kV loop in MVEA's central system. The 115 kV line will improve system reliability by looping the existing radial 115 kV and 69 kV substations in MVEA's system and provide increased voltage support. The 115 kV line also will help serve MVEA's customer load growth in the area.

Lost Canyon Main Switch

See description in Section III.B.2, Load Serving.

San Luis Valley-Poncha 230 kV #2

New high-voltage transmission must be built in the San Luis Valley ("SLV") region of south-central Colorado to maintain electric system reliability and customer load-serving capability, and to accommodate development of potential generation resources. Tri-State and Public Service, working through CCPG, facilitated a study of the transmission system immediately in and around the SLV and developed system alternatives that would improve the transmission system between the SLV and Poncha Springs, Colorado. Both Tri-State and Public Service have electric customer loads in the SLV region that are served radially from transmission that

originates at or near Poncha. The study concluded that, at a minimum, an additional 230 kV line is needed to increase system reliability. Studies show that this could be accomplished by either adding a new 230 kV line or rebuilding an existing lower voltage line and operating it at 230 kV.

Southwest Weld Expansion Project

See description in Section III.B.2, Load Serving.

Del Camino-Slater 115 kV Line Uprate

See description in Section III.B.2, Load Serving.

JG Kalcevik Project

See description in Section III.B.2, Load Serving.

Lamar Front Range

The Lamar Front Range Project was developed jointly through the CCPG to significantly improve load-serving capability, reliability, and potential resource accommodation in eastern and southeastern Colorado. The project could provide connectivity to the bulk transmission systems of Tri-State and PSCo, and provide strong “looped service” to areas with long radial transmission configurations. In concept, the project could create a transmission system capable of at least 2000 MW of new generation in eastern and southeastern Colorado. As the actual transmission needs in the original Lamar Front Range Project area have been smaller over the last few years, several projects have been implemented at a smaller scale, but in a manner consistent with the outline of the original Lamar Front Range Project.

This conceptual project is currently being re-evaluated in the Lamar Front Range Task Force under CCPG. The project identifies transmission element additions that are needed to meet both companies’ needs, including delivery of future generation to loads in the Denver and Front Range areas. The conceptual Lamar Front Range

project under study envisions 345 kV transmission lines connecting Lamar to the Pueblo area, Lamar to the Burlington area, and the Burlington area to the Missile Site, Story and Pawnee areas.

Table 7. Generation Congestion projects in the Tri-State 2020 10-Year Plan

Project Name	Estimated In-Service Date	Cost (millions)	CPCN
Burlington-Lamar 230 kV	2024	$58.4	Issued
Lamar Front Range**	TBD	TBD	Req'd
Lamar-Vilas 230 kV**	TBD	$90	Req'd

***These are conceptual projects**

Burlington-Lamar

Lamar Front Range

See description in Section III.B.2, Reliability.

Lamar-Vilas 230 kV Transmission

See description in Section III.C.2, Public Service Conceptual Plans.

Information concerning the specific Colorado projects included in the Tri-State 2020 10-Year plan is contained in Appendix E. Additional information and supporting documentation can be found at:
*http://*www.tristate.coop/transmission-planning

C. Public Service 10-Year Plan Overview

Public Service is one of four electric utility operating companies of Xcel Energy Inc., which is an investor-owned utility serving approximately 1.5 million electric customers in the State of Colorado. Public Service serves approximately 75 percent of the state's

population. Its electric system is summer-peaking with a 2019 peak customer demand of 6881 MW. The entire Public Service transmission network is located within the State of Colorado and consists of over 4,700 miles of transmission lines. Colorado is on the eastern edge of the WECC transmission system, which constitutes the Western Interconnection. The Western Interconnection operates asynchronously from the Eastern Interconnection. The Public Service transmission system is interconnected with the transmission system of its affiliate, Southwestern Public Service Company, via a jointly owned tie line with a 210 MW High Voltage Direct Current ("HVDC") back-to-back converter station. Most of the Public Service retail service customers are located in the Denver-Boulder metro area. However, the Public Service retail service territory also includes the I-70 corridor to Grand Junction, the San Luis Valley region, and the cities and towns of Greeley, Sterling, and Brush. The Company's largest retail electric customer is EVRAZ North America, an industrial steel mill, located in Pueblo.

1. Public Service Planning Process

The goal of coordinated planning, as described in Commission Rule 3627 and historically practiced by Public Service and other TPs, is to develop the best possible transmission plan to meet present and future demands for electricity, taking into account a number of diverse factors. At its most basic level, transmission planning strives to meet customers' energy needs in a reliable and cost-effective manner.

The Public Service transmission planning process is intended to achieve the following objectives:

- Maintain reliable electric service;
- Improve the efficiency of electric system operations, including the provision of open and non-discriminatory access to our transmission facilities pursuant to FERC requirements;
- Identify and promote new investments in transmission infrastructure in a coordinated, open, transparent, and participatory manner; and

- Involve stakeholders during the transmission planning process and review of alternatives.

There are multiple drivers to the planning process, including customer load growth, accommodation of new resources, retirement of existing resources, compliance with state and federal rules and standards, replacement of aging infrastructure, and public policy initiatives. The planning process is coordinated with all the other transmission providers in the state to avoid duplication and reduce costs to the end use customer.

As described in earlier sections, coordinated transmission planning in the State of Colorado depends on careful consideration of numerous factors and variables, as well as thoughtful consideration of input from organizations and individuals on the regional, sub-regional, and local level.

One of the strategic priorities for Public Service is to be a leader in transitioning its generation toward cleaner energy. The goal is to serve customers with cleaner, reliable energy through increased ownership of wind and solar generation, invest in the grid, including advanced technologies and transmission that enable more renewable energy, and reduce carbon and other emissions. This strategy has impacted transmission planning over the last two years and will continue to impact planning into the future.

In September 2018, the Commission approved the 2017 Company's Preferred Colorado Energy Plan Portfolio (CEPP), which stemmed from the PSCo 2016 Electric Resource Plan. As a result of the CEPP, PSCo will be retiring 660 MW of coal-fired generation at Comanche, and adding almost 1000 MW of new wind generation and over 700 MW of new solar generation to its system. In 2019, Xcel Energy released its Corporate Responsibility Report, also referred to as Destination 2050, which describes the Company's vision for a carbon-free future by 2050.

Destination 2050 lays out an interim goal to reduce carbon emissions produced from the electricity that serves our customers by 80 percent from 2005 levels by 2030.

The 2017 CEPP, the Clean Energy Plan (to be filed by Public Service in its next Electric Resource Planning process) and Destination 2050 have had significant impacts to the Public Service transmission planning processes as will be described in later sections of this report.

2. Public Service Projects

Table 8, below, lists the Public Service projects. Note that some costs may have changed from previous filings with the PUC, due to changes in costs for issues such as materials, permitting, construction, and administration.

Table 8. Public Service 10-Year Plan

Project Name	ISD	Cost (millions)	CPCN
Completed			
Missile Site - Shortgrass 345 kV Transmission	2018	$104.9	G
Two Basins Relocation	2018	$24.1	NR
Bluestone Valley Substation Phase 1	2019	$12.0	NR
Moon Gulch 230 kV Substation	2018	$1.7	G
Thornton Substation	2019	$21.4	G
Pawnee-Daniels Park 345 kV Transmission	2019	$169.4	G
New to 2020 Filing			
Shortgrass Switching Station	2020	$20.6	G
CEPP Voltage Support	2020	$93.6	R
Greenwood – Denver Terminal 230kV line	2022	$50.3	R
CEPP Switching Station Bid X645	2022	$20.0	R
CEPP Switching Station Bid S085	2022	$12.0	R
Shortgrass – Cheyenne Ridge 345 kV Transmission	2020	$62.3	G
Previously Listed Projects			
NREL Substation	2020	$10.4	NR
Avery Substation	2021	$10.3	G
Ault-Cloverly 230/115 kV Transmission	2022	$66.7	G

Project Name	ISD	Cost (millions)	CPCN
Avon-Gilman 115 kV Transmission	2022	$11.4	NR
CSU Flow Mitigation	2022	TBD	R
Mirasol (formerly Badger Hills) Switching Station (CEPP Bid X647)	2022	$12.0	R
Conceptual			
Weld-Rosedale-Box Elder – Ennis 230/115kV	TBD	TBD	R
Weld County Expansion Transmission	TBD	TBD	R
Bluestone Valley Substation Phase 2	TBD	TBD	NR
Glenwood-Rifle 115 kV Transmission	TBD	TBD	U
Hayden-Foidel-Gore 230 kV	TBD	TBD	U
Lamar-Front Range Transmission	TBD	TBD	R
Lamar-Vilas 230 kV Transmission	TBD	TBD	R
Parachute-Cameo 230 kV #2 Transmission	TBD	TBD	R
Rifle-Story Gulch 230 kV Transmission	TBD	TBD	R
Wheeler-Wolf Ranch 230 kV Transmission	TBD	TBD	NR
San Luis Valley – Poncha 230 kV[3]	TBD	TBD	R
Poncha – Front Range 230 kV	TBD	TBD	R
Distribution Driven Projects			
Barker Distribution Substation	2021	$29.8	NR
Wilson Distribution Substation	TBD	$4.0	NR
Titan Distribution Substation	2022	$13.0	G
Dove Valley Distribution Substation	2023	TBD	NR
High Point Distribution Substation	2022	$9.0	R
Stock Show Distribution Substation	2026	TBD	NR
New Castle Distribution Substation	TBD	TBD	NR
Solterra Distribution Substation	TBD	TBD	U
Superior Distribution Substation	TBD	TBD	U
Sandy Creek Distribution Substation	TBD	TBD	U

[3] Tri-State lists as “planned” with 2025 ISD.

Key: R – Required, NR – Not Required, G – Granted, U - Uncertain

Public Service’s transmission plan does not currently include multi-state transmission projects. However, Public Service watches for such opportunities. While some of the elements of the current transmission plan could be used as components of a regional transmission project, Public Service has not identified regional project opportunities at this time to include in this plan.

Following is a brief, narrative description of each Public Service project included in Table 1 and how it fits into the overall 2020 Plan. Information for the auxiliary projects shown in Table 8, as well as maps of the Public Service projects for each of the time-frames listed below can be found in Appendix F. Projects are arranged by their anticipated in-service dates.

Planned Projects

Public Service's planned transmission projects can generally be placed in two basic categories. The first category consists of projects that are needed primarily for load growth or reliability purposes. These include both new projects as well as rebuilds or upgrades to existing transmission lines. Native load peak demand in Public Service's service territory has remained fairly flat during the past five years. The expiration of wholesale contracts and the participation of wholesale customers in the Comanche 3 power plant have contributed to this flat load growth. Since 2009, the Public Service firm wholesale load has decreased, but the loss of wholesale load was offset by load growth within the retail sector. The level of load growth also is due to increases in energy efficiency and demand-side management programs, changes in appliance efficiency, and the increase in use of on-site photovoltaic energy systems. Public Service presently projects the native load to grow by about 0.7% from 2019 to 2026.

The second category consists of projects that are planned primarily to accommodate new generation resources. For Public Service, these projects tend to be associated with its electric resource plans, such as the 2017 CEPP. Senate Bill 07-100 also plays a role in the development of those plans, since it is intended to promote proactive planning to accommodate beneficial resources. These projects tend to include large transmission projects to access specific areas of the state that have the potential to host future generation facilities. Through the SB07-100 process, Public Service has developed plans to access each ERZ in Colorado. Some of these plans may be used or modified to accommodate the future Clean Energy Plan and Destination 2050 goals.

Projects Implemented Since 2018

This section describes the Public Service projects that have been placed in-service since the 2018 Rule 3627 10-Year Transmission Plan ("2018 Filing"). The following project(s) consisted of upgrades or additions to existing substations.

Missile Site - Shortgrass 345 kV Transmission

This project was described in the 2018 filing as the Rush Creek – Missile Site 345 kV Transmission Project, or Rush Creek Gen-tie. The project includes the 600 MW Rush Creek wind generation project and an approximately 82-mile 345 kV transmission line that has been built in parts of Arapahoe, Elbert, and Lincoln counties. Since the transmission line is a radial line that accommodates new generation, it is sometimes referred to as a "gen-tie". The Rush Creek wind project includes two collector stations. One collector is located at the new Pronghorn Switching Station, located approximately 42 miles from Missile Site Substation. The second collector is located at the new Shortgrass Switching Station, which is located at the eastern end of the gen-tie, approximately 40 miles from Pronghorn Switching Station.

Construction started on the transmission line in August 2017 and it was placed in service in July 2018 with an approximate cost of $104.9 million.

As part of the Settlement Agreement for the Rush Creek Wind Project proceedings, Public Service took a leadership role in the Rush Creek Task Force created within the CCPG. The task force analyzed the costs and benefits of 19 alternative proposals to potentially integrate the gen-tie as a network facility. The process provided a forum for stakeholder participation and comment.

Two Basins Relocation Project

This project consisted of relocating three existing 115 kV transmission lines that connect to the North Substation. The project was necessary to accommodate the City and

County of Denver ("CCOD") Two Basins Storm Water Drainage Project, which provides 100-year storm protection for certain areas of the city. The project also was required to accommodate the Colorado Department of Transportation ("CDOT") I-70 Expansion Project. The project involved: 1) Re-locating a portion of the existing North-Capitol Hill 115 kV underground line. 2) Re-locating the entire existing North-California 2.25-mile 115 kV underground line and replacing it with new conductor, and 3) Re-locating and replacing four overhead structures on the existing North-Sandown 115 kV line. The CPUC determined that the project was in the ordinary course of business and did not require a Certificate of Public Convenience and Necessity ("CPCN"). The project was placed in-service in 2018 and a cost of $24.1 million.

Bluestone Valley Substation (Phase 1)

The 2018 filing listed Bluestone Valley Substation as a new substation project to improve reliability and provide additional load interconnections for customers in the area. The original scope of this project consisted of a new Bluestone Valley 230/69 kV Substation. The substation would include a 230/69 kV transformer and would interconnect the existing Parachute-Cameo 230 kV line and the existing DeBeque-Cameo 69 kV line. From Bluestone Valley Substation, a new line would be constructed to a new Grand Valley Power Clear Creek Substation. Public Service split this project into two phases: A 69 kV phase ("Phase 1") and a 230 kV phase ("Phase 2"). To expedite reliability improvements to the lower voltage network, Public Service has completed Phase 1. Phase 2 is still considered conceptual and may be constructed at a later time based on local load growth. Phase 1 included construction of a new Bluestone Valley 69 kV Switching Station that connects to the existing DeBeque-Cameo 69 kV line. The project resulted in a DeBeque-Bluestone Valley-Cameo 69 kV line. Phase 1 of this project was placed in-service 2019, at a cost of $12.0 million.

Moon Gulch Substation

Moon Gulch Substation is a new distribution substation built in the City of Arvada within Jefferson County. The substation taps the existing Plains End-Simms 230 kV line. The substation was built to serve load growth in the Arvada area and also to provide backup

service to the existing Eldorado and Ralston distribution substations. The project was placed in-service in 2018 at a cost of $1.7 million.

Thornton Substation

This project consisted of constructing a new substation in Thornton to serve the increase in customer distribution load in that area. This new substation serves the City of Thornton in the north metro Denver area and provides back-up support to the existing Glenn and Washington distribution substations. The project was placed in-service in 2019, at a transmission cost of $21.4 million.

Pawnee-Daniels Park Transmission

The Pawnee-Daniels Park 345 kV Transmission Project consists of a new 125-mile 345 kV transmission line from the Pawnee Substation in northeastern Colorado to the Daniels Park Substation, south of the Denver-Metro area. The project also resulted in the construction of a new Harvest Mile 345 kV Substation, near Smoky Hill Substation, and a new Harvest Mile-Daniels Park 345 kV line. The project also interconnects with the Missile Site 345 kV Substation. This project was planned in accordance with Senate Bill 07-100, in that it accommodates generation in designated ERZs 1 and 2. The Pawnee-Daniels Park Project was placed in-service in December 2019, at a cost of $169.4 million.

Planned Transmission and Substation Projects (Not Previously Listed)

This section describes the Public Service projects that have not been included in previous Rule 3627 filings.

Planned Projects Related to the 2017 Colorado Energy Plan Portfolio

Shortgrass – Cheyenne Ridge 345 kV Transmission Line Project and Shortgrass Switching Station

The Shortgrass – Cheyenne Ridge 345 kV Transmission Line Project consists of an approximately 73-mile, 345 kV transmission line which will extend from the Shortgrass Switching Station to the Cheyenne Ridge wind farm collector stations. The Shortgrass Switching Station not only provides an interconnection for part of the Rush Creek wind generation, but also will interconnect the 300 MW Bronco Plains wind project and the Cheyenne Ridge 500 MW wind project that are included in the Company's CEPP. The project is located in Lincoln, Kit Carson and Cheyenne counties. The project was granted a CPCN, is estimated to cost approximately $52.7 million, and is scheduled to go in service in 2020.

Greenwood -Denver Terminal 230 kV Transmission Project

The Greenwood – Denver Terminal Project consists of an approximately 15 miles of new 230 kV transmission line between the Company's existing Greenwood and Denver Terminal substations. The line is needed to accommodate the 2017 CEPP. The new line will be implemented by rebuilding existing transmission facilities from the Greenwood Substation to the Denver Terminal Substation within existing right-of-way (ROW). The existing Greenwood, Arapahoe, and Denver Terminal substations all will require modifications to accommodate the project. The project is located in six different city boundaries: Centennial, Greenwood Village, Littleton, Englewood, Sheridan and Denver. The Project is estimated to cost approximately $50.3 million and it is planned to be in service by December 31, 2022. The Company plans to file a CPCN for this project early in 2020.

CEPP Voltage Control Facilities

A series of network voltage control devices need to be installed on the Public Service transmission system to accommodate the CEPP generation. The Company is proposing the facilities described in the table below.

Table 9. CEPP Voltage Control Facilities

Substation / Switchyard Location	Implementation Devices to be installed	Estimated In-Service Date	Estimated Cost (millions)
CF&I Furnace	± 95 MVAR STATCOM	Dec. 2023	$32.0
	One (1) dynamic voltage support device		
	85 MVAR of shunt capacitance		
	One (1) 85 MVAR capacitor		
Daniels Park	120 MVAR of shunt capacitance	Dec. 2020	$3.6
	One (1) 120 MVAR capacitor		
Harvest Mile	240 MVAR of shunt capacitance	June 2020	$5.4
	Two (2) 120 MVAR capacitors		
Missile Site	360 MVAR of shunt capacitance	June 2020	$9.5
	Three (3) 120 MVAR capacitors		
	Rush Creek Master Voltage Controller AVSO	Dec. 2020	$5.2
Pronghorn	± 150 MVAR STATCOM	Dec. 2020	$31.7
	One (1) dynamic voltage support device		
Shortgrass	60 MVAR of shunt reactance	April 2020	$6.2
	Two (2) 30 MVAR reactors		
Total			**$93.6**

The cost of the combined facilities is estimated to be approximately $93.6 million and they will be placed in service between 2020 and 2023. A CPCN was filed for this project in December 2019.

CEPP Generation Interconnection Facilities

In addition to the Shortgrass Pronghorn, and Mirasol (formerly Badger Hills – discussed in the Planned Transmission Projects from Previous Filings below) switching stations, other interconnection facilities must be constructed to accommodate the CEPP generation. At this time, the facilities include expanding two existing substations and constructing two new switching stations. The new switching stations include one that will connect to the Hartsel – Tarryall 230 kV line, and one that will connect to one Comanche – Daniels Park 345 kV line. The two existing substation that are proposed to be modified are the Boone and Midway 115 kV substations. The Company intends to file a CPCN for these facilities in 2020.

Planned Transmission Projects (Listed in Previous Rule 3627 Filings)

NREL Switching Station

This project consists of a new switching station that taps the existing Plainview-Eldorado 115 kV line south of Boulder. The U.S. Department of Energy's National Renewable Energy Laboratory ("NREL") operates a hybrid generation facility at its National Wind Technology Center, located approximately 1 mile east of the line. This facility is currently interconnected via distribution service, so the generation capacity is limited. This project is needed to interconnect the generation to the transmission system and allow for additional generation interconnections. The project does not require a CPCN, has a planned in-service date of 2020, with an estimated cost of $10.4 million.

CSU Flow Mitigation Project

This project was described in the 2018 filing as the addition of a phase shifting transformer ("PST") to the Monument Substation on the Monument-Flying Horse 115 kV transmission line, to control power flows through the Colorado Springs Utilities ("CSU") transmission system. Studies have shown that when there are heavy power transfers on the transmission system between Pueblo and the Denver, there is a potential for unacceptable loading to occur on the CSU transmission system. As a temporary mitigation measure, Public Service has implemented an operating procedure that opens up a 115 kV line on the north end of the system where the CSU and Public Service systems connect. The issue has been studied through the Douglas Elbert and El Paso (DEEP) Subcommittee of the CCPG. Upon completion of additional studies, the DEEP Subcommittee developed an alternative solution that consisted of a series reactor rather than a phase shifting transformer. The series reactor alternative accomplishes the same goal, but with advantages to the phase shifting transformer. The series reactor project had an estimated cost of $9.9 million and a potential in-service date of 2022. Recently, CSU has been evaluating additional alternatives. Public Service is continuing to work with CSU, TSGT, and the DEEP Subcommittee to determine a final long-term

transmission solution to mitigate the potential overloads. The project will likely require a CPCN.

Mirasol Switching Station

This project was described in the 2018 filing as a Badger Hills 345/230 kV substation. The project is presently planned as a 230 kV switching station. This project is one of several interconnecting switching stations that will be needed to accommodate generation associated with the Public Service 2017 CEPP. The Mirasol Switching Station will be located approximately 12 miles southeast of Comanche Substation, and will interconnect one of the Comanche - Midway 230 kV lines. The project is being designed to have the flexibility to allow for additional generation interconnections, as well as existing and future transmission lines. The project has a planned in-service date of 2022, with an estimated cost of $12 million. The Company intends to include this project with the other interconnection switching stations when it files a CPCN for these facilities in 2020.

Ault-Cloverly 230/115 kV Transmission Project

The Ault-Cloverly Project consists of approximately 25 miles of new 230 kV and 115 kV transmission lines originating at the existing Western Area Power Administration ("WAPA") Ault Substation near the town of Ault, and terminating at the Public Service Cloverly Substation on the northeast edge of Greeley. The transmission also will interconnect with two new PSCo substations: Husky Substation, which will replace and is planned to be built near the existing PSCo Ault 44 kV Substation, and Graham Creek Substation, which will replace and is planned to be built near the existing PSCo Eaton 44 kV Substation. One objective of the project is to improve reliability by replacing the existing 44 kV system in the area with higher voltage transmission facilities. However, the project also will increase the load-serving and generation resource capability in the area.

The project was granted a CPCN and has a planned in-service date of 2022 with an estimated cost of $66.7 million.

Avon-Gilman 115 kV Transmission Project

The Avon-Gilman 115 kV Transmission Project consists of constructing a new 10-mile 115 kV line in Eagle County for reliability and to provide an alternate transmission source to Holy Cross Energy customers. The project does not require a CPCN, has a planned in-service date of 2022, and has an estimated cost of $11.4 million.

3. Public Service Conceptual Plans

Conceptual Plans

The following transmission plans are considered conceptual in that they have no specific in-service date. Implementation of these plans is primarily affected by load forecasts and electric resource needs. Once a need is established, in-service dates can depend on many factors, including but not limited to regulatory proceedings, siting and land permitting, coordination of construction outages, and material delivery times. Public Service continues to assess the system conditions that may drive implementation for these plans.

Conceptual Plans Related to Load Growth

Bluestone Valley Substation (Phase 2)

As mentioned previously, this project has been divided into two phases. Phase 2 of the project would consist of expanding the substation to include 230 kV facilities, which would include a 230/69 kV transformer and interconnect the Rifle-Cameo 230 kV line. Implementation of Phase 2 will depend on the local load growth.

Glenwood-Rifle Transmission

This plan has been described in previous filings, and consists of upgrading the Glenwood Springs-Mitchell Creek-New Castle-Silt Tap line from 69 kV to 115 kV and new construction to reroute the Silt-Rifle line to the Rifle Substation at 115 kV. A portion

of the rerouted 115 kV line will be double-circuited with the Rifle-Hopkins 230 kV line. Costs for the plan have not been estimated, and moving forward with the plan will depend on load growth around Glenwood Springs.

Hayden-Foidel Creek-Gore Pass 230 kV Transmission

This plan has been described in previous filings and would consist of tying the Hayden-Gore Pass 230 kV line into the Foidel Creek Substation to increase reliability in the region. Reliability concerns are being mitigated by adding reactors at the Wolcott 230 kV bus, so there are no plans to move forward with this project at this time.

Parachute-Cameo 230 kV #2 Transmission

This project has been described in previous filings and is an extension of the Rifle-Parachute 230 kV line. It would consist of a new, approximately 30-mile 230 kV transmission line that would connect the existing Parachute and Cameo substations on the western slope of Colorado. Its primary purpose would be to increase reliability and to serve load growth in the region. Preliminary analysis estimated the cost to be approximately $48 million, but actual costs, and implementation of the project will depend on load growth in the area.

Rifle-Story Gulch Transmission

The project has been described in previous filings and would consist of a new radial 230 kV transmission line that would be used to serve customer loads in Garfield County. The line would be approximately 25 miles long and run between the existing Rifle (Ute) Substation to a new Story Gulch Substation. Preliminary analysis estimated the project cost to be approximately $24 million, but actual costs and implementation will depend on load growth in the area.

Wheeler-Wolf Ranch

The project has been described in previous filings and would consist of a new radial 230 kV transmission line that would be used to serve customer loads in Garfield County. The line would be approximately 18 miles long and run between the existing Wheeler

Substation to a new Wolf Ranch Substation. The line also would interconnect to the Middle Fork Substation. Preliminary analysis estimated the project to cost approximately $17 million, but actual costs and implementation will depend on load growth in the area.

Conceptual Plans Related to SB07-100 / Clean Energy Plan Goals

Weld-Rosedale-Box Elder - Ennis 230 & 115 kV Transmission Lines

This project was referred to in the 2018 filing as the Weld – Rosedale – Milton 230 kV project. However, Public Service has been evaluating alternatives that would terminate at locations other than Milton within its service territory. As mentioned in the 2018 filing, Public Service has been working through the CCPG Northeast Colorado ("NECO") Subcommittee to develop a transmission plan for the area south of Greeley. The objective is to continue the replacement of the existing 44 kV system in the area, increase the ability to accommodate future load growth, and allow for beneficial resource development. The plan also should align with other transmission projects and plans in the area, including the Ault-Cloverly Project and the Southwest Weld Expansion Project ("SWEP"). A 230 kV line from Weld to Rosedale and a 230 kV or 115 kV line from Rosedale to Box Elder to Ennis would meet the objectives. However, until the NECO studies are completed and an actual project is recommended, the projects are listed as conceptual with no specified in-service date or estimated costs.

Weld County Transmission Expansion

This plan was described in the 2018 filing as a means to allow interconnection of new resources and complement other transmission plans in Northeast Colorado such as the Ault-Cloverly 230/115kV Project and the Weld-Rosedale-Box Elder-Ennis 230 and 115kV Transmission Project. The Weld County Expansion continues to be a general planning placeholder that captures the planning efforts for Northeast Colorado, including the Greeley area. This project may be considered as a third or eastern phase of the planning efforts in the area that have been taking place in the CCPG NECO Subcommittee. The Weld County Expansion could be a combination of planned and

conceptual projects, such as the Ault-Cloverly Project, and the Weld-Rosedale-Box Elder - Ennis 230 & 115 kV lines, or, the Weld County Expansion could be a new project. Regardless, the Weld County Expansion may be a project that could enable Public Service to meet its Clean Energy Plan goals.

Lamar-Front Range Transmission

The Lamar-Front Range plan originally was planned as a means to deliver an estimated 2000 MW of new generation from energy resources near Lamar and Burlington to load centers along the Front Range. The plan was conceived as a joint project between Public Service and Tri-State. A primary driver for Public Service was to meet an SB07-100 objective to plan transmission from the ERZ-3. The original plan included the following transmission components:

- Two 345 kV transmission circuits between Lamar and Avondale
- Two 345 kV transmission circuits between Lamar and Burlington
- Two 345 kV transmission circuits between Burlington and Big Sandy
- One 345 kV transmission line between Big Sandy and Missile Site
- One 345 kV transmission line between Big Sandy and Story
- One 345 kV transmission line between Story and Pawnee
- A new Avondale Substation
- Two 230 kV transmission circuits between Lamar and Vilas

The original Lamar-Front Range project was estimated to cost approximately $900 million. However, since the project is being re-evaluated, revised cost estimates have not been determined.

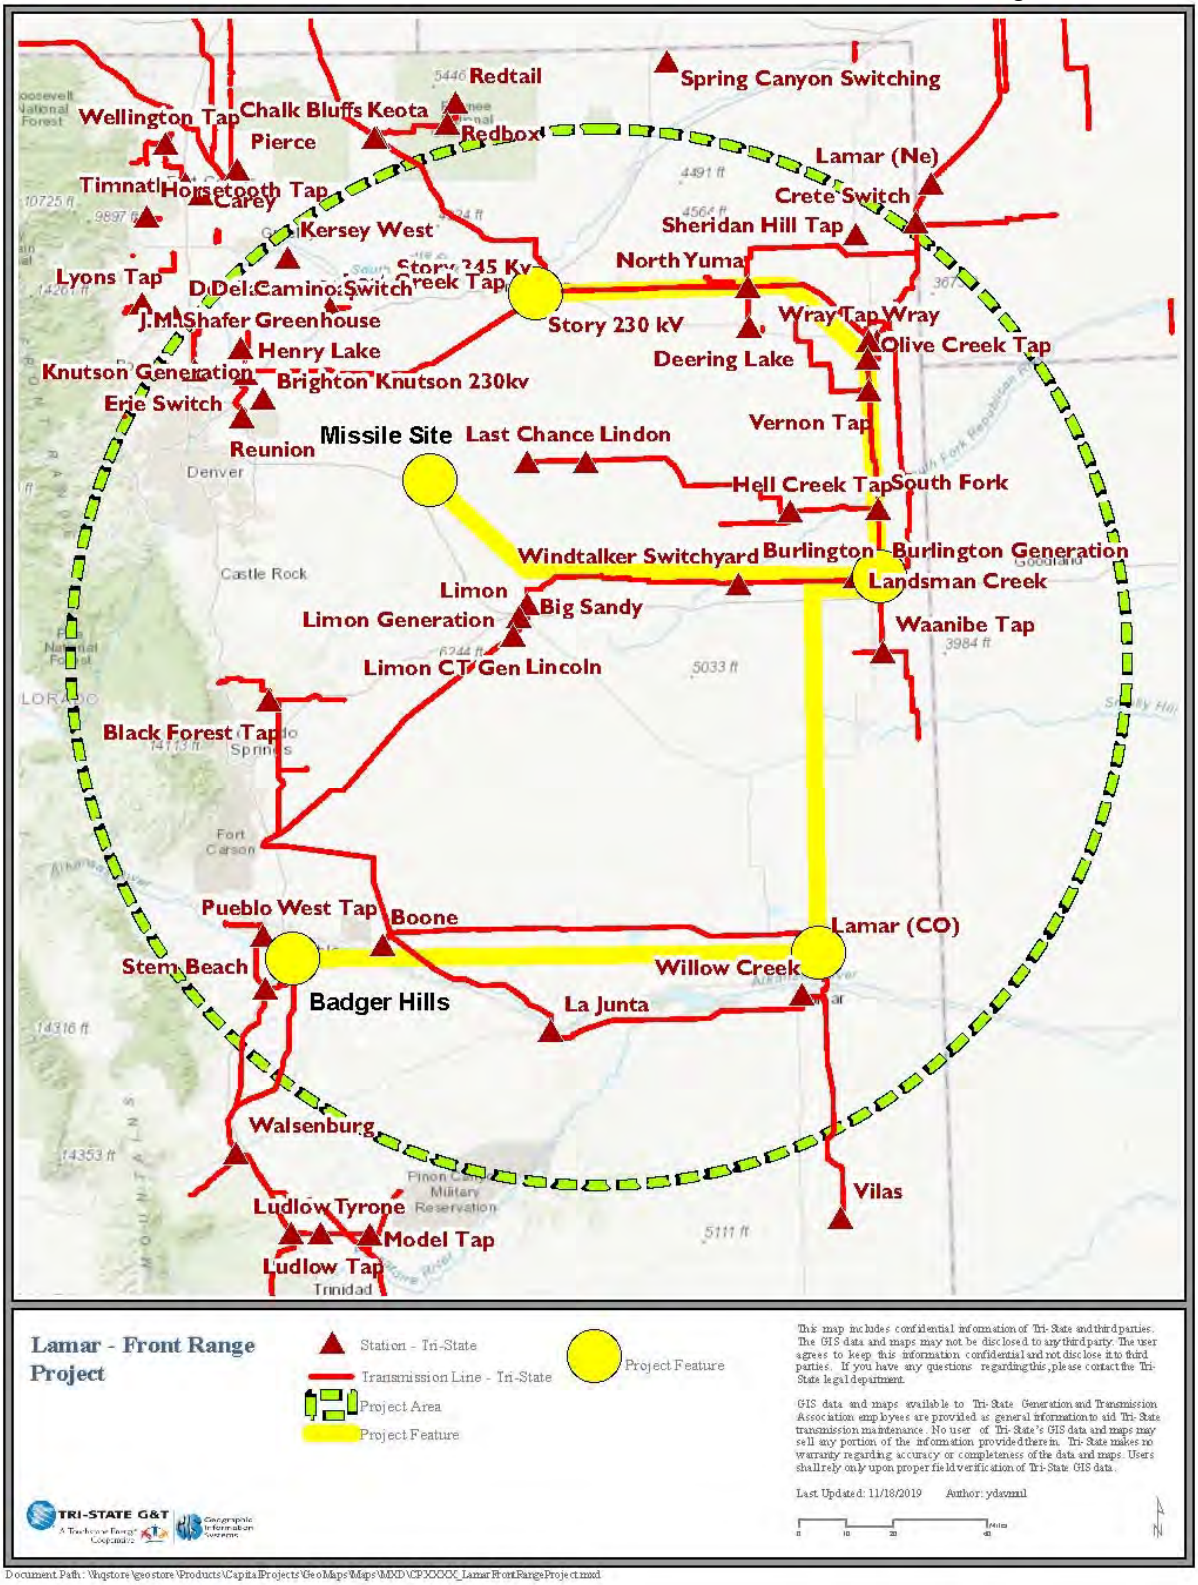
Since the plan was developed, a number of significant projects that could either be considered segments of, or are consistent with the design of the plan have been implemented or planned. These include:

- Construction of the Missile Site – Pronghorn – Shortgrass 345 kV line
- Construction of the Burlington – Wray 230 kV line
- Plans for the Shortgrass – Cheyenne Ridge 345 kV line
- Plans for a Burlington – Lamar 230 kV line

As a result, in 2019, the CCPG Lamar-Front Range Task Force (LFRTF) was formed to revisit the Lamar-Front Range Transmission Project. The objective of the task force is to evaluate transmission alternatives in eastern and southeast Colorado that will facilitate the delivery of new renewable and other low-cost generation to load centers, improve transmission system reliability, and increase the operational flexibility of both transmission and generation assets.

The LFRTF evaluated numerous transmission alternatives. No preferred alternative has been identified, but some alternatives and combinations of alternatives show technical merit and meet the overall objective. For example, a potential plan that may be able to advance Public Service's future Clean Energy Plan objectives might include the following components:

- Networking the Missile Site – Cheyenne Ridge 345 kV line to Burlington
- New 345 kV transmission from Burlington – Lamar – Comanche
- New 345 kV transmission from Burlington – Missile Site
- New 345 kV transmission from Burlington - Pawnee



Document Path: \\hqstore\geostore\Products\CapitalProjects\GeoMaps\Maps\MXD\CP\XXXX_LamarFrontRangeProject.mxd

San Luis Valley

Similar to Tri-State, Public Service also recognizes that new high-voltage transmission in the San Luis Valley would improve electric system reliability and customer load-serving capability, and accommodate development of potential generation resources. Studies indicated that a new 230 kV transmission line from the San Luis Valley Substation to Poncha Substation would be a first step to accomplish the reliability objectives. Transmission beyond Poncha to the Front Range would enhance reliability and provide additional generation export out of the San Luis Valley and help meet the Public Service Clean Energy Plan goals.

Other Long-Range Distribution Planning Substation Projects

Public Service, the Colorado Office of Consumer Counsel, ("OCC") and Staff of the Colorado Public Utilities Commission agreed through discussions related to Proceeding No. 14A-1002E to identify potential new distribution substation sites in rapidly growing areas. Below is a list of conceptual new substation projects under consideration by the Company. This is provided for informational purposes only. At this time, Public Service is not seeking Commission determination of the need for CPCNs for these projects or any Commission action. Most in-service dates for these projects are TBD.

Table 10. Long-Range Distribution Planning Substation Projects

Substation Project Name	Transmission Voltage	Approximate location	Potential ISD	Cost ($M)
Barker	230 kV	Across from Coors Field in Denver	2021	$29.8
Dove Valley	115 kV	Near I-25 and C-470 in Arapahoe County	2023	TBD
High Point	115 kV or 230 kV	Near Denver International Airport; Adams County	2022	$9
Titan	230 kV	Near Sterling Ranch in Douglas County	2022	$13
Stock Show	115 kV	Denver	2026	TBD
Wilson	115 kV	Loveland	TBD	TBD
Solterra	230 kV	Lakewood	TBD	TBD
New Castle	69 kV	New Castle	TBD	TBD
Superior	115 kV	Town of Superior	TBD	TBD
Sandy Creek	230 kV	Arapahoe County, near future Sandy Creek development	TBD	TBD

Additional Information

Information concerning the specific Colorado projects included in the Public Service 2020 10-Year Plan is contained in Appendix F. Additional information and supporting documentation can be found at:

http://www.transmission.xcelenergy.com/Planning/Planning-for-Public-Service-Company-of-Colorado

https://www.rmao.com/public/wtpp/PSCO_Studies.html

http://www.oatioasis.com/psco/index.html

IV. Projects of Other CCPG Transmission Providers

In addition to the projects planned by Black Hills, Tri-State, and Public Service contained in this 2020 Plan, a thorough understanding of all transmission projects planned in Colorado requires consideration of projects planned by other utilities and TPs.

Table 11. Colorado Springs Utilities Projects

In-Service	Project Name	Description	Purpose
2020	Williams Creek 230 kV Switching Station	Install a new substation on the Nixon-Claremont 230 kV line necessary to interconnect new Palmer Solar PV plant	Generation interconnection
2020	Nixon-Kelker 230 kV Line Uprate	Increase clearance on Nixon-Kelker 230 kV line to increase facility rating on the line.	Increase facility rating
2019	Cottonwood 230/115kV Autotransformer Replacement.	Install a new, upgraded 230/115 kV autotransformer at Cottonwood substation.	Increase system load serving capacity and provide compliance with the Long Lead Time Equipment requirement in the NERC Transmission Planning Standard TPL-001-4. (The existing Cottonwood auto will be refurbished and stored on site as a system spare.)

This information is provided voluntarily by CSU for the purposes of making sure the CPUC has the most complete information for planned project coordination purposes only.

Additional information concerning the specific Colorado projects included in the CSU Plan are contained in Appendix G.

Table 12. Platte River Power Authority Projects

In-Service	Project Name	Description	Purpose
2018	Boyd 230/115kV Substation Expansion	Add 230/115kV transformer T2 and reconfigure 230kV and 115kV yards to breaker-and-a-half arrangement.	Improve system reliability in the Loveland area.

This information is provided voluntarily by Platte River Power Authority ("PRPA") for the purposes of making sure the CPUC has the most complete information for planned project coordination purposes only.

Additional information concerning the specific Colorado project included in the PRPA is contained in Appendix H.

Table 13. Western Area Power Authority Projects

In-Service	Project Name	Description	Purpose
2020	Midway KV1A Replacement	Replacing KV1A at Midway	Replacing aging equipment and increasing size
2020	Ault 345/230 kV XFMR Replacement	Replacing the 345/230 kV Transformer at Ault	Increased reliability

This information is provided voluntarily by WAPA for the purposes of making sure the CPUC has the most complete information for planned project coordination purposes only.

Additional information concerning the specific Colorado projects included in the WAPA are contained in Appendix I.

V. Senate Bill 07-100 Compliance and Other Public Policy Considerations

In addition to planning for load growth and reliability, Companies must consider proposed and enacted public policies. Two of the Companies, Black Hills and Public Service, are subject to the requirements of Colorado Senate Bill 07-100 ("SB07-100") (codified at C.R.S. § 40-2-126).

Historically, the SB07-100 filings were made by Black Hills and Public Service by October 31 of each odd-numbered year. Those filings were subsequently combined into a single Proceeding with the Rule 3627 filing pursuant to Decision No. R17-0747 in Proceeding 17R-0489E, which amended Rule 3627 to require electric utilities subject to Commission rate regulation to include their transmission plans for energy resource plans specified in C.R.S. 40-2-126(2) with their transmission plans due February 1 of each even-numbered year. As stated in SB07-100, Black Hills and Public Service are required to:

a. Designate ERZs
b. Develop plans for the construction or expansion of transmission facilities necessary to deliver electric power consistent with the timing of the development of beneficial energy resources located in or near such zones
c. Consider how transmission can be provided to encourage local ownership of renewable energy facilities
d. Submit proposed plans, designations, and applications for Certificates of Public Convenience and Necessity to the Commission for simultaneous review

Black Hills and Public Service have performed transmission planning activities to comply with the requirements of SB07-100 as part of the larger, coordinated planning efforts described above. As of 2017, Colorado's ERZs remain as they were defined in the 2015 SB07-100 reports, created by consulting multiple sources of information as well as public feedback. As shown in Figure 7, Colorado's five ERZs are:

ERZ 1 (Northeast Colorado)

Includes all or part of Sedgwick, Phillips, Yuma, Washington, Logan, Morgan, Weld, and Larimer Counties. ERZ 1 presents energy development opportunities for natural gas, wind, and thermal resources.

ERZ 2 (East-central Colorado)

Includes all or part of Yuma, Washington, Adams, Arapahoe, Elbert, El Paso, Lincoln, Kit Carson, Kiowa, and Cheyenne Counties. ERZ 2 presents energy development opportunities for natural gas, wind, and thermal resources.

ERZ 3 (Southeast Colorado)

Includes all of part of Baca, Prowers, Kiowa, Crowley, Otero, Bent, and Las Animas Counties. ERZ 3 represents the potential for wind resource development.

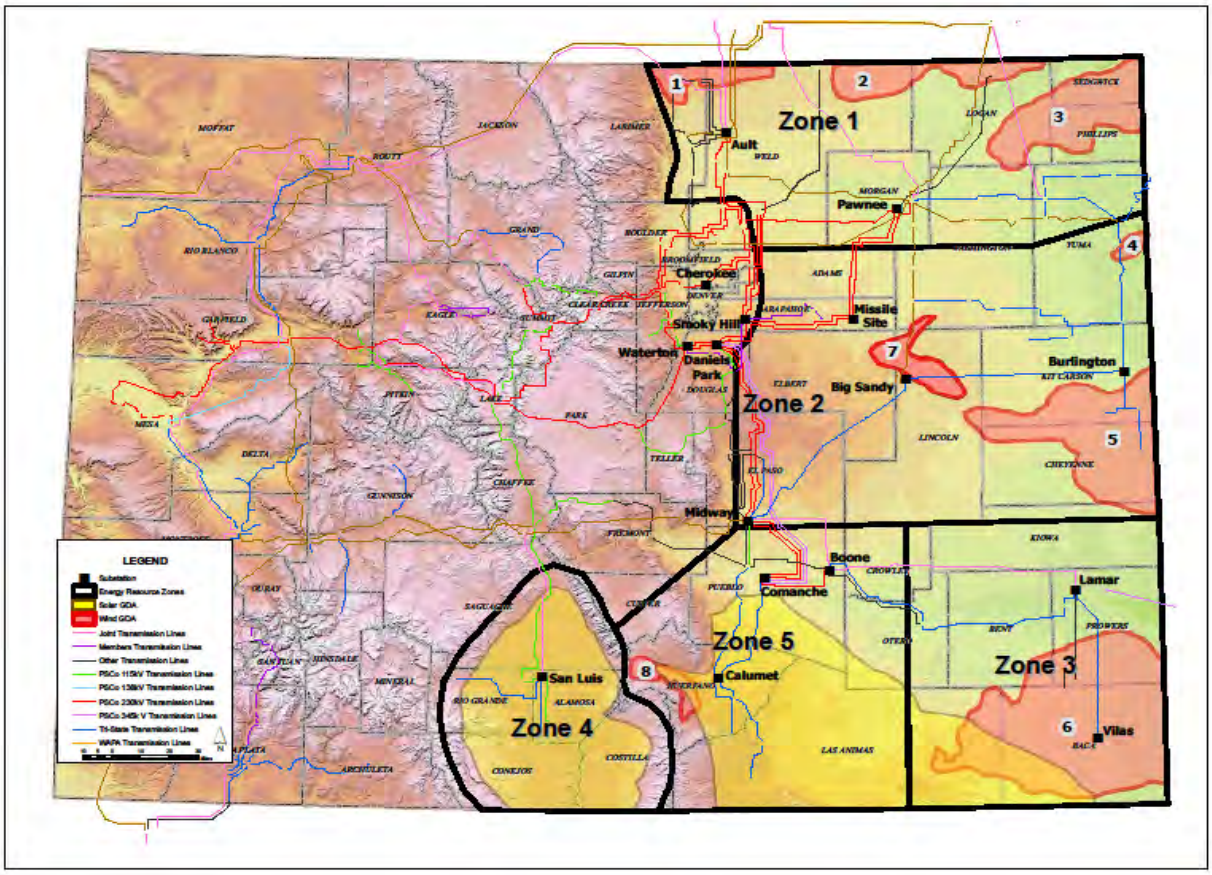
ERZ 4 (San Luis Valley)

Includes all or part of Costilla, Conejos, Rio Grande, Alamosa, and Saguache Counties. ERZ 4 presents energy development opportunities for solar resource development.

ERZ 5 (South-central Colorado)

Includes all or part of Huerfano, Pueblo, Otero, Crowley, Custer, and Las Animas counties. ERZ 5 in South Central Colorado includes the area around Pueblo and south along the I-25 corridor which includes both potential wind and solar resources.

Figure 7. Map of SB07-100 Energy Resource Zones



In addition to the public policy requirements of SB07-100, all three Companies may be subject to federal and Colorado state regulations related to carbon emission reductions from existing power plants. The Companies will continue to coordinate with each other and stakeholders with respect to the transmission planning implications of any new federal regulations and may address issues in subsequent 10-Year transmission plans.

A. Black Hills Summary

Black Hills encouraged all interested parties to participate in the 2019 SB07-100 study process. An open stakeholder SB07-100 Kick-off Meeting was held in conjunction with the Q1 Black Hills Colorado Transmission ("BHCT") Transmission Coordination and Planning Committee ("TCPC") on April 23, 2019, to inform stakeholders of the proposed study plan and to provide an opportunity for suggestions and feedback on the study process. The kick-off meeting had no external participants. A follow-up e-mail was sent on October 10, 2019, to invite stakeholders to respond with their input while updating them on the progress of the study work. Meeting notices and presentations were distributed via e-mail and posted on the Black Hills Open Access Same-Time Information System ("OASIS") page at http://www.oatioasis.com/bhct/ as well as on a Colorado SB07-100 webpage established on the Black Hills Corporation website; https://www.blackhillsenergy.com/our-company/transmission-rates-and-planning.

For the 2019 SB07-100 cycle, Black Hills selected to re-evaluate the resource injection capacity from ERZ-5, which initially was performed as part of the 2013 SB07-100 cycle. That decision was based on the completion of transmission system upgrades since that time, as well as ongoing interest to develop generation in the area as indicated by Black Hills' generation interconnection queue. The transmission system was evaluated under 2023 peak summer load levels to identify any significant adverse impact to the reliability and operating characteristics of the Western Electricity Coordinating Council ("WECC") bulk transmission system and, more specifically, to the Black Hills and surrounding transmission systems. Steady state voltage and thermal analyses examined system performance without additional projects in order to establish a baseline for comparison. Performance was re-evaluated with resource injections modeled and compared to the baseline performance to determine the impact of the injections on area transmission reliability.

The power flow analysis was performed with pre-contingency solution parameters that allowed adjustment of load tap-changing ("LTC") transformers, static VAR devices

including switched shunt capacitors and reactors, and DC taps. Post-contingency solution parameters allowed adjustment of DC taps and automatically switched shunt devices, as well as adjustment of manually switched shunt devices outside the study area. Area interchange control was disabled and generator VAR limits were applied immediately for all solutions. The solution method implemented was a fixed-slope decoupled Newton solution.

Black Hills SB07-100 Conclusions

Black Hills utilized an open and transparent process in conducting its 2019 Colorado Senate Bill 07-100 study. Stakeholders were provided several opportunities for involvement and input into the study process and scope. Through this process, Black Hills believes it has fulfilled the requirements of Colorado Senate Bill 07-100, codified at C.R.S. § 40-2-126.

Baculite Mesa 115kV Substation: The 2023HS study results indicated that the BHCE transmission system could accommodate a 200MW injection at the Baculite Mesa 115kV substation with no required upgrades, assuming all planned projects are in service.

Nyberg 115kV Substation: Additionally, the study results indicated that the BHCE transmission system could accommodate a 75MW injection at the Nyberg 115kV substation. Higher levels of injection into this substation caused overloads on XCEL's Boone 230/115kV transformer during a P2 breaker failure contingency at Nyberg.

South Fowler 115kV Substation: The analysis also looked at injections at the planned South Fowler 115kV substation. The results indicated that the BHCE transmission system could accommodate at 75MW injection at this location. Higher levels of injection into this substation caused overloads on XCEL's Boone 230/115kV transformer during a P2 breaker failure contingency at Nyberg. The breaker failure at Nyberg cuts off the

only 115kV paths to the west portion of BHCE's system. This forces the power through the Boone 230/115kV transformer.

West Station 115kV Substation: The last injection point that was included in the analysis was the West Station 115kV substation. The results indicated that the BHCE transmission system could accommodate a 175MW injection at this location. High levels of injection caused overloads on the Fountain Valley – Midway 115kV transmission line. These results included the planned rebuild rating for this line. Increasing this rating further would require substantial terminal equipment upgrades at the Midway substation.

Designate Energy Resource Zones

On November 24, 2008, Public Service filed with the Commission an information report that identified its five ERZs within Colorado. Four of the ERZs identified by PSCo are located in close geographical proximity to the Black Hills system, specifically ERZs 2, 3, 4 and 5. In the 2011 SB07-100 study report, Black Hills identified two ERZs (ERZ-1 & ERZ-2), both of which were located within the PSCo defined ERZ-5. In order to avoid confusion, Black Hills has adopted the five PSCo defined ERZs within Colorado.

Develop plans for the construction or expansion of transmission facilities necessary to deliver electric power consistent with the timing of the development of beneficial energy resources located in or near such zones.

Black Hills identified the impacts of the various resource scenarios on the Black Hills transmission system and identified projects that ensure reliable delivery of beneficial energy resources from the designated ERZ-5 to customer loads.

Consider how transmission can be provided to encourage local ownership of renewable facilities, whether through renewable energy cooperatives as provided in Colo. Rev. Stat. § 7-56-210, or otherwise.

The identified new transmission projects will facilitate renewable resource development in ERZ-5 in excess of Black Hills' forecasted resource needs. The studied resource injections are in relatively close proximity to Black Hills customers and would be facilitated by a direct physical connection to the Black Hills electric system.

Submit proposed plans, designations, and applications for Certificates of Public Convenience and Necessity to the Commission for simultaneous review.

Black Hills believes that the 115 kV transmission projects it has identified to facilitate the reliable delivery of beneficial energy resources to customer load are "in the ordinary course of its business" and do not require CPCNs, pursuant to Colo. Rev. Stat. §§ 40-2-126(3) and 40-5-101. The resource injection amounts identified in this report are indicative of potential system performance under the evaluated scenarios, but should not be construed to reflect firm system capability. In-depth analysis and coordination is required to establish a more comprehensive projection of potential system performance following implementation of the identified system upgrades.

B. Public Service Summary

Public Service began filing SB07-100 reports in October 2007. Public Service has developed plans for nine transmission projects to expand transmission capability for the delivery of beneficial energy resources from ERZs. These projects are listed in Table 14.

Public Service has completed the first five projects listed in Table 14. These projects have enabled Public Service to interconnect 1400 MW of wind in eastern and northeastern Colorado, and accommodates an additional 600 MW of wind from the Rush Creek Wind Project. The table below lists the name of the project, the ERZ that the project would serve, and a tentative schedule for implementation. The status of the projects that remain planned or conceptual are described in more detail in Section III.

Table 14. Public Service SB07-100 Projects

	Project	ERZ	ISD	Status
1	Missile Site 230 kV Switching Station	2	2010	Project placed in-service November 2010.
2	Midway-Waterton 345 kV Transmission Project	3,4,5	2011	CPCN granted on July 16, 2009. Project placed in-service May 2011.
3	Pawnee-Smoky Hill 345 kV Transmission Project	1,2	2013	CPCN granted on February 29, 2009. Project placed in-service June 2013.
4	Missile Site 345 kV Substation	2	2012	CPCN granted on June 8, 2010. Project placed in-service December 2012.
5	Pawnee-Daniels Park 345 kV	1,2	2019	CPCN granted on April 9, 2015. Project placed in service December 2019.
6	Lamar-Front Range 345 kV	2,3	TBD	Plan being re-evaluated through CCPG. Certain segments may be implemented in a phased approach.
7	Lamar-Vilas 230 kV	3	TBD	(See Lamar – Front Range)
8	Weld County Expansion	1	TBD	Studies ongoing through CCPG
9	San Luis Valley	4,5	TBD	Studies Complete

1. *Projects That Have Been Completed or Planned*

Missile Site 230 kV Switching Station (ERZ-2)

The Missile Site 230 kV Switching Station Project consisted of a new switching station near Deer Trail, Colorado, that connects the existing Pawnee-Daniels Park 230 kV transmission line into and out of the Missile Site 230 kV Switching Station. The project has allowed interconnection of new generation in ERZ-2.

The Missile Site 230 kV Switching Station was placed in-service in November 2010. Public Service interconnected the 250 MW Cedar Point wind project in 2011.

Missile Site 345 kV Switching Station (ERZ-2)

The Missile Site 345 kV Substation expanded the Missile Site 230 kV Switching Station to allow additional generation and transmission interconnections from ERZ-2 at the 345 kV voltage level. The substation bisects the Pawnee-Smoky Hill 345 kV Transmission Project. In addition to connecting the Pawnee-Smoky Hill 345 kV line, the substation also allows for future 345 kV transmission connections. These include connections to the Pawnee-Daniels Park 345 kV Project. The Missile Site 345 kV Substation was placed in-service in December 2012. The Limon Wind Energy Center brought about 600 MW of wind generation into Missile Site in 2014, and in 2018, the Rush Creek Project added another 600 MW. The Bronco Plains and Cheyenne Ridge projects will interconnect another 800 MW in 2020.

Midway-Waterton 345 kV Transmission Project (ERZs 3, 4, and 5)

The project consists of 82 miles of 345 kV transmission line from the Midway Substation, near Colorado Springs, to the Waterton Substation, southwest of Denver. The Midway-Waterton 345 kV project accommodates additional generation resources in ERZs 3, 4, and 5. The Midway-Waterton 345 kV Transmission Project was placed in-service in May 2011.

Pawnee-Smoky Hill 345 kV Transmission Project (ERZs 1 and 2)

This project consists of developing approximately 95 miles of 345 kV transmission line between the Pawnee Substation near Brush, Colorado, and the Smoky Hill Substation, east of Denver. The project allowed for additional resources in ERZ-1 and ERZ-2, interconnected at or near the Pawnee and Missile Site substations. The project was designed to facilitate construction of the Pawnee-Daniels Park 345 kV Project. This project was placed in-service in June 2013.

Pawnee-Daniels Park 345 kV (ERZs 1 and 2)

The Pawnee-Daniels Park 345 kV Transmission Project is described in Section III.C.2. The project consists of building a 125-mile 345 kV transmission line from the Pawnee Substation in northeastern Colorado to the Daniels Park Substation, south of the Denver-Metro area. The project also will result in constructing a new Harvest Mile 345 kV Substation, near Smoky Hill Substation, and a new Harvest Mile-Daniels Park 345 kV line. The project also will interconnect with the Missile Site 345 kV Substation. This project was planned in accordance with Senate Bill 07-100, in that it will accommodate generation in designated Energy Resource ERZs 1 and 2. The project was placed in-service in December 2019, at an estimated cost of $169.4 million.

2. *Projects that are Planned or Conceptual*

The projected in-service dates of these conceptual projects identified in Table 13 above can be affected by CPCN approval, revisions to load forecasts, resource plans, siting and land permitting, coordination of construction outages, and material delivery times. Because all of these projects are presently in the conceptual stage, assessments will continue on whether the stated factors will cause any modifications to these projects, in terms of configuration, timing, or otherwise.

Lamar-Front Range 345 kV (ERZs 2 and 3)

This project is described in Section III.C.2 and was planned as a high voltage project that covered vast portions of eastern Colorado to accommodate resources in ERZs 2 and 3. The original Lamar-Front Range project was estimated to cost approximately $900 million. Recently, Tri-State and Public Service have been planning and implementing projects that align with the original Lamar-Front Range plan. These include the Tri-State Burlington-Lamar 230 kV line and the Public Service Missile Site – Cheyenne Ridge 345 kV line.

Also, since 2019, the CCPG LFRTF has been re-evaluating how the Lamar – Front Range plan might be modified, based on recent changes and plans to the transmission system in Colorado. As mentioned in the Public Service 10-Year Plan Overview, a plan evaluated by the LFRTF that shows technical merit and could meet Public Service SB07-100 and SB19-236 Clean Energy Plan objectives includes the following components:

- Networking the Missile Site – Cheyenne Ridge 345 kV line to Burlington
- New 345 kV transmission from Burlington – Lamar – Comanche
- New 345 kV transmission from Burlington – Missile Site
- New 345 kV transmission from Burlington - Pawnee

Lamar-Vilas 230/345 kV (ERZ-3)

The Lamar-Vilas project has been associated with the Lamar-Front Range Plan. The Lamar-Vilas line could consist of approximately 60 miles of high-voltage transmission from Lamar Substation to the existing Vilas Substation to provide access to additional resources in ERZ-3 and Baca County.

Weld County Transmission Expansion (ERZ-1)

This plan is described in Section III.B.2 as a means to accommodate additional generation resources in ERZ-1. As a result of the potential for load growth and the Public Service plan to replace aging 44 kV infrastructure in the area, other projects have been planned and are being developed in the area that align with, and may ultimately replace the Weld County Expansion Project. Public Service is implementing the Ault-Cloverly 230/115kV Project and Tri-State is implementing the planned SWEP, which may connect transmission from the Denver-Metro area to the south of Greeley system. The CCPG NECO Subcommittee has been working to develop a comprehensive transmission plan for Northeast Colorado to serve a variety of needs. Studies indicate that a Weld-Rosedale 230 kV line and a Rosedale Box Elder - Ennis 115 kV

Transmission Lines would be a prudent next step to meet the objectives. The Weld County Expansion could be a combination of the planned Ault-Cloverly Project, and SWEP and conceptual Weld-Rosedale-Box Elder - Ennis 230 & 115 kV lines, or the Weld County Expansion may be a new project that could be considered as a third or eastern phase of the planning efforts in the area.

When specific projects have been recommended, Public Service will inform stakeholders and develop plans for implementation.

San Luis Valley (ERZs 4 and 5)

This plan has been described in Section III.B.2 and has been planned as a means to accommodate potential generation from ERZs 4 and 5, in addition to improving the reliability of the transmission system in the San Luis Valley area of Colorado. Studies were performed in the CCPG San Luis Valley Subcommittee, which identified that additional 230 kV transmission from San Luis Valley to Poncha to the Front Range would enable additional resource accommodation. As specific projects are planned and recommended, Public Service will inform stakeholders and develop plans for implementation.

VI. Stakeholder Outreach Efforts

Per Rule 3627(g), "Government agencies and other stakeholders shall have an opportunity for meaningful participation in the planning process." "Government agencies include affected federal, state, municipal and county agencies. Other stakeholders include organizations and individuals representing various interests that have indicated a desire to participate in the planning process." *See* Rule 3627(g)(I). The following sections summarize each Company's approach to government agency and stakeholder outreach and participation pertaining to Rule 3627. Processes specific to the stakeholder input directives of FERC Order No. 890 are discussed in Section VII.D.

A. Black Hills Outreach Summary

Black Hills recognizes the importance of stakeholder involvement throughout the transmission planning process and considers a stakeholder to be any person, group or entity that has an expressed interest in participating in the planning process, is affected by the transmission plan, or can provide meaningful input to the process that may affect the development of the final plan.

Stakeholders are encouraged to participate in Black Hills' transmission planning through the regular meetings held by the TCPC as part of the annual study process under FERC Order No. 890. The TCPC is an advisory committee consisting of individuals or entities who are interested in providing input to Black Hills' Transmission Plan. The TCPC study process consists of a comprehensive evaluation of the Black Hills and surrounding transmission systems for critical scenarios throughout the 10-year planning horizon. Stakeholders are notified of the initial meeting at the start of the study cycle and invited to participate. An opportunity is provided to comment on the scope of the study at this point in the process. Relevant system modeling data is requested from the stakeholders, as well as any economic study or alternative scenario requests. Once the study cases are compiled, another open stakeholder meeting is held to review and

finalize the data and study scope. A third stakeholder meeting is held to review preliminary study results and discuss potential solutions to any identified problems. This process allows the TCPC to develop a comprehensive transmission plan to meet the needs of all interested parties. A final stakeholder meeting is held to approve the study report and Local Transmission Plan ("LTP"). Following each meeting, contact information for the transmission planner performing the study is provided to allow for ongoing questions or comments regarding the study process. Updates on the progress of the TCPC study efforts also are provided to regional planning groups, such as the CCPG, to promote involvement from a larger stakeholder body.

A list of potential stakeholders was created during the initial TCPC study cycle and has continued to evolve through active invitations, recommendations from existing participants, and outreach at CCPG meetings. Black Hills is continually modifying its stakeholder list in order to invite a more comprehensive group of participants into the transmission planning process.

Two quarterly meeting invites were sent in 2019 as part of Black Hills' annual TCPC process. The primary kick-off taking place on April 23, 2019, and a second invite on October 10, 2019. Meeting notifications were sent to the stakeholder contact list, announced at the CCPG meetings and posted on Black Hills' OASIS web page.

Black Hills' Q1 stakeholder meeting is typically more educational in nature and was held via web/phone conference on April 23, 2019. It served the purpose of presenting the transmission planning process to stakeholders, describing the scope of the 2019 assessment, reviewing the current 10-Year Transmission Plan and soliciting feedback on the study scope, the stakeholder outreach process, and potential alternatives to the projects within the 10-Year Plan.

Black Hills' Q3 stakeholder meetings were sent out via e-mail on October 10, 2019. This meeting served the purpose of an update and solicitation for feedback regarding the progress of the study and conclusions. Although there were no updates made since

the kick-off meeting, this invite was to allow any part to request a meeting if it was deemed necessary. No interest was shown to pursue an official meeting after the invite was sent.

Black Hills' Q4 stakeholder meeting was not held, as cases from CCPG were not received until the week of December 20, 2019. At that time, an e-mail was sent to stakeholders presenting our updated study scope and list of scenarios included for stakeholder question and comment. The study work has been started and results will be presented at the 2020 Q1 stakeholder meeting.

A limited number of external stakeholders attended the quarterly meetings. The stakeholder meetings produced some dialog on specific projects, but substantive feedback regarding the planning process and future projects was not received. Black Hills relied heavily on coordination with affected utilities and internal review of alternatives to ensure that the projects selected and presented in the Rule 3627 Transmission Plan were optimal and adequate for the needs of its network transmission system and Colorado's goals of fostering beneficial energy resources to meet load growth.

For more information regarding the stakeholder process utilized in the 2019 or earlier Black Hills TCPC planning processes, including meeting notices, notes, presentations and contact information, refer to the Black Hills' Transmission Planning page; https://www.blackhillsenergy.com/our-company/transmission-rates-and-planning
Stakeholder outreach information also is available in the Transmission Planning folder on the Black Hills OASIS at: http://www.oatioasis.com/bhct

B. Tri-State Outreach Summary

Tri-State performs transmission planning-related stakeholder outreach as a standard part of its day-to-day business consistent with its policy of planning in an open, coordinated, transparent and participatory manner. This outreach encompasses

various efforts including: Rule 3627 specific meetings and stakeholder communications; FERC Order No. 890 specific meetings and communications; project-specific meetings and communications; and CCPG participation.

As described in Rule 3627(g)(I), stakeholders include federal, state, county, and municipal government agencies as well as other non-governmental organizations and individuals having an interest in the transmission planning process. Tri-State identifies potential governmental stakeholders based generally on a five-mile area surrounding proposed transmission facilities. Federal agencies in the areas of the transmission projects included in Tri-State's 2020 10-Year Transmission Plans typically include the Bureau of Land Management, the U.S. Forest Service, the National Park Service, and the Department of Defense. Potentially interested state agencies include the Colorado State Land Board and associated Stewardship Trust Lands, and the Colorado Division of Parks and Wildlife. Outreach to county and local governments typically includes communications to relevant elected officials as well as administrators, managers, and land planning, economic development, and legal staffs. In some instances, Tri-State's governmental outreach also included agencies such as parks and school districts.

Contact lists for non-governmental stakeholders were developed through various transmission planning forums such as CCPG and other WestConnect planning groups, as well as individuals and organizations that have participated in previous Tri-State stakeholder meetings. When known, Tri-State also included stakeholders identified as being interested in specific proposed projects. The resulting non-governmental stakeholders included other utilities, Tri-State Member Systems, energy and transmission project developers, environmental groups, economic development organizations, various advocacy groups, and elected officials not already included in the governmental outreach communications.

In 2019, Tri-State hosted one transmission planning-related stakeholder outreach meeting in connection with development of the 2020 10-Year Transmission Plan. The meeting was on August 21, 2019, and provided a summary of new information related

to Tri-State's ongoing transmission planning activities as well as updates on current projects and coordination with CCPG's long range transmission planning efforts. This meeting also constituted Tri-State's FERC Order No. 890 stakeholder meeting and provided an opportunity for stakeholders to provide input in connection with all of Tri-State's long-range transmission plans. All such input and relevant alternatives were considered and included in the appropriate biennial transmission plans submitted to the Colorado Public Utilities Commission pursuant to Rule 3627. No alternatives were proposed at this meeting.

In addition to this larger stakeholder meeting addressing system-wide and Colorado-specific transmission projects, Tri-State also conducted a number of meetings related to individual proposed transmission projects. These meetings and other project-related communications included relevant government agencies, economic development entities, and other interested organizations and persons to inform them of the proposed project and provide an opportunity for feedback and consideration of potential alternatives. The nature and timing of outreach efforts related to specific projects was generally dependent on the development status of the project.

Details of Tri-State's meetings, including a list of attendees and a meeting presentation video which includes questions and comments received together with Tri-State's responses thereto, and relevant presentations can be found at:
http://www.tristategt.org/stakeholder-outreach

Tri-State also participates in the CCPG's transmission planning efforts. As discussed in Section VI.D. of this Plan, the CCPG planning process includes additional stakeholder outreach and a further opportunity for stakeholder participation in and input into the overall Colorado coordinated transmission planning process, which includes Tri-State's proposed projects. Additional information concerning CCPG stakeholder opportunities is available at the WestConnect website.

Tri-State confirms that, as required by Commission Rule 3627(g)(V), this 2020 10-Year Transmission Plan is available to all government agencies and other stakeholders through Tri-State's Transmission Planning website at:
*http://*www.tristate.coop/transmission-planning

Tri-State has informed all stakeholders of the availability of the 2020 10-Year Transmission Plan.

C. Public Service Outreach Summary

Rule 3627 requires a summary of stakeholder participation and input and how this input was incorporated in the transmission plan. The rule states that government agencies and other stakeholders shall have an opportunity for meaningful participation in the planning process. The government agencies include affected federal, state, municipal and county agencies. In addition, Rule 3627 provides that other stakeholders, including organizations and individuals representing various interests that have indicated a desire to participate in the planning process, must also have an opportunity for meaningful participation. Under Rule 3627, Public Service is required to actively solicit input from the appropriate government agencies and stakeholders to identify alternative solutions. In addition to the Public Service outreach efforts listed below, the Company actively participates in numerous CCPG groups, where it also engages with and responds to comments presented by stakeholders. The following is a synopsis of the outreach that the Company performed relevant to this rule. Also, Appendix K lists some responses to comments received from two stakeholders.

Rule 3627 Webinars

The Company developed an informational PowerPoint presentation that included information on the long-range plans developed as part of Rule 3627. Two, two-hour-long webinars were held – the first on Friday, August 16, 2019, and the second on Wednesday, September 11, 2019 - to give stakeholders opportunity to participate and comment on transmission plans, either in person (at the Xcel Energy offices in

downtown Denver) or via the Internet. E-mail invitations with exact verbiage will be provided at the request of the Commission.

More than 500 individuals representing the following stakeholder groups—including all state legislators in both the House and Senate—received invitations to the webinars:

- Elected officials
- Federal, state and local government officials
- Environmental groups
- Energy developers
- Chambers of commerce
- Business and industry
- Planning and economic development agencies
- Large energy users
- Citizens and advocacy groups
- Intervenors on past PSCo filings
- Organizations involved in transmission planning (*e.g.*, CCPG members)

Invitations also were sent to the CCPG's distribution list, which includes representatives from other utilities including Black Hills, WAPA and Tri-State, as well as stakeholders representing environmental interests, consulting firms, law firms, and other individuals and groups. Local government elected officials, including county commissioners in counties that could be impacted by projects in the Public Service's portion of the 2020 Plan, were also invited along with local planning office representatives and other staff officials from local governments and agencies. Because routing had not been started on some of these projects, which were still in the planning phase, individual landowners who might be impacted were not identified.

Information on Xcel Energy's transmission projects in Colorado was provided to all invitees via a link in the e-mail, but since then, the web address was redirected to the following: http://www.transmission.xcelenergy.com/Projects/Colorado

Attendance at the August 16, 2019, session included eight in-person attendees external to PSCo and approximately 60 webinar attendees, although an actual count was difficult to gauge, as participant count decreased and increased during the course of the presentation. Since self-identification was optional, it was not possible to determine whether additional participants entered the webinar or participants already in attendance reconnected after becoming disconnected from the webinar. Attendance at the September 11, 2019, session included five in-person attendees external to Public Service and approximately 20 webinar attendees.

The PowerPoint presentation discussed at the session consisted of three basics parts. Because the level of knowledge surrounding transmission and transmission planning of the attendees was not known, part one provided an overview of electric transmission to acquaint attendees with basic information about how the system works and what constitutes the transmission system. Part two covered the transmission planning process, provided an overview of how and why planning is done, and outlined the many factors that are considered when developing plans. Part three reviewed all projects included in Public Service's portion of the 2020 Plan. Public comment from the webinar covered a wide range of topics. Written comments were received from the Office of Consumer Council and Western Resource Advocates. The written comments and Public Service responses to these comments are included in Appendix K.

FERC Order 890 Stakeholder Meetings

The Company facilitates two open stakeholder meetings per year to meet the requirements of FERC Order 890. The meetings are held in the first and fourth quarters every year at the Xcel Energy office in Denver, and the content is very similar to that presented in the Rule 3627 webinars. In the last two years, FERC Order 890 meetings were held on March 15, 2018, December 5, 2018, March 20, 2019, and December 4, 2019. Public Service has taken a similar approach to Tri-State, where the Rule 3627 and FERC Order 890 meetings are referred to as open stakeholder meetings that will

meet the objectives of both rules. Meeting agendas, presentations (referred to as "Transmission Plans", and notes are available at:
http://www.oatioasis.com/psco/index.html under "FERC 890 Postings".

PROJECT-SPECIFIC OUTREACH

Pawnee-Daniels Park Project

The Pawnee-Daniels Park Project was energized on December 26, 2019. Final site restoration and revegetation work will continue throughout spring and summer 2020. Public Service will continue to work with landowners and impacted communities throughout the remainder of restoration activities.

Avery Substation Project

Public Service is proposing to construct the Avery Substation and Transmission Line project. The new Avery Substation will enable the company to serve existing and new load in the vicinity of Timnath, Severance and Windsor along the eastern side of the Interstate 25 corridor. Avery Substation will assist in providing back up to the existing Cobb Lake and Windsor Substations, which are reaching their capacity. It also will provide reliability to our existing and future customer load. The project consists of a new electric distribution substation, an associated overhead double-circuit 230 kV electric transmission line and overhead distribution feeder lines near the towns of Windsor, Severance and Timnath, Colorado. Power for the proposed 1.4-mile 230 kV transmission line will be provided by interconnecting the existing PRPA Timberline-Ault 230 kV transmission line. Public Service is currently evaluating in the land use permitting process with the Town of Windsor for the substation and a portion of the transmission line. Land use permits for other portions of the transmission line have been approved. This connection will supply the proposed Avery Substation with the electrical supply needed to power the distribution feeders serving the immediate communities.

Land use permitting for portions of the transmission line in unincorporated Weld County was completed in September 2018. A Conditional Use Grant application for the substation and the last half-mile of line was submitted to the Town of Windsor in December 2018. Hearings were held at the Windsor Planning Commission and Town Board in February 2019. The Town Board continued the hearing due to questions about the location and information needed from the landowner. Based on landowner feedback, Public Service decided to withdraw the application and attempt to resolve the primary concerns from the public and the town. This resulted in a new site alternative that was presented to the public at an open house on July 9, 2019.

Based on feedback at the open house, the new site was chosen as the preferred location and a new application was submitted on August 27, 2019, with this proposed site.

The Conditional Use Grant was recommended for approval by the Planning Commission on November 6 and was approved by the Town Board on November 25, 2019. It is anticipated that construction on the substation will commence at the end of Q1 or beginning of Q2 2020. Public Service staff will conduct public outreach as needed to support construction.

Ault-Cloverly 230/115 kV Transmission Project

The Ault-Cloverly 230/115 kV Transmission Project will increase electric reliability and load-serving capability of the Xcel Energy electric transmission system in and around the Greeley area, and will provide accommodation for new generation resources in the region while aligning with other transmission planning efforts in the area. The company filed a CPCN application with the CPUC on March 9, 2017, to construct the Northern Colorado Area Plan; Proceeding Number 17A-0146E.

The company held three open house meetings for the Northern Colorado Area Plan in 2018, and submitted a 1041 permit application in November 2018. Following several public comments voicing opposition to the southwestern portion of the preferred route,

the company amended its application to include the WAPA/Ault to Husky to Graham Creek portion of the line, with the intention of applying for a separate permit for the Graham Creek to Cloverly portion of the line. On June 18, 2019, the Weld County Planning Commission unanimously recommended denial to the Board of County Commissioners. Following this denial, the company determined the best course of action would be to withdraw the 1041 permit application. The company is now starting over with a new siting and community engagement effort. In the coming months, we will be hosting a Community Working Group, consisting of 12 to 20 community members and leaders to participate in the routing effort. Additionally, the second of four planned open house meetings (the first meeting was held in November 2019) will be hosted in late January in the town of Eaton. The 1041 Areas and Activities of State Interest land use permit application will be submitted in late spring/summer 2020, with Planning Commission and Board of County Commissioner hearings taking place in summer/fall 2020.

Greenwood - Denver Terminal

The Company is proposing the upgrade of approximately 15.4 miles of existing transmission facilities to 230 kV by rebuilding and/or reconductoring existing transmission facilities from the Greenwood Substation to the Denver Terminal Substation within existing right-of-way (ROW). The CPCN submittal for the project is targeted for early 2020. The project is located in six different jurisdictional boundaries: Centennial, Greenwood Village, Littleton, Englewood, Sheridan and Denver.

Outreach activities completed to date have been with elected officials and planning staff. The list below summarizes meetings that have taken place to date:

- September 16, 2019 – City of Englewood City Manager
- September 23, 2019 – City of Centennial Councilmembers
- September 25, 2019 – City of Greenwood Village Mayor and City Manager
- September 27, 2019 – City of Littleton staff
- October 3, 2019 – City of Sheridan City Manager and staff

- October 4, 2019 – City of Greenwood Village staff
- October 9, 2019 – City of Centennial Mayor and City Manager
- The City of Denver Council members were notified informally by the Company Area Manager
- November 4, 2019 – City of Littleton School District
- November 6, 2019 – City of Centennial City Planner and Public Works
- November 11, 2019 – City of Englewood City Planner and Public Works
- January 7, 2020 – Pre-Submittal Application submitted to City of Denver Planning and Development
- February 11, 2020 – Scheduled informal presentation at City of Littleton City Council public hearing.

Future meetings with the City of Englewood elected officials and the staff of the remaining cities are being scheduled. Public meetings, including open houses and neighborhood associations, will be held in February 2020.

Barker Substation

The Company is proposing the installation of equipment in the currently empty Barker Substation site and a new double circuit buried transmission line from the Barker Substation to the existing LaCombe Substation. The project is located within the City of Denver and outreach to the city is anticipated to begin in January 2020.

Glenwood-Rifle Transmission Line

In 2019, Public Service staff met with Glenwood Springs city management to discuss the Glenwood to Mitchell Creek Transmission Line Rebuild project. The Project consists of rebuilding approximately two miles of 69kV transmission line to 115kV transmission line, which will be initially operated at 69kV. Currently, the team is evaluating alternatives that include rebuilding outside of the existing alignment due to vegetation and ROW constraints in the current alignment. Public outreach is planned to begin in 2020, with a public open house and communications with elected officials tentatively planned in the first quarter of 2020.

Cheyenne Ridge Wind Farm and 345 kV Transmission Line Project

The Cheyenne Ridge 500 MW wind farm and 73-mile 345 kV transmission line is one of the projects that makes up a portion of the company's Colorado Energy Plan. The project is located in Lincoln, Kit Carson and Cheyenne counties, and, when complete, will generate enough renewable energy to power 270,000 homes. The company completed its purchase of the project asset from Tradewind Energy, who developed and permitted the project, in June 2019.

During the development phase of the project, Tradewind Energy engaged with many stakeholders, including county planning staff, landowners, Colorado Division of Wildlife, Colorado Department of Public Health and Environment, the Nature Conservancy, United States Fish and Wildlife Service, Colorado Department of Transportation, and the Colorado State Historic Preservation Office. After the company's purchase of the project, engagement with these stakeholders has continued.

The project commenced construction in July 2019 and is expected to reach commercial operations in December 2020. Since taking ownership of the project in June 2019, the company has sent a brochure on project updates to stakeholders and landowners. The brochure contains an update of the construction activities that have occurred to date and a high-level project schedule. The company also is hosting a project website that provides project updates, project photos, and contact information for questions and concerns. The website can be found at the following URL: https://www.xcelenergy.com/energy_portfolio/renewable_energy/wind/co_wind_power/cheyenne_ridge_wind_project

The Company plans to continue stakeholder engagement in 2020 with the issuance of future project brochures, updates to the project website, landowner liaison efforts, and coordination with Lincoln, Kit Carson and Lincoln counties, and the Colorado Department of Transportation.

D. CCPG Outreach Summary

To ensure stakeholders in Colorado have multiple opportunities to provide input and receive a broader perspective on the evolution of Colorado's transmission system, TPs also leverage the CCPG stakeholder input process in developing the 10-Year transmission plan. CCPG has a subgroup called the 3627 Subcommittee. The Subcommittee serves as a forum for coordination among the Colorado electric utilities that are required to comply with PUC Rule 3627, and for receipt and consideration of stakeholder proposals submitted in connection with 10-Year transmission plans. Since the 2012 filing, TPs have worked with CCPG to formalize and document processes for receiving, evaluating, and providing feedback on stakeholder submitted alternatives. Stakeholders are provided opportunities for meaningful participation through multiple channels, including an online form that can be emailed, by participating in open meetings via teleconference, or by actively attending quarterly meetings. Full documentation of the process by which stakeholder input, suggestions, and alternatives are to be categorized, evaluated, and recorded is included in Appendix J as well as on the CCPG website at:
http://regplanning.westconnect.com/ccpg_stakeholder_opportunities.htm

Generally, the process is initiated by the stakeholder filling out a form and supplying it to the CCPG chair. The form requests the following information:

- Study or project name
- New study or alternative
- Narrative description
- Study horizon date
- Geographic footprint of interest
- Load and resource parameters
- Transmission modeling
- Suggested participants
- Policy issues to address

- Type of study
- Other factors

Once the CCPG chair receives the request, a determination will be made as to whether adequate information has been provided. The chair may contact the requester to ask for additional details. The chair will facilitate an ad-hoc review group ("Review Group") to review and categorize the request. The Review Group will determine:

- If the request is reasonable from a reliability planning perspective.
- Who should be responsible? (CCPG or a smaller sub-group of CCPG; or should the study be forwarded to a larger group such as WestConnect or WECC)?
- The likely schedule for completing the analysis requested.

The Review Group may consider the following questions to determine the response to the request:

- Which portion(s) of the CCPG transmission system shall be under consideration in the study?
- Would the request be of interest to multiple parties?
- Does the request raise policy issues of national, regional, or state interest?
- Can the objectives of the study be met by existing or planned studies?
- Would the study provide information of broad value to customers, regulators, transmission providers and other interested Stakeholders?
- Does the request require an economic (production cost) simulation or can it be addressed through technical studies, (power flow and stability analysis)?

Once the Review Group has determined that the request is reasonable and has verified the purpose and intent of the request, a written response will be developed and provided to the requester and CCPG.

If the Review Group determines that the request cannot be accommodated by CCPG or any TP, an explanation will be provided. If the Review Group determines that the request can be accommodated, then the response will provide information as to the recommended logistics for how the request will be handled, including the responsible parties and a schedule for completion. CCPG maintains a record of all comments and requests received, as well as their disposition. These records also will be posted on the CCPG section of the WestConnect website.

CCPG Northeast Colorado Subcommittee Stakeholder Input Process

The CCPG NECO Subcommittee is the forum for coordinated planning of the transmission system that generally covers Weld, Morgan, Adams, Washington, Logan, Sedgwick, Phillips and Yuma counties and also extends to portions of Boulder and Larimer counties. The objective of the NECO Subcommittee consists of developing transmission plans that will support and facilitate load growth, allow for future generation injection, coordinate with reliability improvements in the Greeley area, and complement other longer-term transmission plans in northeast Colorado. In 2017, the group recommended the Ault – Cloverly 230/115 kV project as the Northern Greeley Area Plan (NGAP).

Public Service filed for a CPCN for the Northern Greeley Area Transmission Plan Project in 2017 and the NECO Study Report was included in the testimony. On March 1, 2018, a CPCN was granted in the Recommended Decision by the Public Utilities Commission for the Proceeding No. 17A-0146E.

In 2017-2019, the NECO Subcommittee changed its focus to the transmission system south of Greeley. The objectives are similar to the north of Greeley studies, which are to reliably replace the existing 44 kV system, increase the ability to accommodate future load growth, allow for beneficial resource development and align with other transmission projects in the area.

In 2018-2019, the NECO Subcommittee met on:

- May 2, 2018
- June 6, 2018
- July 17, 2019

The subcommittee has performed studies to evaluate the present load-serving and generation interconnection capabilities. At least 11 alternatives were evaluated. Presently, the alternative that meets not only the NECO objective, but also can assist with the Public Service 80x30 objectives appears to be a new 230 kV line from Weld – Rosedale, and a 115 kV line from Rosedale – Box Elder – Ennis.

Colorado Energy Plan Task Force

The Colorado Energy Plan Task Force (CEPTF) was formed to inform stakeholders of the studies being performed to evaluate the Company's 2016 ERP and 2017 CEP. Public Service chaired and performed the study work for the CEPTF.

The following stakeholders participated in the CEPTF:

- Basin Electric Power Company
- Black Hills Corporation
- Bright Energy Storage
- Buckyball Systems
- Colorado Public Utilities Commission
- Colorado Springs Utilities
- Dietze & Davis
- Intermountain Rural Electric Association
- Lucky Corridor
- Tormoen Hickey LLC
- Colorado Office of Consumer Council
- Western Area Power Administration
- Western Resource Advocates

- Tri-State
- TradeWind Energy

Meetings were held on:

- November 1, 2017
- November 27, 2017
- March 8, 2018
- October 18, 2018
- March 1, 2019
- July 17, 2019

The CEPTF provided a forum to inform stakeholders of key findings and recommendations related to the transmission issues associated with implementation of the CEP Portfolio, which include:

- There are no significant transmission deficiencies caused directly by the retirement of Comanche Units 1 & 2. The system will remain reliable and there are no transient stability issues.
- Implementation of the CEP Portfolio requires additional voltage control facilities and a network upgrade in the Denver metro area.
- The voltage control facilities include a mix of static and dynamic devices that are needed to maintain adequate voltage performance.
- The recommended network upgrade consists of a new Greenwood Denver Terminal 230 kV line. At least eight transmission alternatives were evaluated based on stakeholder input.

CCPG Lamar Front Range Stakeholder Input Process

In 2019, the Lamar-Front Range Task Force (LFRTF), which was facilitated by Tri-State, revisited the Lamar-Front Range studies completed in 2013. In 2013, the Lamar-Front Range plan was identified through extensive transmission analysis to facilitate

addition of new resources in eastern Colorado, improve transmission system reliability, and increase operational flexibility. The 2013 plan was conceived as a joint project between Public Service and Tri-State. A primary driver for Public Service was to meet an SB07-100 objective to plan transmission from the ERZ-3. The overall plan included the following transmission components:

- Two 345 kV transmission circuits between Lamar and Avondale
- Two 345 kV transmission circuits between Lamar and Burlington
- Two 345 kV transmission circuits between Burlington and Big Sandy
- One 345 kV transmission line between Big Sandy and Missile Site
- One 345 kV transmission line between Big Sandy and Story
- One 345 kV transmission line between Story and Pawnee
- A new Avondale Substation
- Two 230 kV transmission circuits between Lamar and Vilas

Since completion of the 2013 Lamar-Front Range studies, the eastern Colorado transmission system has materially changed with the addition of new resources and transmission facilities. The goal of the task force was to evaluate potential transmission alternatives to the Lamar-Front Range plan.

In April 2019, the LFRTF finalized a study scope and began evaluating transmission alternatives. The LFRTF performed technical analysis of 26 alternatives that facilitated the addition of new resources in eastern Colorado. Several other alternatives were considered, but not included in the technical analysis. The costs of the alternatives for this analysis were based on indicative (planning level) capital construction costs. The benefits of the alternatives were measured primarily in terms of how much incremental generation a particular alternative could accommodate compared to cost of the alternative. Other costs and benefits may be achieved, but were not the focus of this analysis. The LFRTF provided an open stakeholder forum to analyze the costs and benefits of alternative transmission proposals.

The LFRTF has held seven regularly scheduled meetings since February 2019 to discuss study assumptions, study methodology, potential alternatives, cost estimates, and benefits. The LFRTF Subcommittee participant list consisted of 38 stakeholders representing the following entities:

- Apex Clean Energy
- Black Hills
- Buckyball Systems
- Colorado Energy Office
- Colorado Springs Utilities
- Dietze and Davis, P.C.
- Juwi
- Independent Transmission Company
- Invenergy
- New Law Group
- Orion Renewable Energy Group
- Platte River Power Authority
- Savion Energy
- State of Colorado – Office of Consumer Counsel
- State of Colorado – Public Utilities Commission
- Tradewind Energy
- Tri-State Generation & Transmission
- Western Area Power Administration
- Xcel Energy

Meetings were held on:

- February 6, 2019
- March 7, 2019
- April 4, 2019

- June 6, 2019
- June 27, 2019
- July 30, 2019
- September 12, 2019

Prior to the March 2019 meeting, four stakeholders submitted transmission alternatives for consideration. The LFRTF addressed the stakeholder comments during the course of the study process, which was documented in meeting notes.

The LFRTF stakeholders evaluated numerous alternative proposals and agreed to perform technical analysis of the following 14 standalone alternatives:

1A. New 345 kV line from Burlington to Shortgrass to Big Sandy to Story to Pawnee Substation
1B. Alt 1A without Big Sandy Substation interconnection
2. New 345 kV line from Cheyenne Ridge to Burlington to Big Sandy to Missile Site Substation
3A. New 345 kV line from Missile Site to Cheyenne Ridge to Wray to Story to Pawnee Substation; Replace Burlington-Lamar 230 kV Project with New 345 kV line from Cheyenne Ridge to Lamar Substation; New 230 kV line from Cheyenne Ridge to Burlington Substation
3B. Alt 3A without Wray Substation interconnection
4A. New 345 kV line from Missile Site to Burlington to Wray to Story to Pawnee Substation; Replace Burlington-Lamar 230 kV Project with New 345 kV line from Burlington to Lamar Substation
4B. Alt 4A without Wray Substation interconnection
5. New 345 kV line from Lamar to Midway Substation
6. New 345 kV line from Lamar to Comanche Substation
7A. New 345 kV line from Badger Hills to Lamar to Boone Substation; Replace Burlington-Lamar 230 kV Project with New 345 kV line from Cheyenne Ridge to Lamar Substation; New 230 kV line from Cheyenne Ridge to

Burlington Substation; Sectionalize Comanche to Daniels Park 345 kV line #1 or # 2 at Badger Hills Substation

7B. Alt 7A without New 345 kV line from Lamar to Boone 345 kV

8A. New 345 kV line from Badger Hills to Lamar to Boone Substation; Sectionalize Comanche to Daniels Park 345 kV line #1 or # 2 at Badger Hills Substation

8B. Alt 8A without New 345 kV line from Lamar to Boone 345 kV

9. New 345 kV line from Badger Hills to Lamar to Boone Substation; Sectionalize Comanche to Daniels Park 345 kV line #1 or # 2 at Badger Hills Substation; New 345 kV line from Lamar to Cheyenne Ridge Substation

The LFRTF stakeholders evaluated the standalone alternative results and agreed to perform technical analysis of the following twelve combined alternatives:

Alt 3A + 5
Alt 3B + 5
Alt 3A + 7A
Alt 3A + 7B
Alt 3B + 7A
Alt 3B + 7B
Alt 4A + 5
Alt 4B + 5
Alt 4A + 7A
Alt 4A + 7B
Alt 4B + 7A
Alt 4B + 7B

Meetings to review and approve a draft study report are forthcoming. All supporting documentation including meeting agendas, presentations, and notes are accessible from the CCPG – Lamar Front Range Task Force website located at:

http://regplanning.westconnect.com/ccpg_lamar_tf.htm

Energy Storage and Non-wires Alternatives Working Group

As the Companies' strive to reduce carbon emissions, it is recognized that future challenges will require leveraging a portfolio of innovative technologies to support the Companies' goals of a cleaner and more reliable bulk electric system. As a part of this effort, Public Service has initiated and established the Energy Storage Work Group (ESWG) within the Colorado Coordinated Planning Group (CCPG). ESWG will analyze the performance and integration of such systems to identify benefits and challenges for energy storage and other non-wire alternative technologies. The ESWG will evaluate these technologies and develop recommendations for consideration of CCPG and stakeholders. Recommendations will focus on the integration of energy storage resources into the bulk electric system as well as non-wire alternative technologies to address capacity needs and reliability constraints as they relate to the bulk electric system. The ESWG aims to accomplish these goals by assembling resources from the various members of the CCPG as well as external subject matter experts as needed.

The ESWG held its first meeting on January 23, 2020. Several meetings will be scheduled through the remainder of the year as need.

VII. 10-Year Transmission Plan Compliance Requirements

A. Efficient Utilization on a Best-Cost Basis: Rule 3627(b)(I)

Each Company endeavors to conduct transmission planning with the goal of achieving best-cost solutions that balance numerous factors and result in optimal transmission projects. Rule 3627(b)(I) defines “best-cost” as “balancing cost, risk and uncertainty and includes proper consideration of societal and environmental concerns, operational and maintenance requirements, consistency with short-term and long-term planning opportunities, and initial construction cost."

The Companies recognize that a project that is financially impractical will experience difficulty in gaining support from the Commission, customers, shareholders in the case of Black Hills and Public Service, and members in the case of Tri-State. However, cost is not the only consideration when selecting and developing transmission projects. The Companies take a number of factors into consideration when planning the long-term build-out of the transmission system, including but not limited to the following:

- Load projections
- Project partnership opportunities
- Regional congestion
- Transportation corridors
- Transmission corridors
- City and county zoning
- Geographic features
- Societal and environmental impacts
- Operational and maintenance requirements
- Consistency with short-term and long-term planning opportunities
- Initial construction cost

The impact each factor has on a particular project varies based on the nature of the project. Nevertheless, each factor is considered to some extent during the planning stage.

Take the fairly broad environmental and societal concerns factor, for example. As its name implies, this factor considers how a project relates to the natural environment and the public in general – both positively and negatively. In the context of transmission planning, this usually means:

- The negative effects to the local environment from constructing a new transmission line or substation.
- The net positive impact to the environment of constructing a particular new transmission facility as an alternative to a different project over a more sensitive area.
- The positive impact to the environment of utilizing existing transmission corridors or upgrading existing facilities rather than constructing new ones.
- The positive impact to the environment and society if a project gives transmission customers access to a more diverse mix of generation resources, which can potentially reduce overall emissions and energy costs.
- The positive impacts to society by providing stable and reliable electricity. This is particularly important in rural areas where a single transmission outage has the potential to de-electrify entire regions.

For example, a planner may determine, by inspection, that a certain alternative is not practical because it would require a new transmission line over sensitive or exceptionally rugged terrain. This occurred in the CCPG San Luis Valley Subcommittee. The Subcommittee was tasked with evaluating the performance of alternatives to improve several deficiencies in the San Luis Valley transmission system, the biggest deficiency being that a single line outage can cause widespread outages to customers served by Public Service and Tri-State in Saguache, Mineral, Rio Grande, Alamosa, Costilla, and Conejos counties. One proposed alternative was to add a second 230 kV line to the

San Luis Valley from either Montrose or Pagosa Springs. Electrically speaking, a new transmission line from either of these sources would likely improve reliability in the San Luis Valley. However, the Subcommittee declined to analyze them in part because these alternatives would require the construction of new transmission lines across rugged mountainous regions. Given the potential costs, environmental impacts, and permitting and construction challenges, it was decided these alternatives did not justify the effort required to model and analyze them. More information on the work of the CCPG San Luis Valley Subcommittee can be found in the Colorado Coordinated Planning Group San Luis Valley Subcommittee report in Appendix M.

Operational and maintenance concerns also are considered in the planning process. These factors include things such as:

- Spare equipment strategies, particularly for equipment that if failed, would take longer than six months to replace.
- The ability of the system to allow maintenance outages of lines and transformers.
- The capability of the system to accommodate required and increased demands on limited transmission path transfer limits.
- The capacity of the system to allow generators to output their full energy without operating restrictions or operating procedures (congestion).
- Increasing system robustness so that the use of load shedding, special protection, and cross tripping schemes can be minimized.

For example, operational and maintenance concerns were considered by the CCPG Northeast Colorado Subcommittee in its 2017 Northern Greeley Area Transmission Plan System Impact Study Report. The study focused on improving the Greeley area 44kV transmission system, which is antiquated and operated in a mostly radial fashion. The Subcommittee proposed and evaluated several potential transmission projects to improve system reliability and maintenance of the transmission system in the Greeley area. More information on this study can be found in the Northern Greeley Area Transmission Plan System Impact Study Report included in Appendix N.

Good transmission planning requires that alternatives be evaluated in the context of short-term and long-term planning opportunities as well. In planning vernacular, this means considering:

- The relative ability of transmission alternatives to serve more loads, whether it is in the near-term or long-term planning horizon;
- The capability of new transmission alternatives to allow the injection and export of new generation resources; and
- The manner in which transmission alternatives align with longer-term transmission strategies.

The CCPG Northeast Colorado Subcommittee explicitly considered each of these factors in the 2017 Northern Greeley Area Transmission study. Voltage Stability ("P-V") analysis was performed for each studied alternative to compare its relative strength. This type of analysis is a common way to consider the relative ability of various transmission alternatives to serve future loads. The Northern Greeley Area Transmission Study considered the ability of each alternative to allow new resources out of the Greeley area and each alternative's ability to align with a longer-term area transmission plan known as the Southwest Weld Expansion Project located to the south of Greeley.

In general, a primary method of identifying and addressing many of the planning factors is through stakeholder participation in the planning process. Since planning is one of the initial stages of transmission project development, a preliminary evaluation of the aforementioned factors is typically performed as a screening process, with progressively more meaningful, in-depth evaluation occurring through the siting, permitting, and construction stages of development.

Adherence to best-cost principles is formally reflected by each Company in its internal policies. For example, Tri-State policy requires careful consideration of:

- Cost comparison of alternatives for providing capacity to serve load
- The use of existing delivery points and sub-transmission system
- Early construction of other delivery points planned by the member and/or neighboring utilities
- Alternate locations for the new delivery point
- Possible augmentation of the distribution system in lieu of transmission facility construction

The Companies perform an economic feasibility study of the best alternatives using the "single-entity concept," taking into consideration the total costs to the lead Company, as well as other affected utilities or member cooperatives. During the economic study, the following criteria are evaluated:

- Electrical performance of existing and proposed facilities, to include voltage drop, power flow, and losses
- Estimated capital and annual costs
- Wheeling costs
- Reliability
- Environmental considerations
- Coordination with other transmission providers' long-range transmission plans

In addition, the Companies incorporate "best cost" considerations through their interactions with various federal, state, and local regulatory bodies. Among other requirements, FERC has imposed planning requirements on utilities through its Order No. 890 and Order No. 1000, both of which include considerations consistent with Rule 3627's "best cost" approach. These FERC requirements are discussed further below.

All of the Companies participate in Commission dockets and initiatives, spending significant time and resources for Notices of Proposed Rulemaking, outreach efforts, meetings with Commission Staff and actively participating in initiatives in which the Commission has expressed interest. In addition, the Companies participate with Commission staff in the development of the conceptual long-range plans for Colorado's electric transmission infrastructure. The Companies individually meet with representatives of the Colorado Energy Office ("CEO") and take into consideration CEO's suggestions. The Companies also meet with local governmental officials. These meetings transcend simple permitting requests and consider factors such as the economic development aspirations of the communities, cultural concerns of communities, and the environmental aspects of transmission infrastructure expansion contemplated in various regions.

B. Reliability Criteria: Rule 3627(b)(II)

The Energy Policy Act of 2005 ("EPAct") amended the Federal Power Act ("FPA") to create mandatory electric reliability standards for the U.S. bulk power system. In compliance with these federal laws, FERC certified NERC as the electric reliability organization responsible for developing and enforcing the mandatory reliability standards authorized by the EPAct. NERC also utilizes delegation agreements with regional reliability organizations, such as WECC. Various mandatory reliability standards relating to bulk power system planning, operations, and maintenance have been implemented by NERC and WECC as a result of the EPAct with the potential for fines of up to $1 million per day for serious violations that could impact the integrity of the bulk power system.

The NERC Reliability Standards can be found at NERC's website.
www.nerc.com/pa/stand/Pages/default.aspx

The WECC TPL Standards can be found at WECC's website.
www.wecc.biz/Standards/Pages/Default.aspx

Each of the Companies take NERC and WECC compliance extremely seriously and stringently adhere to all applicable standards and criteria. Additional information concerning each Company's reliability compliance efforts is provided below.

1. *Black Hills Reliability Criteria*

On top of NERC and WECC requirements, the following additional guidelines are utilized in the planning process for determining acceptable levels of service for the Black Hills service territory:

- Transmission line loadings should not exceed 100 percent of continuous seasonal rating or the established equipment or operating limits.
- Transformer loading under system intact conditions should not exceed 100 percent of the normal rating.
- Transformer loading under contingency conditions should not exceed 100 percent of the emergency rating.
- Transmission bus voltage levels during normal conditions will be maintained between 0.95 p.u. and 1.05 p.u. of nominal system voltage.
- Transmission bus voltages during contingency conditions will be maintained between 0.90 p.u. and 1.1 p.u. of nominal system voltage.
- Following a disturbance, all machines in the system shall remain in synchronism as demonstrated by their relative rotor angles for all Category P1 contingencies.
- A generator that pulls out of synchronism in the simulation shall not result in the tripping of any additional transmission facilities.
- If a machines maximum relative rotor angle swing exceeds or equals 16 degrees any time two seconds after the fault has cleared, the damping shall be greater than 3% as defined by:

$$\%\,Damping = \frac{\ln\left[\frac{1st\ Cycle\ Peak - 1st\ Cycle\ Min}{Final\ Cycle\ Peak - Final\ Cycle\ Min}\right]}{Cycle\ Count * 2\pi} * 100$$

- For events where the maximum machine relative rotor angle swings are within a 16 degree window are assumed adequately damped

Additional details on the reliability criteria observed by Black Hills are provided on pages 15-18 of the Black Hills Open Access Transmission Tariff ("OATT") Attachment K Methodology, Criteria, and Process Business Practices document, available in Appendix L.

2. *Tri-State Reliability Criteria*

In addition to complying with NERC and WECC standards and criteria, Tri-State observes its own set of internal criteria for planning studies. Tri-State performs an annual assessment of its regional interconnected transmission system elements utilizing simulation modeling cases created by WECC members. This annual assessment takes into account Tri-State's members in four states, with associated projects located in Colorado included in this plan.

The modeling cases selected represent projected loads and transmission system topology for the year one through five horizon and the year six through ten horizon. These cases are selected to demonstrate system performance covering a range of forecasted demand levels and the most critical system conditions and study years. This analysis examines heavy and light loading scenarios, typically in cases modeling year one, year five, and year ten, unless other factors, such as known major system changes, dictate selection of another year. Cases created by WECC ensure that all projected firm transfers and established normal (pre-contingency) operating procedures are modeled, as well as existing and planned reactive power resources.

The transmission system is analyzed considering the planned projects for each utility in the study area. This assessment includes one or more current or past studies, which together address the entire Tri-State area of service.

Additional information concerning Tri-State's reliability criteria is available in its Engineering Standards Bulletin and is updated periodically. The most current version at the time of this filing can be found in Appendix M.

3. *Public Service Reliability Criteria*

In addition to fulfilling NERC and WECC standards and criteria, Public Service observes internal company criteria for planning studies. The most recent internal criteria can be found in Appendix N.

C. Legal and Regulatory Requirements: Rule 3627(b)(III)

Per Rule 3627(b)(III), “Each ten year transmission plan shall demonstrate compliance with…[a]ll legal and regulatory requirements, including renewable energy portfolio standards and resource adequacy requirements.” The following sections provide information concerning each Company's compliance with such legal and regulatory requirements.

1. Black Hills Legal Requirements

Black Hills’ portion of the 2020 Plan complies with all applicable NERC and WECC reliability standards, as well as other applicable legal and regulatory requirements, including the Colorado RES. For information on resource planning, for both resource adequacy and RES statutory compliance, please refer to the most current Proceeding 16A-0436E as follows:

Proceeding No. 16A-0436E

- Resource Planning, ERP - Phase I 2016 and Phase II 2017

  Black Hills' 2016 ERP was docketed at the Colorado Public Utilities Commission in Proceeding No. 16A-0436E. The Company's ERP application was filed on June 3, 2016, pursuant to Commission rules and the RES codified at C.R.S. § 40-24-124.

  The ERP covered a Planning Period of 25 years from January 2016 through December 2040, and a Resource Acquisition Period of seven years from January 2016 through December 2022. The Planning Period pertains to ERP Phase I, a Commission determination of resource need. The Resource Acquisition Period pertains to ERP Phase II, a competitive solicitation for resource acquisition.

  On January 17, 2017, Recommended Decision No. R17-0039 was entered for Phase I and became a decision of the Commission by operation of law. The decision adopted a settlement agreement filed on November 10, 2016. The settlement agreement modified certain terms of the Company's ERP application. Specifically, the settlement agreement approved, in pertinent part, a resource need of up to 60 MW from RES-eligible energy resources for commercial operation in 2019. The 60 MW will enable the Company to comply with the 30% RES requirement in 2020. Standalone REC bids, to fulfill the 60 MW resource need, were not allowed under the settlement agreement. The settlement agreement approved evaluation criteria for utility-owned resource bids. Finally, the settlement agreement stipulated a timeline for Phase II to ensure that federal production tax credits can be advantaged for eligible bids.

  A Phase II competitive solicitation for 60 MW of eligible energy resources was conducted by the company on June 23, 2017. The Company received over 100 individual bids from multiple project developers for

eligible energy resources from wind, solar PV, and other resources. An independent evaluator was retained (Accion Group) to observe the Company's bid solicitation and evaluation process, and report findings. Based on the evaluation process, Bid 1117-1 was ranked the highest overall, including both economic and noneconomic evaluation criteria. Economic criteria identified Bid 1117-1 with the lowest NPVRR and the most avoided cost savings of all the bids offered in the Company's solicitation.

Bid 1117-1 is a PPA for 60 MW supplied by a wind facility located in Huerfano and Las Animas counties. The output of approximately 201,500 MWh of energy and renewable energy credits annually will enable the Company to comply with the 30% RES beginning in 2020. The awarded Bid 1117-1 will be online for commercial operation no later than December 31, 2019.

- RES Compliance Plan, 2018-2021

  The settlement agreement in ERP Proceeding No. 16A-0436E approved acquisition of on-site solar photovoltaic ("PV") and community solar garden ("CSG") resources for RES compliance.

  The PV capacity is established at 1,500 kW per year for the compliance period, 2018-2021. The settlement agreement stipulated categories for PV system sizes and incentive levels.

  The CSG program was defined in the settlement agreement to be comprised of two RFP offerings by the Company based on the type of subscribers. Each year, the Company will solicit and award up to 500 kW of CSGs for 100% low-income subscribers and up to 2,000 kW of CSGs for open subscribers. The settlement agreement stipulated 0 kW as the minimum purchase amount and 2,500 kW as the maximum purchase

amount from CSG installations each compliance year, 2018-2021. The Company expects that 15.12 MW of CSGs will operate by end of 2021.

2. Tri-State Legal Requirements

Tri-State's 2020 Plan complies with all applicable NERC and WECC reliability standards, as well as other applicable legal and regulatory requirements including Company and member compliance with the Colorado RES.

For the period 2015 through 2019, the Colorado RES requires that 6 percent of Tri-State's Member Systems' retail energy sales be served by renewable generation, growing to 20 percent in 2020 and beyond. In addition, as a qualifying wholesale utility, the Colorado RES requires Tri-State to generate or cause to be generated at least 20 percent of the energy it provides to its Colorado Member Systems at wholesale from eligible energy resources in the year 2020 and thereafter. As the wholesale power provider for its Member Systems, Tri-State's 2020 Plan is developed to ensure that the necessary transmission system capabilities will be in place to meet both its Colorado Members Systems' and its own RES requirements.

For additional information on resource adequacy requirements and resource requirements to meet the RES, please refer to Tri-State's Integrated Resource Plan/Electric Resource Plan and Electric Resource Plan Annual Progress Reports available in Appendix M.

As discussed previously, Tri-State may be subject to federal and state regulations related to carbon emission reductions from existing power plants, such as the regulations that will be promulgated pursuant to Colorado HB 19-1261. While no such regulations have been promulgated as of the date of this 10-Year Plan, Tri-State anticipates that such regulations may be promulgated within the next two years and, if so, will address them in the next 10-Year Transmission Plan. Tri-State also notes that, since it operates an interconnected, interstate transmission system,

its transmission system may be impacted as a result of federal compliance and carbon emission reduction plans enacted in other states in which Tri-State operates.

3. Public Service Legal Requirements

Public Service's 2020 Plan complies with its currently operative ERP, approved by the Commission in Proceeding 16A-0396E in its Phase II decision, C18-0761. Additional information on Public Service resource adequacy and compliance with Commission rules related to ERPs is available at:
https://www.xcelenergy.com/company/rates_and_regulations/resource_plans

Public Service's 2020 Plan additionally complies with its currently operative RES Compliance Plan approved by the Commission as modified by settlement in Decision C16-1075 in Proceeding 16A-0139E. [5] Public Service's 2020 Plan also complies with the specifications set forth in its 2020-2021 RES Compliance Plan, filed in Proceeding 19A-0369E, and currently under Commission consideration.

Information on Public Service compliance with RES requirements is available at:
https://www.xcelenergy.com/company/rates_and_regulations/filings

D. Opportunities for Meaningful Participation: FERC Order No. 890

In addition to the CCPG planning processes, each of the Companies has its own FERC Order No. 890 stakeholder process as described below. For additional information on stakeholder involvement pertinent to Rule 3627, please refer to Section VI.

[5] Public Service's 2017-2019 RES Compliance Plan was subsequently extended through the first quarter of 2020 by Decision R19-0807 in Proceeding No. 19A-0369E.

1. *Black Hills Participation Strategy*

For Black Hills, the FERC Order No. 890 Stakeholder Process is included in its Attachment K to its Open Access Transmission Tariff ("OATT"), which is included in Appendix L of this document. Additional information concerning Black Hills' FERC Order No. 890 processes can also be found in Appendix L.

2. *Tri-State Participation Strategy*

Attachment K to Tri-State's OATT demonstrates Tri-State's transmission planning processes consistency with FERC Order No. 890 planning principles. As discussed previously in this 2020 Plan, all projects included herein have been identified and developed through Tri-State's transmission planning process.

Attachment K to Tri-State's OATT can be updated periodically, and is available on Tri-State's OASIS at:
http://www.oasis.oati.com/tsgt/index.html

The most current version at the time of Attachment K is located in Appendix M.

3. *Public Service Participation Strategy*

For Public Service, the FERC Order No. 890 stakeholder process is included in the Xcel Energy Joint OATT Attachment R, available at the following website:
https://www.oasis.oati.com/woa/docs/PSCO/PSCOdocs/PSCo_Attachment_R_5-5-2020.pdf
Additional information concerning the Public Service FERC Order No. 890 processes can be found at:
http://www.oatioasis.com/psco/index.html under "FERC 890 Postings".

E. Coordination Among Transmission Providers: FERC Order No. 1000

In July 2011, FERC issued a final rule related to transmission planning and cost allocation, FERC *Order 1000, Transmission Planning and Cost Allocation by Transmission Owning and Operating Public Utilities* ("Order 1000"). This order builds on planning principles already established in FERC Order No. 890, as previously discussed. FERC Order No. 1000 requires that transmission owning and operating public utilities:

1) Participate in a regional transmission planning process that produces a regional transmission plan.
2) Amend their OATT to describe procedures that provide for the consideration of transmission needs driven by public policy requirements in the local and regional transmission planning processes.
3) Remove from Commission-approved tariffs and agreements a federal right of first refusal for certain new transmission facilities.
4) Improve coordination between neighboring transmission planning regions for interregional transmission facilities.
5) Participate in a regional transmission planning process that has a regional cost allocation method for the cost of new transmission facilities selected in a regional transmission plan for purposes of cost allocation.
6) Participate in a regional transmission planning process that has an interregional cost allocation method for the cost of certain new transmission facilities that are located in two or more neighboring transmission planning regions and are jointly evaluated by the regions.

WestConnect is one of four planning "regions"[6] within WECC established for regional transmission planning to comply with Order 1000. Public Service and Black Hills have designated WestConnect as their Order 1000 compliant planning regions. Tri-State has joined WestConnect as a coordinating transmission owner, which means it is not subject to all of the requirements under Order 1000 such as accepting binding cost allocation for regional transmission projects. The WestConnect planning process is described in Black Hills' and Public Service's OATTs (Attachment K and R respectively; links are provided above) as well in documentation found on the WestConnect website (http://www.westconnect.com/). The WestConnect website also houses information and announcements for many public planning meetings. WestConnect accepts stakeholder input throughout the planning process.

WestConnect develops a regionally coordinated transmission plan that begins with the determination of regional reliability, economic and public policy needs. The more cost-effective or efficient solutions to meet identified regional needs are included in the regional plan. These regional projects may be new projects in addition to the projects developed through the local or sub-regional planning processes or may replace local projects in some instances. If WestConnect determines Colorado utilities benefit from a regional project, then those Colorado utilities may be responsible for a portion of the cost of the regional project.

Additionally, WestConnect coordinates with the other western Order 1000 planning regions. This coordination also is described in Black Hills' and Public Service's planning attachments to their respective OATTs.

[6] The other three are Columbia Grid, Northern Tier Transmission Group, and the California Independent System Operator.

VIII. 10-Year Transmission Plan Supporting Documentation

A. Methodology, Criteria, & Assumptions

1. *Facility Ratings (FAC-008-3)*

NERC Reliability Standard FAC-008-3 requires that transmission and generation owners document the methodology used to develop ratings of their equipment. The standard requires that the transmission or generation owner supply its methodology to specific NERC registered entities upon request. FAC-008-3 also requires transmission and generation owners to establish facility ratings per the methodology established through FAC-008-3. Each transmission and generation owner has documented ratings for each of its facilities. The standard requires the transmission or generation owner to supply its facility ratings to specific NERC registered entities (i.e. associated Reliability Coordinator(s), Planning Authority(ies), Transmission Planner(s), and Transmission Operator(s)) upon request. These documents are not publicly available and are not required to be per NERC standards. NERC Reliability Standard MOD-032-1 requires applicable entities to provide equipment characteristics, including established facility ratings, to NERC and WECC according to established reporting requirements. This is accomplished through the WECC Base Case Compilation Schedule as prescribed by the Data Preparation Procedural Manual.

a. Black Hills Ratings

Documentation of Black Hills' FAC-008-3 methodology is available in Appendix L.

b. Tri-State Ratings

Documentation of Tri-State's Facility Rating's methodology is available in its Engineering Standards Bulletin. The most current version of Tri-State's

Engineering Standard's Bulletin at the time of this filing can be found in Appendix M.

c. Public Service Ratings

Documentation of Public Service FAC-008-003 methodology can be found in Appendix N.

2. *Transmission Base Case Data: Power Flow, Stability, Short Circuit*

The Companies utilize transmission system power flow and transient dynamics modeling data prepared by WECC. Through its Annual Study Program, WECC facilitates the preparation of at least 10 models per year. The models represent a variety of system conditions out to a 10-Year planning horizon. WECC's 10-Year Regional Transmission Plan is an Interconnection-wide perspective on: 1.) expected future transmission and generation in the Western Interconnection, 2.) what transmission capacity may be needed under a variety of futures, and 3.) other related insights.

WECC members participate in the data preparation process for the models and Public Service coordinates the data for the Rocky Mountain region. Prior to being used for planning studies, the models are reviewed and adjusted to reflect the most current and accurate system elements, ratings, and operating conditions for the region to be studied. Short circuit data is coordinated between neighboring TPs as needed and periodically coordinated at the CCPG level.

Instructions for obtaining access to WECC base cases are as follows:

a. An organization requesting WECC base case(s) must either be a WECC member or they must execute the "Nonmember Confidentiality Agreement for WECC Data."

b. Non-members may obtain the confidentiality agreement from WECC by requesting the agreement from a WECC Stakeholder Services representative.

The submission must include a statement from the organization explaining why they have a legitimate business need for the WECC base case(s).

B. Load Modeling

Pursuant to each Company's OATT, network customers are required to submit 10-Year projected network loads and network resources by October 1 of each year. This information is then compiled with existing data and information to provide a basis for identification of the minimum transmission system enhancements required to ensure that a sufficiently robust transmission system is in place to meet all network customer requirements under all scenarios.

1. *Forecasts*

The Companies rely on the most recent and accurate load forecasts when developing system planning models. General load forecast assumptions are posted on each transmission provider's Company or OASIS site.

a. Black Hills Forecasts

In 2016, Black Hills filed with the Commission its latest ERP, which included details on expected customer growth based on load forecast information submitted annually by network customers. The ERP, in conjunction with the network customer forecast updates, is used in the development of Load and Resource ("L&R") reports submitted to WECC on an annual basis. Once the L&R report is developed, this forecast is disaggregated to the respective transmission system load buses. There are two types of load buses: (1) a load bus where the

load does not change over time (e.g. a single large industrial load bus); and (2) a load bus where the load changes over time (e.g. a residential load). Black Hills uses its knowledge of load characteristics along with historical loading observations to estimate the individual load bus data in time. The load bus forecasts are summed and compared to the WECC L&R report aggregate load forecast. If the two forecasts do not match, the variable bus load forecasts are adjusted until the two forecasts match. Through this procedure, the WECC L&R reports, including the assumptions in the latest ERP, are reflected in the transmission planning models used within the WECC footprint. Deviations from the ERP load forecast are commonplace in transmission studies depending on the purpose of the planning analysis being performed and the study scenario of interest. The load assumptions included in the planning model are typically specified within each planning study report for reference.

Details related to Black Hills' load forecast can be found in Black Hills' 2016 ERP in Colo. Consolidated Proceeding No. 16A-0436E; specifically, Attachment LS-1 included in Appendix L of this report.

b. Tri-State Forecasts

General load forecast information is available on Tri-State's OASIS at:
http://www.oasis.oati.com/tsgt/index.html
The Load Forecast Descriptive Statement available at the time of this filing is located in Appendix M.

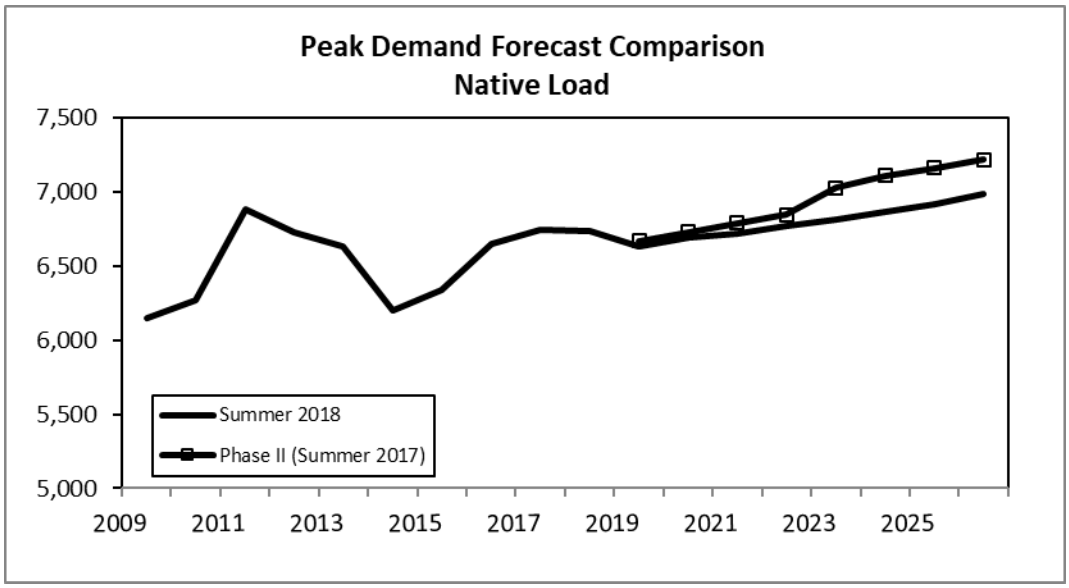
Tri-State prepares load forecasts on a system-wide and regional basis with regional forecasts used for resource planning purposes. Tri-State receives load forecasts from its network customers by October 1 of each year. These loads are modeled as required for inclusion in the planning models developed in conjunction with neighboring entities.

Tri-State's most recent transmission plans utilize 2018 load forecast data. Base forecast data for these plans is available in Appendix A of Tri-State's ERP/APR, located in Appendix M.

c. Public Service Forecasts

The load forecast used in this filing is the Summer 2018 PSCo Load Forecast, which was provided publicly in the Company's 2016 Electric Resource Plan Annual Progress Report filed dated October 31, 2018 (Proceeding No. 16A-0396E) and the PSCo Load Forecast that was provided publicly in the Company's 2016 Electric Resource Plan Modeling Assumptions Update filed in August 2017. The following figure shows a comparison between the two forecasts. The drivers of the changes in the forecast are discussed in Appendix N. The Company notes that while it has developed more recent load forecasts (e.g., as provided in the Company's 2016 Electric Resource Plan Annual Progress Report dated October 2019 filed in Proceeding No. 16A-0396E and in Proceeding No. 19A-0409E), the Summer 2018 forecast was the most current publicly available forecast at the time the Company began the analysis and preparation of this Rule 3627 Report.

Figure 8. Public Service Historic and Forecast Demand



In addition to native load forecasts, Public Service receives forecasts from its wholesale customers, which it incorporates into the overall forecast. Transmission planners allocate the loads on a substation-by-substation basis, based on historical trends. Additional information is included in Appendix N.

2. *Demand-Side Management*

The effects of Demand-Side Management ("DSM") program savings are typically taken into account within the load forecasts described previously. Within the context of power system modeling, DSM is simply reflected in the power flow model as reduced load and therefore included in planning studies.

a. Black Hills DSM

Details related to the effects of DSM savings estimates on Black Hills' load forecast can be found in the 2016 Black Hills ERP; specifically, Attachment LS-1, which is included in Appendix L of this document.

b. Tri-State DSM

Load forecasts provided for bulk electric transmission planning typically include existing DSM and other load-reducing programs, including member energy efficiency programs and local distributed generation. These programs are reflected in the power flow model as reduced load and are inherently included in studies. For transmission planning, load forecasts that contain load-reducing factors may be used for specific projects or for individual Tri-State members with DSM, local distributed generation, or other energy efficiency programs. For such cases, please refer to individual project planning studies. For Tri-State's system load forecast, these are described in Tri-State's 2018 Annual Progress Report to the 2015 ERP found at:
https://www.tristategt.org/resource-planning

c. Public Service DSM

Public Service accounts for DSM through reduction in its load forecast based, in part, on the goals established by the Commission. Additional information is included in Appendix N.

C. Generation and Dispatch Assumptions

Generator and associated equipment models are typically included in the WECC Annual Base Case Compilation Schedule base cases as required by the Data Preparation Manual. The detail of generation models utilized within planning studies can vary depending on the nature of the study. For example, a Large Generator Interconnection study for a wind facility may explicitly model each individual wind turbine and the associated collector system to properly assess the low voltage ride through capabilities of the facility. That same facility may be modeled as a single equivalent wind turbine with an equivalence collector system within a long-range planning study where the

performance of individual wind turbines is not a concern. The scope of the technical study will influence the level of detail that is modeled.

1. *Black Hills Assumptions*

At the most basic level, Black Hills dispatches existing generation to meet the demand requirements of its system, including load and losses. The objective of a particular study often drives the individual generator dispatch levels. For example, a peak demand summer baseline scenario may consist of a majority of dispatchable baseload generation online and an appropriate mix of wind and solar PV to meet the demand requirements. An off-peak demand spring or fall scenario may have the available wind generation dispatched at its nameplate capacity with the dispatchable baseload generation and solar generation reduced to capture the impacts of that particular dispatch pattern. Existing power purchase agreements and other contractual arrangements may be reflected in certain study scenarios to further stress the transmission system. Black Hills also may include speculative generation (as identified in the current version of the Black Hills Colorado Electric Generation Interconnection Request Queue, included in Appendix L) in certain transmission studies as dictated by the study objective. Additionally, existing and/or conceptual generation may be dispatched beyond the demand requirements of the study case to facilitate a net export of energy from the study area. A listing of existing and planned resources utilized in planning studies is typically included in each specific study report.

2. *Tri-State Assumptions*

Tri-State's transmission planning function receives generation assumptions from its network customers--Tri-State Power Management, Arkansas River Power Authority (“ARPA”), Municipal Electric Agency of Nebraska (“MEAN”), Raton Public Service Company (“City of Raton”), Public Service Company of Colorado (“PSCO”), Kit Carson Electric Cooperative (“KCEC”) and Public Service Company of New Mexico

("PNM")--annually by October 1. These generation assumptions are utilized to ensure a sufficiently robust transmission system to meet network customers' needs over a 10-Year planning horizon.

Generation assumptions, including dispatch assumptions, and corresponding data for other transmission plans are project-specific. Therefore, the individual transmission studies should be referenced for generation assumptions relative to each such project.

3. Public Service Assumptions

Public Service transmission planning models reflect generation dispatch based on internal procedures that take into account production costs, maintenance schedules, and other factors. Procedures include:

- Modeling of generator planned outages with outage period of 6 months or more
- In general, if not needed to meet load requirements, high production cost generation plants are modeled out of service. If resources are needed, these units may be modeled
- Public Service combustion turbine generators are typically modeled at or near full output
- Public Service large coal-fired plants are typically modeled at or near full output. These units are considered "base loaded", in that they usually operate around the clock if generation adjustments are necessary, these generators are generally adjusted last
- Hydro generation has net dependable seasonal ratings. Each seasonal rating reflects the average generation that can be continuously maintained over the duration of the daily peak period for the respective season. In winter, the daily period is approximately five hours long. All generators on-line should be

producing reactive power ("MVARs"). Generator bus voltage scheduling may be necessary if the generating unit is acting in a condensing mode (consuming MVARs)

- Pumped Hydro generators are modeled appropriately in pumping mode during off peak hours.

Renewable generation, including wind and solar are modeled based on Public Service Variable Energy Resource Dispatch Assumptions. System changes, load transfers, and other topology changes also are coordinated through CCPG.

D. Methodologies

1. *System Operating Limits (FAC-010)*

System Operating Limits ("SOL") is defined in NERC Reliability Standard FAC-010-3 as the responsibility of the Planning Authority ("PA") to ensure reliable planning of the Bulk Electric System. SOL is required to be established per FERC standards but is not required to be publicly available.

a. Black Hills SOL

Black Hills has defined both Operational Criteria, which are limits for typical every day/normal operations, and SOLs, which are limits that are of an emergency nature and must be acted upon promptly to ensure facility ratings are not exceeded. Black Hills' SOLs are communicated to the Southwest Power Pool ("SPP") Reliability Coordinator so that when an SOL is exceeded, the Reliability Coordinator will be aware of the concern and be able to provide assistance in ensuring the SOL violation is removed. Black Hills' SOLs are summarized below:

- BES Transmission Line SOLs are exceeded when the line rating is exceeded.

- BES Voltage SOLs are exceeded when the Emergency Voltage rating is exceeded. The Emergency Voltage is plus/minus 10% of the nominal voltage.
- BES transformer SOLs are exceeded when their loaded MVA is between 100% and 125% of the established FOA Rating for more than 30 minutes, OR, their loaded MVA exceeds 125% of the established FOA Rating for any period of time.

b. Tri-State SOL

Tri-State is not a PA and, therefore, uses the SOL methodology as defined by the applicable PA.

c. Public Service SOL

Public Service has one SOL for the TOT7, which is located north of the Denver metro area. SOLs are required to be established per FERC standards, but are not required to be publicly available. The TOT7 studies are conducted annually. The results of those studies are available upon request.

2. *Available Transmission System Capability Methodology (MOD-001)*

Available Transmission System Capability Methodology is available and posted per NERC Standard MOD-001 at NERC's website.

a. Black Hills TTC

Black Hills utilizes the Rated System Path Methodology for determining Total Transfer Capability ("TTC") and Available Transfer Capability ("ATC") for all Posted Paths and in all ATC time horizons. The determination of TTC is based on the maximum flow of a path while meeting all reliability criteria for single initiating event outages. In the event that the path is flow-limited and a reliability limit

cannot be reached, the transfer capability of the path is set to the thermal rating of the path. For further details on the calculation of transfer capability, refer to Black Hills' ATC Implementation Document ("ATCID") included in Appendix L.

b. Tri-State TTC

Tri-State's TTC path values for jointly owned paths that are interfaces identified and rated through WECC processes and OTC determinations are based upon the Rated System Path Methodology (NERC MOD-29-2a). Tri-State has TTC allocations on WECC rated Paths 30 (TOT1A), 31 (TOT2A), 36 (TOT3), 39 (TOT5), 47 (SNMI), and 48 (NNMI). These paths are studied by the path operator with actual flow levels at the combined path ratings under simulated N-1 scenarios to ensure that the planning reliability criteria are being met. The path participants have previously used studies and negotiations to determine the manner in which the TTC will be allocated to each of the participants.

For jointly owned paths that are not WECC-rated paths, the TPs determine the appropriate combined TTC and the allocation of it is based upon contractual capacity entitlements. This allocation is done outside of any WECC approval process since these are Tri-State TTC/ATCID minor paths that are not part of an interface and do not impact any major recognized WECC paths.

Tri-State utilizes TTC values based upon thermal facility ratings for all flow-limited paths that are owned solely by Tri-State. If the NERC MOD-029-2a requirement R2.1 simulation studies result in sufficient flow ability on a path segment to determine a reliability limit, then the TTC on the ATC path segment is set to the simulated flow corresponding to the reliability limit while at the same time satisfying all planning criteria.

In addition, Tri-State has created many extended ATC paths that are defined by a serial concatenation of rated path segments. The resulting TTC and ATC for

each extended ATC path is based upon the lowest TTC and ATC of all the serial path segments included in each path definition.

The ATCID provides for the documentation of required information as specified in the NERC MOD Standards and the NAESB OASIS Standards regarding the calculation methodology and information sharing of ATC specific to this TP. The ATCID for Tri-State is available on Tri-State's OASIS at: http://www.oasis.oati.com/tsgt/index.html

The ATCID can be updated periodically and the most recent version of the ATCID at the time of this filing can be found in Appendix M.

c. Public Service TTC

The ATCID (MOD-001) for Public Service is available on Public Service's OASIS, by clicking on "ATC Information" and then "ATCID Implementation Document".

The ATCID can be updated periodically, and the most recent version at the time of this filing can be found in Appendix N.

3. *Capacity Benefit Margin (MOD-004)*

Capacity Benefit Margin ("CBM") methodology is available and posted per NERC Standard MOD-004.

a. Black Hills Capacity Benefit Margin (MOD-004)

Black Hills does not implement CBM in the assessment of ATC. The Capacity Benefit Margin Implementation Document ("CBMID") for Black Hills is included in Appendix L.

b. Tri-State CBM

Based on FERC's allowance for TPs to not use CBM, Tri-State does not allow for the use of CBM and, as such, its value is set to zero (0) in the ATC equations for all paths posted by Tri-State. Furthermore, Tri-State's practice is to not maintain CBM. Tri-State will review its CBM practice, at least annually, and will post any changes to the OASIS as needed. The CBMID for Tri-State is available on Tri-State's OASIS, by clicking on "ATC Information" and then "Capacity Benefit Margin Statement (CBMID)".

The CBMID can be updated periodically, and the most recent version at the time of this filing can be found in Appendix M.

c. Public Service CBM

The CBMID for Public Service is available on Public Service's OASIS, by clicking on "ATC Information" and then "CBM Implementation Document (CBMID)".

The CBMID can be updated periodically, and the most recent version at the time of this filing can be found in Appendix N.

4. *Transmission Reliability Margin Calculation Methodology (MOD-008)*

NERC Standard MOD-008-1, Transmission Reliability Margin Calculation Methodology, requires that each Transmission Operator prepare and keep current a Transmission Reliability Margin Implementation Document ("TRMID").

a. Black Hills Transmission Reliability Margin (MOD-008)

A copy of the current TRMID for Black Hills is located in Appendix L.

b. Tri-State TRM

The TRMID for Tri-State is available on Tri-State's OASIS at:
http://www.oasis.oati.com/tsgt/index.html

The TRMID can be updated periodically, and the most recent version at the time of this filing is located in Appendix M.

c. Public Service TRM

The TRMID for Public Service is available on Public Service's OASIS, by clicking on "ATC Information" and then "TRM Implementation Document (TRMID)".

The TRMID can be updated periodically and the most recent version at the time of this filing is located in Appendix N.

E. Status of Upgrades

Projects that constitute upgrades to existing transmission facilities are discussed in Section III of this Plan and the associated appendices.

F. Studies and Reports

Most of the Companies' study documentation can be found by starting at the sections of the WestConnect website that are dedicated to the CCPG:

http://www.westconnect.com/planning_ccpg.php
Additional Company-specific study and reporting resources are described below.

1. Black Hills Reporting

Public access to transmission market information, generator interconnection and transmission service requests, business practices, planning study reports and other topics related to the Black Hills transmission system is provided on Black Hills' OASIS at:

http://www.oatioasis.com/bhct

2. Tri-State Reporting

Planning studies and related reports for Tri-State transmission projects in Colorado are located at Tri-State's website at:

http://www.tristategt.org/transmission-projects

Generator interconnection, transmission service request, and other OATT study reports related to Tri-State's transmission system are provided on Tri-State's OASIS at:

http://www.oasis.oati.com/tsgt/index.html

3. Public Service Reporting

Planning studies and related reports for Public Service transmission projects in Colorado are located at the following links:

https://www.rmao.com/public/wtpp/PSCO_Studies.html
http://www.oatioasis.com/psco/index.html
http://www.transmission.xcelenergy.com/Planning/Planning-for-Public-Service-Company-of-Colorado

G. In-Service Dates

Information concerning the expected in-service date for each utility's facilities identified in the 2020 Plan and the entities responsible for constructing and financing each facility is contained in Table 1, Section III and Appendices A-I.

H. Economic Studies

The purpose of economic planning studies is to identify significant and recurring congestion on the transmission system and/or address the integration of new resources and/or loads. Such studies may analyze any or all of the following: (i) the location and magnitude of the congestion, (ii) possible remedies for the elimination of the congestion, (iii) the associated costs of congestion, (iv) the costs associated with relieving congestion through system enhancements (or other means), and, as appropriate (v) the economic impacts of integrating new resources and/or loads. Economic studies are generally described as being either “local” or “regional” in nature.

1. *Black Hills Economic Study Policies*

Black Hills conducts economic planning studies through the procedures outlined in its OATT Attachment K, which is included in Appendix L.

Black Hills will accept requests for economic studies on an annual basis. Information on making a request is available in the Attachment K Economic Study Request Form, as shown in Appendix L. Upon receiving a valid request for an economic study, Black Hills, with input from its stakeholder committee, will classify the request as local, subregional or regional. Black Hills will engage the appropriate resources to study up to one economic study request that has been classified as local on a biannual basis. All economic study requests that have been classified as subregional or regional will be forwarded to the WECC for inclusion in the appropriate study program. Since the 2018 Rule 3627 filing, Black Hills has not received any economic study requests, nor has it performed any economic studies.

2. *Tri-State Economic Study Policies*

Western Interconnection-wide congestion and economic planning studies are conducted by WECC in an open stakeholder process that holds region-wide stakeholder meetings on a regular basis. The WECC planning process is posted on its website (see http://www.wecc.org/Pages/home.aspx). Tri-State participates in the regional planning processes, as appropriate, to ensure data and assumptions are coordinated. Tri-State did not perform any economic studies this cycle nor were any requested by Tri-State stakeholders.

3. *Public Service Economic Study Policies*

Public Service facilitates priority local economic planning studies for its transmission system, pursuant to the procedures in its OATT Attachment R. Regional economic planning studies shall be performed by WECC, pursuant to procedures posted on the WECC website. Public Service did not perform any economic studies this cycle nor were any requested by stakeholders.

EXECUTIVE SUMMARY

Project Overview

Mesa Point Energy, along with their subcontractor Brightline Group, (collectively the Mesa Point Team or the Team) performed a demand side management potential study in support of Tri-State Generation and Transmission's (Tri-State) resources planning initiatives. The study is intended to assist Tri-State in developing their Integrated Resource Plan (IRP) and Electric Resource Plan (ERP). The Mesa Point Team assessed the available technical, economic, and achievable energy and demand savings potential from energy efficiency (EE), demand response (DR), and behind-the-meter distributed energy resources (DER) from 2021 to 2040 for the electric cooperatives served by Tri-State.

The study focuses on energy efficiency, DR, and DER *achievable* potential; it is not a *program* potential study meaning it does not take into consideration program budget and design constraints. Therefore, the study examines what *could be* (i.e., what savings could accrue from considered cost effective measures) but does not account for structural and organizational limitations inherent and unique to the cooperative utility structure where each member can choose which products and measures to offer.

This Executive Summary presents an overview of the analysis approach, key assumptions, and study findings and the main report report goes into more detail on methods, savings, and findings.

A separate electronic reporting tool serves as an appendix to the report. The tool provides the ability to view findings in greater detail by sector, end-use, and region.

Results by Resource: EE, DR, DER

There are significant opportunities for cost-effective EE and DR savings in the Tri-State service territory. Behind-the-meter DER resources hold significant technical potential but realize limited cost-effective potential based on the analysis framework used for the study.

Given the uncertainty associated with customer adoption of energy-saving technologies, the Mesa Point Team developed achievable scenarios based on four different incentive and program delivery spending levels – from low to maximum levels of program funding.

These scenarios were:

1. Low – assumes incentivizing 25% of incremental cost
2. Moderate – 50% incentive level
3. Aggressive – 75% incentive level
4. Maximum – 100% of incremental cost. Note that maximum funding was assumed to be limited to 100% of the incremental cost to install a measure.

Key findings from each of the three resources assessed, EE, DR, and DER, are summarized below.

Energy Efficiency (EE) Resource

As summarized in Table ES-1, the Mesa Point Team found that the Achievable-moderate scenario would result in approximately 38 GWh (0.25% of sales) of energy efficiency saving in 2021 rising to 1,718 GWh (8.16% of sales) of savings through 2040.

Table ES-1. Portfolio Cumulative Energy Efficiency Savings by Scenario by Time Horizon

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE _MAX	ACHIEVABLE _ AGG	ACHIEVABLE _MOD	ACHIEVABLE _ LOW
Cumulative Energy Savings (MWh)						
2021 (first year)	130,384	98,221	75,523	55,330	38,083	27,043
2025	1,293,033	928,122	539,750	393,656	266,309	179,222
2030	3,868,940	2,851,171	1,372,971	1,062,225	723,605	475,993
2040	9,081,432	6,956,507	2,876,487	2,354,365	1,718,357	1,193,109
% of Baseline Sales						
2021 (first year)	0.85%	0.64%	0.49%	0.36%	0.25%	0.18%
2025	7.88%	5.65%	3.29%	2.40%	1.62%	1.09%
2030	21.74%	16.02%	7.71%	5.97%	4.07%	2.67%
2040	43.14%	33.04%	13.66%	11.18%	8.16%	5.67%

Energy effiency savings potential breakdown shares similarities to energy load in terms of distribution by region and by sector (Figure ES-1 and Figure ES-5). Front Range Colorado has the largest cumulative energy savings potential with 860 GWh. Across all regions, the industrial customer sector has more than 744 GWh of cumulative energy savings potential, followed by the residential sector at just under 600 GWh.

Figure ES-1. 2040 Cumulative Energy Efficiency Savings Potential by Region by Customer Sector (Achievable-Moderate Scenario)

	Eastern Colorado	Front Range Colorado	Mountain Colorado	Western Colorado	Nebraska	Southern New Mexico	Northern New Mexico	Wyoming
Irrigation	29,895	68	-	220	16,315	3,631	2,735	270
Industrial	48,525	363,476	69,968	36,409	7,214	12,277	86,024	120,651
Commercial	32,506	142,190	19,629	49,150	9,063	23,289	29,223	21,334
Residential	23,366	354,282	27,962	72,760	13,675	28,489	33,310	40,453

Table ES-2 summarizes the key cumulative energy efficiency cost metrics across the portfolio at four time horizons under the Achievable-Moderate scenario, as well as 20-year averages across the full study time horizon. It is estimated that over the 20-year study horizon approximately 114 GWh of energy savings is achievable, on average, per year at a cost of $24.3 million for an acquisition cost of $212/MWh. Over the 20 year study horizon, and on a levelized basis, the cost to acquire all energy savings under the Achievable-Moderate scenario is $21.55/MWh.

Table ES-2. Portfolio Energy Efficiency Cost Metrics by Time Horizon (Achievable-Moderate Scenario)

MILESTONE YEAR	TRC RATIO	SUM OF ANNUAL PROGRAM COSTS ($)[1]	SUM OF FIRST YEAR MEASURE SAVINGS (MWH)	FINAL YEAR DEMAND SAVINGS (MW)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	2.08	$6,957,787	38,083	5.28	$182.70	$15.25
2025	1.91	$54,155,251	279,461	9.91	$193.78	$17.41
2030	1.72	$164,148,094	797,374	17.25	$205.86	$20.18
2040	1.64	$486,794,842	2,290,399	23.11	$212.54	$21.55
20-year avg.	**1.64**	**$24,339,742**	**114,520**	13.89	**$212.54**	**$21.55**

Demand Response (DR) Resource

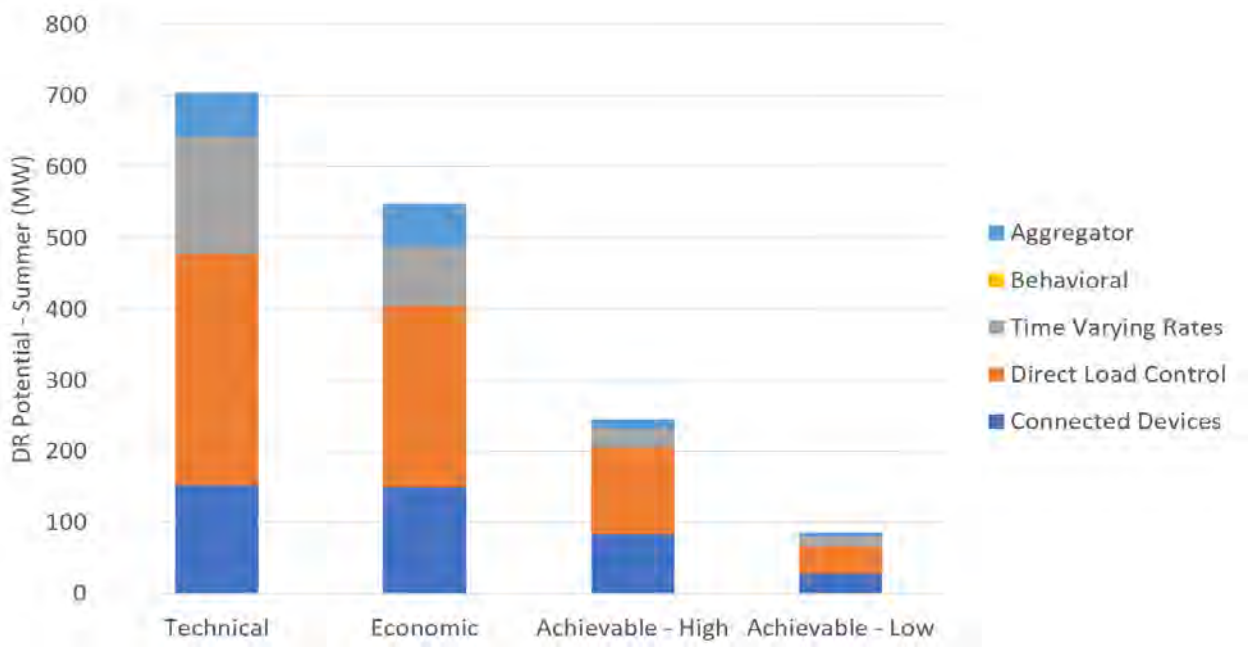
The study considered five different types of DR programs:

1. Aggregator – Capacity bidding programs managed by 3rd party aggregators
2. Behavioral – Personalized communication to customers requesting curtailed usage during peak events
3. Time varying rates – Customer retail electricity rates designed to shift usage by charging more during peak periods
4. Direct load control – Centralized remote control of customer equipment through installation of switches
5. Connected devices – Interaction with and control of internet-connected customer devices through web-based portals (e.g. Bring Your Own Thermostat programs)

Figure ES-2 shows the available DR potential across the portfolio by 2040 by program type. Connected device programs (primarily for Smart Thermostats) and Direct Load Control (DLC) (primarily for irrigation pumping) are the most significant program types.

[1] Includes administrative and incentive costs

Figure ES-2. Portfolio Demand Response Potential by Program Type (2040)



The DR analysis considered two different time-varying rates programs – **Critical Peak Pricing without Enabling Technology** (CPP no tech), and **Time Of Use** (TOU) – in each sector. Because Tri-State does not control customer rates, implementing a CPP or TOU rate demand response programs would require a high level of collaboration with electric cooperatives.

Table ES-3 summarizes the demand response cost metrics across the portfolio at each time horizon under the Achievable-Low scenario. By the end of the 20-year study horizon, the estimated 86 MW of peak demand savings is achievable at a cumulative total cost of $39 million. The Net Present Value TRC ratio of the demand response portfolio is cost effective by the end of the horizon (1.16 TRC), but not cost effective in the more immediate time horizons. This characteristic is largely driven by Tri-State's negligible costs of capacity until 2027.

Table ES-3. Portfolio Demand Response Cost Metrics by Time Horizon (Achievable-Low Scenario)

MILESTONE YEAR	TRC RATIO	CUMULATIVE PROGRAM COST ($)	DR POTENTIAL (MW)
2021	0.02	$5,440,119	5
2025	0.09	$13,818,802	30
2030	0.60	$24,286,062	78
2040	1.16	$39,068,285	86

Distributed Energy Resource (DER)

The Team limited resources for the DER potential study to technologies that are behind-the-meter and owned by the customer; we did not consider market potential for supply-side resources within this assessment. The market potential assessment for DERs focused on solar photovoltaic (PV) systems across Tri-State's region for the period 2021 to 2040. We performed review and preliminary cost screens for other potential DER technologies such as combined heat and power and small wind but ultimately did not find these technologies applicable and/or cost effective.

Overall, solar PV generation has the technical capability of providing over half of Tri-State's sales. However, this value varies considerably by region. Figure ES-3 and Figure ES-4 below illustrate cumulative technically possible PV generation in 2040 compared to cumulative 2040 sales. It is interesting to note that in some areas of New Mexico solar power has the technical potential to produce more energy than is used. New Mexico's PV generation exceeds sales due to a high solar irradiance which improves solar efficiency and relatively low consumption on average.

Figure ES-3. 2040 Technical Potential for Cumulative Residential PV Generation vs Sales by Region

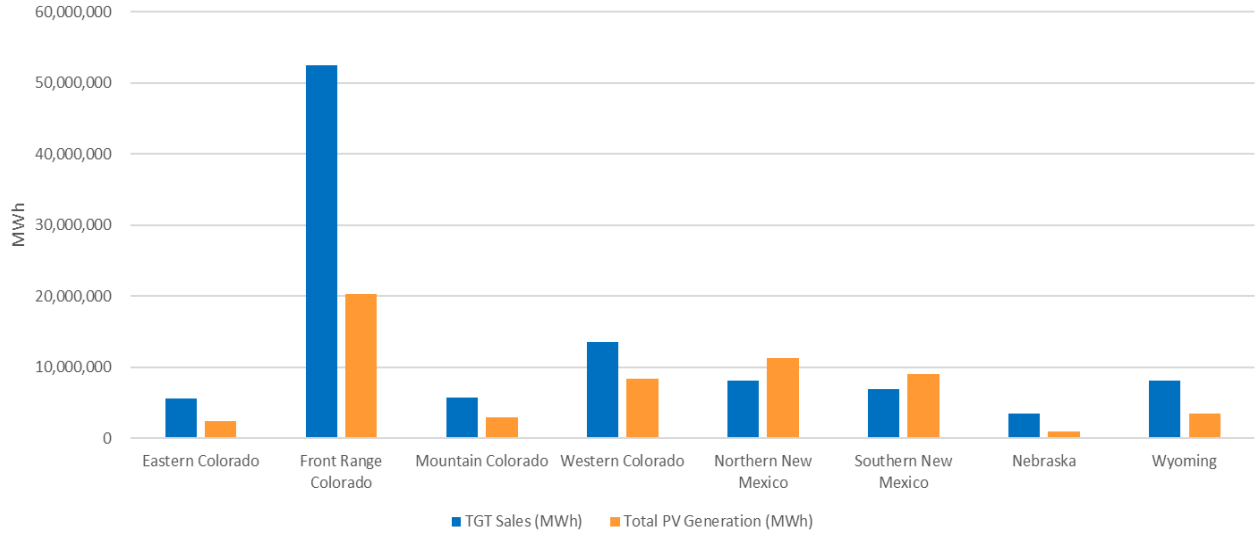


Figure ES-4. 2040 Technical Potential for Cumulative Non-Residential PV Generation vs Sales by Region

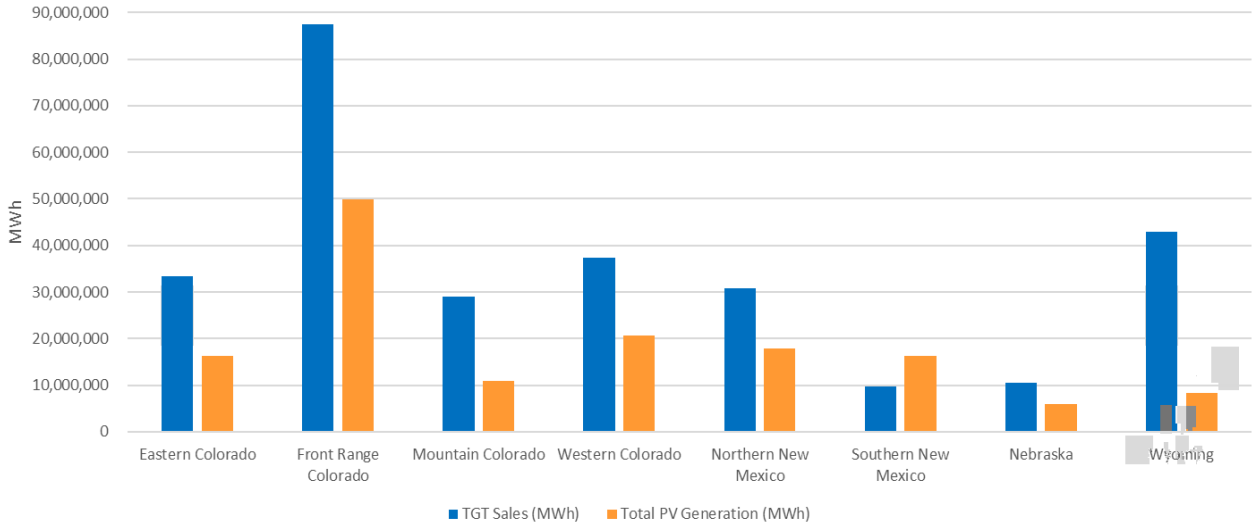
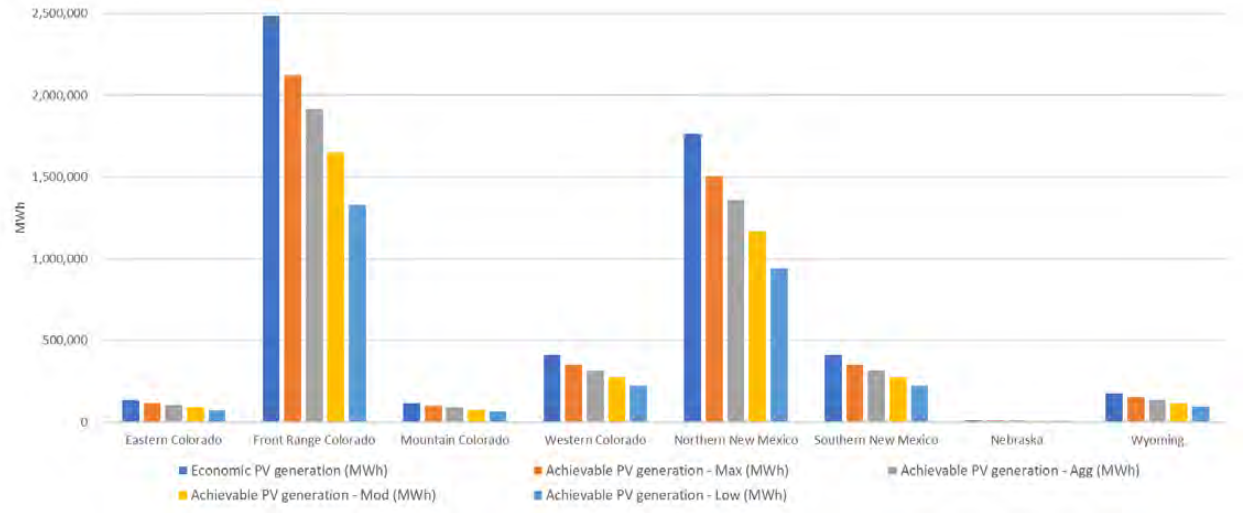


The results of the economic and achievable potential analysis are presented below in Figure ES-5. Only non-residential measures passed cost effectiveness, and those cost effective measures comprised just 9% of analyzed measure permutations. Cumulative non-residential economic potential solar PV generation equates to 2.0% of 2040 cumulative sales; achievable potential solar PV generation equates to 1.7% - 1.1% of 2040 cumulative sales. It is noted that while this potential generation reflect the entire Tri-State territory, the cost effective scenario used in this analysis includes CO_2 emission benefits which are not applicable to regions outside of Colorado, as emissions are not a quantifiable benefit at the time of this report publication.

Figure ES-5. 2040 Cumulative Non-Residential Economic and Achievable Potential PV Energy Generation by Region



Results Summary

In summary, Tri-State and its member co-ops could save the following energy and dollars with the corresponding investment, on a levelized basis over the 20-year study period:

Table ES-7. DSM Investment Outlook through 2040 (Achievable-Moderate Scenario)

RESOURCE TYPE	RESULTS
EE	Average annual savings of 114,520 MWH/year and 14 MW at a levelized cost of $15.25/MWH (TRC = 1.64)
DR	86 MW of demand response potential by 2040 at a cumulative cost of $39M (TRC = 1.16)
DER	3,661,295 MWH and 50 MW potential by 2040 at a cumulative administrative cost of $183M (TRC = 1.04)

Market Characterization & Baseline Forecast Results

In order to develop the results presented above, the Team developed a detailed characterization of Tri-Stat's customer base. This section summarizes the market and baseline forecast characterization including Tri-State's energy usage by sector and end use (additional details about customer segment and end use breakdowns within each sector are provided in Section 3). Tri-State's forecasted 2021 electricity sales to member cooperatives is just over 15 TWh, estimated to grow to just over 20 TWh by 2040 (Figure ES-6). In the base year of the analysis industrial is the largest market sector at 44% of load, followed by the residential sector at 30% of load, commercial at 18% and finally irrigation at 8%. These sector load shares remain fairly steady during the study horizon. The distribution of energy load by customer sector varies among the eight regions modeled in this study – for example, Eastern Colorado has a large irrigation sector load share while Mountain Colorado has almost no irrigation energy load (Figure ES-7). Front Range Colorado is the largest region at 5 TWh of energy load; it also has the largest Residential load share.

Figure ES-6. Baseline Load Forecast by Sector by Milestone Year

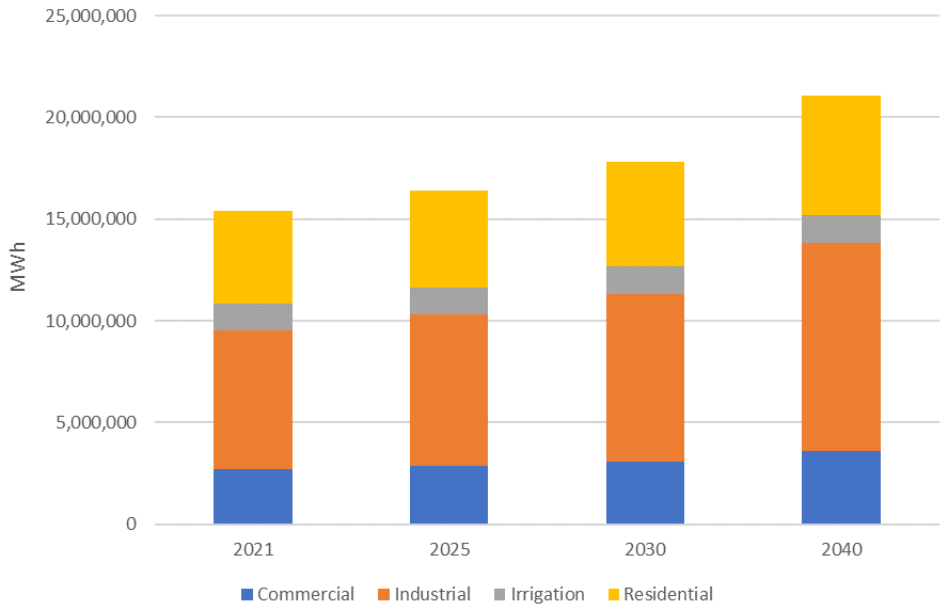


Figure ES-6. 2018 Baseline Energy Load by Customer Sector by Region

	Eastern Colorado	Front Range Colorado	Mountain Colorado	Nebraska	Northern New Mexico	Southern New Mexico	Western Colorado	Wyoming
Irrigation	554,724	31,967	861	237,972	41,763	85,091	116,352	119,890
Industrial	494,719	2,061,346	814,705	79,803	903,438	107,893	1,104,101	1,268,084
Commercial	268,177	964,547	176,453	78,733	289,986	197,934	444,417	173,590
Residential	276,257	1,944,118	241,514	173,762	406,734	328,318	606,582	380,071

Study Approach and Methods

The study approach undertaken to develop the results presented above consists of three main tasks. These tasks are summarized below and discussed in more detail in Section 2 of this report. The tasks include:

- Customer Segmentation and Forecast Disaggregation
- Measure Impact Research
- Modeling and Data Analysis

Segmentation and forecast: For the market segmentation analysis, the Team collected relevant customer and forecast datasets from Tri-State to disaggregate customer energy load by region, sector, building/business type (i.e. segment), and end use for each year in the study's 20-year time horizon. This task identifies the available energy load within the various market and end use sectors available for conversion to higher efficiency or demand reduction technologies.

Measure impacts: With the market segemented and forecast disaggregated across the study horizon, the Team then characterized the universe of efficiency, demand response, and DER measures and their end-use-specific savings, costs, and lifetimes. Measures currently implemented in Tri-State's and Xcel Energy's DSM programs received careful consideration since these measures have a historical record and vendors have proven processes for implementation. Each measure was assigned to the relevant resource, region(s), sector(s), segment(s), and end use(s) for modeling. Each measure permutation was screened for cost effectiveness according the Total Resource Cost (TRC) test with a passing threshold of 0.7 for EE measures (thus allowing some less cost-effective measures to be assessed so long as the portfolio remained above a TRC of 1.0) and a passing threshold of 1.0 for DR and DER resources.

Modeling and data analysis: The Mesa Point Team used industry-standard modeling approaches to estimate the technical, economic, and achievable potential and associated costs for EE, DR and DER resources. Specifically, a discrete model was developed for each resource and potential estimates were developed independent of one-another – for example, each resource used the same baseline disaggregated load forecast and energy efficiency improvements did not reduce the opportunity for demand response potential. The energy savings and associated costs of each resource was forecasted for a 20-year time horizon (2021 – 2040). Two to four achievable potential scenarios were developed for each resource so that varying levels of market opportunities could be assessed given variances in measure incentive levels and aggressiveness of program delivery. Outputs from each resource model were developed at high levels of resolution, showing annual energy savings, lifetimes, and costs for each measure permutation (by region, sector, segment, end use, and vintage) for each year of the study horizon.

1. INTRODUCTION

1.1. Background, Project Scope, and Objectives

Tri-State retained Mesa Point Energy, along with their subcontractor Brightline Group, (collectively the Mesa Point Team or the Team) to perform a demand side management study in support of the company's resources planning initiatives. The primary objective of this study is to assess the available technical, economic, and achievable energy savings potential from energy efficiency (EE), demand response (DR), and behind-the-meter distributed energy resources (DER) from 2021 to 2040 for the electric cooperatives served by Tri-State Generation and Transmission (Tri-State). Measures considered are limited to technologies that are behind-the-meter and owned by the end-user.

The potential study is intended to assist Tri-State in developing their Integrated Resource Plan (IRP) and Electric Resource Plan (ERP). Tri-State will use the results of this market potential study to analyze and incorporate potential EE, DR and DER impacts at various levels of program investment over the planning horizon from 2021 to 2040.

The study focuses on energy efficiency, DR, and DER *achievable* potential. As discussed further in Section 2, the study is not a *program* potential study meaning it does not take into consideration program budget and design constraints. Therefore, this report's conclusions and recommendations do not include program-specific recommendations; rather, the report focuses on identifying market opportunities and costs for EE, DR, and DER.

1.2. Achievable v. Planned Savings

This potential study examines what *could be* (i.e., what savings could accrue from considered cost effective measures) but does not account for structural and organizational limitations to that potential.

Tri-State member cooperatives are responsible for implementing measures and programs on a voluntary basis. Tri-State does not have control over which measures its members choose to offer nor how the measures are bundled into program offerings. Some co-ops may choose not to offer incentive programs, or to incent only a subset of cost-effective measures.

The study only takes into consideration barriers on the market side and does not attempt to predict if and at what levels co-ops will choose to move forward with programs.

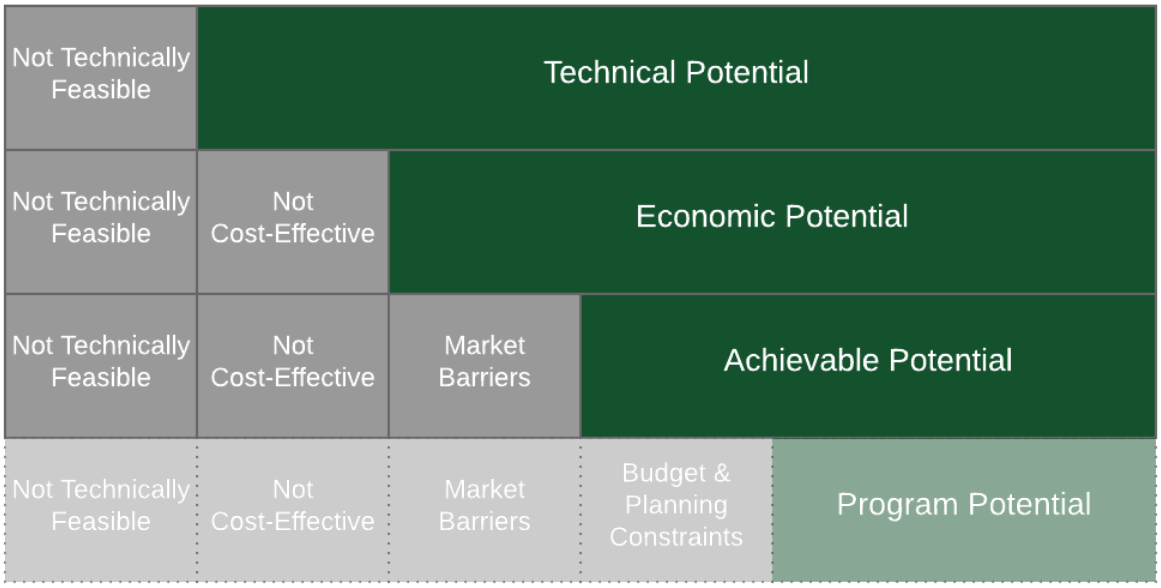
1.3. Study Approach Overview

In accordance with standard industry practice for DSM potential studies, this study considers measures from the perspective of theoretical maximum savings, and then accounts for barriers to estimate actual achievable savings.

Specifically, the study begins with *technical potential*, wherein all technically viable measures are included without regard to costs or other barriers. Knowing the technical potential, *economic potential* is assessed by estimating costs to implement measures, and then applying economic criteria to the measures. Finally, *achievable potential* is calculated by considering non-economic factors affecting DSM measure implementation. Not considered in the report are factors affecting *program potential*.

This analysis approach is based on standard perspectives of DSM resource potential according to the Environmental Protection Agency's (EPA) National Action Plan for Energy Efficiency (NAPEE)[2] as illustrated in Figure 1.

Figure 1: Conceptual Overview of DSM Resource Potential Defintions



- **Technical Potential** is the theoretical maximum amount of energy and capacity that could be displaced by an efficient technology, regardless of cost and other barriers that may prevent the installation or adoption of a measure. Technical potential is only constrained by factors such as technical feasibility and applicability of measures.
- **Economic Potential** is the amount of energy and capacity that could be reduced by measures that pass a cost-effectiveness test. This analysis used the Total Resource Cost (TRC) Test, which estimates the measure costs to both the utility and customer.
- **Achievable Potential** is the energy savings that can feasibly be achieved through program and policy interventions. Achievable potential takes into account barriers that hinder consumer adoption of energy efficiency measures such as financial, political and regulatory barriers, and the capability of programs and administrators to ramp up activity over time.
- **Program Potential** reflects the realistic quantity of energy savings the utility can realize through DSM programs during the horizon defined in the study. Potential delivered by programs is often less than achievable potential due to real-world constraints such as program budgets, effectiveness of outreach, and market delays. Program potential would also incorporate go-to-market considerations, such as practical limitations for Tri-State to deliver programs to

[2] The EPA National Action Plan for Energy Efficiency: http://www.epa.gov/cleanenergy/documents/suca/napee_report.pdf

customers through the rural electric cooperative members. As noted previously and as shown in Figure 1, this study does not address program potential.

1.4. Cost Effectiveness

At the core of DSM potential is the concept of cost-effectiveness. To assess cost effectiveness, the total cost of implementing measures is compared to the cost of business as usual with energy being provided to the baseline energy using equipment and behaviors. A DSM measure is considered cost effective if it is less costly than simply providing energy to baseline systems.

The California Standard Practice Manual (SPM) provides the methodology for estimating cost effectiveness of technologies, bundles, programs, or portfolios based on a series of tests representing the perspectives of the utility, customers, and societal stakeholders. "Low," Moderate ("Mod"), Aggressive ("Agg"), and Maximum ("Max") scenarios vary based on the assumptions for level of incentive, staffing, and marketing investment.

1.5. Presentation of Savings

This report represents savings in several different ways. For the most part, savings across years is presented as cumulative, but there are cases in which the savings may be presented in one of the other ways defined below. Following are the various methods for presenting savings:

- **Annual Incremental**: Energy savings acquired in the year in which measures are installed
- **Cumulative**: Total energy savings acquired over a given time horizon, accounting for measure decay (i.e. retired energy savings after an installed measure reaches the end of its useful life)
- **Sum of Annual Incremental**: Total energy savings acquired over a given time horizon, not accounting for measure decay

1.6. Organization of the Report and Related Deliverables

This report presents a summary of the analysis approach, key assumptions and study findings. Two separate electronic reporting tools serve as an appendices to the report. The tools provide the ability to view findings by sector, end-use, and region from both annual and hourly perspectives. The intent is for Tri-State and stakeholders to make use of both work products depending on the desired level of detail. Figure 2 summarizes the structure for the remainder of this report.

Figure 2. Summary of Report Structure

Section 2

- Describes the study approach and methods.

Section 3

- Discusses the team's efforts to disaggregate and analyze Tri-State's baseline forecast. That work serves as the foundation for the analysis and findings presented in the remainder of the report.

Sections 4-8

- Present sector-level findings for energy efficiency potential.

Section 9

- Presents findings for the demand response potential analysis.

Section 10

- Presents findings from the distributed energy resource (DER) potential analysis.

Section 11

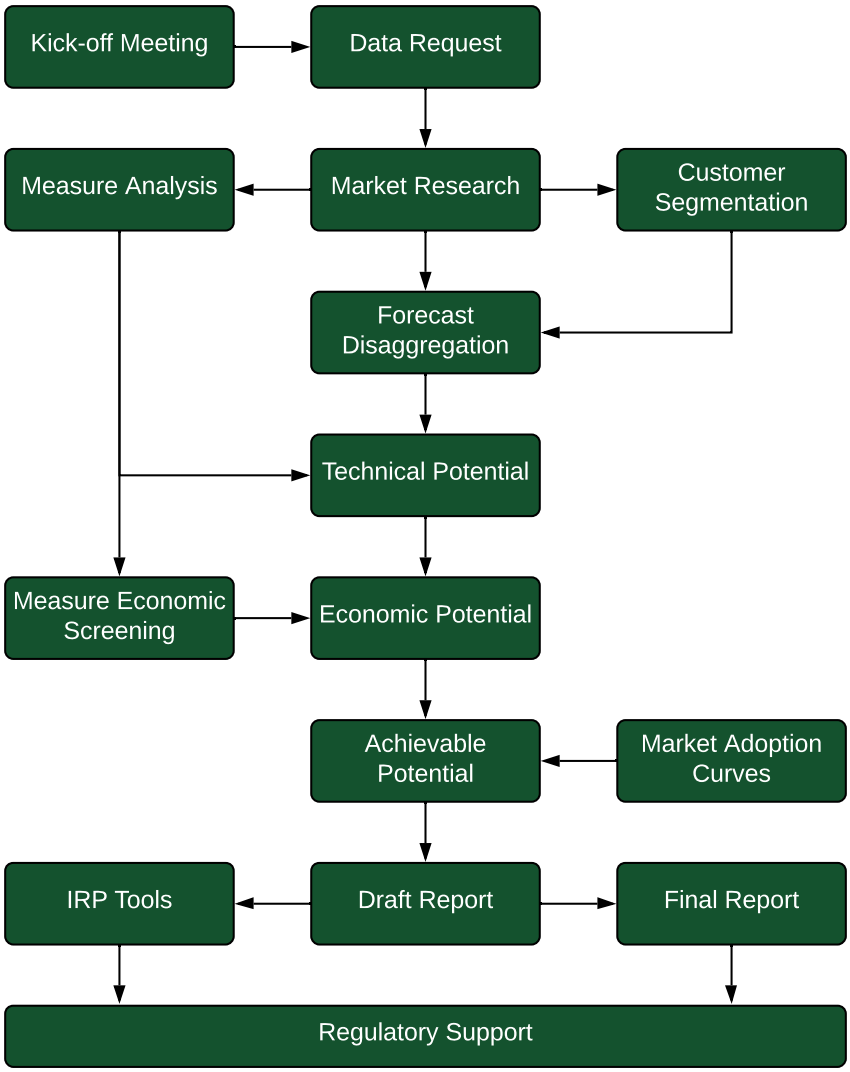
- Presents overall findings and recommendations.

2. STUDY APPROACH AND METHODS

2.1. Overview

The process shown in Figure 3 depicts the steps taken during a market potential study.

Figure 3. Approach for Demand Side Resource Potential Modeling



These steps generally apply to all three demand-side management (DSM) resources considered: energy efficiency, DR, and DER. Each step is described in detail in the sections that follow. Sections 2.2–2.4 generally apply across all three resources. Sections 2.5 and 2.6 provide additional detail for the approach and methods used for the DR and DER analyses.

2.2. Customer Segmentation and Forecast Disaggregation

An accurate assessment of achievable savings potential requires a thorough characterization of the baseline energy usage. This characterization involves the following steps:

- Determine the energy consumption per region, customer class and segment in baseline year.
- Disaggregate customer class loads into end-use loads, such as water heating.
- Analyze and calibrate data to 2018.
- Forecast the 20-year end-use energy consumption through 2040.

To complete these steps the Team relied on a large dataset consisting of:

- Information on Tri-State member cooperative customers
- Historical loads
- Market data including fuel shares, equipment saturations, and structural characteristics
- End-uses including energy use intensities and load shapes
- Measure characteristics including technologies, costs, life, and savings

These data were drawn from a combination of primary and secondary research. An overview of the steps involved in this process follows. The findings of the market characterization is presented in Section 3.

2.2.1.Customer Segmentation

To begin, the Team analyzed the portion of Tri-State's forecasted sales attributable to DSM-ineligible accounts. This included the share of the load that is served by re-sale customer or non-premise accounts. This portion of the load was removed from the load considered eligible for energy efficiency and demand reduction measures.

Next the Team determined energy and demand loads for the appropriate regions, sectors, market segments, vintages, and end-uses as follows:

- **Regions**: Sales for rural electric cooperatives were aggregated into regional definitions; including Front Range Colorado, Nebraska, North New Mexico, Wyoming, etc., as shown in Table 1.
- **Customer Sectors**: Residential, commercial, irrigation, and industrial (including agricultural)
- **Market Segments:**
  - **Commercial**: Typically based on major Commercial Buildings Energy Consumption Study (CBECS) business types.
  - **Industrial**: All major industrial segments in Tri-State service territory using NAICS classification from the Form 345 information.
  - **Residential and Irrigation**: No further segment-level breakdown

- **Vintages:** Existing and New Construction
- **End-uses:** Those shown by sector in Table 2

2.2.1.1. Primary Market Research

Primary market research guided customer segmentation. In 2012, Tri-State distributed a mail-in residential end-use survey requesting information on consumers' residence structure and energy consuming equipment type, age, fuel type, end-uses, and behavior. The survey yielded over 300 customer responses, with each cooperative providing a minimum confidence level of 90% with 10% precision for each surveyed technology at the cooperative level. This data was used to guide the disaggregation of the residential sector load.

The Team also used North American Industry Classification System (NAICS) data that provides business type data on large customers (greater than 250KW) and their associated energy consumption from the Rural Utilities Service (RUS) Form 345. Business type information for energy sales of non-residential customers less than 250KW was not available. Secondary research was necessary to estimate segmentation of business types for customers less than 250KW.

2.2.1.2. Secondary Market Research

The Team utilized secondary resources to complete the customer segmentation. Examples of these resources include the 2010 Tri-State System-Wide Electric Energy Efficiency Potential Study , United States Energy Information Administration (EIA) Residential Energy Consumption Survey (RECS)[3], the EIA Commercial Buildings Energy Consumption Survey (CBECS)[4], 2016 NorthWestern Energy End-Use and Load Profile study[5], the 2015 Platte River Power DSM Potential Study, among other references.

2.2.2.Segmentation of Regions

To accurately characterize Tri-State's large geographic service territory, the Team segmented end-use load profiles and energy efficiency potential by region. Eight (8) regions were defined based on geographic location of the co-ops[6]. Segregating the co-ops by region, instead of producing one set of potential values for all of Tri-State's territory has several advantages:

- Energy efficiency measures more accurately match building codes in each region. For example, envelope construction requirements are different depending on climate zone.

[3] *https://www.eia.gov/consumption/residential/*

[4] https://www.eia.gov/consumption/commercial/

[5] https://www.northwesternenthinkergy.com/docs/default-source/documents/etac/2017/nexant_energy_end_use_and_load_profile_study.pdf

[6] This report and the associated Reporting Tool, described in this report, utilize the regional breakdown characterized here. The Load Shape Tool, also described in this report, utilizes an adapted breakdown to accommodate for member coops that cross certain regional boundaries. This alternative breakdown of potential savings is to allow for more accurate output data for input into Tri-State's resource planning models. The adjustment reflects where coop service territory extends across eastern and western interconnects.

- Regional segmentation captures a higher resolution of equipment end-use saturation and energy intensity. For instance, direct expansion (DX) cooling in the residential sector has a higher saturation and energy intensity in southern New Mexico as compared to northern Wyoming.
- This segmenation accommodates regional cost variances for participant energy efficiency implementation or utility avoided costs.
- Barriers to achievable potential may be regionally specific.

Based on evaluation of climatic impacts, sector segmentation and end-uses, the Team developed the regional electric cooperative groups shown in Table 1.

Table 1: Tri-State Cooperative Regional Groups

EASTERN COLORADO	FRONT RANGE COLORADO	MOUNTAIN COLORADO	WESTERN COLORADO
Highline	Mountain View	Gunn County	Empire
K.C.	Poudre Valley	Mountain Parks	La Plata
Morgan County	San Isabel	White River	San Luis Valley
Southeast	United		San Miguel
Y-W			Sangre De Cristo
NEBRASKA	**SOUTHERN NEW MEXICO**	**NORTHERN NEW MEXICO**	**WYOMING**
Chimney Rock	Central NM	Cont. Divide	Big Horn
Midwest	Columbus	Jemez Mtns	Carbon
Northwest	Otero County	Mor San Miguel	Garland
Panhandle	Sierra	North. Rio Arriba	High Plains
Roosevelt	Socorro	Southwestern	High West
Wheat Belt		Springer	Niobrara
			Wheatland
			Wyrulec

2.3. End-Use Load Classification

To further disaggregate the load the Team established end-use loads within each sector.[7] Table 2 presents a summary of those end-uses.

[7] The irrigation sector is solely composed of the motor end-use.

Table 2: End-Uses for Each Tri-State Sector

RESIDENTIAL	COMMERCIAL	INDUSTRIAL
Central Air Conditioning	Cooking	Lighting
Central Heating	Cooling	HVAC
Clothes Washer	Heat Pump	Motors
Dishwasher	HVAC Aux	Pumps
Electric Cooking	Lighting	Process Heat
Electric Dryer	Plug Load	Process Cool
Freezer	Refrigeration	Pumps
Exterior Plug Load	Space Heating	
HVAC Aux	Water Heating	
Heat Pump		
Lighting		
Plug Load		
Refrigerator		
Second Refrigerator		
Room AC		
Electric Water Heater		

The primary regional inputs needed to model each end-use were the total premise count, fuel shares, end-use Unit Energy Consumption (UEC), and saturation. Expected improvements in building energy code requirements and other general trends were incorporated into the UECs based on data found in the U.S. Energy Information Administration's forecasts. In general these trends showed a decrease in all end-use UECs with the exception of plug loads, which showed an increasing trend.

2.3.1.Codes and Standards

There is uncertainty about future federal standard updates and enforcement. While the study considers current codes and standards, the analysis is not intended to predict how or when energy codes and standards will change over time. As a result, there are only limited known improvements to federal codes and standards to reasonably account for in this analysis.

The primary adjustment made in the Team's methodology impacts residential screw-in lighting. Based on the current Department of Energy final rule that did not trigger the Energy Independence and Security Act (EISA) backstop, the potential analysis does not model Tier II EISA efficiency requirements. However, the study does model the transitioning screw-based lighting market that is rapidly being

saturated with LED technology. The Team modeled this market transition by limiting the future potential for residential lighting starting in 2027. The analysis assumes only a limited number of direct-install screw-based lighting opportunities for standard, specialty, and reflector bulbs over the latter analysis period.

Although not exhaustive, the following list outlines additional key standards the Team considered:

- The baseline efficiency for air source heat pumps (ASHP) is anticipated to improve to 15 SEER/8.8 HSPF.
- The baseline efficiency for split system central AC systems is anticipated to improve to 14 SEER in 2023.
- In July 2019, the DOE makes new standards effective for more efficient furnace fan/motors. The standards are expected to improve the efficiency by approximately 45% over the current baselines. The new standard will create a shift to electronically commutated motors (ECMs).

2.4. Energy Efficiency Potential Modeling

Drawing on outcomes from of the disaggregated the Team modeled first technical, then economic, and finally achievable energy savings potential. Those steps are described in the following sections.

2.4.1. Estimate Technical Potential

Technical potential is the theoretical maximum amount of energy use that could be displaced by efficiency, disregarding all non-engineering constraints such as cost-effectiveness and the willingness of end-users to adopt the efficiency measures. Technical potential is only constrained by factors such as technical feasibility of measures. The model applies the measure-level inputs to the disaggregated baseline sales forecast to estimate technical savings and demand reduction potential over the planning horizon.

As an example, the core equation used in the residential sector energy efficiency technical potential analysis for each individual efficiency measure is shown in Equation 1.

Equation 1. Core Equation for Residential Sector Technical Potential

Where:

Total Number of Households *= Count of customer households in the subject region.*

Base Case Equipment Energy Use Intensity *= the electricity used per customer per year by each base-case technology in each market segment. In other words, the base case*

equipment energy-use intensity is the consumption of the electrical energy using equipment that the efficient technology replaces or affects.

Saturation Share = *the fraction of the end-use electrical energy that is applicable for the efficient technology in a given market segment. For example, for residential water heating, the saturation share would be the fraction of all residential electric customers that have electric water heating in their household.*

Remaining Factor = *the fraction of equipment that is not considered to already be energy efficient. To extend the example above, the fraction of electric water heaters that is not already energy efficient.*

Applicability Factor = *the fraction of the applicable units that is technically feasible for conversion to the most efficient available technology from an engineering perspective—i.e., it may not be possible to install a heat pump water heater in all homes due to space constraints.*

Savings Factor = *the percentage reduction in electricity consumption resulting from the application of the efficient technology*.

2.4.1.1. Measure Definitions

Once the baseline forecast is disaggregated, the next step to assessing technical market potential is to accurately detail the universe of efficiency measures and their end-use-specific savings, costs, and lifetimes. Measures currently implemented in Tri-State's and Xcel Energy's DSM programs received careful consideration since these measures have a historical record and vendors have proven processes for implementation. Additionally, our Team compiled all measures available from such sources as the Pacific NorthWest Regional Technical Forum (RTF), Xcel Energy's Demand Side Management Plan, and technical reference manuals (TRMs) from jurisdictions like the states of New Mexico, Pennsylvania, and Minnesota. The Team also leveraged measure data it has characterized in similar studies. From these regionally relevant databases, the Team selected measures that are commonly available, based on well-understood technology, and applicable to the buildings and end-uses in Tri-State's service territory. The Team also considered measures that show promise for future viability but have not yet gained a foothold in the market.

Energy efficiency measures are characterized in three main vintages:

- **Replace on Burnout:** As equipment replacements are made normally in the market when a piece of equipment is at the end of its effective useful life (also referred to as "turnover").
- **Retrofit:** At any time in the life of the equipment or building (referred to as "early-retirement").
- **New:** When a new home or building is constructed.

Upon finalizing the energy efficiency measure list, the Team collected data on energy savings, costs, lifetime, and applicability to determine potential measure impacts. This work involves a multi-step process described here.

Step 1: Define market classifications for application of measures

The Team established market classifications as a framework for documenting applicability of each measure. These classifications were based on factors including region, fuel type, sector, market segment, and end-use as defined in the disaggregated forecast (Section 2.2). Additionally, the Team further defined permutations for each measure based on the following parameters:

- **Climate Zone:** This measure research includes savings estimates for weather-dependent measures specific to ASHRAE climate zones 4 through climate zone 6
- **Measure Type:** Equipment vs. Non-equipment
- **Vintage:**
  - **Equipment** – Turnover, Retrofit, New
  - **Non**-equipment – Existing, New

Step 2: Screen sectors, segments, and end-uses for eligibility

The Team screened market segments and end-uses for applicability of specific energy efficiency measures. For example, certain commercial end-uses, such as cooking, may not be appropriate for segments such as offices and warehouses and therefore were analyzed only in limited market segments.

Step 3: Develop base case impacts and costs

The Team determined base case equipment and practices for each of the energy efficiency measures on the final list, and developed a description and rationale for each. This included all base case assumptions and data, such as state building codes (the 2012 International Energy Conservation Code (IECC) in most cases) and federal standards. Base case assumptions included projected future adjustments, such as upcoming federal standards.

Step 4: Develop energy efficiency measure impacts and costs

The Team developed a description of all energy efficiency (or "change case") measure equipment and practices, including all measure energy savings assumptions and calculation parameters, such as equivalent full load hours (EFLH). For each measure, the Team estimated energy savings as a percentage of base equipment and/or end-use consumption.

In addition to energy savings, the Team collected incremental measure costs pertinent to Tri-State's service territory from appropriate TRM references and internet retailer data and researched measure life drawing on TRM documentation.

2.4.1.2. Screw-in Lighting

The Team reviewed the residential, commercial, and industrial lighting measures and lighting end-use assumptions to incorporate recent changes to the lighting market. This included reviewing and updating savings, measure cost, saturation, and expected useful life assumptions for each lighting measure. Based on federal policy projections, the Team made the assumption that the EISA "backstop" would not be enacted beginning in 2020. Additionally, the Team characterized the lighting market to transform primarily to an LED baseline for screw-in lighting by the end of the decade.

2.4.2. Estimate Economic Potential

Economic potential represents the savings possible given full adoption of all cost-effective efficiency measures. For this study, the Team utilized the Total Resource Cost (TRC), which is commonly considered the preferred test to assess measure benefits and costs from the perspective of the utility and society as a whole. Equation 2 presents the TRC ratio equation.

The benefits in the TRC test are the net present value of the lifetime avoided energy and capacity costs. The costs in this test are the net present value incremental measure costs.

Equation 2. TRC Ratio

$$\textbf{TRC Ratio} = \textbf{NPV}(\textbf{Avoided Costs})/\textbf{NPV}(\textbf{Incremental Measure Costs})$$

Where*:*

$$\text{Avoided Cost} = \text{NPV}\left(\sum_{\text{year}=1}^{\text{measure life}}\left(\sum_{\text{i}=0}^{\text{i}=8760}(\text{impact}_{\text{i}} \times \text{avoided cost}_{\text{i}})\right)\right)$$

The **benefits** include the net present value of the energy and capacity saved by the measures along with any natural gas or other fossil fuel benefits. The forecast of electric avoided costs of energy and capacity were obtained from Tri-State and represent their most recent forecast of avoided electric benefits. The avoided costs are calculated by applying end-use-specific annual hourly load shapes to measure savings impacts and determine the time-differentiated value of energy and capacity benefits. The annual hourly load shapes were developed from industry-specific energy load profiles, and a peak definition (noon – 22nd hour in weekday summer months) was provided by Tri-State to estimate coincident peak demand.

To accurately value avoided energy savings for Tri-State, the expected losses were estimated from the customers' meters to Tri-State's generation source. These losses were calculated for each climate zone, and reflected the losses from the customer to the co-op and the losses from the co-op to Tri-State. In addition to line losses, a discount rate of 5% was applied to value future avoided costs.

The **costs** are the net present value of all costs to implement those measures. These costs include full incremental costs (both utility and participant contributions), but no incentive payments that offset incremental costs to customers and no lost revenues. The full incremental costs include single upfront costs and operational & maintenance costs where applicable. Incentives are not included, because they are transaction between the utility and customer, thus the costs and benefits negate each other. While non-incentive costs were not included in the measure-level screening of electric energy efficiency potential, they were included in further assessments of potential at the achievable potential level described below.

Additionally the social cost of carbon at $46/ton of carbon dioxide (CO_2) was incorporated as an avoided benefit in the TRC calculations. This value was escalated annually over the study time horizon based on figures provided by Tri-State.

The measure screen from technical potential to economic potential utilized a cost-effectiveness hurdle of 0.7 in order that the sector level TRC test would be closer to 1.0. This reduction in the screening threshold permits non cost-effective measures into the portfolio so that a potential program

intervention is more well-rounded and can include a limited number of non-cost-effective measures. However, the forecasted sector portfolio must have an estimated TRC greater than 1.0 when program administrative costs are included.

2.4.3.Estimate Achievable Potential

Finally, the assessment of realistically achievable energy efficiency potential required estimating, among other parameters, the rate at which cost-effective measures can be adopted over time. The Team incorporated individually developed sets of market penetration curves corresponding to implementation scenarios to account for the fact that program implementation scenarios have a direct influence over such market penetration rates. These scenarios were correlated to differing levels of urgency in program implementation, tolerance for rate impacts, macroeconomic conditions, and other situations.

The following are important components in determining achievable potential:

- **Benchmarking.** The amount of savings expected to be achievable through DSM programs will be informed by the experience of utilities across the region and nation.
- **Customers' willingness to participate.** The likelihood that customers will participate in energy efficiency programs is a function of several factors, most notably incentive level.
- **Uncertainty.** Planning requirements often necessitate a point-estimate of potential, however, this is not an accurate reflection of the reality of DSM programs. We prefer to think of achievable potential as a range, or probability distribution, where the point-estimate is the most likely outcome. This distribution defines the lower and upper bounds of expected savings, as well as the most likely value.

Achievable potential energy efficiency impacts were evaluated based on four incentive scenarios as a function of the incremental costs of efficiency measures:

- 25% "Low"
- 50% Moderate ("Mod")
- 75% Aggressive ("Agg")
- 100% Maximum ("Max")

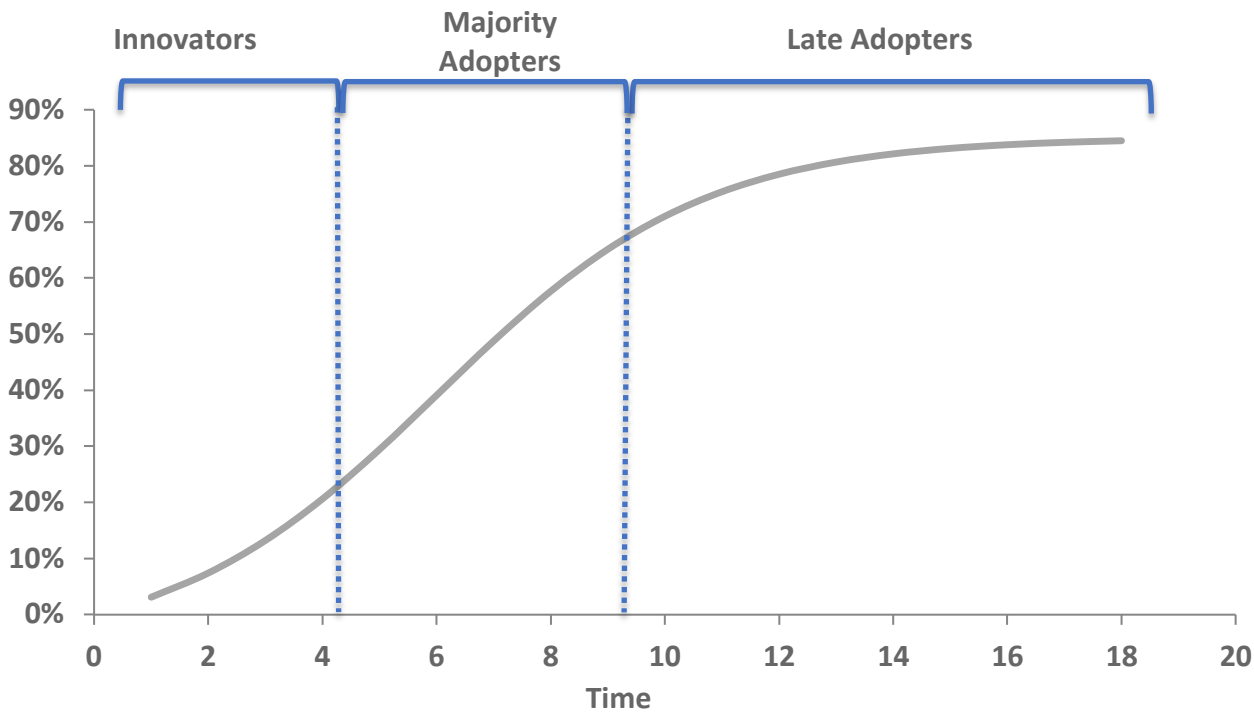
For instance, the moderate scenario approximates the market adoption achievable by incentivizing 50% of the incremental cost of the measure. Results are presented from the perspective of the Achievable Moderate scenario unless otherwise specified. This scenario represents a reasonable progression from Tri-State's current program offerings.

2.4.3.1. Market Adoption Rates

In order to characterize the rate of market adoption for each of the specified scenarios, the Team developed a quantitative approach based on a Bass Diffusion Model. This method relies on scientific theory and historic program participation data based on Tri-State experience and other DSM programs in North America.

The Bass Diffusion Model is a mathematical description of how the rate of product diffusion in a market changes over time. When the product is introduced, there is a slow rate of adoption while customers become familiar with the product. When the market accepts a product, the adoption rate accelerates to relative stability in the middle of the product cycle. The end of the product cycle is characterized by a low adoption rate because fewer customers remain that have yet to adopt the product. This concept of forecasting future adoption rates is illustrated in Figure 4.

Figure 4: Typical Product Diffusion in the Marketplace



The rate of adoption in a discrete time period is determined by external influences on the market, internal market conditions, and the number of previous adopters.

- Initial Year Measure Adoption
  - First year adoption levels were informed by recent Tri-State historical performance where possible.
- Long-Term Market Adoption Rates
  - The final adoption scores that resulted from willingness to pay surveys serve as the point-estimate for the long-term market adoption potential for the realistic achievable scenario.
- Adoption Curve Shape
  - Once the initial year adoption rate (Point A) and long-term adoption rates (Point B) are determined, the remaining step was to determine the rate and duration to get from Point A to Point B.

Unique end-use adoption curves were developed based on the following three parameters:

- **Customer Sector:** Residential, Commercial, and Industrial
- **End-Use**: Lighting, Motors, etc.
- **Incentive Level based on Achievable Scenario**: 25%, 50%, etc.

2.4.3.2. Program Costs

Finally, to capture the full cost of achievable energy efficiency potential, the Team added program non-incentive costs in the overall assessment of cost-effectiveness. Non-incentive program cost categories included: (1) Administration, (2) Marketing, (3) Technical, and (4) Measurement & Verification and Planning. Program non-incentive costs were calculated on a gross $ per first-year kWh saved. Non-incentive costs were developed for each program by sector. The included program cost assumptions are shown in Table 3.

Table 3: Summary of Non-Incentive Program Costs ($/kWh)

SECTOR	ACHIEVABLE LOW	ACHIEVABLE MOD	ACHIEVABLE AGG
Residential	$0.100	$0.115	$0.150
Commercial	$0.050	$0.058	$0.075
Industrial	$0.100	$0.115	$0.150
Irrigation	$0.050	$0.058	$0.075

2.4.4. Data Analysis and Reporting Tool

A set of dynamic analysis tools were developed to provide Tri-State staff access to the data outputs from the modeling efforts. These consist of a Reporting Tool and a Load Shape Tool specifically created for this project. The Reporting Tool summarizes and illustrates the savings potential and associated costs by sector, year, and scenario enabling the user to select results for a specific region or for the entire service territory. The results are depicted in tabular form and in associated charts that update dynamically based on the selected region.

The Load Shape Tool was developed to convert the model's annual energy savings and cost outputs into 8760 hourly load profiles for direct input into Tri-State's ERP planning tool. The tool bundles and maps measures to associated 8760 hourly load profiles to illustrate at what hours during the day and year energy savings are likely to be incurred for each bundle of measures. The tool also shows the associated levelized cost of each bundle of measures on an 8760-hourly basis. The data is represented by sector, interconnect region, scenario, and load shape bundle. This tool will allow Tri-State to compare energy efficiency resource savings and levelized costs and compare them with other supply-side and demand-side resources during its ERP development process.

2.5. Demand Response Potential Assessment

Demand response refers to the reduction of electric demand by way of altering the operation of some piece of technology or equipment. Demand response programs take several forms, but most rely on

direct control of energy-using equipment via communication infrastructure like radio or WiFi or the change in customer behavior from time-based rates.

There are a few important differences between the assessment of demand response programs and other demand-side management options, such as energy efficiency. First, demand response programs require active, ongoing participation by customers. Second, unlike energy efficiency programs, demand response is designed to shift load from peak periods of energy use to non-peak periods, which can affect the availability of service to the customer. These programs use independent concepts and technologies and not 'upgrades' in the sense that energy efficiency measures are upgrades from some similar baseline option. These programs use independent concepts or technologies and are not 'upgrades' in the sense that energy efficiency measures are upgrades from similar baseline options. Thus, demand response technologies have no incremental cost. Finally, demand response depends on a customer's willingness to participate in individual events. This willingness to participate is a function of program design, which includes the number of events, incentive levels, the stipulation of mandatory or voluntary participation, and the existence of penalties for non-compliance. Hence, estimating demand response potential involves in a number of steps. The final potential number is a product of the base peak demand, eligibility rates, technical load impact rates, program participation rates, and event participation rates.

2.5.1.Estimate Peak Demand

Coincident peak demand data was available for each of the eight regions in the Tri-State system. This system-level peak demand was divided to estimate the contributions from each sector (residential, irrigation, commercial, and industrial) by using sector energy use during the peak month relative to the system energy use during the same time period. Per premise demand estimates were generated by dividing by the number of premises in each sector.

2.5.2.Apply Eligibility Rates

Eligibility rates customized to each program were applied to the base peak demand to determine the peak load eligible to participate. For example, a Direct Load Control (DLC) program capturing residential central HVAC load will require premises to have central air conditioners, while a Smart Thermostat DR program would additionally require the residence to have broadband service and a WIFI network. Irrigation load reduction is generally limited to customers with pumping power greater than 75 horsepower. Commercial and industrial customers in a capacity bidding program typically need to have a peak demand of greater than 250 kW.

2.5.3.Estimate Technical DR Potential

Technical potential for demand response is the theoretical maximum level of peak demand that could be curtailed through DR programs. This scenario disregards non-engineering constraints such as cost-effectiveness and willingness of end-users to enroll. All eligible customers are modelled as if enrolled in one or more DR programs and participating in DR events.

In the Technical Potential scenario, care must be taken to avoid double-counting participation in programs that affect the same end-uses. For example, a customer cannot be modelled as curtailing its HVAC load in both a DLC program and a rate program during the same event. We applied a hierarchy of

demand response programs for each sector based on Tri-State's unique market position, as shown in Table 4.

Table 4. Demand Response Programs Applied by Sector

RESIDENTIAL	AGRICULTURAL	COMMERCIAL	INDUSTRIAL
Smart Devices	Direct Load Control	Capacity Bidding	Capacity Bidding
Behavioral	Time Varying Rates	Smart Devices	Time Varying Rates
Direct Load Control		Direct Load Control	
Time Varying Rates		Time Varying Rates	

2.5.4. Estimate Economic DR Potential

Economic potential is a subset of technical potential that is economically cost-effective. A full cost-benefit analysis was conducted for each DR program incorporating Tri-state's avoided energy and capacity costs, program start-up costs, on-going administrative costs, equipment costs for the program and the participant, and discount rates.

Resource acquisition costs fall into one of two categories. Fixed costs include program start-up, infrastructure, maintenance, administration, and data acquisition. Variable costs include hardware costs, which vary by the number of customers, and incentive costs, which can vary by number of customers or kW reduced.

Fixed and variable costs were estimated for each program type according to comparable programs implemented by other utilities or other potential studies. In cases where published cost information could not be found, the Team used assumptions based on other comparable program data points. The Team also incorporated a multiplier of 8 into start-up costs and administration costs, to represent the complexity of managing a program with multiple co-op partners. This analysis assumes a cost of $640,000 or more to start a demand response program. Lower costs were incorporated for time-vary rates programs - $100,000 for start-up and $23,000 per year for administration. Lower costs were also assumed for some commercial programs where commercial participation could be assumed as an addition to an existing residential program. All programs were assumed to require an annual evaluation at a cost of $50,000. Average hardware, communication, and incentive levels were estimated based on published values from other utilities or studies.

Program cost assumptions are summarized in Table 5.

Table 5. Demand Response Program Cost Assumptions

SECTOR	PROGRAM	START-UP	ADMIN	EVAL	MARKETING	EQUIP
Residential	Smart Tstat	$640k	$538k/yr	$50k/yr	$50/signup	$0
	Smart Water Heater	$665k	$543k/yr	$50k/yr	$50/signup	$175
	DLC Central AC	$665k	$543k/yr	$50k/yr	$50/signup	$225
	DLC Room AC	$665k	$543k/yr	$50k/yr	$20/signup	$50
	DLC Pool Pump	$665k	$543k/yr	$50k/yr	$20/signup	$200
	CPP no tech	$100k	$23k/yr	$50k/yr	$25/signup	$200
	Time of Use	$100k	$23k/yr	$50k/yr	$25/signup	$200
	Behavioral	$640k	$7/meter	$50k/yr	$0	$0
Irrig-ation	DLC	$665k	$862k/yr	$50k/yr	$63/premise	$500
	CPP no tech	$100k	$23k/yr	$50k/yr	$25/signup	$200
	Time of Use	$100k	$23k/yr	$50k/yr	$25/signup	$200
Commer-cial	Capacity Bidding	$640k	$184k/yr	$50k/yr	$50/premise	$0
	Smart Tstat	$128k	$107k/yr	$50k/yr	$50/signup	$0
	DLC Water Heater	$128k	$107k/yr	$50k/yr	$50/signup	$175
	DLC Room AC	$665k	$543k/yr	$50k/yr	$20/signup	$50
	CPP no tech	$100k	$23k/yr	$50k/yr	$25/signup	$200
	Time of Use	$100k	$23k/yr	$50k/yr	$25/signup	$200
Indust-rial	Capacity Bidding	$640k	$184k/yr	$50k/yr	$50/premise	$0
	CPP no tech	$100k	$23k/yr	$50k/yr	$25/signup	$200
	Time of Use	$100k	$23k/yr	$50k/yr	$25/signup	$200

2.5.5.Estimate Achievable DR Potential

The Team applied program participation rates to economic potential to incorporate each sector's willingness to participate in demand response programs. This participation rate is expressed as a percentage of eligible customers. As it takes some time for a utility to fully implement a demand response program, program participation rates are assumed to reach a mature participation rate after 10 years.

Combining economic potential with program and event participation rates yields "achievable potential," or the load that can reasonably be reduced during any one event for a certain program. The Team modeled two achievable potential scenarios for demand response to illustrate the impacts of varying incentive levels to drive program participation. Adoption for both scenarios were selected based on achieved participation rates from similar program types in other jurisdictions.

- 'High' scenario represents best-in-class participation for programs with non-mandantory (opt-in) enrollment
- 'Low' scenario represent more typical or 'average' participation rates from the body of similar programs.

Steady-state participation rates are summarized in Table 6 for each achievable scenario.

Table 6. Demand Response Program Achievable Scenario Participation Rates

SECTOR	PROGRAM	ACHIEVABLE HIGH	ACHIEVABLE LOW
Residential	Smart Tstat	59%	20%
	Smart Water Heater	59%	20%
Irrigation	DLC	48%	15%
	CPP no tech	18%	8%
Commercial	Capacity Bidding	20%	10%
	Smart Tstat	20%	8%
	CPP no tech	18%	8%
Industrial	Capacity Bidding	20%	10%
	CPP no tech	18%	8%

The results of the approach described in this section are presented in Section 9.

2.6. Behind-the-Meter Distributed Energy Resource Potential Assessment[8]

For the purposes of this report, distributed energy resources is defined as equipment installed at customer premises behind-the-meter that generates electricity. This study reviewed the potential for end users of Tri-State's electricity to install and operate these types of resources.

The DER potential study followed the same method as energy efficiency potential in that the DER assessment reviews the opportunity for technical, economic, and achievable potential. The analysis limited resources for this potential assessment study to technologies that are behind-the-meter and owned by the customer. The analysis did not consider market potential for supply-side resources within this assessment. The market potential assessment for DERs focused on solar photovoltaic (PV) systems across Tri-State's region for the period 2021 to 2040, because it was the most probable technology to be cost effective and applicable to Tri-State's territory. We performed review and preliminary cost screens for potential DER technologies such as combined heat and power and small wind but did not find these technologies to be applicable and/or cost-effective.

2.6.1. Estimate Technical DER Potential

The technical potential of a DER is the amount of energy that can be generated at a customer's site behind the meter.

Photovoltaic systems utilize solar panels, a packaged collection of photovoltaic cells, to convert sunlight into electricity. A system is constructed with multiple solar panels, a DC/AC inverter(s), a racking system to hold the panels, and electrical system interconnections. These systems are often roof-mounted and face south-west, south, and/or, south-east.

The study analyzed the potential associated with roof-mounted systems installed on residential and non-residential sector buildings. For the non-residential sector, the analysis estimated potential for ground mounted (or covered parking) systems for a few specific business types such as municipal

[8] Actual results for DER analysis are not included in this draft report pending gathering of additional information

facilities, parking enclosures, and some manufacturing facilities. The analysis also included battery storage as an additional configuration with each solar PV system type. This study did not explore the market potential associated utility-scale solar PV installations.

The approach to estimating technical potential required calculating the total square footage of suitable rooftop area within Tri-State's territory and calculating solar PV system generation based on building and regional characteristics. Technical potential is computed using Equation 3.

Equation 3: Solar PV Technical Potential Calculation

$$\boldsymbol{PV\ Technical\ Potential} = \boldsymbol{\Sigma}(\boldsymbol{Suitable\ Rooftop\ Square\ Footage} \times \boldsymbol{PV\ System\ Generation\ per\ Sq.Ft.})$$

The two key parameters in Equation 3 were estimated based on multiple data sources relevant to Tri-State's territory. A discussion of methods for defining these parameters follows.

The Team estimated total rooftop square footage using the forecast disaggregation analysis to characterize the existing and new residential and non-residential building stocks. The building stocks were characterized based on relevant parameters such as number of facilities, average number of floors, average premise consumption, and premise EUI by region. The Team used these parameters to estimate the total rooftop square footage for each Tri-State region.

To estimate the fraction of the total roof area that is suitable for rooftop solar PV, the Team relied on research completed by the National Renewable Energy Laboratory (NREL). NREL has developed estimates of the portion of total rooftops across the country that are suitable for solar PV based on analysis of LIDAR data. NREL criteria for suitable roof area include:

- **Contiguous rooftop area size:** Rooftops with fewer than 10 square meters of contiguous roof area excluded.
- **Rooftop orientation (tilt and azimuth):** Northeast through northwest orientation and roof pitches greater than 60 degrees excluded.
- **Shading:** Roof areas that had a minimum solar exposure of less than 80% relative to an unshaded roof were excluded.

Based on NREL's data, the Team was able to apply unique suitability factors to estimate the total square footage of suitable rooftop for residential and non-residential buildings for each Tri-State region. The Team further adjusted the total suitable rooftop square footage by accounting for existing systems. Data on existing systems was captured from Google's Project Sunroof and applied to the NREL suitability factors.

The second key parameter – PV system generation – was estimated by developing standardized solar PV system configurations. These included system sizes for residential premises ranging from 3 to 20 kW (DC) and 10 to 2,000 kW (DC) for non-residential premises. Additionally, the Team selected battery system sizes for each solar PV system size to dispatch energy for 2-4 hours during low and/or non-generation time periods.

The Team relied on NREL's PVWatts[9] (Version 6) and System Advisor Model (SAM)[10] tools to estimate system generation for both residential and non-residential sited systems. These tools model PV power density based on site specific data from NREL's LIDAR-based NSRDB to estimate total solar irradiance in conjunction with PV system specifications. The PV system simulations were generated for various cities within each Tri-State region. The Team based assumptions for PV system azimuth on rooftop orientation data sourced from Google's Project Sunroof. For the analysis the following assumptions are summarized in Table 7.

Table 7: Key Assumptions in Solar PV Analysis

PARAMETER	ASSUMPTIONS
Residential System Sizes (Nominal DC Capacity)	3 kW, 5 kW, 7.5 kW, 10 kW, 15 kW, 20 kW
Non-Residential System Sizes (Nominal DC Capacity)	10 kW, 15 kW, 20 kW, 25 kW, 50 kW, 100 kW, 250 kW, 500 kW, 1,000 kW, 2,000 kW
System losses	14.1%
Tilt	By region
Azimuth:	By region
DC to AC size ratio	1.2
Inverter efficiency	96% (micro-inverter)
Battery Round-Trip Efficiency	85%
Technology Useful Life	20 years

Based on the simulations and resulting capacity factors for residential and non-residential buildings for each Tri-State region, we applied the capacity factor to the system size and multiplied by 8,760 to estimate annual electricity generation. These system generation values were used to calculate total energy generation per square foot of rooftop and extrapolated based on the total suitable rooftop square footage to estimate overall all technical potential.

2.6.2. Estimate Economic DER Potential

As discussed in Section 2, economic potential represents the savings possible given full adoption of all cost-effective efficiency measures according to the Total Resource Cost (TRC) test or other commonly used tests. For the cost effectiveness analysis on solar PV, the Team set a TRC hurdle of 1.0[11]. To estimate economic potential for solar PV, we gathered pertinent data on system costs along with calculated generation benefits to use in the benefit-cost analysis which we conducted at the system measure level. The Team screened solar PV measures with an assumed program administration cost of $0.05 per kWh generated.

9 PVWatts estimates solar PV energy production and costs. Developed by the National Renewable Energy Laboratory. (NREL) *http://pvwatts.nrel.gov/*

10 SAM estimates houlry solar PV energy production and costs with more detailed inputs and outputs than PVwatts. Developed by the National Renewable Energy Laboratory. (NREL) *http:// https://sam.nrel.gov/*

11 The TRC hurdle is higher than the hurdle used for the energy efficiency study as the solar PV systems have a much more homogenous benefit-cost profile relative to the portfolio of diverse energy efficiency measures that when combined elevated the overall TRC ratio for the portfolio.

The Team relied on multiple data sources to determine the solar PV system costs for the system sizes and configurations mentioned above. We assessed system component costs based on data included in the National Renewable Energy Laboratory's (NREL) Q1 2018 Benchmarking report[12] which provided detailed cost information on modules, inverters (by technology), structural and electrical balance of system, supply chain, permitting-inspection-interconnection, marketing, overhead, and profit. We adjusted cost parameters from a national level to Tri-State region-specific values by using various market data provided by Energy Sage[13] for residential cost estimates and the Lawrence Berkeley National Laboratory Tracking the Sun[14] data for non-residential cost estimates. This analysis produced an estimated installation cost per watt installed which we applied to various system sizes to estimate total installed cost. Additionally, the Team included O&M costs that scale with system size. Finally, we assumed the impact of the federal investment tax credit (ITC) to follow the existing schedule at the time of this report which equates to a 10% tax credit for commercial systems by 2022 and a 0% tax credit for residential systems by 2022.

In addition to modeling solar PV system costs, the Team estimated cost impacts for solar PV systems coupled with battery storage. Because these systems are far less prevalent in both residential and non-residential systems at the time of reporting, fewer published data on battery costs, balance of system costs, and maintenance were available. Moreover, the battery capacity is also variable based on the service need. Ultimately, multiple data sources were used to assume an overall capital cost per kWh based on a 3- or 4-hour battery for various measure permutations. O&M costs were largely defined by a ten-year amortized battery replacement cost.

Table 8: Average Solar PV Installation Cost

SECTOR	SYSTEM COST ($/ DC W)[1]
Residential	$3.22
Residential (Battery)	$4.88
Non-Residential (<250 kW)	$2.73
Non-Residential (<250 kW w/ Battery)	$3.52
Non-Residential (≥250 kW)	$1.50
Non-Residential (≥250 kW w/ Battery)	$1.87
Operations & Maintenance	$10-$15/kw/yr
Operations & Maintenance w/Battery	$24-$76/kw/yr

[1]Costs reflect impact of federal investment tax credit and are averages across regions. Analysis uses region-specific costs.

2.6.3. Estimate Achievable DER Potential

The approach to assessing achievable potential for solar PV follows the same logic and methods as outlined in Section 0. Similar to the energy efficiency analysis, the Team defined adoption curves based on a Bass diffusion model. The data informing the adoption curves were based on two key parameter inputs:

- Maximum estimated number of buildings suitable for solar
- Adoption rates based on customer willingness to participate

The Team estimated the first parameter based on the count of buildings suitable for solar PV measures. For example, if a 7.5 kW solar PV measure passed cost effectiveness, the total count of applicable buildings is defined as residential buildings that do not consume more than the total annual generation of the PV system and have sufficient rooftop area to support a system of that size. The second parameter of customer adoption is based on secondary data collected from the Midwest that surveyed residential and non-residential customers' willingness to install solar PV on their home or facility with varying incentive levels. Residential customers were asked their willingness to install based rebate values that covered a percent of the total system cost while non-residential customers were asked their willingness to install based on number of years of payback. With these parameters defined, the Team developed Bass diffusion curves to approximate adoption at various incentive levels. Innovation and imitation coefficients were defined based on state-specific research conducted by NREL[15].

3. MARKET CHARACTERIZATION & BASELINE FORECAST FINDINGS

3.1. Overview

As outlined in Section 2, the analysis of theoretically achievable savings potential requires an accurate characterization of the baseline energy usage and customer characterization. This section summarizes the market and end-use characterization including Tri-State's energy usage by sector, region, and end-use. Tri-State's 2018 electricity sales to member cooperative customers were found to be 14,974 GWh with distribution of sales by customer sector shown in Figure 5, sales by region in Figure 6, and finally with detail conjoined by customer sector and region included in Figure 7.

[15] Sigrin, B, et. al. The Distributed Generation Market Demand Model (dGen): Documentation. National Renewable Energy Laboratory. February 2016.

Figure 5. 2018 Energy Sales by Customer Sector

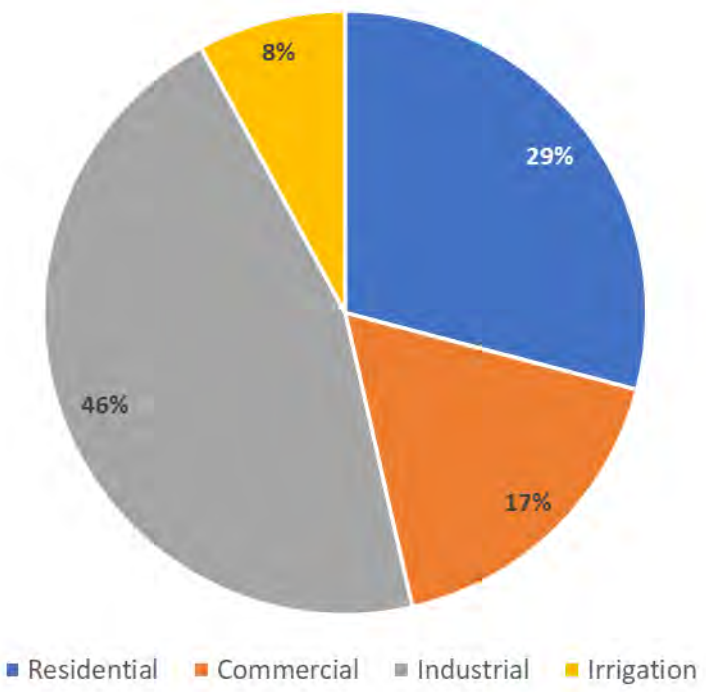

Figure 6. 2018 Energy Sales by Region

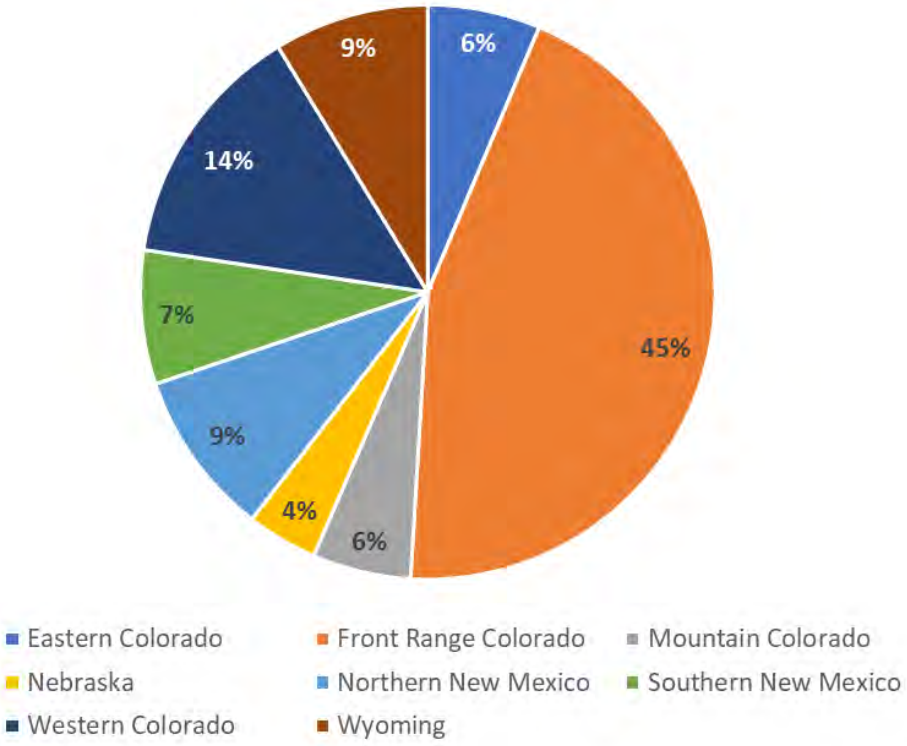

Figure 7. 2018 Energy Sales by Customer Sector and Region

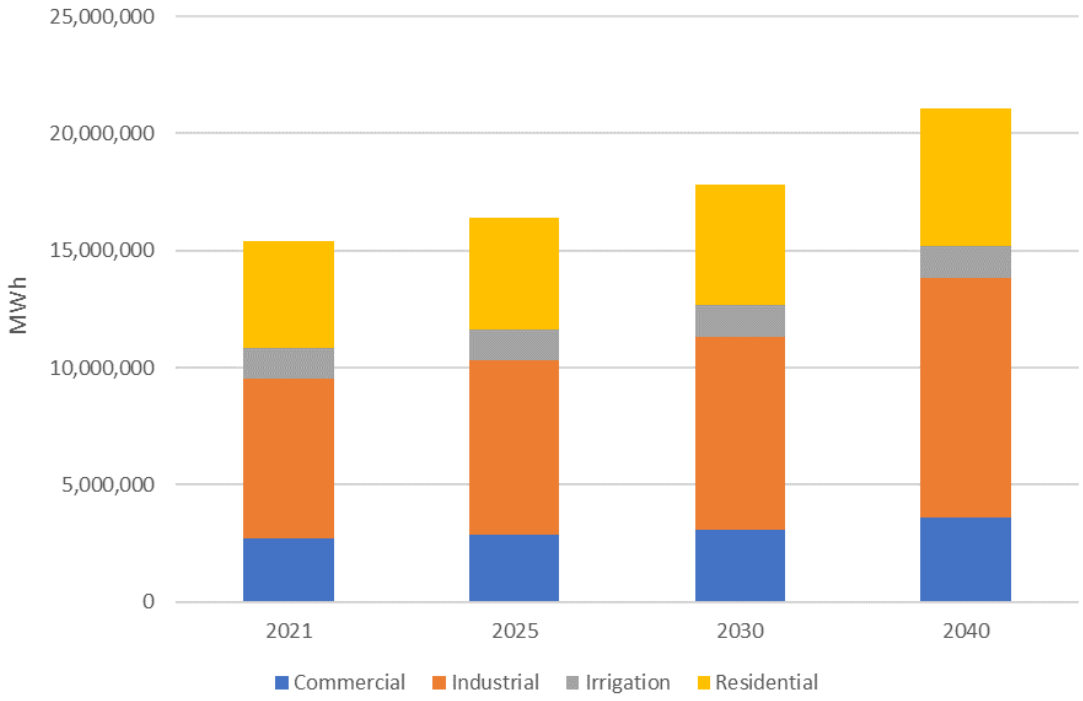
	Eastern Colorado	Front Range Colorado	Mountain Colorado	Nebraska	Northern New Mexico	Southern New Mexico	Western Colorado	Wyoming
Irrigation	554,724	31,967	861	237,972	41,763	85,091	116,352	119,890
Industrial	494,719	2,061,346	814,705	79,803	903,438	107,893	1,104,101	1,268,084
Commercial	268,177	964,547	176,453	78,733	289,986	197,934	444,417	173,590
Residential	276,257	1,944,118	241,514	173,762	406,734	328,318	606,582	380,071

The industrial sector comprises a very large share of the energy load (46%). Energy use in this sector is predominately focused around the oil, gas, and mining industries, as described further in section 4.3. Conversely, the commercial sector share, at 17%, is lower than other electric utilities that serve metropolitan communities and typically have a commercial sector share closer to 40 to 50% of all energy sales. Tri-State's relatively low commercial sector values reflect the fact that many of the member cooperatives do not serve the city and town customers within their service territories. Municipal electric utilities are common for many rural towns within western Nebraska, eastern Colorado, and most of Wyoming. Eastern Colorado and Nebraska regions have significant shares of their overall electricity sales in the irrigation sector.

Figure 8 presents the baseline load forecast at key milestone points during the analysis period. The industrial sector will see the largest amount of load growth, increasing by approximately 50% by 2040.

Commercial and residential sector load will each increase by approximately one-third. The load growth estimate for the irrigation sector is negligible.

Figure 8. Baseline Load Forecast by Sector by Milestone Year



3.2. Residential End-Uses and Loads

The residential sector is responsible for 4,357 GWh of electric consumption, includes approximately 470,000 unique residential dwellings and accounts for 29% of Tri-State's total electricity sales. Average per dwelling energy usage was in line with an annual consumption of 9,260 kWh per home. Based on the limited information available to segment single-family, multi-family, and/or manufactured homes energy use or equipment saturations, it was determined that the existing residential sector should be analyzed in its entirety with no sub-sectors analyzed.

There are notable variations in average home size, average annual energy consumption, and equipment saturations across the different regions as shown in Figure 9.

Figure 9. Average Annual End-Use Consumption per Residence by Region (2018)

	Eastern Colorado	Front Range Colorado	Mountain Colorado	Western Colorado	Nebraska	Southern New Mexico	Northern New Mexico	Wyoming
Water Heat	653	540	668	444	955	298	334	785
Plug Load	1,786	1,569	865	1,441	2,590	948	887	2,478
Appliances	3,279	3,527	2,557	2,972	3,621	2,564	2,868	3,225
Lighting	1,919	2,280	1,308	1,718	1,909	1,356	1,290	1,810
HVAC	2,443	2,674	2,818	1,662	4,928	1,269	890	2,757

The Team utilized the 2012 Tri-State residential end-use survey to compile end-use saturations and average residential premise square footage as in Table 9.

Table 9: Tri-State End-Use Saturations per Region

END-USE	EASTERN COLORADO	FRONT RANGE COLORADO	MOUNTAIN COLORADO	WESTERN COLORADO	NEBRASKA	SOUTHERN NEW MEXICO	NORTHERN NEW MEXICO	WYOMING
Central Heating	13.2%	16.0%	22.7%	15.6%	25.5%	8.4%	6.3%	15.4%
HVAC Aux	67.9%	91.7%	78.3%	78.6%	72.6%	57.5%	39.4%	71.8%
Room AC	18.1%	6.9%	1.8%	5.8%	23.3%	11.3%	11.8%	16.1%

Central Air	44.8%	49.9%	1.4%	7.4%	44.6%	19.7%	12.5%	26.3%
Heat Pump	4.2%	3.9%	0.2%	1.2%	14.4%	2.6%	2.6%	2.0%
Interior Lighting	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%
Exterior Lighting	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%
Electric Cooking	56.4%	70.2%	65.8%	54.1%	71.3%	38.8%	71.0%	64.6%
Washer	81.1%	94.0%	79.8%	89.5%	89.6%	82.3%	76.8%	86.2%
Electric Dryer	75.3%	83.7%	67.5%	69.5%	85.6%	67.7%	61.3%	80.8%
Dish Washer	67.9%	91.7%	78.3%	78.6%	72.6%	57.5%	39.4%	71.8%
Electric Water Heater	29.7%	20.3%	40.9%	31.4%	53.7%	25.7%	25.8%	44.7%
Refrigerator	84.5%	96.1%	93.3%	94.3%	91.1%	90.6%	91.5%	89.1%
Second Refrig	23.4%	24.5%	14.1%	14.8%	27.5%	16.6%	14.6%	21.8%
Freezer	69.1%	62.6%	40.6%	54.3%	77.0%	53.6%	58.5%	72.0%
Exterior Plug Loads	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%
Plug Loads	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%	100.0%

The saturations of 'plug loads' and 'lighting' are both 100% by definition. Therefore, the contribution of these end-uses to the overall energy usage is driven by the unit energy consumption (UEC) and by the prevalence of certain equipment within the end-use category.

The analysis finds lower appliance saturations and smaller premise square footage for the New Mexico region residences. As expected, there is a higher prevalence of electric space and water heating in the colder climates of mountain Colorado, Nebraska, and Wyoming due to the lack of available natural gas in the rural environment.

3.3. Commercial End-Uses and Loads

The commercial sector is responsible for 2,594 GWh of electric consumption, which accounts for 17% of Tri-State's total electricity sales. In general, the commercial sector covers a large spectrum of customers, usually smaller in size as compared to the remainder of the non-residential customers, with 71% having a peak demand less than 250 kW.

Since the Team only had business type data for large commercial/industrial customers over 250KW, an analysis step was to segment the remainder of customers into distinct commercial business types. Assumptions largely based on secondary data used in this segmentation analysis were checked in the load calibration analysis of the end-use profile.

Figure 10. Commercial Sector Energy Shares by Business Segment and Region (2018)

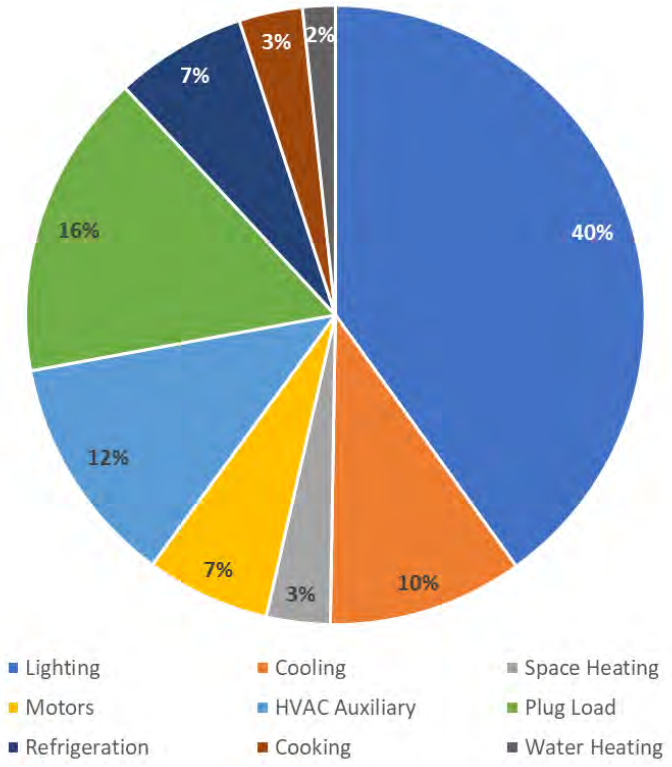
	Eastern Colorado	Front Range Colorado	Mountain Colorado	Nebraska	Northern New Mexico	Southern New Mexico	Western Colorado	Wyoming
Warehouse	9%	7%	6%	11%	6%	5%	6%	8%
Restaurant	4%	3%	3%	4%	3%	3%	3%	4%
Office	15%	13%	14%	15%	12%	10%	12%	15%
Retail	22%	22%	20%	20%	18%	18%	21%	21%
Miscellaneous	20%	18%	27%	19%	28%	14%	23%	21%
Lodging	6%	6%	10%	6%	5%	13%	7%	6%
Health	7%	6%	6%	7%	10%	5%	9%	7%
Government	2%	11%	2%	4%	5%	11%	4%	3%
Grocery	5%	5%	5%	5%	4%	4%	4%	6%
Education	9%	9%	7%	9%	9%	17%	10%	9%

The Team next identified the appropriate energy usage intensity (EUI), or end-use energy consumption per square foot, for each end-use studied. These EUIs were calculated based on other applicable

regional commercial end-use studies, such as those found in Wyoming, Montana, Utah, Colorado, New Mexico, and Iowa. Figure 11 summarizes the energy consumption for each end-use.

Lighting makes up forty-five percent of the total electricity consumption, which is attributable to the fact that this end-use is common in all sub-sectors and does not have any seasonal operation. Lighting is followed by HVAC Auxiliary which included fans, pumps, motors, and electronics used to move or control HVAC air and water systems.

Figure 11. Commercial Energy End-Use Consumption Shares



3.4. Industrial End-Uses and Loads

Industrial is the largest sector, accounting for 6,834 GWh of electric consumption and 46% of Tri-State's total electricity sales. In general, Tri-State's industrial sector is unique since approximately 77% of the sector's consumption is from the oil and gas industry and less than 15% is from manufacturing industries (Figure 12).

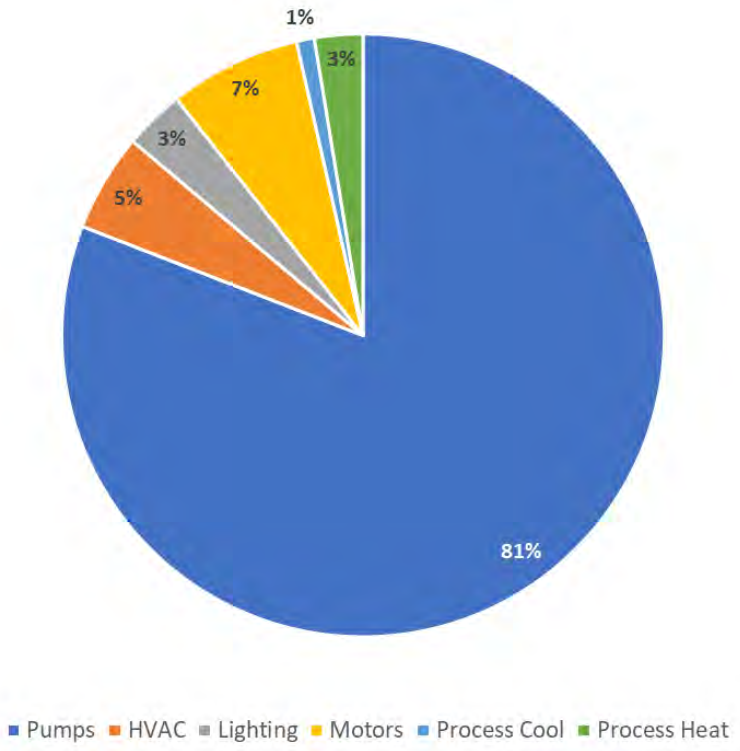
Since the Team only had business type data for large commercial/industrial customers over 250KW, an analysis step was to segment the remainder of customers into distinct industrial business types. Assumptions used in this segmentation analysis were checked in the load calibration analysis of the end-use profile.

Figure 12. Industrial Sector Energy Shares by Business Segment and Region (2018)

	Eastern Colorado	Front Range Colorado	Mountain Colorado	Nebraska	Northern New Mexico	Southern New Mexico	Western Colorado	Wyoming
TCU	4%	5%	1%	11%	2%	35%	3%	4%
Pipeline Transportation	59%	24%	17%	41%	54%	38%	80%	34%
Mfg - Misc.	2%	11%	1%	2%	1%	7%	1%	1%
Mfg - Chemical	5%	3%	0%	28%	8%	1%	5%	0%
Mfg - Paper	0%	0%	0%	0%	14%	0%	0%	0%
Mfg - Nonmetallic Mineral Product	0%	13%	0%	1%	0%	2%	0%	2%
Liquid Mining (Oil, Gas, and Carbon Dioxide)	22%	38%	74%	4%	19%	5%	8%	56%
Mining	3%	2%	6%	10%	1%	9%	2%	3%
Agriculture	5%	2%	1%	3%	1%	4%	2%	0%

The Team identified the appropriate energy usage fraction for each industrial end-use studied. These energy end-use shares were calculated based on other applicable regional and national industrial end-use studies (Figure 13).

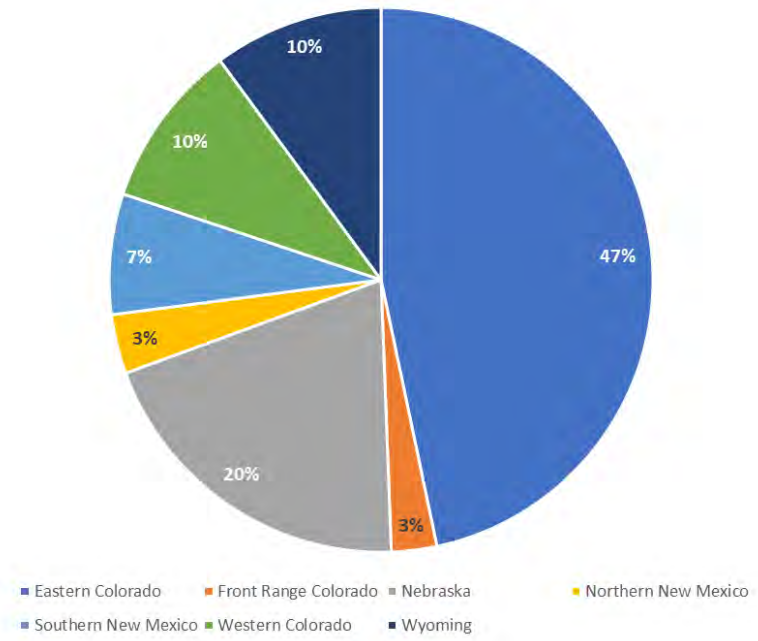
Figure 13. Industrial Sector Energy Shares by End-Use



3.5. Irrigation End-Uses and Loads

Figure 14 summarizes the irrigation energy consumption share for each region analyzed. Eastern Colorado has the largest share of irrigation energy consumption by a wide margin and is followed by the Nebraska region. The Mountain Colorado region has a negligible market share of irrigation sales and is not shown for clarity.

Figure 14: Irrigation Energy Shares by Region



Irrigation energy usage is entirely attributable to electric motors. These motors serve several different purposes, including well lift pumps, supplemental pressure boost pumps, drive motors for center pivots, and gate motors. Based on the Team's experience and research, it was determined that the major application for irrigation electricity is well lift pumps and supplemental pressure boost pumps; consequently, analyses and measures were developed for these end-uses.

3.6. Peak Demand Characterization

This section summarizes the market and end-use characterization of Tri-State's summer peak demand by sector and region. Tri-State's 2018 coincident peak demand used by member cooperatives was 2,887 MW, observed during the month of July. Figure 15 shows the distribution of the coincident peak demand by region. Energy sales by sector were used to estimate coincident peak demand allocation by sector, as described in Section 3. Figure 16 shows the results of this estimation for the Tri-State system as a whole and Figure 17 presents results by region. Notable contributors to the coincident peak demand are the residential and industrial sectors in the Front Range region, as well as the irrigation sector in Eastern Colorado and Nebraska.

Figure 15. 2018 Coincident Peak Demand by Region

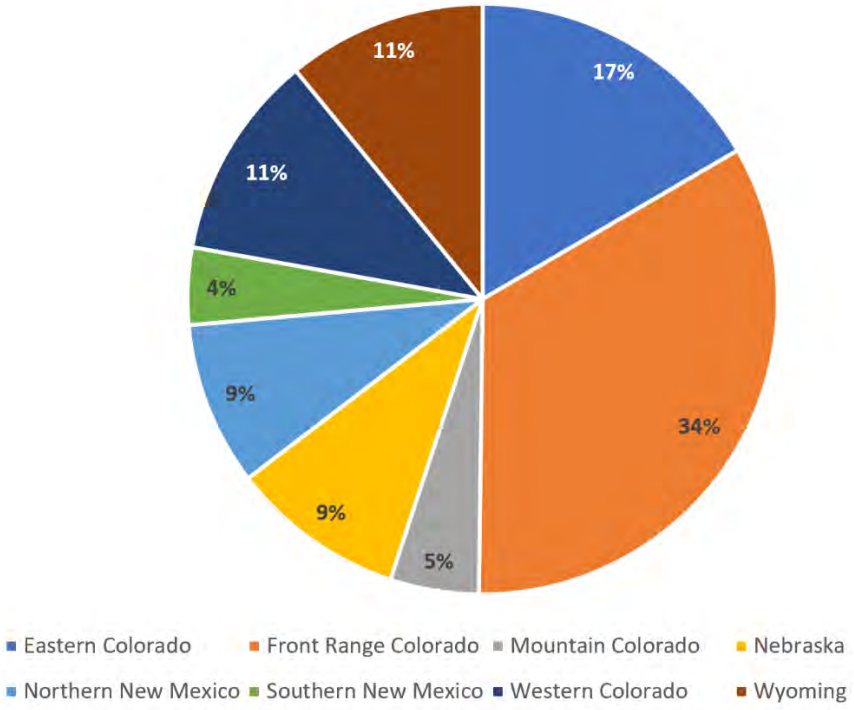


Figure 16. 2018 Coincident Peak Demand by Sector

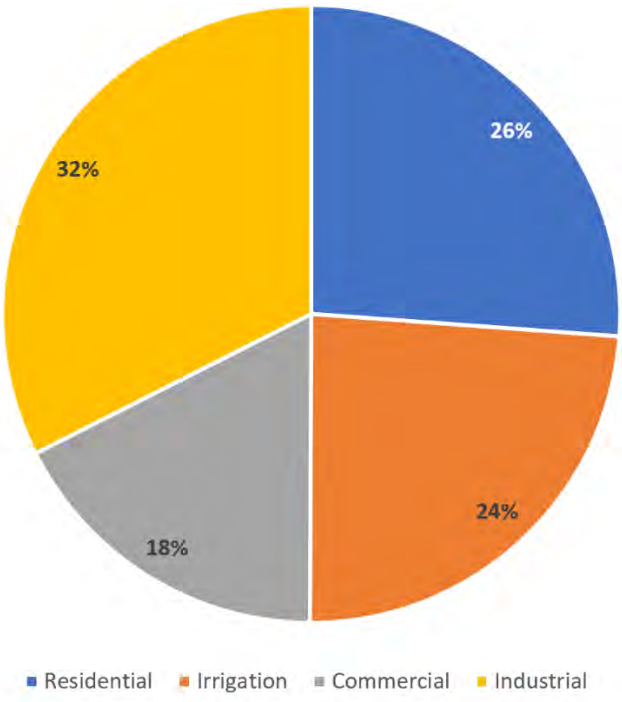

Figure 17. 2018 Coincident Peak Demand by Sector and Region

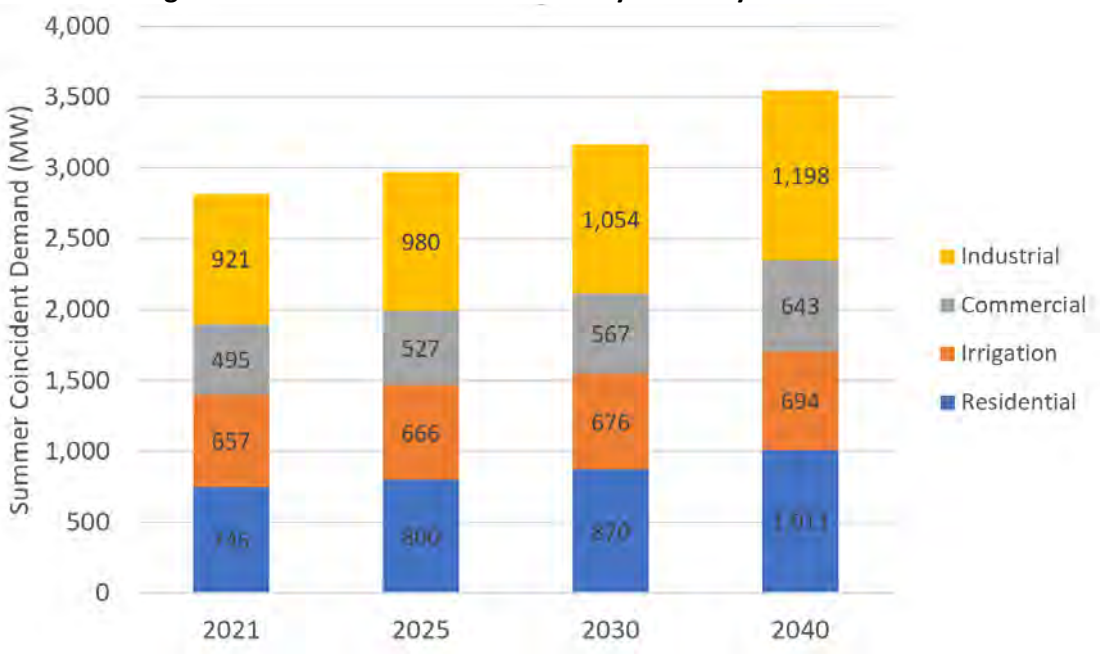
	Eastern Colorado	Front Range Colorado	Mountain Colorado	Nebraska	Northern New Mexico	Southern New Mexico	Western Colorado	Wyoming
Industrial	78	354	78	15	106	30	89	131
Commercial	42	190	42	8	57	16	48	71
Irrigation	309	14	0	185	11	22	46	61
Residential	47	402	21	22	52	48	68	49

Figure 18 presents the baseline demand forecast at key milestone points during the analysis period. Industrial, commercial, and residential sectors will increase by about 30%. The irrigation sector's coincident peak is not expected to increase significantly.

Figure 18. Baseline Demand Forecast by Sector by Milestone Year



4. PORTFOLIO LEVEL ENERGY EFFICIENCY POTENTIAL

4.1. Overview

The analysis finds that at the portfolio level Tri-State can achieve an average annual savings of 115 GWh from a collection of energy efficiency measures at an average annual cost of $24.3 million during the 20-year time horizon. This includes incentives and administrative costs and equates to an acquisition cost of $0.22/kWh which is in line with industry benchmarks.

4.2. Detailed Results

Table 10 presents portfolio-level energy efficiency savings potential by time horizon and Figure 19 shows the growth in cumulative savings potential through 2040. The Achievable-Moderate scenario estimates 38,083 MWh of savings potential in 2021 rising to 1,718,357 MWh of cumulative savings potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive) could increase cumulative savings potential by approximately 40%. The maximum achievable scenario increases savings potential by approximately 25% over the aggressive scenario, resulting in cumulative savings of approximately 2,876,487 GWh. First-year savings potential for the Achievable-Moderate scenario represents an increase of approximately 19% over Tri-State's 2018 energy efficiency program performance.

Table 10 Cumulative Savings Potential (MWh) by Scenario by Time Horizon

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021	130,384	98,221	75,523	55,330	38,083	27,043

2025	1,293,033	928,122	539,750	393,656	266,309	179,222
2030	3,868,940	2,851,171	1,372,971	1,062,225	723,605	475,993
2040	9,081,432	6,956,507	2,876,487	2,354,365	1,718,357	1,193,109

Figure 19. Portfolio Energy Efficiency Savings Potential by Scenario by Year

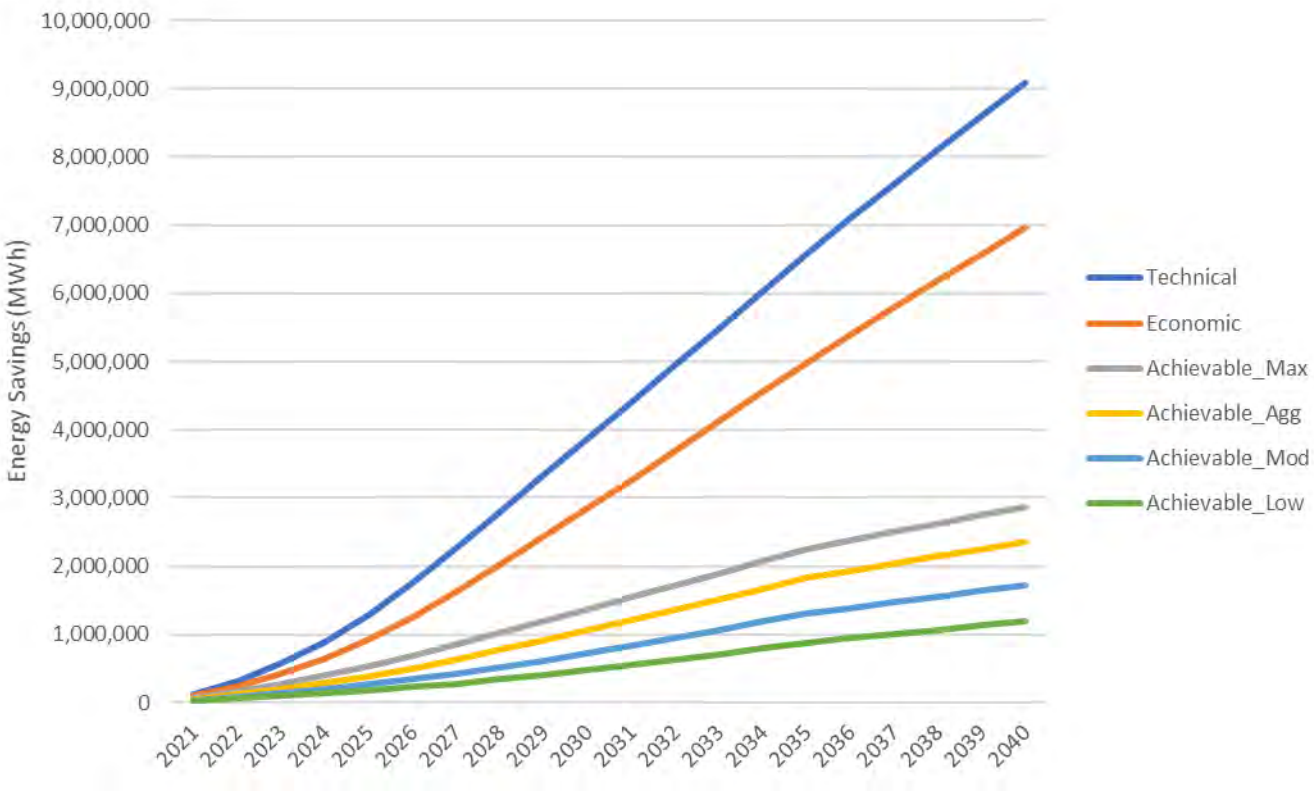


Table 11. shows the impacts of cumulative savings potential on Tri-State's baseline energy consumption forecast. The cumulative savings associated with the Achievable Moderate scenario would decrease Tri-State's baseline forecast consumption by approximately 0.25% in 2021. The reduction in baseline energy consumption would grow to 1.62% by 2025 and ultimately 8% through 2040. The range of potential reduction in baseline consumption across the achievable scenarios spans from 5.7% (Achievable-Low) to 13.7% (Achievable-Max) by 2040.

Table 11. Portfolio Cumulative Savings Potential as % of Baseline Forecast by Sector by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	0.85%	0.64%	0.49%	0.36%	0.25%	0.18%
2025	7.88%	5.65%	3.29%	2.40%	1.62%	1.09%

2030	21.74%	16.02%	7.71%	5.97%	4.07%	2.67%
2040	43.14%	33.04%	13.66%	11.18%	8.16%	5.67%

Figure 20 shows the impact of the modeled scenarios on the baseline forecast. The Achievable-Max scenario would reduce Tri-State's overall load growth significantly, though Tri-State's load will continue a steady growth trajectory under all Achievable scenarios.

Figure 20. Impact of Portfolio Energy Efficiency Savings on Baseline Forecast by Scenario by Year

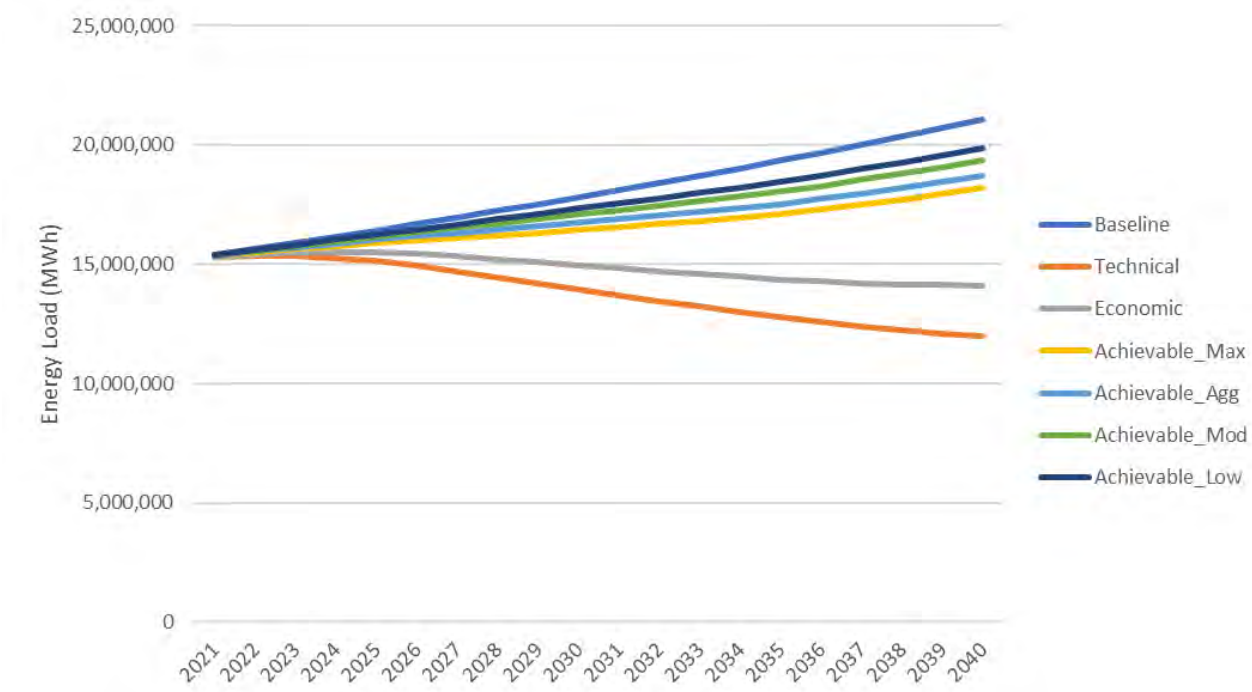

Figure 21 and Table 12 present energy savings potential by region. Front Range Colorado represents the largest share making up half the total. The other regions within Colorado account for nearly one quarter of the remaining savings potential. The two regions within New Mexico together comprise approximately 13% of total savings potential, while Wyoming accounts for approximately 10% of the total. Nebraska's savings potential is much smaller at just 2.7% of the total. This savings potential is generally aligned with the distribution of forecast energy load by region. However, Front Range Colorado's share of energy savings (50%) is larger than its share of forecast baseline energy consumption (39.5%) by a notable margin.

Figure 21. Baseline Forecast and Portfolio Energy Efficiency Savings by Region

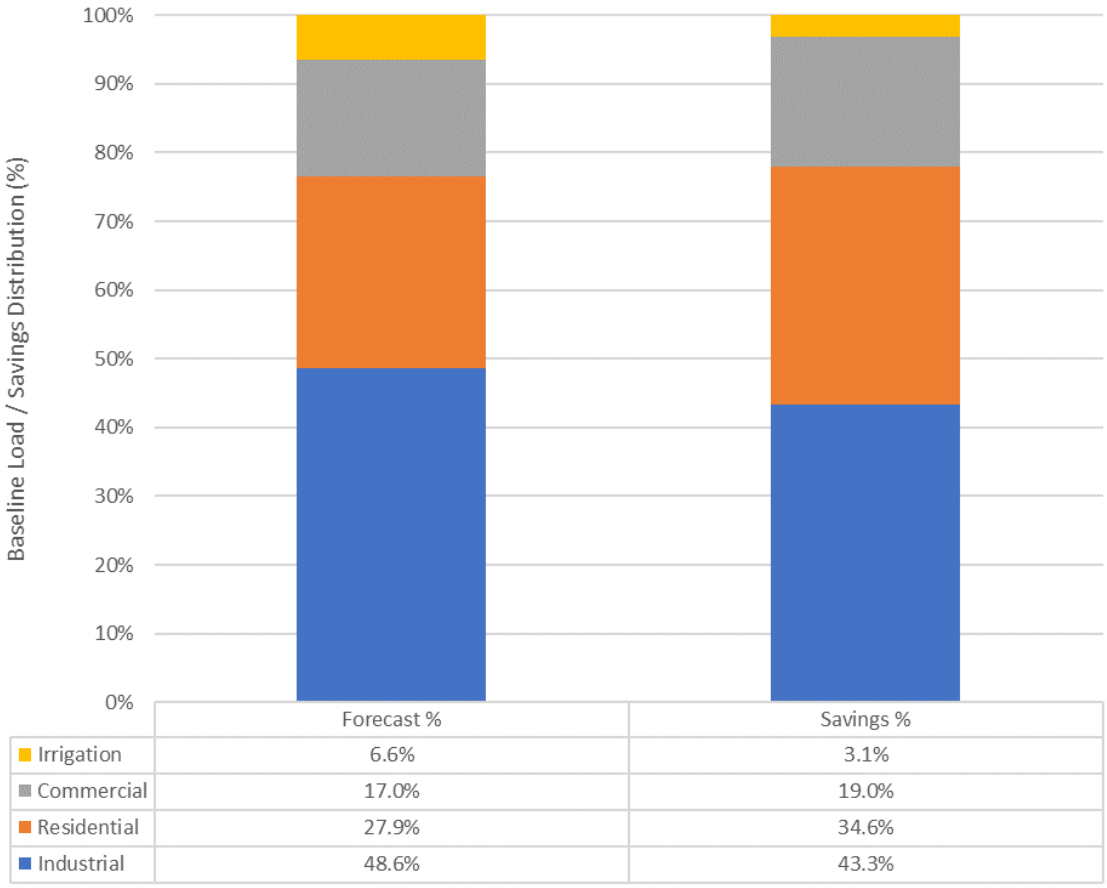
	Forecast %	Savings %
Nebraska	3.4%	2.7%
Southern New Mexico	4.1%	3.9%
Mountain Colorado	9.8%	6.8%
Eastern Colorado	10.2%	7.8%
Northern New Mexico	9.5%	8.8%
Western Colorado	9.6%	9.2%
Wyoming	13.9%	10.6%
Front Range Colorado	39.5%	50.0%

Table 12. Cumulative Savings Potential by Region, Achievable-Moderate Scenario (2040)

STATE / SUB-REGION	POTENTIAL SAVINGS (MWH)
Colorado	1,270,405
Front Range	*860,016*
Western	*158,539*
Mountain	*117,559*
Eastern	*134,292*
Wyoming	182,708
New Mexico	218,977
Northern	*151,292*
Southern	*67,685*
Nebraska	46,267
Total	**1,718,357**

As shown in Figure 22 the industrial and residential sectors represent the largest opportunity for savings. The industrial sector comprises 43% of the total savings potential and its share of the baseline forecast consumption is slightly higher at 49%. This sector's oil and gas-related energy consumption is exceptionally high, and motor-related efficiency improvements can go a long way toward reducing that load, as discussed further in Section 7. The residential sector makes up 35% of the total savings potential, and a slightly smaller portion of the baseline forecast consumption at 28%. Numerous measures are available to reduce residential energy load, with the most substantial savings coming from lighting and central heating, as discussed further in Section 5. The commercial sector also holds substantial potential energy savings at 19% of the total, which is generally in line with its share of the baseline forecast energy consumption. Heavy use of energy for lighting coupled with the availability of numerous lighting efficiency-related measures account for this sector's substantial share of savings potential. The irrigation sector contributes substantially less, both in terms of overall savings potential and in terms of its share of baseline forecast load.

Figure 22. Energy Efficiency Savings Potential by Sector (2040)



The portfolio of energy efficiency measures can achieve a cumulative demand savings of 23 MW by 2040 (Table 13.) under the Achievable-Moderate scenario. The industrial sector accounts for the largest share of demand savings, followed by the residential sector.

Table 13. Portfolio Cumulative Demand Savings Potential by Sector by Year (MW)

MILESTONE YEAR	INDUSTRIAL	RESIDENTIAL	COMMERCIAL	IRRIGATION	**TOTAL**
2021 (first year)	1.8	2.1	1.1	0.12	**5.3**
2025	3.7	3.5	2.3	0.37	**9.9**
2030	6.7	5.8	3.7	1.1	**17.2**
2040	10.3	6.2	4.5	2.1	**23.1**

Table 14 presents cumulative and average annual cost, savings and TRC metrics associated with the Achievable-Moderate scenario. As shown, in the first year Tri-State can achieve 38,083 MWh of energy savings at a cost of approximately $7 million, or $183/MWh. As programs expand and become more established annual costs and savings increase substantially to reach a cumulative program expenditure of nearly $500 million by 2040 and savings of approximately 2,290,400 MWh. The 20-year average annual program costs are approximately $24.3 million and savings are 114,520 MWh.

Table 14. Portfolio Cost Metrics by Time Horizon (Achievable-Moderate Scenario)

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	SUM OF FIRST-YEAR MEASURE SAVINGS (MWH)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	2.08	$6,957,787	38,083	$182.70	$15.25
2025	1.91	$54,155,251	279,461	$193.78	$17.41
2030	1.72	$164,148,094	797,374	$205.86	$20.18
2040	1.64	$486,794,842	2,290,399	$212.54	$21.55
20-year avg.	1.64	$24,339,742	114,520	$212.54	$21.55

5. RESIDENTIAL ENERGY EFFICIENCY POTENTIAL

5.1. Overview

The residential sector accounts for just under one-third of the total baseline forecast energy load, and 35% of energy savings potential. Cumulative savings potential for this sector is approximately 5,880 GWh through 2040 (Achievable-Moderate scenario) with lighting efficiency improvements making up over half the total energy savings potential. Central heating improvements comprise almost one-sixth of the residential sector savings potential.

Notable assumptions for the residential sector analysis include: 1) the speed with which lighting market transformation will occur, and 2) the timing of the roll-out and accrual of demand impacts associated with Home Energy Reports (HERs). With regard to lighting, research indicates that LED lamps will become standard technology within 10 years despite delays in implementing lighting efficiency standards under the Energy Independence and Security Act (EISA) of 2007. Lighting measures commonly account for the largest share of savings for residential energy efficiency programs. However, since residential lighting market transformation is well underway, savings from lighting measures are limited for the second half of the evaluation period.

For the home energy reports measure (HER) the analysis assumes a seven-year implementation delay in order to capture demand benefits associated with this measure. This is because Tri-State is not capacity

constrained during this period and avoided cost of capacity benefits do not apply. The addition of demand benefits along with energy savings benefits allows the HERs measure to achieve cost effectiveness for various measure permutations in varying regions.

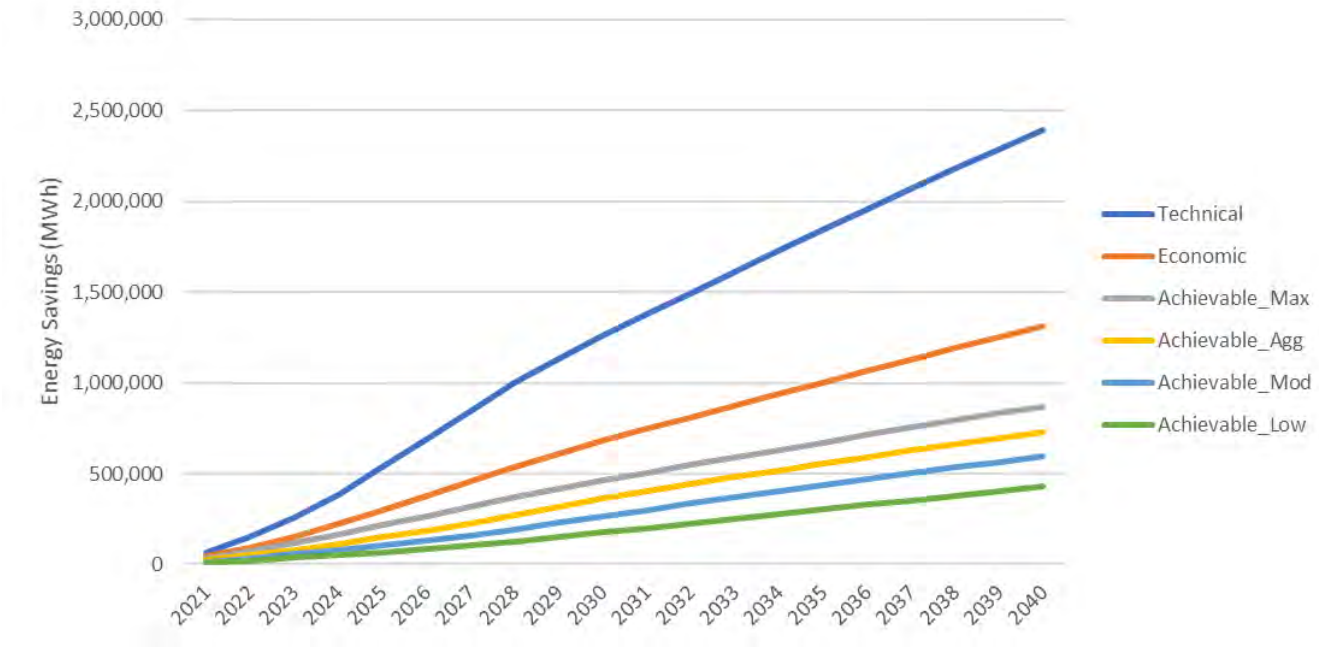
5.2. Detailed Results

Table 15 presents cumulative savings potential for the residential sector by scenario at various milestones in the analysis period and Figure 23 shows the growth in cumulative savings potential through 2040. The Achievable-Moderate scenario estimates 14,649 MWh of savings potential in 2021 rising to 594,298 MWh of cumulative savings potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive scenario) could increase cumulative savings potential by approximately 22%. The maximum achievable scenario estimates savings potential approximately 46% higher than the aggressive scenario, equating to cumulative savings of approximately 870,669 MWh through 2040.

Table 15. Cumulative Residential Savings Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	63,817	42,581	34,166	22,384	14,649	9,539
2025	532,961	299,459	214,988	149,245	104,278	68,016
2030	1,257,012	679,699	461,040	361,598	263,762	175,118
2040	2,395,940	1,313,384	870,669	726,771	594,298	427,615

Figure 23. Residential Energy Efficiency Savings Potential by Scenario by Year



The cumulative residential savings potential under the Achievable-Moderate scenario equates to 9.1% of the residential baseline load forecast for 2040 (see Table 16.). The maximum achievable savings would equate to 16.2% of the forecast energy load for this sector.

Table 16. Residential Savings Potential as % of Baseline Forecast by Scenario by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	1.10%	0.75%	0.57%	0.45%	0.32%	0.24%
2025	12.48%	8.63%	4.36%	3.36%	2.25%	1.54%
2030	38.13%	26.76%	10.02%	8.03%	5.53%	3.74%
2040	76.33%	53.93%	16.19%	13.21%	9.14%	6.54%

As shown in Figure 24, lighting accounts for the greatest share of energy savings potential at 55% of the total followed by central heating at approximately 15% of total savings. Plug loads, central air, HVAC auxiliary, and refrigerator/freezer end-uses combined comprise over a quarter of savings potential.

Figure 24. Residential Baseline Energy Load and Cumulative Energy Efficiency Savings Potential by End-Use (2040)

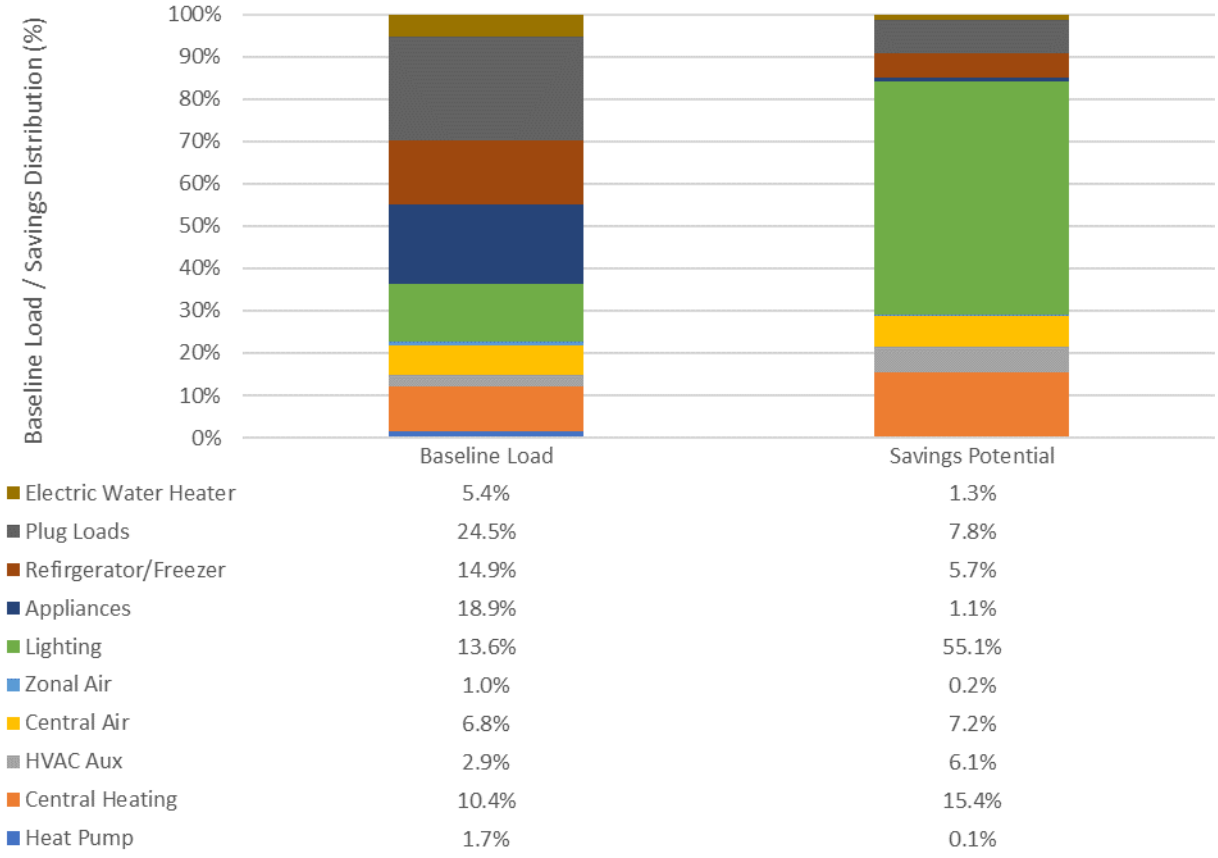


Table 17 presents cumulative residential demand savings by end-use by milestone year. High efficiency lighting is by far the greatest contributor to demand savings from residential energy efficiency measures producing 2,722 kW of cumulative demand savings through 2040. Additional measures with relatively large volumes of demand savings include plug loads and central air.

Table 17. Residential Cumulative Demand Savings Potential by End-Use by Year (MW)

YEAR	HEAT PUMP	CENTRAL HEATING	HVAC AUX	CENTRAL AIR	ZONAL AIR	LIGHTING	APPLIANCES	REFRIG-ERATOR / FREEZER	PLUG LOADS	ELECTRIC WH	TOTAL

2040	0.0037	0.0440	0.2012	1.7245	0.0829	2.7220	0.1116	0.3383	0.7502	0.1771	**6.1554**

Table 18. presents cumulative program cost metrics by milestone year. As shown, first-year program costs are approximately $3.0 million, rising to a 20-year average annual cost of approximately $8.9 millon. Acquisition costs rise from $206/MWh in 2021 to $251/MWh in 2040. A change in lighting market measures available during the analysis period drives this increase in acquisition costs, as LEDs become the market baseline within ten years. The decline in highly cost-effective lighting measures also has a downward effect on the TRC ratio, as it decreases from 2.15 in 2021 to 1.36 in 2040.

Table 18. Cumulative Residential Cost Metrics by Time Horizon

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	SUM 1st-YEAR MEASURE SAVINGS (MWH)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	2.15	$ 3,013,704	14,649	$ 205.72	$ 14.90
2025	1.84	$ 23,693,929	104,884	$ 225.91	$ 18.61
2030	1.50	$ 68,913,983	280,300	$ 245.86	$ 23.95
2040	1.36	$ 177,217,648	705,466	$ 251.21	$ 26.52
20-year avg.	1.36	$ 8,860,882	35,273	$ 251.21	$ 26.52

6. COMMERCIAL ENERGY EFFICIENCY POTENTIAL

6.1. Overview

The commercial sector accounts for 17% of the total baseline forecast energy load, and 19% of cumulative energy savings potential in 2040. Cumulative savings potential for this sector is approximately 326 GWh through 2040 (Achievable-Moderate scenario) with lighting measures making up 74% of the total energy savings potential. Other end-uses comprising a notable share of savings potential include refrigeration, motors and plug load at 7.5%, 5% and 4% of savings respectively. The retail segment holds the largest opportunity for savings at roughly 27% of the cumulative savings potential in 2040.

6.2. Detailed Results

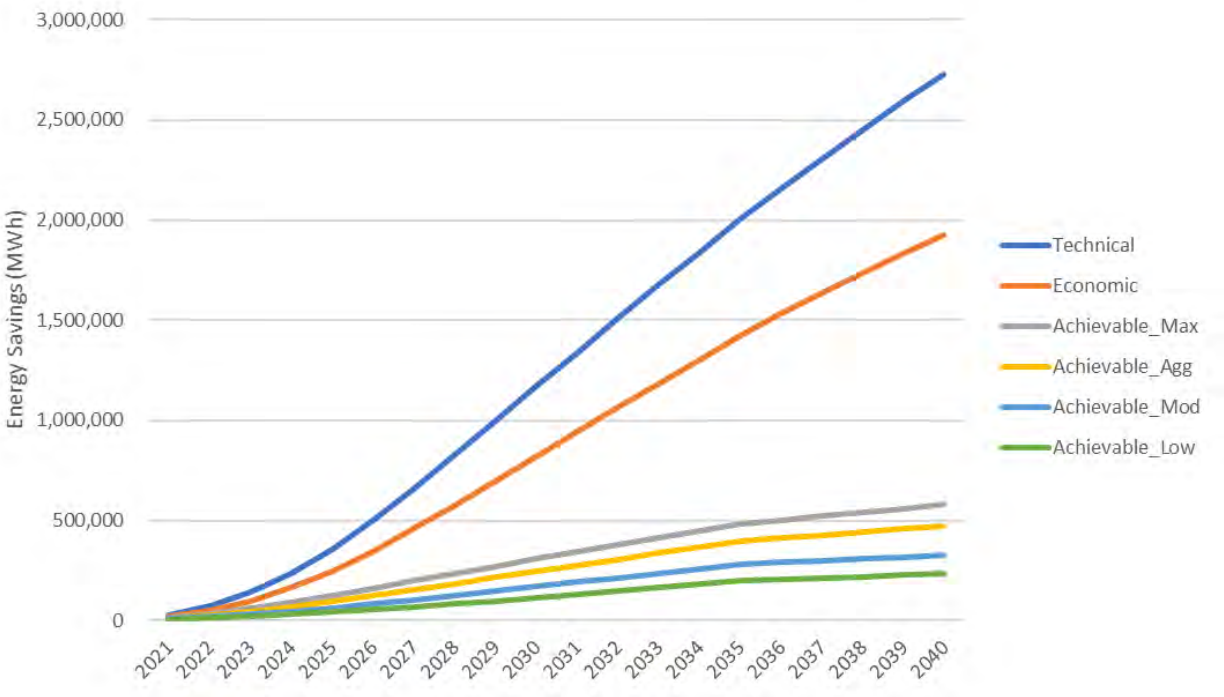
Table 19. presents cumulative savings potential for the commercial sector by scenario at various milestones in the analysis period and Figure 25 shows the growth in cumulative savings potential through 2040. The Achievable-Moderate scenario estimates 8.6 GWh of savings potential in 2021 rising to approximately 326 GWh of cumulative savings potential through 2040. Pursuing an aggressive program-delivery approach (Achievable-Aggressive scenario) could increase cumulative savings potential

by approximately 45% to 472 GWh. A less aggressive program delivery approach (Achievable-Low scenario) would reduce savings by approximately 30% relative to the Achievable-Moderatemoderate scenario.

Table 19. Cumulative Commercial Savings Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	29,723	20,331	15,375	12,230	8,626	6,372
2025	356,164	246,342	124,400	95,929	64,202	43,820
2030	1,167,833	819,729	307,053	245,955	169,298	114,633
2040	2,726,737	1,926,747	578,473	472,062	326,383	233,706

Figure 25. Commercial Cumulative Energy Efficiency Savings Potential by Sector by Year



The cumulative commercial savings potential under the Achievable-Moderate scenario equates to a reduction of 0.32% of commercial baseline sales in 2021, a 2.25% reduction by 2025 and a 9.14% reduction by 2040 (see Table 20.). The Mesa Point Energy Team esimates a range in reduction of baseline energy sales for the achievable scenarios from 6.5% (Achievable-Low) to 16.2% (Achievable-Max) by 2040.

Table 20. Commercial Cumulative Savings Potential as % of Baseline Forecast by Sector by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	1.10%	0.75%	0.57%	0.45%	0.32%	0.24%
2025	12.48%	8.63%	4.36%	3.36%	2.25%	1.54%
2030	38.13%	26.76%	10.02%	8.03%	5.53%	3.74%
2040	76.33%	53.93%	16.19%	13.21%	9.14%	6.54%

As shown in Figure 26 lighting makes up a large majority of the commercial sector's energy savings potential at 74%, a significant increase in its baseline load share. Refrigeration, motors and plug loads comprise most of the remaining savings potential for this sector at 7.5%, 5.5% and 4% respectively.

Figure 26. Commercial Baseline Energy Load and Cumulative Energy Efficiency Savings Potential Distribution by End-Use (2040)

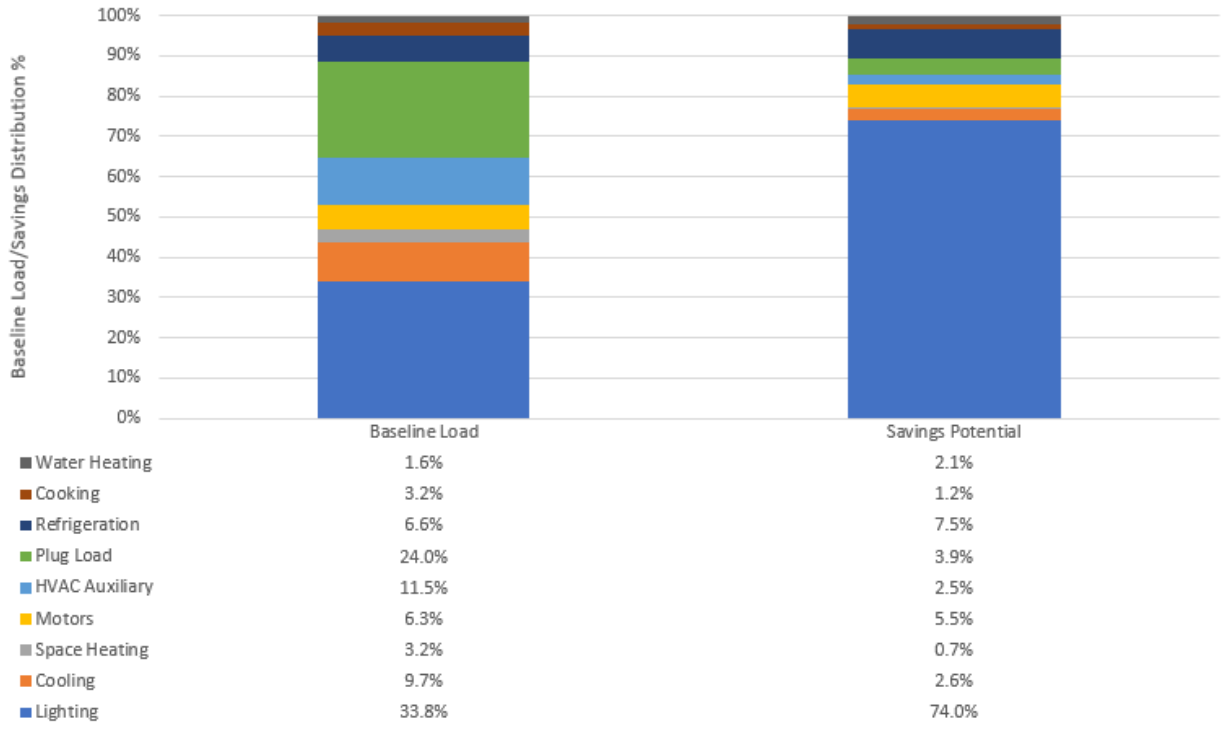


Table 21 presents cumulative commercial demand reductions by end-use by milestone year. Lighting accounts for nearly 55% of demand savings from commercial energy efficiency measures, producing almost 2,500 kW of demand reductions by 2040. Relative to their energy savings, the Cooling and HVAC Auxillary end-uses provide a large demand reduction opportunity at 430 kW and 424 kW respectively.

Table 21. Commercial Cumulative Demand Savings Potential by End-Use by Year (MW)

YEAR	LIGHTING	COOLING	HEATING	MOTORS	HVAC AUX	PLUG LOAD	REFRIGER-ATION	COOKING	DHW	TOTAL
2021 (first year)	0.763	O.054	0.001	0.0251	0.054	0.102	0.108	0.011	0.014	**1.133**
2025	1.526	0.147	0.002	0.0693	0.145	0.161	0.230	0.025	0.039	**2.344**
2030	2.171	0.310	0.004	O.1529	0.305	0.233	0.353	0.041	0.082	**3.653**
2040	2.476	0.430	0.006	0.2206	0.424	0.357	0.434	0.053	0.116	**4.517**

Figure 27 presents baseline energy load and cumulative savings by commercial market segment through 2040. The savings potential for each segment is generally similar to its share of total baseline energy load. The retail segment has the largest share of 2040 cumulative savings potential (27.4%), an increase of just over 7% of its baseline energy load share. This is a result of the large lighting load share in retail buildings. The Miscellaneous and Office segments comprise the next largest opportunities at 17.7% and 10.4% of cumulative savings potential respectively.

Figure 27. Commercial Baseline Load and Cumulative Energy Efficiency Savings Potential Distribution by Segment (2040)

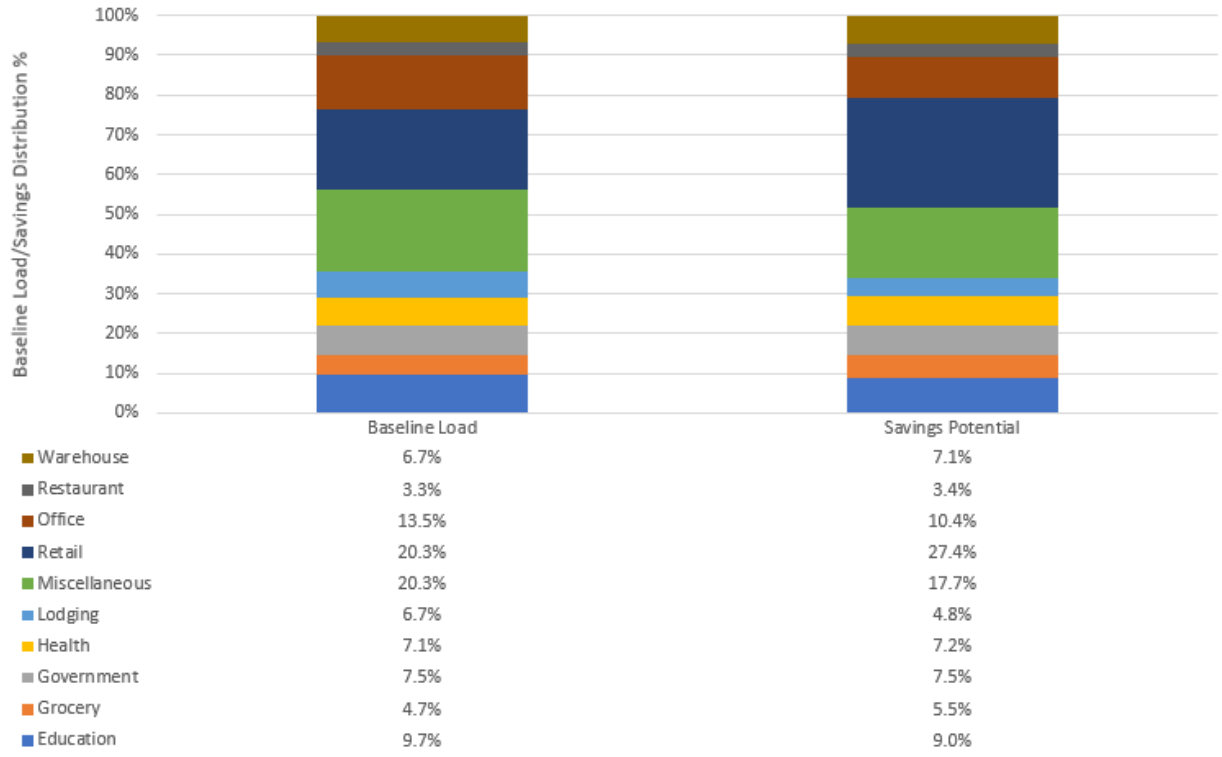

Table 22. summarizes cumulative commercial program cost metrics by milestone year. As shown, first-year program costs are approximately $1.4 million, rising to a 20-year average annual cost of roughly $4.1 millon. Acquisition costs start at $159/MWh during the first year of analysis and see a gradual increase through 2040. The TRC ratio remains solid for the commercial sector starting at 2.11 in 2021 and decreasing modestly to 1.93 in 2040.

Table 22. Commercial Cost Metrics by Time Horizon

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	SUM 1st-YEAR MEASURE SAVINGS (MWH)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	2.11	$ 1,367,761	8,626	$ 158.57	$ 18.87
2025	2.07	$ 10,437,397	64,743	$ 161.21	$19.27
2030	2.01	$ 30,065,223	181,191	$ 165.93	$ 20.13
2040	1.93	$ 82,522,317	481,235	$ 171.48	$ 21.24
20-year avg.	1.93	$ 4,126,116	24,062	$ 171.48	$ 21.24

7. INDUSTRIAL ENERGY EFFICIENCY POTENTIAL

7.1. Overview

The industrial sector makes up roughly one-half of Tri-State's total baseline forecast energy load, and 43% of potential energy savings. Cumulative savings potential for this sector is approximately 745 GWh through 2040 (Achievable-Moderate scenario) with pump-related savings accounting for a majority of potential savings at 58%. Efficiency measures for the oil and gas segment of the market comprise nearly 55% of potential savings for this sector. Manufacturing-related efficiency opportunities account for most of the remaining energy savings potential.

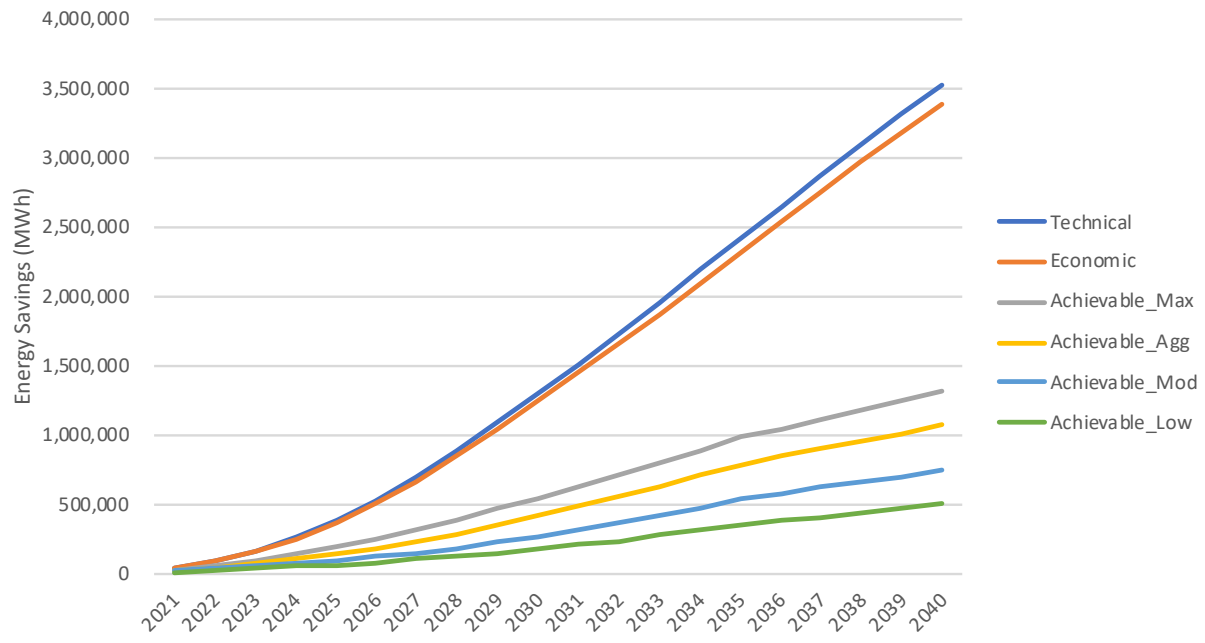
7.2. Detailed Results

Table 23 presents cumulative savings potential for the industrial sector by scenario at various milestones in the analysis period and Figure 28 shows the growth in cumulative savings potential through 2040. The Achievable-Moderate scenario estimates 14 GWh of savings potential in 2021 rising to approximately 745 GWh of cumulative savings potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive scenario) could increase cumulative savings potential by approximately 43%. Savings potential increases by an additional 22% under the maximum achievable scenario, equating to a a cumulative maximum achievable savings of approximately 1,308 GWh through 2040.

Table 23. Cumulative Industrial Savings Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	35,303	34,181	24,956	19,902	14,224	10,678
2025	378,791	363,954	186,953	139,453	92,325	63,777
2030	1,294,201	1,240,358	544,166	414,383	268,351	173,960
2040	3,523,534	3,381,672	1,307,552	1,066,805	744,543	502,719

Figure 28. Industrial Energy Efficiency Savings Potential by Scenario by Year



The cumulative industrial savings potential under the Achievable-Moderate scenario equates to a reduction of 0.21% of industrial baseline sales in 2021, a 1.24% reduction by 2025 and a 7.28% reduction by 2040 (see Table 24.). The analysis estimates a range in reduction of baseline energy sales for the achievable scenarios from 4.9% (Achievable-Low) to 12.8% (Achievable-Max) by 2040.

Table 24. Industrial Cumulative Savings Potential as % of Baseline Forecast by Sector by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	0.52%	0.50%	0.36%	0.29%	0.21%	0.16%
2025	5.09%	4.89%	2.51%	1.87%	1.24%	0.86%
2030	15.66%	15.01%	6.58%	5.01%	3.25%	2.10%
2040	34.44%	33.05%	12.78%	10.43%	7.28%	4.91%

As shown in Figure 29 efficient pumps and related measures hold by far the greatest energy savings potential for the industrial sector, accounting for nearly 60% of the total. This is in part due to the fact that pumps account for such a large portion of the industrial sector's forecast baseline energy load (81%). Lighting and HVAC also hold substantial energy savings potential for this sector at 17% and 18% of the total, respectively.

Figure 29. Industrial Baseline Energy Load and Cumulative Energy Efficiency Savings Potential Distribution by End-Use (2040)

	Baseline Load	Savings Potential
Pumps	81.0%	58.0%
Process Heat	2.6%	0.5%
Process Cool	1.0%	0.5%
Motors	6.8%	6.7%
Lighting	3.3%	16.6%
HVAC	5.3%	17.7%

Table 25. presents cumulative industrial demand savings by end-use by milestone year. As with energy savings potential, pumps are also the leader in terms of demand savings potential. Pump-related

measures contribute nearly 6.6 MW of cumulative demand savings potential. Lighting efficiency measures have the potential to decrease demand by almost 1.3 MW and HVAC by nearly 1.7 MW.

Table 25. Industrial Cumulative Demand Savings Potential by End-Use by Year (MW)

YEAR	HVAC	LIGHTING	MOTORS	PROCESS COOL	PROCESS HEAT	PUMPS	TOTAL
2021 (first year)	0.165	0.201	0.132	0.008	0.008	1.364	**1.878**
2025	0.469	0.496	0.242	0.022	0.020	2.456	**3.705**
2030	1.076	0.898	0.424	0.047	0.037	4.187	**6.669**
2040	1.686	1.258	0.672	0.070	0.052	6.597	**10.335**

Figure 30 shows that liquid mining and pipeline transportation are the two segments of the industrial sector that account for the most energy savings potential, at more than one-quarter of the total for each segement. Together, these two segments account for approximately 55% of the savings potential. Manufacturing-related segments (i.e., non-metallic mineral products, chemical, paper and other manufacturing segments) together make up over one-third of the total energy savings potential.

Figure 30. Industrial Baseline Load and Cumulative Energy Efficiency Savings Potential Distribution by Segment (2040)

	Baseline Load	Savings Potential
TCU	4.2%	6.6%
Pipeline Transportation (Oil, Gas, and CO2)	35.6%	25.5%
Mining	3.0%	2.0%
Mfg - Paper	1.6%	3.2%
Mfg - Nonmetallic Mineral Product	5.3%	15.9%
Mfg - Misc.	4.6%	12.1%
Mfg - Chemical	3.2%	3.9%
Liquid Mining (Oil, Gas, and Carbon Dioxide)	40.8%	29.2%
Agriculture	1.8%	1.7%

Table 26. summarizes cumulative industrial program cost metrics by milestone year. As shown, first-year program costs are approximately $2.4 million, rising to a 20-year average annual cost of roughly $9.6 millon. Acquisition costs start at $168/MWh during the first year of analysis and see only a slight increase through 2040. The TRC ratio remains solid for the industrial sector starting at 2.08 in 2021 and decreasing modestly to 1.92 in 2040.

Table 26. Industrial Cost Metrics by Time Horizon

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	SUM 1st-YEAR MEASURE SAVINGS (MWH)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	2.08	$2,391,009	14,224	$168.09	$11.67
2025	2.02	$18,273,240	104,319	$175.17	$12.80
2030	1.96	$57,536,744	311,837	$184.51	$14.14

2040	1.92	$192,026,153	993,332	$193.32	$15.25
20-year avg.	1.92	$9,601,308	**49,667**	**$193.32**	**$15.25**

8. IRRIGATION EFFICIENCY POTENTIAL

8.1. Overview

Irrigation accounts for a small fraction of energy consumption and savings potential; it represents approximately 8% of Tri-State's total baseline energy load, and 3% of potential energy savings. Cumulative savings potential for this sector is approximately 53,134 MWh through 2040 (Achievable-Moderate scenario). Measures with notable savings potential include high efficiency motors, motor VFDs and base boot gasket improvements, making up approximately 63%, 18% and 17% of total savings potential respectively.

8.2. Detailed Results

Table 27 presents cumulative savings potential for the irrigation sector by scenario at various milestones in the analysis period and Figure 31 shows the growth in cumulative savings potential through 2040. The Achievable-Moderate scenario estimates 584 MWh of savings potential in 2021 rising to approximately 53,134 MWh of cumulative savings potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive scenario) could increase cumulative savings potential by approximately 70%. Savings potential increases by an additionad 39% under the maximum achievable scenario, equating to a a cumulative maximum achievable savings of approximately 119,793 MWh through 2040.

Table 27. Cumulative Irrigation Savings Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	1,541	1,128	1,026	814	584	454
2025	25,117	18,368	13,409	9,028	5,504	3,609
2030	149,894	111,385	60,712	40,289	22,193	12,282
2040	435,221	334,704	119,793	88,727	53,134	29,070

Figure 31. Irrigation Energy Efficiency Savings Potential by Scenario by Year

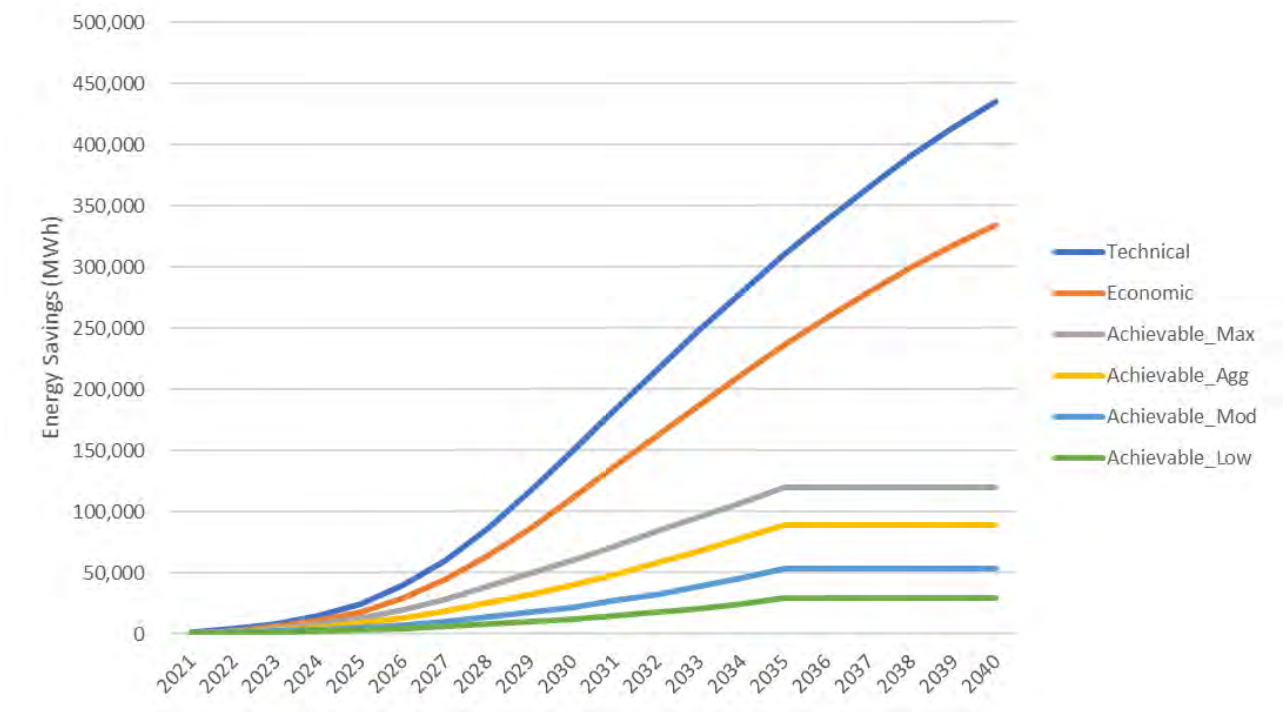


Table 28. shows the percentage impact of cumulative irrigation savings on the baseline forecast by scenario for each milestone year. Under the Achievable-Moderate scenario irrigation measures have the potential to reduce baseline load by nearly 4%. The maximum achievable scenario would more than double those savings to reduce baseline load by approximately 9%.

Eastern Colorado accounts for approximately half the irrigation savings potential, followed by Nebraska at approximately 30% of the total. Northern and Southern New Mexico together account for approximately 12% of total irrigation savings potential with the remaining regions making up a nominal share of total irrigation savings potential.

Table 28. Irrigation Cumulative Savings Potential as % of Baseline Forecast by Sector by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	0.12%	0.09%	0.08%	0.06%	0.04%	0.03%
2025	1.90%	1.39%	1.01%	0.68%	0.42%	0.27%
2030	11.17%	8.30%	4.52%	3.00%	1.65%	0.91%
2040	31.51%	24.23%	8.67%	6.42%	3.85%	2.10%

Figure 32 shows the range of measures examined as part of the analysis, as well as the share of total demand and energy savings each measure represents. High efficiency motors comprise by far the largest share of savings at 63% of demand and approximately 74% of energy savings. Motor VFDs and base boot gaskets also represent notable savings opportunities. Other measures, like upgrades to Low Elevation Spray Application (LESA) and Low Energy Precision Application (LEPA) and scheduling-related measures may hold potential for improving customer satisfaction, as they can reduce water use and improve crop yields. However, LESA and LEPA are not found to provide substantial energy savings, and the analysis Team did not explore scheduling-related measures as part of this analysis.

Figure 32. Irrigation Cumulative Demand and Energy Savings by Measure (2040)

	Demand Savings	Energy Savings
HE Motor	63.07%	73.81%
Motor VFD	18.02%	21.18%
Base boot gasket	16.91%	4.52%
Cut and press repair	0.43%	0.12%
Hub gasket	0.25%	0.11%
Upgrade from high pressure to LESA/LEPA/MDI	0.22%	0.10%
Upgrade from high pressure to MESA	0.20%	0.09%
Sprinkler package replacement, high pressure	0.41%	0.03%
Nozzle replacement	0.24%	0.02%
Gaskets	0.15%	0.02%
Drains	0.08%	0.01%
Sprinkler package replacement, MESA	0.02%	0.00%

Table 29. presents cumulative and average annual costs, savings and TRC metrics associated with the Achievable-Moderate scenario for irrigation efficiency measures. As shown, in the first year Tri-State can achieve approximately 584 MWh of energy savings at a cost of approximately $185,313, or a levelized cost of $47.49/MWh. As programs expand and become more established annual costs and savings increase substantially. The 20-year average annual program costs are approximately $1.75 million and savings are 5,518 MWh.

Table 29. Irrigation Cumulative Cost Metrics by Time Horizon

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	SUM OF 1st-YEAR MEASURE SAVINGS (MWH)	ACQUISTION COST ($/MWH)	LEVELIZED COST ($/MWH)
2021	0.99	$185,313	584	$317.40	$47.49
2025	0.99	$1,750,685	5,516	$317.39	$47.50
2030	0.99	$7,632,143	24,046	$317.40	$47.51
2040	0.99	$35,028,723	110,365	$317.39	$47.53
20-year avg.	**0.99**	$1,751,436	5,518	$317.39	$47.53

9. DEMAND RESPONSE POTENTIAL STUDY

9.1. Overview

The analysis finds that a Tri-State portfolio of demand response programs could cost effectively contribute 86 MW of demand curtailment during the summer peak window by the end of the 20-year analysis time horizon. This result (the Achievable-Low scenario) assumes conservative realistic participation rates across Tri-State's territory.

Table 30 presents portfolio-level demand response potential by time horizon. As Tri-State does not currently offer demand response programs, each scenario ramps from zero and then plateaus when the program achieves maturity. The Achievable-Low scenario estimates 86 MW of cumulative summer demand response potential in 2040. Achieving more aggressive participation rates through increased marketing and incentive costs could yield an estimated 245 MW of potential (Achievable-High scenario).

Table 30. Cumulative Demand Response Potential (MW) By Scenario By Time Horizon

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE HIGH	ACHIEVABLE LOW
2021	46	30	12	5
2025	297	196	85	30
2030	647	500	222	78
2040	704	548	245	86

Figure 33. Portfolio Demand Response Potential by Scenario by Year

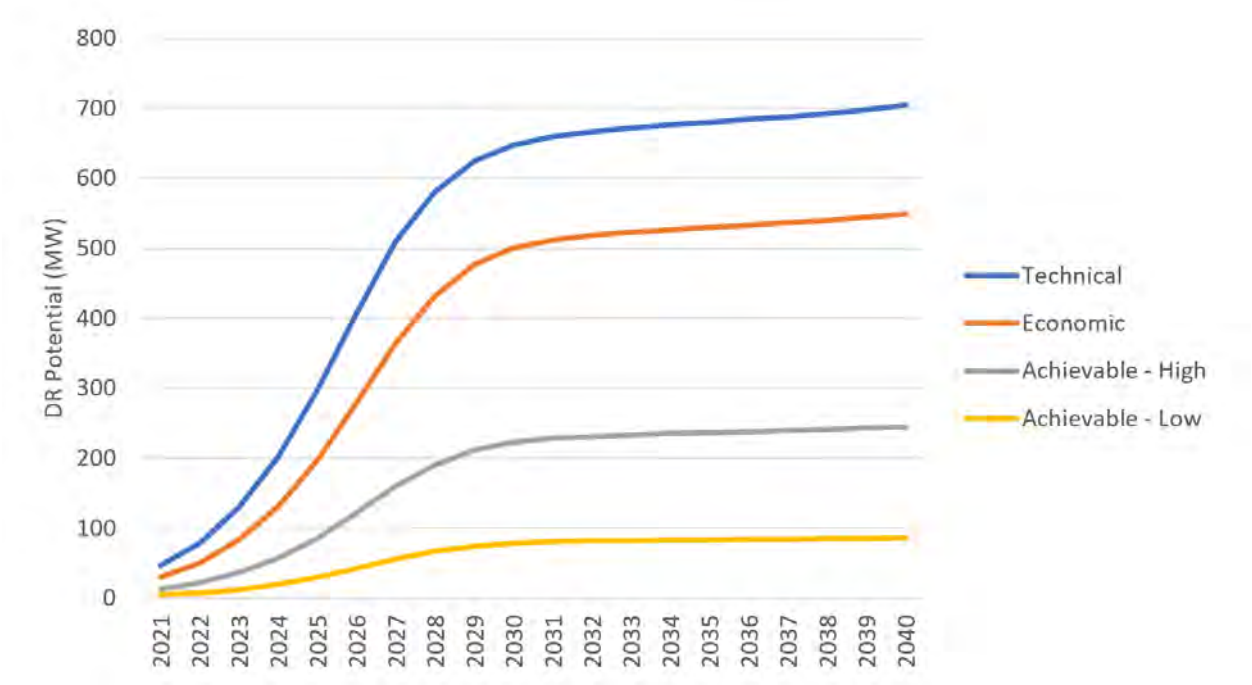

Table 31. shows the impacts of demand response potential relative to Tri-State's baseline demand forecast. The Achievable-High and -Low scenarios represent about 6.90% and 2.43% of forecasted coincident demand in 2040 respectively.

Table 31. Portfolio Demand Response Potential as % of Baseline Forecast by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE HIGH	ACHIEVABLE LOW
2021	1.65%	1.07%	0.48%	0.16%
2025	9.99%	6.61%	2.87%	1.00%
2030	20.43%	15.79%	7.03%	2.47%
2040	19.85%	15.46%	6.90%	2.43%

Figure 34 and Figure 35 show contributions to the portfolio-level demand response potential by sector and by program type respectively. In each scenario, the largest contributors to the demand response potential are the residential and irrigation sectors. Connected device programs, primarily Smart Thermostat programs, and Direct Load Control (DLC), primarily for irrigation pumping, are the most significant program types.

This analysis considered two different time-varying rates programs – **Critical Peak Pricing without Enabling Technology** (CPP no tech), and **Time Of Use** (TOU) – in each sector. As Tri-State does not control customer rates, implementing this type of demand response program would require a high level of collaboration with electric cooperatives.

Figure 34. Portfolio Demand Response Potential by Sector (2040)

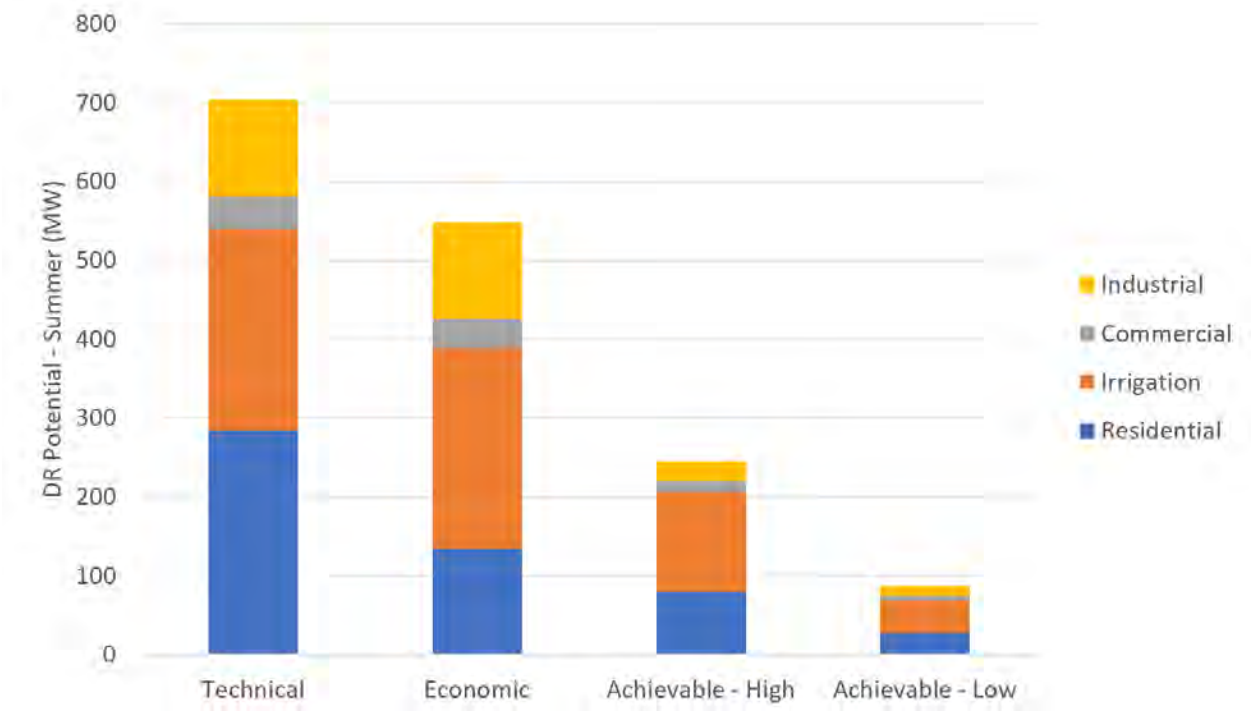

Figure 35. Portfolio Demand Response Potential by Program Type (2040)[16]

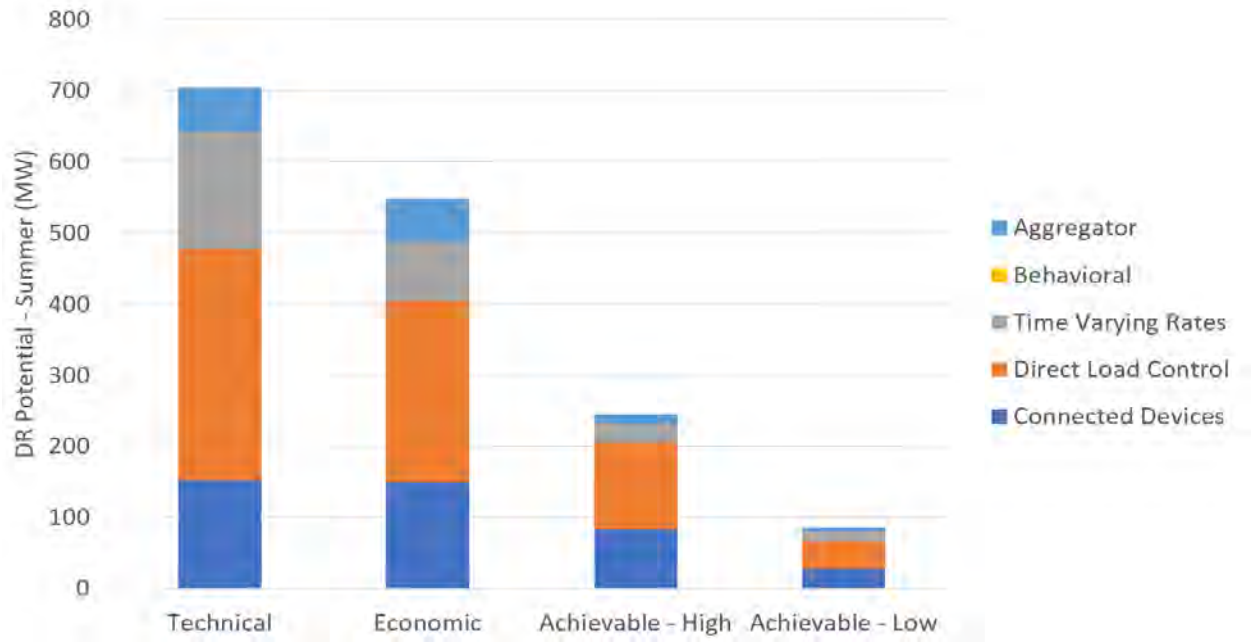

[16] Behavioral value is too small to observe.

Table 32 summarizes the demand response cost metrics across the portfolio at each time horizon under the Achievable-Low scenario. By the end of the 20-year study horizon, the estimated 86 MW of peak demand savings is achievable at a cost of $39 million. The Net Present Value TRC ratio of the demand response portfolio is cost effective by the end of the horizon (1.16 TRC), but not cost effective in the more immediate time horizons. This characteristic is largely driven by Tri-State's negligible costs of capacity for 2021 through 2026 with an increase in 2027.

Table 32. Portfolio Demand Response Cost Metrics by Time Horizon (Achievable-Low Scenario)

MILESTONE YEAR	TRC RATIO	CUMULATIVE PROGRAM COST ($)	DR POTENTIAL (MW)
2021	0.02	$5,440,119	5
2025	0.09	$13,818,802	30
2030	0.60	$24,286,062	78
2040	1.16	$39,068,285	86

9.2. Residential Sector Demand Response Potential

Figure 36 shows how demand response potential for residential sector programs grows over the study horizon as program participation increases. Figure 37 shows the contribution from each modeled demand response program for the four considered scenarios in 2040. Two programs were cost effective and thus included in the economic and achievable scenarios – Smart Thermostats and Smart Water Heaters. In the Achievable scenarios, Smart Thermostats achieve the largest share of the demand response potential.

Traditional DLC programs are not cost effective given their higher switch and controller hardware costs. The analysis shows that demand response for residential HVAC unit loads could be more cost effectively managed with a Bring-Your-Own-Thermostat program format utilizing customer-purchased smart thermostat devices. This finding aligns with a nationally observable trend away from the older DLC technology and pager network communications protocols towards programs that use customer-purchased devices and device internet access for communication.

Although a less mature program model, Smart Water heater programs are also increasing in popularity in many jurisdictions nationwide. Some versions of these programs similarly use internet-based communications and would be the most cost effective for Tri-State. Water heaters with built-in grid connection technology are also becoming more widely available, thus eliminating the need for installation of a separate device. As this technology matures, Tri-State could likely develop a successful demand response program to control residential water heaters during peak periods.

Figure 36. Residential Sector Demand Response Potential by Scenario by Year

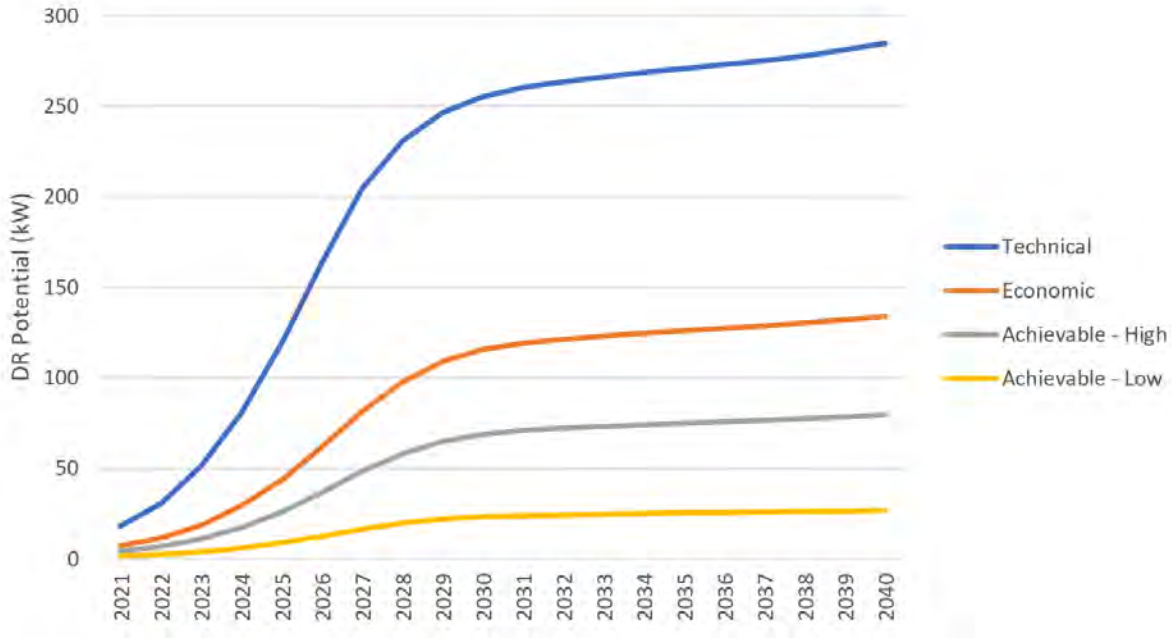

Figure 37. Residential Sector Demand Response Potential by Program (2040)

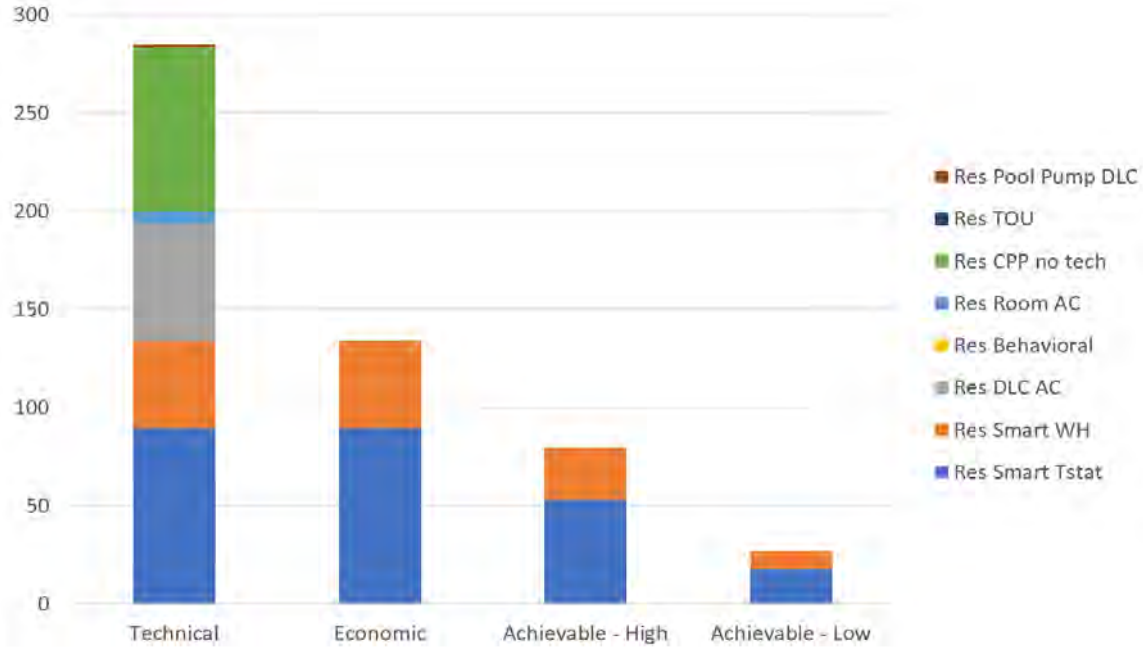

9.3. Irrigation Sector Demand Response Potential

Figure 38 shows how demand response potential for the irrigation sector programs grows over the study horizon as program participation increases. Figure 39 shows the each modeled demand response program's contribution to the four considered scenarios in 2040. Two programs were cost effective and therefore included in the economic and achievable scenarios – Direct Load Control and Critical Peak Pricing without Enabling Technology. In the Achievable scenarios, Direct Load Control achieves the largest share of the demand response potential.

Successful irrigation DLC programs are currently operational in regions similar to portions of Tri-State's territory, such as Idaho Power's Irrigation Peak Rewards program. That program is designed to target only customers with pumping demand greater than 75 horsepower, thereby focusing economic resources for maximum demand reduction. This analysis included eligibility rates for each region in Tri-State's territory to estimate the regional prevalence of large irrigation pumps. Mountain Colorado, for example, has a 0% eligibility rate because of presumed reliance on lower horsepower pumps for horizontal pumping.

Figure 38. Irrigation Sector Demand Response Potential by Scenario by Year

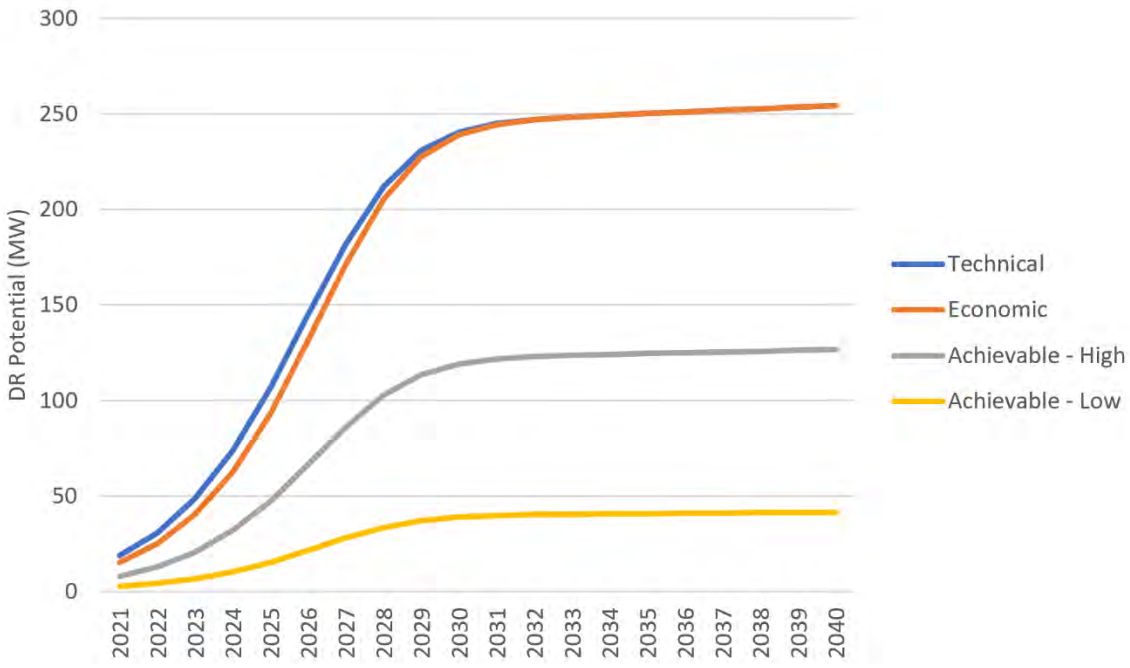

Figure 39. Irrigation Sector Demand Response Potential by Program (2040)

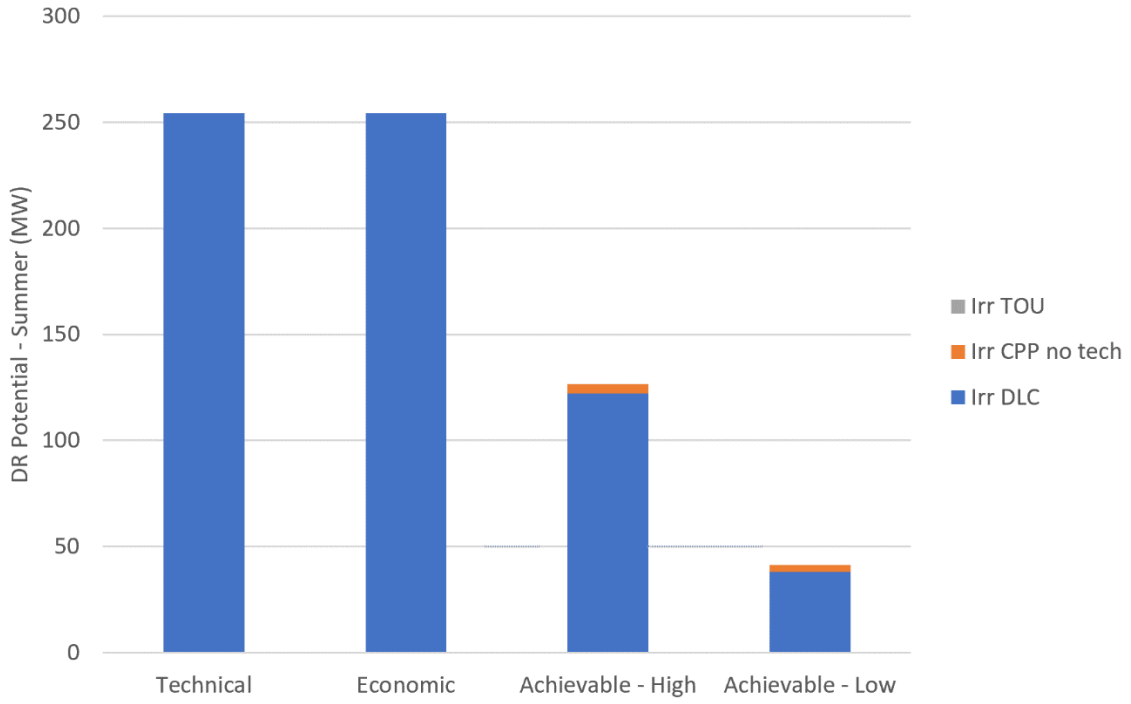

9.4. Commercial Sector Demand Response Potential

Figure 40 shows how demand response potential for irrigation sector programs grows over the study horizon as program participation increases. Figure 41 shows each modeled demand response program's contribution to the four considered scenarios in 2040. Three programs were cost effective and therefore included in the economic and achievable scenarios – Demand Bidding, Smart Thermostats, and Critical Peak Pricing without Enabling Technology. The Smart Thermostats program option was modelled as an extension of the residential Smart Thermostats program and assuming the residential program sector carries a majority of program set-up and administration costs.

Capacity bidding programs offer qualified businesses incentive payments for agreeing to reduce load (for example, lighting, HVAC, escalators/elevators, pumps or some manufacturing equipment) when an event is called. Third-party aggregators often manage these types of programs; thefore, this could be a strategy to overcome Tri-State's lack of direct access to end-users.

Figure 40. Commercial Sector Demand Response Potential by Scenario by Year

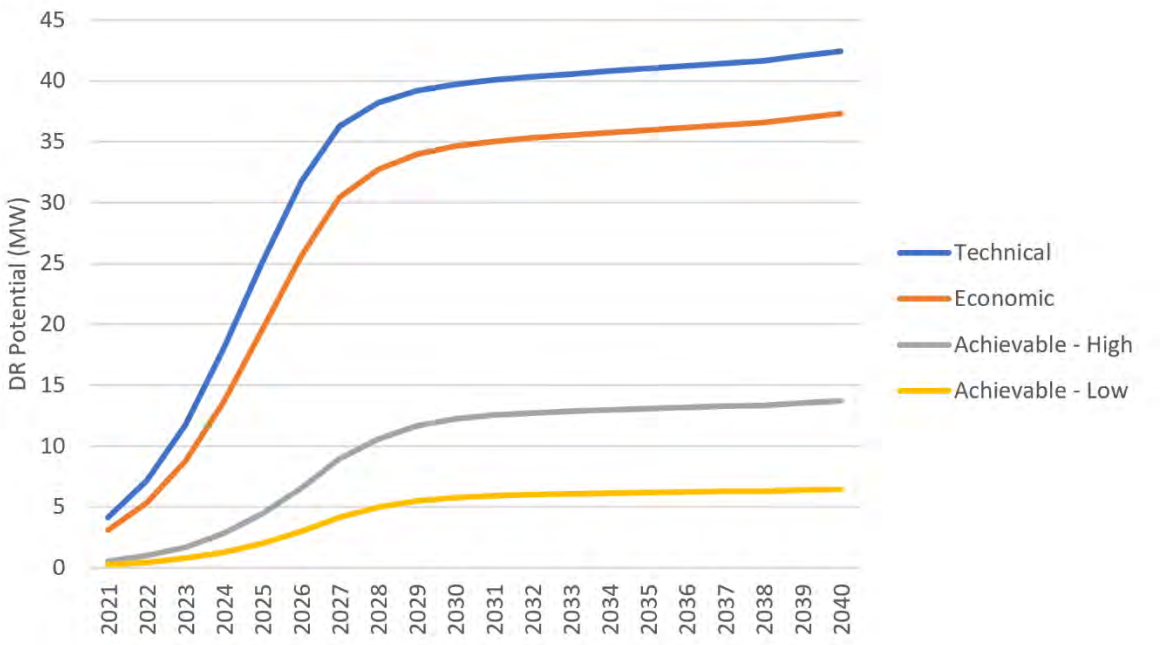

Figure 41. Commercial Sector Demand Response Potential by Program (2040)

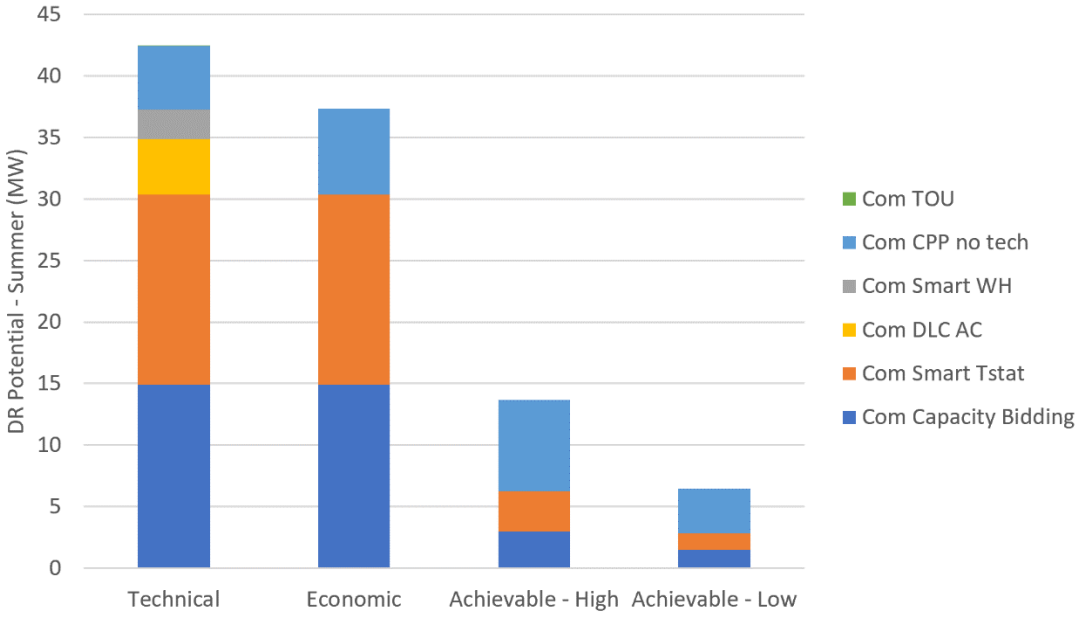

9.5. Industrial Sector Demand Response Potential

Figure 42 shows how demand response potential for industrial sector programs grows over the study horizon as program participation increases. Figure 43 shows each modeled demand response program's

contribution to the four considered scenarios in 2040. Two programs are cost effective and therefore included in the economic and achievable scenarios – Capacity Bidding and Critical Peak Pricing without Enabling Technology.

As in the commercial sector, capacity bidding programs offer qualified businesses incentive payments for agreeing to reduce load (for example, lighting, HVAC, escalators/elevators, pumps or some manufacturing equipment) when an event is called. These types of programs are often managed by third-party aggregators, and thus could be a strategy to overcome Tri-State's lack of direct access to end-users.

10. BEHIND-THE-METER DISTRIBUTED ENERGY RESOURCE POTENTIAL STUDY FINDINGS

10.1. Overview

As discussed in Section 3, the Team assessed rooftop solar PV potential for the residential and non-residential sectors. The technical potential analysis considered the total rooftop area suitable for solar PV within Tri-State's territory and extrapolated potential solar generation based on solar system power density per square foot for each Tri-State region. The Team subsequently screened systems for cost effectiveness and adjusted potential accordingly followed by further adjustments using adoption curves to represent achievable potential.

The Team found no systems to be cost effective for the residential sector under any TRC scenario analyzed. The highest TRC ratio achieved under the residential sector was 0.45 which reflects capacity and CO_2 emissions benefits.

The non-residential sector's very large PV systems are marginally cost effective for specific scenarios. Of these scenarios, the Team found the presence of CO_2 emissions benefits to be crucial as no PV system analyzed surpassed a TRC of 1.0 without inclusion of these benefits.

10.2. Detailed Results

Table 33 and Table 34 summarize the solar PV cumulative annual potential estimated generation for the residential and non-residential sectors, respectively. Electric demand impacts are presented for each sector in Table 35 and Table 36. While technical potential represents 100% adoption for each year, economic and achievable potential reflect applied adoption rates across the study time horizon.

Table 33. Cumulative Residential Generation Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE _MAX	ACHIEVABLE _AGG	ACHIEVABLE _MOD	ACHIEVABLE _LOW
2021 (first year)	2,548,130	0	0	0	0	0
2025	13,139,699	0	0	0	0	0
2030	27,290,122	0	0	0	0	0
2040	58,657,889	0	0	0	0	0

Table 34. Cumulative Non-Residential Generation Potential by Scenario by Time Horizon (MWh)

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	6,417,504	10,322	10,310	10,300	10,284	10,256
2025	33,037,716	141,370	139,829	138,809	137,108	134,198
2030	68,427,022	1,011,060	951,078	911,778	851,923	764,606
2040	146,160,272	5,512,777	4,705,933	4,254,001	3,661,295	2,952,911

The demand impacts presented in Table 35 and Table 36 reflect technical capacity based on operational capacity (based on installed nameplate) and coincident peak capacity. Economic and achievable scenarios reflect coincident peak capacity benefits.

Table 35. Summary of Residential Solar PV Electric Demand Market Potential (MW)

MILESTONE YEAR	TECHNICAL DC CAPACITY	TECHNICAL PEAK CAPACITY	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	1,644	400	0	0	0	0	0
2025	1,747	425	0	0	0	0	0
2030	1,878	457	0	0	0	0	0
2040	2,141	521	0	0	0	0	0

Table 36. Summary of Non-Residential Solar PV Electric Demand Market Potential (MW)

MILESTONE YEAR	TECHNICAL DC CAPACITY	TECHNICAL PEAK CAPACITY	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	4,139	1,106	2	2	2	2	2
2025	4,384	1,172	9	9	9	9	9
2030	4,686	1,252	49	45	42	37	31
2040	5,281	1,411	83	69	61	50	39

The cumulative residential generation potential under the technical scenario equates to 57% of the cumulative residential baseline load sales forecast for 2040 (see Table 37). Similarly, the non-residential cumulative generation represents 52% of the cumulative residential baseline load forecast for 2040 (see Table 38). Non-residential economic potential equates to 2.0% of the cumulative residential baseline load forecast for 2040 and ranges from 1.7% to 1.1% under the achievable potential scenarios.

Table 37. Cumulative Residential Generation Potential as % of Baseline Forecast Sales by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	56.1%	0	0	0	0	0
2025	56.3%	0	0	0	0	0
2030	56.4%	0	0	0	0	0
2040	56.5%	0	0	0	0	0

Table 38. Cumulative Non-Residential Generation Potential as % of Baseline Forecast Sales by Year

MILESTONE YEAR	TECHNICAL	ECONOMIC	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	53.9%	0.1%	0.1%	0.1%	0.1%	0.1%
2025	53.4%	0.2%	0.2%	0.2%	0.2%	0.2%
2030	53.1%	0.8%	0.7%	0.7%	0.7%	0.6%
2040	52.0%	2.0%	1.7%	1.5%	1.3%	1.1%

10.3. Technical DER Potential Findings

Overall, solar PV generation has the technical capability of providing over half of Tri-State's sales. However, this value varies considerably by region. Figure 44 and Figure 45 below illustrate cumulative PV generation in 2040 compared to cumulative 2040 sales. For both the residential and non-residential

sectors, PV generation is well below total sales for each region with the exception of Northern New Mexico (for residential) and Southern New Mexico. New Mexico's PV generation exceeds sales due to a high solar irradiance which improves solar efficiency, a relatively high number of buildings, and relatively low energy consumption on average.

Figure 44. 2040 Cumulative Residential PV Generation vs Sales by Region

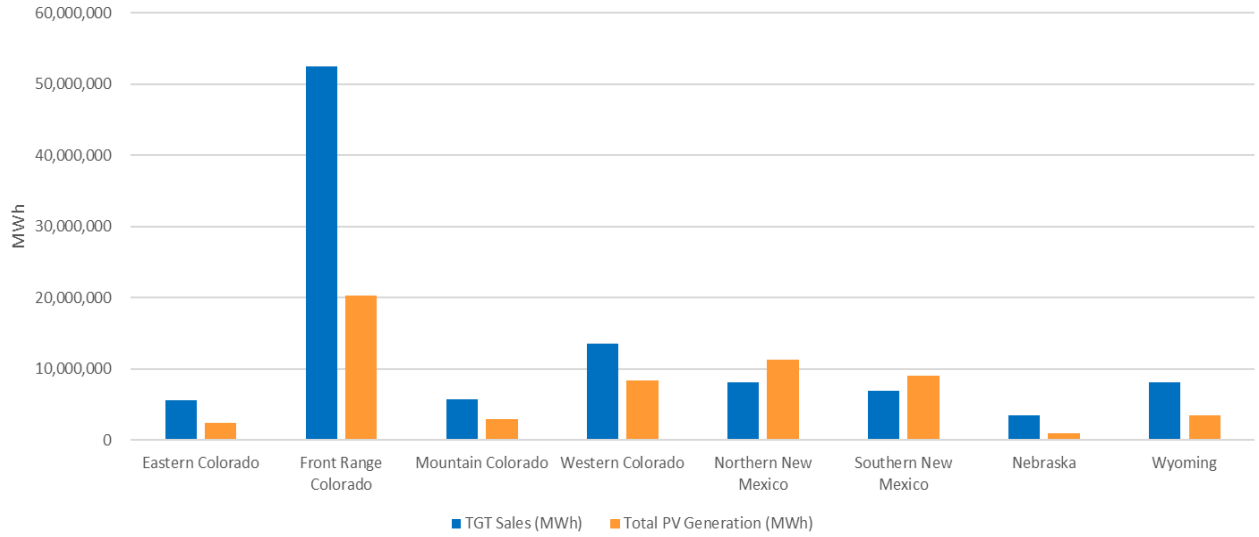

Figure 45. 2040 Cumulative Non-Residential PV Generation vs Sales by Region

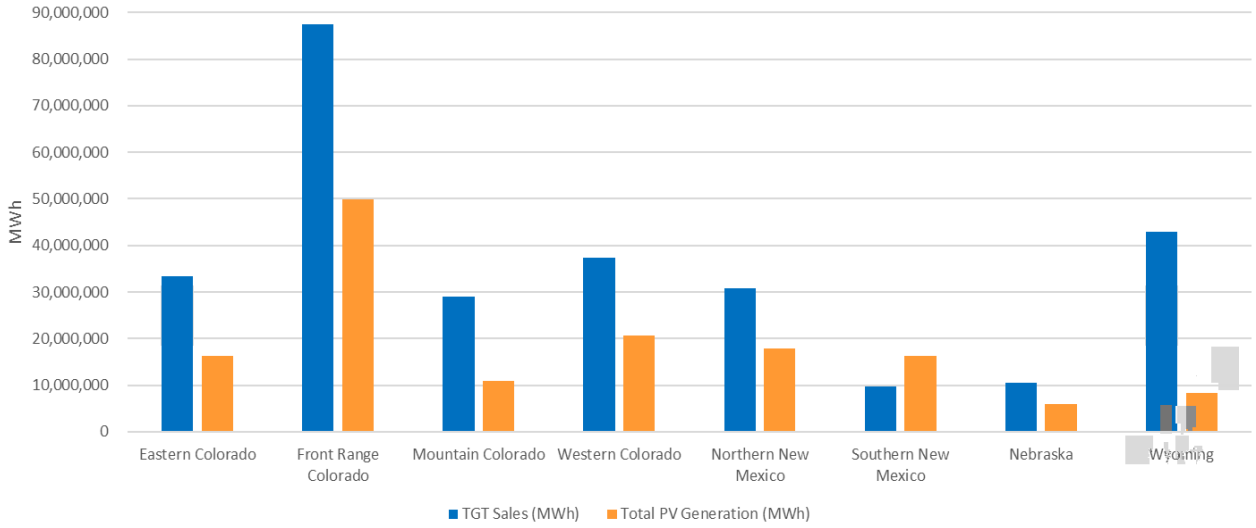


10.4. Economic and Achievable DER Potential Findings

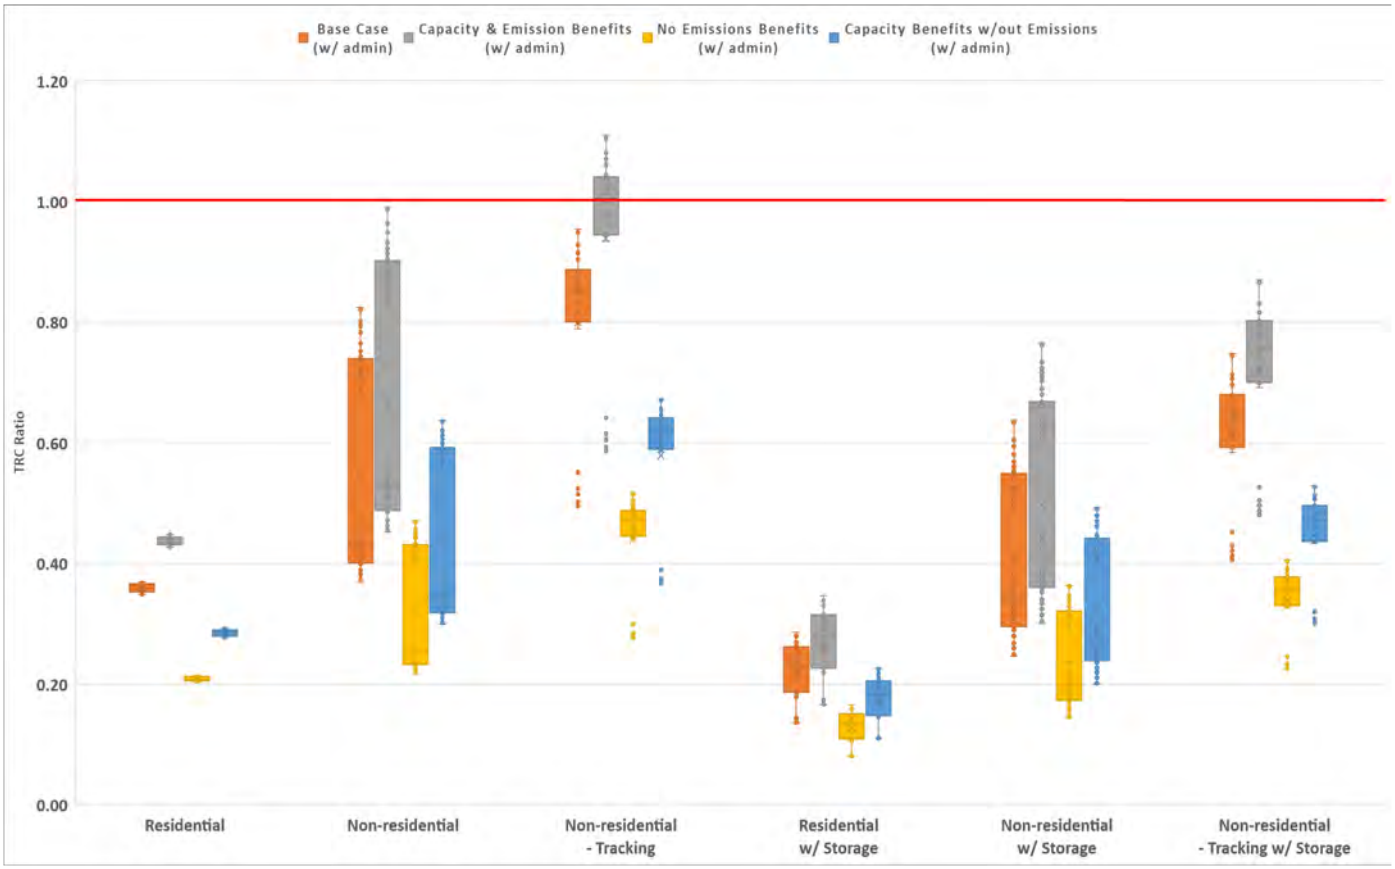
The Team screened economic potential using a TRC hurdle of 1.0 with the inclusion of CO_2 emission benefits based on the social cost of carbon of $46/ton and administrative costs of $0.05/kWh. However,

to understand the sensitivity of various benefit parameters, the team modeled cost effectiveness for multiple scenarios that included various combinations of benefits. Scenarios reviewed included:

- Base case
  - Inclusive of CO_2 emission reduction benefits
- Capacity and emission benefits
  - Base case inclusive of benefits resulting from reduced capacity needs
  - Inclusive of CO_2 emission reduction benefits
- No emissions benefits
  - Base case exclusive of CO_2 emission reduction benefits
- Capacity benefits without emissions benefits
  - Base case inclusive of benefits resulting from reduced capacity needs
  - Exclusive of CO_2 emission reduction benefits

Figure 46 illustrates the results and sensitivities of the solar PV cost effectiveness under each of these scenarios for various categories of solar PV systems included in the potential study. Only one scenario yields TRC ratios that exceed 1.0 – non-residential tracking systems assuming the presence of capacity and CO_2 emission benefits benefits. Also noted is any scenario excluding CO_2 emission benefits results in all solar system configurations analyzed to fail pass cost effectiveness.

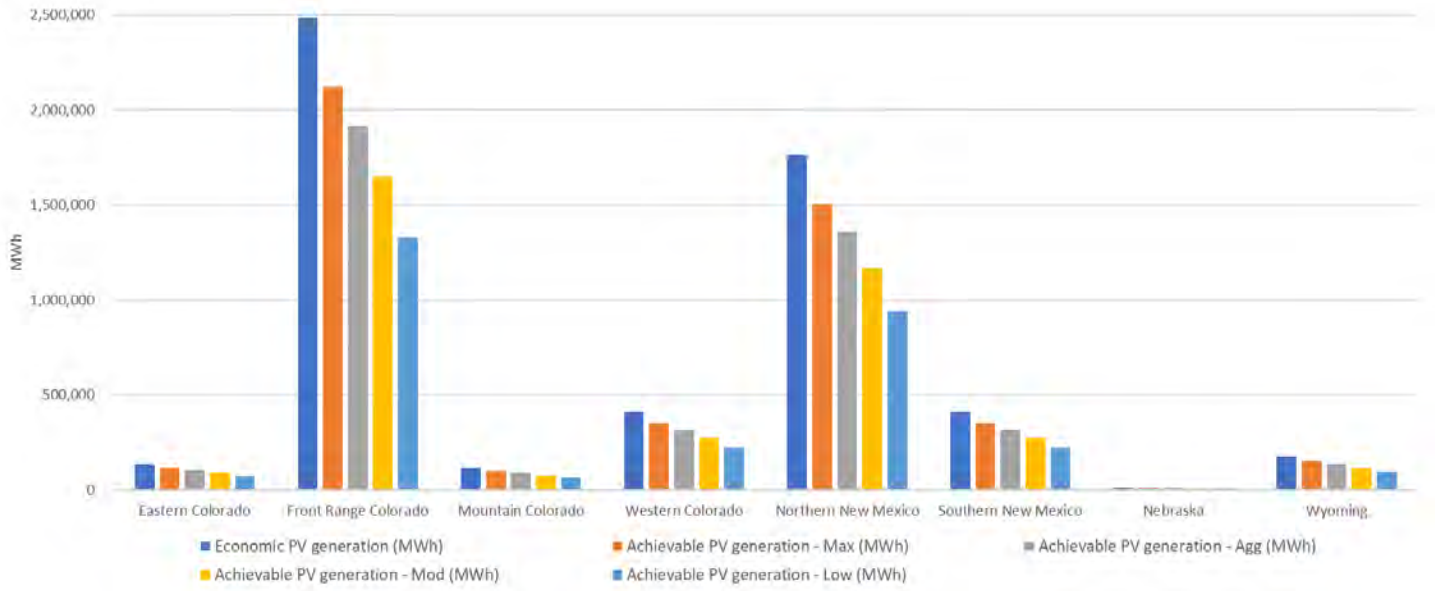
Figure 46. Solar PV TRC Ratios - Multiple Scenarios



Based on the cost effectiveness analysis, the Team modeled economic and achievable potential based on the sole cost effective scenario – non-residential tracking solar systems with capacity and emission benefits. Twenty two solar PV system configurations (9% of all tested measure permutations) passed cost effectiveness including tracking systems varying in size from 250 kW to 2000 kW system capacity. These passing measures have an average TRC of 1.04. This scenario, however, is not applicable throughout the Tri-State territory insofar as capacity constraints are not expected until 2027 (and therefore capacity benefits would not be realized until that time) and carbon benefits are only applicable to Colorado regions (at the time of report publication). Regardless, for the purposes of this report, the Team opted to model economic and achievable potential for all regions in order to inform Tri-State of how solar adoption may occur throughout its territory.

The results of the economic and achievable potential are presented below in Figure 47. Economic and achievable potential is limited due to the small number of solar systems that pass cost effectiveness and due to the physical requirements of these systems – tracking systems are considered ground-mounted for this analysis and therefore are only applicable to sites that are expected to have sufficient land space to host these systems and the system does not generate more energy than the site consumes. Based on these constraints, the team estimated 66 eligible sites across Tri-State's territory for the economic scenario. The number of eligible systems decreases for each achievable potential scenario as solar system payback time increases.

Figure 47. 2040 Cumulative Non-Residential Economic and Achievable Potential by Region



As illustrated in Figure 47, the highest concentration of eligible sites, and thereby the highest potential, are in the Front Range and Northern New Mexico regions. However, as noted earlier, carbon emission benefits at the time of this report publication are not currently a quantifiable benefit in New Mexico, Wyoming, or Nebraska and therefore this reported economic and achievable potential should be considered with that perspective.

11.KEY FINDINGS

At present Tri-State and its member cooperatives deliver some energy efficiency and DR programs, and no DER programs, to their customers. Even with low avoided energy cost benefits for DSM programs within Tri-State's service territory this study identifies significant cost-effective opportunities for energy and demand savings for energy efficiency programs. There are also opportunities for DR programs, but in some cases those program require long term operation to provide cost-effectiveness. DER programs are generally not cost-effective except for larger systems in specific regions. Key findings and observations related to each of these resources is summarized below. It should be noted that the results of this study and the findings presented here are uncertain to a degree and are sensitive customer adoption of DSM intervetions. Furthermore, the dynamic relationship between Tri-State and the member co-ops presents instrinsic challenges to the seamless implementation of DSM programs. These variables should be take into account when considering the results of this study.

11.1. Energy Efficiency

In 2018, Tri-State cooperative members acquired roughly 30 GWh of energy efficiency savings (~0.2% of baseline energy load)[17]. This suggests that Tri-State's members are currently operating programs somewhere between the Achievable-Low and Achievable-Moderate scenarios, which identified energy savings of 27 GWh and 38 GWh respectively in 2021. With coordinated efforts among cooperative members the long-term market opportunity for cost-effective energy efficiency savings in the region served by Tri-State is considerably higher; the average annual savings potential is 115 GWh over the study's 20-year time horizon for the Achievable-Moderate scenario. Additional key findings within the energy efficiency assessment include:

- 20-year average annual energy savings are just under 115 GWh (0.66% of baseline energy load) at a total program cost of $24M per year ($212/MWh acquired).
- 20-year levelized cost of energy to acquire all energy savings is $21.55/MWh.
- While the industrial sector represents the largest market opportunity (43% of 20-year potential), the residential sector represents the biggest opportunity (35% of potential) compared to its load share (28% of load).
- The commercial sector holds the most cost-effective savings opportunities with a TRC of 1.93 and average 20-year acquisition cost of $171/MWh.
- Pumps (primarily within the industrial sector) represent the largest end-use opportunity across the portfolio at 25% of 20-year cumulative energy savings – much of this opportunity resides with several large Liquid Mining and Pipeline Transportation customers.
- Even with rapid market transformation to LEDs for A-lamp bulbs, there is still considerable savings opportunities in the commercial lighting (21% of potential) and Residential lighting (19% of potential) end-uses – these end-uses are also among the most cost effective with acquisition costs of $150/MWh and $200/MWh respectively.

[17] Tri-State Generation and Transmission, Inc. 2018 Annual Report. (p. 12).

- HVAC measures account for 18% of savings potential – though are relatively expensive with an average acquisition cost of roughly $275/MWh.
- With zero capacity benefits in the first seven years, Home Energy Reports did not pass the study's TRC cost-effectiveness screen until 2028; after which the measure becomes a major opportunity contributing to almost 6% of portfolio savings potential.
- High/medium bay linear lamp and fixture conversions to LED technology represents more than 60% of cumulative energy savings potential in the commercial sector by 2040.
- Non-EISA compliant light bulbs contribute more than 45% to cumulative energy savings potential by 2040 in the residential sector.
- Upgrading existing air source heat pumps to higher efficiency models represent more than 6% of cumulative energy savings potential by 2040 in the residential sector.

11.2. Demand Response

The analysis finds that a Tri-State portfolio of demand response programs could cost effectively contribute 86 MW of demand curtailment during the summer peak window by the end of the 20-year time horizon. This result (the Achievable-Low scenario) assumes conservative realistic participation rates across Tri-State's territory. Additional key findings from the demand response potential analysis include:

- High levels of investment in marketing and incentives could yield up to 245 MW of potential (Achievable-High scenario).
- Potential reduction in portfolio-level baseline forecast demand ranges from 2.4% (Achievable-Low) to 6.9% (Achievable-High).
- The residential and irrigation sectors hold the greatest potential for demand response program savings.
- In general, the Direct Load Control program model holds the greatest potential for savings. Among the two Achievable scenarios the most promising program models within each each sector are:
    - Residential: Smart Thermostats and Smart Water Heaters
    - Commercial sector: Critical Peak Pricing and Smart Thermostats
    - Industrial: Critical Peak Pricing
    - Irrigation: Direct Load Control

11.3. Behind-The-Meter Distributed Generation

We analyzed potential for rooftop solar PV across Tri-State's territory for both the residential and non-residential sectors. Ultimately we found rooftop solar PV to not be cost effective for the residential sector. The non-residential sector is cost effective for very large ground-mounted tracking solar arrays when including key benefits of capacity and emission benefits. Additional findings from the distributed energy resource potential analysis include:

- Technical potential solar generation for both residential and non-residential sectors can equate to just over half of total sales.
- No residential solar PV measures pass cost effectiveness under any benefit-cost scenario analyzed in the study.
- The sole cost effective scenario includes both capacity benefits and CO_2 emissions benefits. Just 9% of analyzed measure permutations pass this cost effectiveness scenario and are characterized as non-residential ground-mounted tracking systems varying from 250 kW to 2000 kW system capacity. These system measures have an average TRC of 1.04.
- Cumulative non-residential economic potential solar PV generation equates to 2.0% of 2040 cumulative sales; achievable potential solar PV generation equates to 1.7% - 1.1% of 2040 cumulative sales. It is noted that while these potential savings reflect the entire Tri-State territory, the sole cost effective scenario is not applicable to regions outside of Colorado as emissions are not a quantifiable benefit at the time of this report publication.

Special Notice

Acceptance of this report, or use of any information contained in this report, by any party receiving this report other than Tri-State Generation & Transmission Association ("Client") (each a "Recipient") shall constitute an acknowledgement and acceptance by such Recipient of, and agreement by such Recipient to be bound by, the following:

(1) This report was prepared for the Client by Black & Veatch Management Consulting, LLC ("Consultant") and is based in part on information provided by the Client and others. In preparing this report, Consultant has assumed that the information, both verbal and written, provided by the Client and others is complete and correct.

(2 Recipient acknowledges and understands that Consultant provides no warranty, guarantee, or promise, express or implied, to the Recipient for the contents of the Report.

(3) Recipient is not entitled to make any copies of any portion of this report, use extracts therefrom or transmit any part thereof to any other party in any form, including without limitation electronic or printed media of any kind.

(4) TO THE FULLEST EXTENT PERMITTED BY LAW, CONSULTANT'S TOTAL LIABILITY, ON A CUMULATIVE AND AGGREGATE BASIS, TO CLIENT AND ALL RECIPIENTS AND OTHER PARTIES, RESULTING FROM CONSULTANT'S ACTIONS IN RELATION TO THE CREATION AND DISSEMINATION OF THIS REPORT, WILL BE LIMITED TO THE AMOUNT OF COMPENSATION (EXCLUSIVE OF THE REIMBURSEMENT OF COSTS AND EXPENSES) ACTUALLY RECEIVED BY CONSULTANT FROM CLIENT FOR THE CREATION OF THIS REPORT UNDER THEIR CONTRACT. Recipient hereby waives any right to seek or collect damages in excess thereof and releases Consultant from any and all damages or losses which, if required to be paid to Recipient, would result in Consultant paying total damages to any and all parties, including Client and all Recipients, in an amount that would exceed the limit set forth in the previous sentence.

The exclusive venue for any claim, cause of action, legal proceeding, or lawsuit relating to this report shall be the federal court or the state court if a federal jurisdiction is not present, located in New York City, Borough of Manhattan, State of New York. Recipient and any other party irrevocably waive each argument, objection, defense, assertion, or claim that venue is improper for any reason in the state and federal courts in New York City, Borough of Manhattan, State of New York for any claim, cause of action, legal proceeding, or lawsuit brought in said courts or that such claims have been brought in an inconvenient forum.

The above terms and conditions are governed by and shall be governed by and construed in accordance with the laws of the State of New York, without giving effect to the conflicts of laws principles thereof other than Sections 5-1401 and 5-1402 of the General Obligations Law of the State of New York.

IF ANY RECIPIENT IS NOT WILLING TO ACKNOWLEDGE AND ACCEPT, OR AGREE TO, THE TERMS SET FORTH ABOVE, IT MUST RETURN THIS REPORT TO CONSULTANT IMMEDIATELY WITHOUT MAKING ANY COPIES THEREOF, EXTRACTS THEREFROM OR USE (INCLUDING DISCLOSURE) THEREOF. A RECIPIENT'S FAILURE SO TO RETURN THIS REPORT SHALL CONSTITUTE ITS ACKNOWLEDGEMENT AND ACCEPTANCE OF AND AGREEMENT TO THE TERMS SET FORTH ABOVE.

1.0 Executive Summary

Black & Veatch Management Consulting LLC (Black & Veatch) was retained by Tri-State Generation & Transmission Association (Tri-State) to analyze the potential for loss of load within the Tri-State system. Black & Veatch ("we" or "us") has utilized production cost modeling software and in-house expertise to conduct a probabilistic loss of load probability (LOLP) analysis for the Tri-State system for two forecast years, 2025 and 2030, under four capacity expansion (CE) plans. The four CE plans were provided to us by Tri-State and include varying load forecast and capacity addition assumptions. The four CE plans are as follows:

1. Base: Business as usual scenario without greenhouse gas (GHG) emissions reduction requirements in Colorado using market parameters and unit conditions as of March 2020.
2. MAX: Low load scenario representing a 10 percent reduction in system demand and related energy with corresponding reductions in losses and planning reserve margin.
3. MARS: High distributed generation scenario representing an increase in distributed generation equivalent to 10 percent of system demand.
4. Carbon Reduction: GHG reduction scenario with substantial reduction in GHG emissions by 2030 from 2005 baseline.

A production cost model using PLEXOS software was configured to represent the Tri-State system under each of these alternative future CE plans. Assumptions and forecasts were provided by Tri-State including load forecasts, contract purchases and sales, hydro monthly energy constraints, and generator financial and operational characteristics. Outputs from initial runs of the PLEXOS model were then compared to outputs from Tri-State's prior simulation of the Base CE using its own production cost modeling tool.[1] This was done to confirm the accuracy of the PLEXOS model prior to conducting the LOLP analysis. For each year and each capacity expansion plan, the PLEXOS model was then run 20 times with different risk draws to simulate random forced outages within the Tri-State system. The mean and standard deviation LOLP was calculated from the 20 risk samples. We found that the LOLP for the Base CE and MARS CE plans exceeded the LOLP target of 1 day in 10 years for the year 2030 while all other CE plans met the LOLP target. To compensate for these exceedances, two (2) and three (3) 100 MW 4-hour batteries with 400 MWh of energy storage capability were added to the Base CE and MARS CE plans, respectively. The PLEXOS model was run again, and results showed that the mean LOLP target was met for both the Base and MARS capacity expansion plans.

[1] File "March Base 2020 PO Annual data Confidential.xls" (March 2020 Base)

2.0 Scope

Tri-State retained Black & Veatch to analyze the impacts of increased renewable generation and thermal power plant retirements on reliability of the Tri-State power generation system. Generation reliability is traditionally measured in a "static" fashion by observing the forecast capacity reserve margin which is the surplus of forecast generation capacity above forecast peak load measured on an annual basis. However, in high renewable scenarios a dynamic LOLP analysis is a more appropriate because both renewable energy available to serve load and net peak load (load net of renewable generation behind the meter) are highly variable resulting in a highly variable reserve margin. An LOLP analysis allows consideration of this variable margin and a more rigorous probabilistic analysis of conventional generating unit outages as opposed to forecasted capacity reserve margin alone.

The objective for this analysis was to use a production cost model (PCM) implemented in PLEXOS to replicate Tri-State's various future expansion and operation scenarios and to examine the resulting LOLP. The LOLP is a measure of the likelihood of failing to meet load which is present on the Tri-State system and being forced to curtail load in a period with higher load than generation capability. The resulting LOLP under each scenario should not exceed a rate of 1 day in 10 years which is the typical reliability threshold expected for resource portfolios such as that of Tri-State.

The scope of the LOLP analysis was limited to two forecast years (2025 and 2030) and the four CE plans (Base, MAX, MARS, Carbon Reduction) developed by Tri-State. Therefore, the LOLP was forecast for a total of eight cases using the PLEXOS PCM developed for this analysis.

3.0 Methodology

Black & Veatch used a commercial PCM software package, PLEXOS[2], for this analysis. PLEXOS is a fundamental-based PCM software package that provides an optimal solution to meet a given load with a set of generators subject to constraints such as generator operational constraints, transmission constraints, and policy constraints. PLEXOS is widely used in the industry for long-term planning, including use by the California Independent System Operator (CAISO) for integrated resource planning (IRP) in the Western Electricity Coordinating Council (WECC)[3]. Key features of PLEXOS include capacity expansion planning, unit commitment and dispatch, co-optimization of energy and ancillary service markets, and evaluation of Monte-Carlo stochastic algorithms.

Tri-State provided data relevant to their system to conduct the LOLP analysis, including load forecasts, transmission transfer limits, operating reserve requirements with the Northwest Power Pool (NWPP) and the Southwest Reserve Sharing Group (SRSG), fuel forecasts, and generator financial and operational characteristics such as capacity, minimum stable level, heat rates, variable costs, minimum up/down time, ramp rates, outage rates, hourly renewable generation profiles, and monthly hydro generation. Contract purchases and sales were also provided and included in the model. Once configured, the model was assessed in comparison to the March 2020 Base dispatch profile provided by Tri-State. The evaluation primarily consisted of verifying annual generation quantities for each generator and contract to ensure PLEXOS was properly configured.

Four Tri-State CE plans were analyzed including the Base, MAX, MARS, and Carbon Reduction plans. Each plan has unique resource additions, and the MAX plan had a lower load forecast as compared to the other scenarios as shown in Table 1.

Table 1 Summary of Installed Capacity for Each Capacity Expansion Plan

	2025				2030			
Plan Name	Base	MAX	MARS	Carbon Red.	Base	MAX	MARS	Carbon Red.
Peak Load (MW)	3076	2636	3076	3076	3350	2904	3350	3350
Solar Additions (MW)	0	0	0	200	800	100	500	1300
Wind Additions (MW)	0	0	0	200	0	100	200	400
Battery Additions (MW)	0	0	0	75	0	0	0	750
Thermal Additions (MW)	0	0	0	0	596	410	575	265
Total Capacity Additions (MW)	0	0	0	475	1396	1410	1275	2715
Capacity Retirements (MW)	0	0	0	0	648	648	648	648
Net Capacity Additions (MW)	0	0	0	475	748	762	627	2067

To determine the LOLP in each scenario, we used PLEXOS' Monte-Carlo stochastic algorithms to randomly generate a set of forced outages based on forced outage rate and mean time to repair

[2] https://energyexemplar.com/solutions/plexos/
[3] http://www.caiso.com/Documents/2019-01-31-Comments_ProductionCostModeling-IRPProceeding-R16-02-007.pdf

assumptions (each a “risk draw”). The “short term” module of PLEXOS was utilized. PLEXOS was configured and run to simulate 20 risk draws for each year assessed (2025 and 2030) under each CE plan. Outputs from the simulation included mean and standard deviation of the number of hours with unserved energy (USE) each year. From this, an LOLP was calculated by dividing the USE by the total number of hours in the year. If the resulting LOLP exceeded the 1 day in 10 years maximum allowed, an amount of additional battery storage capacity was added to the capacity expansion plan and the simulation rerun. This was done in an iterative fashion until the target LOLP was achieved.

4.0 Results & Discussion

An LOLP of less than 1 day in 10 years corresponds to an LOLP of less than 0.0274 percent on an annual hour basis. The results of the LOLP analysis, including the mean and standard deviation of unserved energy (USE) hours and LOLP percent for each scenario, are shown in Table 2.

Table 2 Summary of USE and LOLP Prior to Battery Additions

	2025				2030			
CE Plan Name	Base	MAX	MARS	Carbon Red.	Base	MAX	MARS	Carbon Red.
Mean USE (hr)	1.95	0.00	1.95	0.00	9.20	1.45	25.75	0.70
Std. Dev. USE (hr)	2.31	0.00	2.31	0.00	4.77	2.48	6.15	1.30
Mean LOLP (%)	0.02	0.00	0.02	0.00	**0.11**	0.02	**0.29**	0.01
Std. Dev. LOLP (%)	0.03	0.00	0.03	0.00	0.05	0.03	0.07	0.01

Results for the year 2025 show that each CE plan was below the LOLP target on a mean LOLP basis. Results for the MAX CE and Carbon Reduction CE plans had zero mean LOLP. This is due to the MAX CE plan having a lower load forecast as compared to the other CE plans and the Carbon Reduction CE plan having capacity additions which are not present in the other CE plans. The MARS CE plan and the Base CE plan had some unserved load and thus non-zero mean LOLPs. Their LOLPs are identical in 2025 because the CE plans are identical up to that point in time.

Results for the year 2030 show that the LOLPs increased for each CE plan, above the LOLP target for two of them (shown in bold). The Base and MARS CE plans exceeded the LOLP target with mean LOLPs of 0.11% and 0.29% respectively. For the Base CE plan, this was due to load growth and not enough firm capacity growth to maintain LOLP below the target level. For MARS, this was due to the plan having the lowest net capacity additions by 2030 as compared to the other CE plans. While the Max CE plan had a mean LOLP (0.02%) under the target LOLP, the standard deviation was high (0.03%) suggesting certain conditions where the LOLP can be exceeded. For the Carbon Reduction CE plan, the mean LOLP (0.01%) was under the LOLP target by enough that the standard deviation (0.01%) does not suggest likely conditions where the LOLP would be exceeded.

To compensate for the excess LOLP in the Base CE and MARS CE plans, additional capacity was added to the Base CE and MARS CE plans in the year 2030 and the simulations re-run. Given Tri-State's long-term goal of achieving GHG reductions, we added generic new battery storage resources instead of thermal resources. The results of the LOLP analysis for the Base and MARS CE plans following addition of the energy storage are shown in Table 3.

Table 3 Summary of USE and LOLP After Battery Additions

	2025				2030			
Plan Name	Base	MAX	MARS	Carbon Red.	Base	MAX	MARS	Carbon Red.
Mean USE (hr)	1.95	0.00	1.95	0.00	1.7	1.45	0.9	0.70
Std. Dev. USE (hr)	2.31	0.00	2.31	0.00	1.92	2.48	1.17	1.30

	2025				2030			
Mean LOLP (%)	0.02	0.00	0.02	0.00	**0.02**	0.02	**0.01**	0.01
Std. Dev. LOLP (%)	0.03	0.00	0.03	0.00	0.02	0.03	0.01	0.01

Results show that both the Base CE and the MARS CE achieve the LOLP target in 2030 with addition of batteries (shown in bold). We found that for the Base CE, two additional 100 MW 4-hour batteries with 400 MWh of storage capacity are required to achieve the LOLP target. These batteries were added in eastern Colorado and Wyoming. For the MARS CE, three additional 100 MW 4-hour batteries with 400 MWh of capacity are required to meet the LOLP target. These batteries were added in western Colorado. While the Base CE plan had a mean LOLP (0.02%) under the target LOLP, the standard deviation was high (0.02%) suggesting certain conditions where the LOLP can be exceeded. As an additional sensitivity, we added three batteries to the Base CE (one in each of eastern Colorado, western Colorado, and Wyoming) and reran the simulation. Results (not shown here) indicated that the sum of the mean LOLP plus standard deviation LOLP was below the LOLP target.

Special Notice

Acceptance of this report, or use of any information contained in this report, by any party receiving this report other than Tri-State Generation & Transmission Association ("Client") (each a "Recipient") shall constitute an acknowledgement and acceptance by such Recipient of, and agreement by such Recipient to be bound by, the following:

(1) This report was prepared for the Client by Black & Veatch Management Consulting, LLC ("Consultant") and is based in part on information provided by the Client and others. In preparing this report, Consultant has assumed that the information, both verbal and written, provided by the Client and others is complete and correct.

(2 Recipient acknowledges and understands that Consultant provides no warranty, guarantee, or promise, express or implied, to the Recipient for the contents of the Report.

(3) Recipient is not entitled to make any copies of any portion of this report, use extracts therefrom or transmit any part thereof to any other party in any form, including without limitation electronic or printed media of any kind.

(4) TO THE FULLEST EXTENT PERMITTED BY LAW, CONSULTANT'S TOTAL LIABILITY, ON A CUMULATIVE AND AGGREGATE BASIS, TO CLIENT AND ALL RECIPIENTS AND OTHER PARTIES, RESULTING FROM CONSULTANT'S ACTIONS IN RELATION TO THE CREATION AND DISSEMINATION OF THIS REPORT, WILL BE LIMITED TO THE AMOUNT OF COMPENSATION (EXCLUSIVE OF THE REIMBURSEMENT OF COSTS AND EXPENSES) ACTUALLY RECEIVED BY CONSULTANT FROM CLIENT FOR THE CREATION OF THIS REPORT UNDER THEIR CONTRACT. Recipient hereby waives any right to seek or collect damages in excess thereof and releases Consultant from any and all damages or losses which, if required to be paid to Recipient, would result in Consultant paying total damages to any and all parties, including Client and all Recipients, in an amount that would exceed the limit set forth in the previous sentence.

The exclusive venue for any claim, cause of action, legal proceeding, or lawsuit relating to this report shall be the federal court or the state court if a federal jurisdiction is not present, located in New York City, Borough of Manhattan, State of New York. Recipient and any other party irrevocably waive each argument, objection, defense, assertion, or claim that venue is improper for any reason in the state and federal courts in New York City, Borough of Manhattan, State of New York for any claim, cause of action, legal proceeding, or lawsuit brought in said courts or that such claims have been brought in an inconvenient forum.

The above terms and conditions are governed by and shall be governed by and construed in accordance with the laws of the State of New York, without giving effect to the conflicts of laws principles thereof other than Sections 5-1401 and 5-1402 of the General Obligations Law of the State of New York.

IF ANY RECIPIENT IS NOT WILLING TO ACKNOWLEDGE AND ACCEPT, OR AGREE TO, THE TERMS SET FORTH ABOVE, IT MUST RETURN THIS REPORT TO CONSULTANT IMMEDIATELY WITHOUT MAKING ANY COPIES THEREOF, EXTRACTS THEREFROM OR USE (INCLUDING DISCLOSURE) THEREOF. A RECIPIENT'S FAILURE SO TO RETURN THIS REPORT SHALL CONSTITUTE ITS ACKNOWLEDGEMENT AND ACCEPTANCE OF AND AGREEMENT TO THE TERMS SET FORTH ABOVE.

1.0 Executive Summary

Tri-State Generation & Transmission Association ("Tri-State") forecasts the effective load carrying capability (ELCC) of its existing and planned new solar photovoltaic (PV) and wind resources for the purposes of modeling the long-term resource adequacy of its resource plans as part of the energy resource planning process. Tri-State retained Black & Veatch ("we" or "us") to forecast ELCC Values for the overall system that includes the planned solar and wind resources of a representative expansion plan, specifically (the "Analysis"). This report presents the results of the Analysis.

Results show that the System ELCC, as a percent of installed capacity, is forecast to decline as additional planned solar and wind resources are added to the Tri-State system. Effectively, the solar resources provide capacity during peak daytime hours only. That causes the "net peak" to shift to non-solar generating hours, in effect, causing additional solar to have lower capacity value because the added solar is not reducing the net peak. In contrast, results show that the planned additional wind resources will have relatively good capacity value. The Wind Only ELCC is generally increasing over time which indicates the planned additional wind resources will be generating during the new net peak hours and therefore contribute to System ELCC. It is also worth noting that the expansion plan evaluated has a specific resource mix of expansion plan additions, and as the mix is modified from plan to plan a reiterative process to address impacts to ELCC is required.

2.0 Methodology

The basis for calculating the ELCC Values for photovoltaic and wind power is partly based on the methods published by the U.S. Department of Energy (DOE) in document number PNNL-22117 entitled Capacity Value of PV and Wind Generation in the NV Energy System (the "DOE Paper"). Determining ELCC Values is important for estimating additional load that can be served by new PV and wind installations. Variability in solar and wind generation causes wind and solar generation's contribution to resource adequacy to be determined differently from conventional generation.

Our Analysis used the capacity value method described in Chapter 5 of the DOE Paper (the "Capacity Value Method"). The Capacity Value Method defines capacity value as the equivalent perfectly reliable generation capacity that, when used to replace intermittent renewable generation, the system has the same loss of load expectation (LOLE). The Capacity Value Method is a reasonable approximation to a full ELCC method which relies on calculation of loss of load probability (LOLP) and LOLE in every hour. When demand is very low compared to installed capacity, as it is in most systems, the LOLP in low demand hours is negligible. Since the LOLP in low demand hours is very small, the contribution to the annual LOLE is very small. The LOLE result will probably not be affected much if the LOLP in those low demand hours is ignored; and determination of the ELCC can be reasonably accurate using the top 2.5% Net Peak Load hours by determining the average contribution of the renewable generation to meet load during the top 2.5% Net Peak Load hours, as is done under the Capacity Value Method. The Capacity Value Method approximates the ELCC method and eliminates the need for conventional generation data and the calculation of the system LOLP. The Capacity Value Method yields results that are nearly as accurate as the full ELCC method and the analysis can be performed very quickly. The Capacity Value Method is also an improvement over the Peak Period Capacity Factor (PPCF) method mentioned in the DOE Paper.

3.0 Scope and Assumptions

A working model of the Capacity Value Method was developed for the Tri-State system. The ELCC was determined for the renewable generators defined in Table 1 below and for the hourly demand summarized in Table 2 for the Colorado, New Mexico, and Wyoming regions of the Tri-State system (excludes Nebraska). The aggregated system results assume no transmission constraints on flow between locations.

Table 1 – Summary of Renewable Generation Characteristics

ENTITY	CAPACITY (MW) AC	INSTALLATION DATE	RETIREMENT DATE	LOCATION

4.0 Results & Discussion

Table 3 contains the results of the Analysis for each of the years 2020 through 2040. The Peak MW is the coincident peak demand for each year for the defined system analyzed. The Installed Solar Capacity, Installed Wind Capacity, and Installed Renewable Capacity columns show each year's installed solar, wind, and total wind and solar capacity based on existing and proposed renewable capacity additions.

Table 1 ELCC for Wind, Solar, and Combined Wind and Solar in Tri-State System (exclusive of the Nebraska area)

	Peak	Installed Solar Capacity	Installed Wind Capacity	Installed Renewable Capacity	Solar Only ELCC	Wind Only ELCC	Combined Solar and Wind (System) ELCC	Solar Only ELCC	Wind Only ELCC	System ELCC	Incremental Solar Only ELCC	Incremental Wind Only ELCC

2036	3,481	2,070	726	2,796	358	276	634	17.3%	38.1%	22.7%	5.1%	40.6%
2037	3,504	2,170	726	2,896	361	281	642	16.6%	38.7%	22.2%	4.5%	39.0%
2038	3,563	2,170	726	2,896	357	270	627	16.4%	37.2%	21.6%	4.5%	39.3%
2039	3,600	1,655	826	2,481	313	313	626	18.9%	37.9%	25.2%	4.2%	38.1%
2040	3,656	1,655	1,226	2,881	328	433	761	19.8%	35.3%	26.4%	3.6%	34.0%

Although wind and solar ELCCs are not separable per sei, in that for example, not only is the Solar ELCC a function of the amount of solar generation in the system, but also a function of how much wind is in the system; one could remove the wind generation and determine the Solar ELCC in the absence of wind; or conversely, leave the wind in and remove the solar and then determine how much the solar generation was contributing to the total system ELCC by subtracting the wind's contribution from the system ELCC assuming the difference is the solar contribution.

Calculations were performed to determine the ELCC with each of the following three configurations: solar only generation (Solar Only ELCC), wind only generation (Wind Only ELCC), and combined solar and wind generation (System ELCC). The Solar Only ELCC was calculated by removing the wind generation from the system. The Wind Only ELCC was calculated by removing the solar generation from the system. The System ELCC is based on the ELCC calculated with both the wind and solar installed as configured. The Solar Only ELCC MW column shows (in megawatts) the average of the Solar Only ELCC and the difference of the System ELCC and the Wind Only ELCC. The Wind Only ELCC MW column shows the average of the Wind Only ELCC and the difference of the System ELCC and the Solar Only ELCC.

The Solar Only ELCC, Wind Only ELCC and System ELCC are also shown as a percent of installed capacity. The System ELCC as a percent of installed capacity is determined by dividing the System ELCC by the total installed solar and wind capacity. The Wind Only ELCC as a percent of installed capacity is determined by dividing the Wind Only ELCC by the total installed wind capacity. A similar calculation was performed to determine the Solar Only ELCC as a percent of installed capacity.

The last two columns in Table 3, labeled Incremental Solar Only ELCC and Incremental Wind Only ELCC as a percent of installed capacity report the incremental ELCC associated with additional wind and solar capacity additions. The incremental Solar Only ELCC was calculated by increasing the Solar generation by five percent. The increase in the system ELCC divided by the increase in solar installed capacity is the Incremental Solar Only ELCC. The five percent increase is based on increasing the output of all installed solar by five percent. A similar method was used to calculate the Incremental Wind Only ELCC.

END OF REPORT

Attachment Vol II 5-4 B&V Report on Review of Existing Resources

August 3, 2020 Revision

Report on Review of Existing Resources

Executive Summary

As part of the energy resource planning process, Tri-State Generation & Transmission Association ("Tri-State") must establish assumptions concerning the future performance and cost of its existing resources for the purposes of modeling the long-term performance and cost of the resource plan ("Modeled Values"). Tri-State retained Black & Veatch ("we" or "us") to review the Modeled Values and as necessary recommend changes to the Modeled Values to better represent future resource performance and cost (the "Review"). The Modeled Values included capacity, heat rate, availability rate, forced outage rate, emissions, renewable production profiles, variable O&M costs and fixed O&M costs. The existing resources included eighteen (18) coal, gas and oil fired resources) two (2) long-term purchase agreements with Basin Electric and seven (7) renewable (solar and wind) facilities located across the Tri-State system. This Report summarizes the scope, methodology and results of our Review.

Our approach was to compare the Modeled Values against actual performance and cost data provided to us by Tri-State, data collected by federal regulatory agencies and national reliability coordinators, and data reported by other generators for resources of similar technology, size, age and location. In cases where a Modeled Value was significantly different from the values shown in the data sources, and if the data was determined to be of reasonable quality, we then recommended an alternative modeled value for consideration by Tri-State (each a "Recommended Modeled Value").

Our review revealed that some of the Modeled Values were significantly different than those shown in one or more of the data sources. Differences included heat rates for the Burlington resources, fixed O&M costs for the Rifle resource, and NOx emission rates for the Burlington and Rifle resources. They also included SO2 emission rates for the Rifle and Shafer resources, availability factors for the Burlington, Limon, Rifle and Shafer resources, and forced outage factors for the Burlington, Knutson, Limon, Rifle and Shafer plants. For each of these we provided a Recommended Modeled Value for consideration by Tri-State. The Recommended Modeled Values are summarized in the Results section of this Report.

Scope

The scope of our Review was defined by Tri-State and included the resources shown in Table 1 below.

Six (6) of the Existing Resources are coal fired. These include the Craig coal-fired Units 1 through 3 located in western Colorado ("wco"), the Laramie River coal-fired station ("LRS") Units 2 and 3 located in Wyoming ("wyo"), and Springerville coal-fired Unit 3 located in Arizona ("arz"). These resources are either partially owned or partially controlled by Tri-State with the exception of Craig Unit 3 which is wholly owned and Springerville Unit 3 which is wholly leased with 100 MW of the Total Capacity sold to a third party under a tolling agreement through the summer of 2036. The capacity currently controlled by Tri-State is shown as the "Tri-State Modeled Capacity".

Another ten (10) of the Existing Resources are oil or gas fired combustion turbines that are fully owned by Tri-State. These include the Burlington Units 1 and 2, the Knutson Units 1 and 2, the Limon Units 1 and 2 and the Pyramid Units 1 through 4. The Burlington, Knutson and Limon Units are located in eastern Colorado and the Pyramid Units are located in southern New Mexico. All of these resources are fully controlled by Tri-State.

Another two (2) of the Existing Resources are gas-fired combined cycle plants that are fully owned by Tri-State. These include the Rifle plant located in western Colorado and the Shafer plant located in eastern Colorado.

These coal, gas or oil fired resources are referred to collectively as the "thermal" resources.

Another seven (7) resources are solar or wind powered "renewable" resources with output purchased by Tri-State under power purchase agreements ("PPA"). Five (5) of these resources are located in eastern Colorado ("eco") and the remaining two (2) are located in New Mexico. All of the output from these resources is purchased by Tri-State.

The remaining two (2) Existing Resources are long-term contract purchases from Basin Electric Power Cooperative ("Basin"), collectively the "Basin Contracts". The first contract is known as the Western CROD Contract ("Basin West") and the other as the Basin Electrically East Contract ("Basin East"). No specific generating resource is associated with each Basin Contract. Basin has the sole discretion to choose how the Basin West contract is supplied on a day ahead and hour ahead basis. The Basin East contract is supplied via Southwest Power Pool (SPP). The Basin West contract has a set hourly energy profile by month for each year of the contract. The Basin East Contract is a full requirements contract and supply is based on actual energy needs of Tri-State's Utility Member Systems located in the Eastern Interconnection. Tri-State purchases all energy as contracted under the Basin Contracts.

The scope of parameters to review for each of these resources was also specified by Tri-State. The parameters included heat rate, variable O&M cost, fixed O&M cost, CO2 emission rate, NOx emission rate, SO2 emission rate, availability rate, forced outage rate, and capacity factor for the renewable resources only (each a "Parameter").

Methodology

Our methodology for the Review was to compare the Modeled Values against historical Parameters from three (3) data sources and base our Recommended Modeled Values on the results of that comparison. The Modeled Values were provided to us by Tri-State and consisted of Parameters for each of the existing resources. The first data source was historical data provided to us by Tri-State for heat rate, availability rate and forced outage rate for the thermal resources ("Tri-State Data"). The second data source was historical data gathered from federal regulators by the S&P Global Market Intelligence

[1] Basin East is a full requirements contract so capacity is not specified in the contract but rather fluctuates with the demand forecast of the members.

service ("S&P")[2] for heat rate, variable O&M cost, fixed O&M cost, CO2 emission rate, NOx emission rate and SO2 emission rate for the thermal resources and capacity factor for the renewable resources ("S&P Data"). The third data source was a compilation of Parameters from S&P and from historical data reported by the North American Reliability Corporation ("NERC") for resources of similar technology, size, age and location to the Tri-State resources but that are owned or controlled by others ("Peer Group Data"). Comparing the Modeled Values against data from these three sources allowed us to evaluate the extent to which the Modeled Values were consistent with the actual historical Parameters of the resource and other similar resources in the market.

A summary of the key features of the Peer Group Data is provided in the table below.

Table 2- Summary of Key Features of the Peer Group Data

-	Plant/Unit	Peer Group	NERC Regions	Capacity	COD	# of Units in GADS	GADS Data	# of Units in S&P	S&P Data
1	GC-Craig 1-NW_CO	Large Coal ST	MRO, WECC and SPP	300 to 500 MW	1980 to 2010	26	2015-2018 Forced Outage Factor (FOF) and Availability Factor (AF)	41	2015-2018 Heat Rate, Non-Fuel O&M Variable Costs ($/MWh), Fixed O&M Costs ($/kw-mo), CO2 Emissions (lb/MMBtu), NOx Emissions (lb/MMBtu), SO Emissions (lb/MMBtu)

For each peer group, the NERC region, capacity range and age range were selected such that the existing resource(s) and a reasonable number of third party resources would fall into the group. The total capacity of the existing resource rather than just the Tri-State share was considered in developing each peer group.

Once the peer groups were established, the associated Tri-State Data, S&P Data and Peer Group Data was acquired. Modeled Values and data were limited for the solar and wind resources. Tri-State has

Modeled Values for only capacity factor and none of the other Parameters (variable O&M, fixed O&M, etc.) since the existing wind and solar resources are not owned by Tri-State. Also, NERC has only recently begun requiring owners of renewable energy resources to submit performance and reliability data and NERC has not yet made the data available. Therefore, capacity factor was the only Parameter considered in Review of the wind and solar resources.

Modeled Values and data were also limited for the Basin Contracts because they are not resource specific. Modeled Values for the Basin Contracts included only CO2, SO2 and NOx emission rates. These Modeled Values were calculated by Tri-State based on historical emission rates for Laramie River Station (LRS2, LRS 3) for Basin West and egrid subregion MRO-W emissions were used for the Basin East. This approach reflects the fact that historically some of the energy from Basin West has likely been generated from coal fired power plants on the Basin system and that Basin East is served by the Southwest Power Pool. Modeled Values for the other Parameters (variable O&M, fixed O&M, etc.) were not available. No Parameters were available in the S&P Data and Peer Group Data because S&P and NERC do not record data for non-resource specific system sales. Therefore CO2, SO2 and NOx emission rates were the only Parameters considered in review of the Basin Contracts. It is also important to note that none of the Parameters reviewed in this report including emissions are specified in the Basin Contracts.

Data analysis began with comparison of each Modeled Value against a four year (2015 – 2018 inclusive) average of the associated Parameter from the Tri-State Data, the S&P Data and the Peer Group Data. Data for the years 2019 and 2020 was excluded because it was either unavailable or incomplete at the time the Review was performed (Spring 2020). Each Modeled Value was then also compared against an average of the three averages (the “Grand Average”). In cases where the Modeled Value was more than 10% greater or less than the Grand Average (5% for the availability factor and forced outage factor Grand Averages), the difference was considered significant and we further examined the data to determine the cause of the difference including whether or not the Grand Average was skewed high or low by the presence of high or low outliers in the underlying data or the underlying data was of poor quality for some other reason. If the Grand Average proved to be of reasonable quality, we then recommended an alternative modeled value for consideration by Tri-State (a "Recommended Modeled Value").

The threshold for significance was only 5% for the availability factor and forced outage factor Grand Averages because the data ranged from only 70% to 100% and therefore, we felt that using a 10% threshold would mask too many significant differences.

Results

Results of the data analysis are summarized in the following tables. Each table summarizes the analysis for one of the Parameters including the relevant Modeled Value, the Tri-State Data value, the S&P Data value, the Peer Group Data value and the Grand Average for each of the existing resources. Grand Averages highlighted in yellow indicate the Grand Average is significantly (+\- 10% or +/- 5%) different than the Modeled Value. Recommended Values highlighted in green indicate Recommended Values different than the Modeled Value.

Heat rate results show that the Grand Average was significantly different than the Modeled Value for several of the resources. However, review of the Grand Average revealed that the underlying Tri-State data and Peer Group data was skewed in most of these cases. For these resources, no change was recommended. The exception are the Burlington combustion turbine Units 1 and 2. A Recommended Modeled Value was therefore provided based on the Grand Average. A heat rate comparison was not applicable to the renewable resources and the Basin Contracts.

Variable O&M cost results show that the Grand Average was significantly different than the Modeled Value for nearly all of the resources. However, review of these Grand Averages revealed that the underlying S&P Data was not actual data (but rather calculated) for the coal-fired units and was skewed by extreme outliers for the combustion turbine units and for the Shafer combined cycle plant. As a result, the Recommended Modeled Values were the same as the Modeled Values for all the resources (no change recommended). A variable O&M Cost comparison was not applicable to the renewable resources and the Basin Contracts.

Fixed O&M cost results show that the Grand Average was significantly different than the Modeled Values for nearly all of the resources. However, the underlying S&P data and Peer Group data was judged to be of poor quality and therefore no changes to the Modeled Values were recommended. The exception was for the Rifle combined cycle plant, where a lower Recommended Modeled Value was provided. The Recommended Modeled Value was also expressed in $000s for convenience since Tri-State models fixed O&M on a dollar basis instead of $/kw-yr. A fixed O&M cost comparison was not applicable to the renewable resources and the Basin Contracts.

CO2 emission rate results show only a few significant differences between the Grand Averages and the Modeled Values. Further investigation into these differences revealed that the S&P Data and Peer Group Data was not actual but rather calculated. As a result, our Recommended Modeled Values were the same as the Modeled Values for all the resources (no change recommended). A CO2 emission comparison was not applicable to the renewable resources. A comparison was not applicable to the Basin Contracts because of the lack of S&P Data and Peer Group Data. As a result, our Recommended Modeled Values were the same as the Modeled Values for the Basin Contracts (no change recommended).

NOx emission rate results show that the Grand Average is significantly different than the Modeled Values for nearly all resources. However, no changes were recommended in most cases due to poor S&P Data and Peer Group Data quality. For Craig 2, no change was recommended because the significant difference is due to NOx emission controls that have been added to the unit. This causes the rate to be much less than Craig 1 as well as the S&P Data and Peer Group Data. Changes were recommended for Burlington Units 1 and 2 and the Rifle combined cycle plant. The Modeled Values are relatively high for these resources. It is possible that the Modeled Values reflect actual emission rates which are relatively high due to use of fuel oil at Burlington or lack of modern emission controls at Rifle. If this is the case, then no change should be made to the Modeled Value. A NOx emission comparison was not applicable to the renewable resources. A comparison was not applicable to the Basin Contracts because of the lack of S&P Data and Peer Group Data. As a result, our Recommended Modeled Values were the same as the Modeled Values for the Basin Contracts (no change recommended).

SO2 emission rate results show that the Grand Average is significantly different than the Modeled Values for all the resources. However, no changes were recommended in most cases due to poor S&P Data quality. The exception is the Rifle and Shafer resources. The Modeled Values are relatively low for these resources and so a higher Recommended Modeled Value is provided. An SO2 emission comparison was not applicable to the renewable resources. A comparison was not applicable to the Basin Contracts because of the lack of S&P Data and Peer Group Data. As a result, our Recommended Modeled Values were the same as the Modeled Values for the Basin Contracts (no change recommended).

Availability factor results show significant differences between the Grand Averages and the Modeled Values for the majority of the resources. However, in some of these cases (Craig Unit 1, Craig Unit 3, Springerville Unit 3, Knutson Unit 2 and Limon Unit 2) no changes were recommended due to the Tri-State data being skewed by low values for the years 2016 or 2018. For the other resources, a Recommended Modeled Value was provided based primarily on the Tri-State Data. The Recommended Modeled Value was also expressed in maintenance outage hours (MOH) for convenience since Tri-State models maintenance outages on an hourly basis instead of a percentage basis. An availability factor comparison was not applicable to the renewable resources and the Basin Contracts.

Forced outage factor results show significant differences between the Grand Averages and the Modeled Values for the majority of the resources. However, in some of these cases (Craig Unit 2, LRS Unit 2) no change was recommended since the Grand Average if rounded would equal the Modeled Value and therefore the Modeled Value was judged to be in a reasonable range. In other cases (Craig Unit 3, Springerville Unit 3) no changes were recommended due to the Tri-State data being skewed by low values for the years 2016, 2017 or 2018. For the other resources, a Recommended Modeled Value was provided based primarily on the Tri-State Data. The Recommended Modeled Value was also expressed in forced outage hours (FOH) for convenience since Tri-State models forced outages on an hourly basis instead of a percentage basis. A forced outage factor comparison was not applicable to the renewable resources and the Basin Contracts.

Renewable capacity factor results show significant differences between the Grand Averages and the Modeled Values for the majority of the resources. However, in some of these cases (San Isabel, Twin Buttes and Carousel) no change was recommended since the Tri-State and S&P data were skewed low due to outlier low values in 2015, 2016 or 2017. In the other cases (Colorado Highlands and Kit Carson) no changes were recommended due to the Peer Group Data being relatively low. A capacity factor comparison was not applicable to the thermal resources and the Basin Contracts.

Table 3 – Results of Review – Heat Rate (Btu/kwh)

	Heat Rate (Btu/kwh)							
Resource	Current Modeled	Tri-State Data	S&P Data	Peer Group Data (S&P)	Avg. Tri-State, S&P, Peer Group Data	Recommendation	Notes	Recommended Modeled

END OF REPORT

Attachment Vol II 5-5 B&V Benchmarking Study

August 3, 2020 Revision

Report on Benchmarking of Existing Resources

Executive Summary

As part of its responsibilities under a recent Energy Resource Planning decision by the Colorado Public Utilities Commission[1], Tri-State Generation & Transmission Association ("Tri-State") must file in support of its Energy Resource Plan (ERP) an assessment of its existing resources including a comparison of the costs and performance of each of its existing resources (utility owned and contracted) to the costs and performance of the generic resources (a "Benchmarking")[2]. Tri-State retained Black & Veatch ("we" or "us") to perform the Benchmarking for the purposes of supporting a filing by Tri-State. Tri-State defined the existing resources to include eighteen (18) of its coal, gas and oil fired resources, two (2) long-term purchase agreements with Basin Electric, and seven (7) of its renewable (solar and wind) facilities totaling twenty seven (27) existing resources ("Existing Resources"). Tri-State did not include its renewable facilities that are under contract but not yet in commercial operation. The generic resources included future potential gas-fired, solar, wind, battery storage, solar plus battery, wind plus battery, and hydroelectric resources located in Colorado, Wyoming and New Mexico totaling sixty one (61) generic resources ("Generic Resources"). This Report summarizes the scope, methodology and results of the Benchmarking.

Our approach was to first identify for each Existing Resource a Generic Resource for comparison based on the type of Existing Resource (thermal or renewable), the location of the Existing Resource, the generating capacity of the Existing Resource, and the annual capacity factor typically expected for a resource of that type. We then forecast the annual energy production and costs of both the Existing Resource and the Generic Resource for the years 2021-2040 assuming each operated at the same capacity factor in isolation from all other resources and under common assumptions for the Colorado social cost of carbon ("Social Cost of Carbon"), fuel costs, interest rates and escalation. Assumptions for heat rate, fixed O&M, variable O&M, capital basis, depreciation, and book life were specific to each resource and were provided by Tri-State. We developed assumptions for a limited number of the Generic Resources where necessary. The forecasts were made on an "equal service life" basis ensuring the Existing Resource and Generic Resource operated for the same years in the study period at the same capacity factor. We then discounted the annual capacity, energy production and annual cost streams to net present values and expressed them as a levelized cost of energy in $/MWh (LCOE) for cases where the capacity factor was relatively high or a levelized cost of capacity in $/kw-yr (LCOC) where the capacity factor was relatively low.

[1] Colorado Public Utilities Decision No. C20-0155 issued March 10, 2020 adopting amendments to the provisions in the rules governing Electric Resource Planning (ERP Rules).

[2] Colorado Department of Regulatory Agencies, Public Utilities Commission, Code of Colorado Regulations (CCR) 723-3, Part 3 Rules Regulating Electric Utilities, Electric Resource Planning, Section 3605 (c)(II).

Results of the Benchmarking show that each coal-fired Existing Resource is more costly than its associated Generic Resource counterpart due primarily to higher Social Cost of Carbon and higher FOM costs. Each oil and gas fired combustion turbine Existing Resource is less costly than its Generic Resource counterpart due primarily to a lower (highly depreciated) capital basis and therefore lower depreciation and interest costs. Each renewable Existing Resource is more costly than its associated Generic Resource counterpart likely due to the fact that the Existing Resources were built in prior years when the cost of solar and wind technology was higher than today and much higher than costs expected in future years (a declining capital cost curve). The Basin West Contract is more costly than its Generic Resources due to an applied social cost of carbon rate, whereas conversely the Basin East Contract is less costly than its Generic Resources due to the need to include a gas-fired peaking resource in the Generic Resources to account for renewable intermittency. Results are shown in the Results section of this Report.

We also performed a supplemental analysis concerning the Existing Resources not located in Colorado to examine how their LCOE and LCOC would change if the Social Cost of Carbon was not applied ("Non-Colorado Benchmarking"). Results of the Non-Colorado Benchmarking revealed that both the Non-Colorado Existing Resources and the Non-Colorado Generic Resources are significantly less costly than under the Benchmarking. Results also revealed that although the Existing Resources are still more costly than the Generic Resources the gap in cost is narrowed significantly. This is particularly true for LRS Units 2 and 3 where the cost difference is narrowed to approximately ten (10) percent.

Scope

The scope of the resources to be Benchmarked was defined by Tri-State and included the Existing Resources shown in Table 1 and the Generic Resources shown in Table 2 below.

Existing Resources

Six (6) of the Existing Resources are coal fired. These include the Craig coal-fired Units 1 through 3 located in western Colorado ("wco"), the Laramie River coal-fired station ("LRS") Units 2 and 3 located in Wyoming ("wyo"), and Springerville coal-fired Unit 3 located in Arizona ("arz"). These resources are either partially owned or partially controlled by Tri-State with the exception of Craig Unit 3 which is wholly owned, and Springerville Unit 3 which is wholly leased with 100 MW of the Total Capacity sold to a third party under a tolling agreement through the summer of 2036. The capacity currently controlled by Tri-State is shown as the "Tri-State Modeled Capacity".

Another ten (10) the Existing Resources are oil or gas fired combustion turbines that are fully owned by Tri-State. These include the Burlington Units 1 and 2, the Knutson Units 1 and 2, and the Limon Units 1 and 2and the Pyramid Units 1 through 4. The Burlington, Knutson and Limon Units are located in eastern Colorado and the Pyramid Units are located in southern New Mexico. All of these resources are fully controlled by Tri-State

Another two (2) of the Existing Resources are gas-fired combined cycle plants that are fully owned by Tri-State. These include the Rifle plant located in western Colorado and the Shafer plant located in eastern Colorado.

These coal, gas or oil fired resources are referred to collectively as the "thermal" resources.

Another seven (7) Existing Resources are solar or wind powered "renewable" resources with output purchased by Tri-State under power purchase agreements ("PPA"). Five (5) of these resources are located in eastern Colorado ("eco") and the remaining two (2) are located in New Mexico. All of the output is purchased by Tri-State.

The remaining two (2) Existing Resources are long-term contract purchases from Basin Electric Power Cooperative ("Basin"), collectively the "Basin Contracts". The first contract is known as the Western CROD Contract ("Basin West") and the other as the Basin Electrically East Contract ("Basin East"). No specific generating resource is associated with each Basin Contract. Basin has the sole discretion to choose how the Basin West contract is supplied on a day ahead and hour ahead basis. The Basin East contract is supplied via Southwest Power Pool (SPP). The Basin West contract has a set hourly energy profile by month for each year of the contract. The Basin East Contract is a full requirements contract and supply is based on actual energy needs of Tri-State's Utility Member Systems located in the Eastern Interconnection. Tri-State purchases all energy as contracted under the Basin Contracts.

Generic Resources

Twenty-eight (28) of the Generic Resources were gas-fired including reciprocating engine ("Recip_Engine"), aeroderivative combustion turbine ("Aeroderivative_CT"), industrial combustion turbine ("Frame_CT") and industrial combined cycle ("Frame_CCCT") technologies that would be located in western Colorado ("wco"), southwestern Colorado ("swco"), northwestern Colorado ("nwco"), northern New Mexico ("nnm") and Wyoming ("wyo"). All of these would be wholly owned by Tri-State with the capacity shown as the "Tri-State Modeled Capacity".

The remaining Generic Resources included:

- Solar PV ("Solar_PV") technologies of various sizes (40, 100, 120, 230 MW) and wind ("Wind") technologies of various sizes (40, 100, 165, 280 MW) to be located in eco, swco, nnm, and wyo either under third party ownership ("PPA") or Tri-State ownership ("Build-Transfer");
- Standalone lithium ion battery storage technology ("Li-Ion Battery") in various combinations of size (25, 100, 500 MW) and duration (4 hour or 8 hour) to be located in eco, swco, wco, nnm, and wyo to be owned ("Owned") by Tri-State;
- 300 MW pumped storage technology located in nnm to be owned by Tri-State;
- 100 MW combined solar PV plus storage ("Solar+Battery") and wind plus storage ("Wind+Battery") technologies to be located in eco, nnm, wyo and swco either under third party ownership or Tri-State ownership

[3] Basin East is a full requirements contract so capacity is not specified in the contract but rather fluctuates with the demand forecast of the members.

Overall Methodology

Our overall methodology for the Benchmarking was to first select for each Existing Resource a Generic Resource for comparison. We identified certain criteria to guide and constrain the selection of the Generic Resource for comparison (the "Selection Criteria"). The Selection Criteria included 1) that the Generic Resource must be of similar technology to the Existing Resource (e.g. a thermal resource could not be compared with a renewable resource), 2) that the Generic Resource must have a similar location as the Existing Resource, 3) that the Generic Resource must have a capacity similar to the Existing Resource and 4) that the Generic Resource must be capable of operating at or above the annual capacity factor typically expected for a resource of that type. Each combination of Existing Resource and its associated Generic Resource for comparison was known as a "Pairing".

The total capacity of the Existing Resource rather than just the Tri-State Modeled Capacity was considered in selecting the Generic Resource for comparison. This was done because the performance and cost of Tri-State's share of the Existing Resource benefits from the economies of scale of the entire Existing Resource (for example, entire resource heat rate, variable O&M cost rate, fixed O&M cost rate) and therefore a Generic Resource of similar size to the entire Existing Resource should be selected for a fair comparison.

Once the Pairings had been made, we then forecast the annual capacity, energy production and annual operating and ownership costs of both the Existing Resource and the Generic Resource for the years 2021-2040 assuming they would operate in isolation from each other and all other resources. Both the Existing Resource and the Generic resource were forecast to operate at a capacity factor consistent with resources of their types and with historical or expected capacity factors for the Existing Resources as reported by Tri-State (the "Common Capacity Factor"). Energy for each Existing Resource was forecast based on the Common Capacity Factor and its Tri-State Modeled Capacity. Energy for each Generic

Resource was forecast to operate based on the Common Capacity Factor but only a portion of the Plant Capacity equal to their Tri-State Modeled Capacity for the Existing Resource (the "Tri-State Share"). This was done so that the forecast energy production for the Existing Resource and the Generic resource were the same, as if Tri-State was to own just a share of the Generic Resource.

Assumptions for fuel cost, heat rate, carbon emission rates, fixed O&M, variable O&M, capital expenditures, capital basis, depreciation, book life and PPA price (for the third party owned renewable resources) were specific to each Existing Resource and Generic Resource. Assumptions for the Existing Resources were provided by Tri-State but reviewed by us and in some cases modified by Tri-State in consultation with us as part of our Existing Resource Review work. Similarly, assumptions for the Generic Resources were provided by Tri-State but reviewed by us and in some cases modified by Tri-State in consultation with us as part of our Generic Resource Review work. Assumptions for a limited number of the Generic Resources were developed by us. Please see the Results section of this report for a more detailed description of these assumptions and the forecasting methodology. The forecasts were made on an "equal service life" basis ensuring the Existing Resource and Generic Resource were modeled to operate for the same years in the study period. Assumptions provided by Tri-State were aligned with those used in their resource capacity expansion modeling software and were not representative of inputs specific to their financial modeling.

We then discounted the annual capacity, energy production and annual cost streams to net present values and used them to calculate a levelized cost in 2020 dollars for both the Existing Resource and Generic Resource. In cases where the Common Capacity Factor was relatively high, we calculated a levelized cost of energy (LCOE) in $/MWh. In cases where the Common Capacity Factor was relatively low, we calculated a levelized cost of capacity (LCOC) in $/kw-yr. We then compared the LCOE or LCOC results for the Existing Resource and the Generic Resource and commented on why they differed.

Expanded Methodology for the Basin Contracts

For the Basin Contracts, a special methodology was necessary because no specific generating resource is associated with either Basin Contract. For the purposes of benchmarking this type of unspecified energy with varying profiles, we expanded the methodology to allow comparison of each Basin Contract against a group of three (3) Generic Resources (a "Generic Composite") instead of just a single Generic Resource. Use of three resources of differing types was judged a reasonable proxy for a system resource for the purposes of benchmarking.

Generic Resources were selected for each Generic Composite based on three general criteria; 1) to maximize the use of renewable resources; 2) to match the forecast delivery profile of the associated Basin Contract as best possible and 3) minimize the overall cost of the Generic Composite. We began the selection process by examining the hourly Basin Contract forecast energy profile for a typical year (8760 hours). We then attempted to replicate the Basin Contract profile with the hourly forecast energy profiles of the various sized solar and wind Generic Resources. Invariably, there were hours in which the combined forecast solar and wind profiles were insufficient to replicate the Basin Contract profile. In these cases, we introduced a forecast hourly profile for a dispatchable resource to fill the gap. The dispatchable resource was either Recip_Engine, Aeroderivative_CT, Frame_CT, Frame_CCCT or Li-Ion

Battery based. For a battery resource, it was assumed to store energy from the selected solar and wind resources only with a certain efficiency "round-trip" loss.

Although specific generating resources are not associated with the Basin Contracts, Tri-State did provide us with carbon emission rates based on how the Basin Contracts primarily have been historically served to apply to the Basin Contracts.

Results

This section includes results of the resource Pairing, a detailed description of the forecasting and costing methodology with detailed results for one of the Pairings, and a summary of the LCOE and LCOC results for all of the Pairings.

Pairings

Table 3 summarizes results of the resource Pairing.

The coal-fired Existing Resources have plant capacities ranging from 410 to 570 MW with relatively high historical capacity factors reported by Tri-State. Therefore, each of these Existing Resources was paired with the large gas-fired combined cycle combustion turbine (545_1x1_7HA03_nwco) Generic Resource. This Pairing satisfies the Selection Criteria except in the case of the Springerville 3 (SV 3) resource and the Laramie River Station (LRS2, LRS 3) resources. With respect to SV 3, the Generic Resource has a northwest Colorado location instead of an Arizona location. However, we judged the pairing as reasonable since no other CCCT Generic Resource is located in Arizona. With respect to LRS 2 and LRS 3, the Generic Resource has a capacity (545 MW) that is smaller than LRS 2 and LRS 3 (570 MW). However, we judged the Pairings as reasonable because no Frame_CCCT Generic Resource has a capacity greater than LRS. The 545_1x1_7HA03_nwco Generic Resource is the largest Frame_CCCT Generic Resource. We also judged the other coal-fired resource Pairings reasonable even though the capacity (545 MW) is much greater than that of the other coal-fired resources (410-448 MW). This is because no other Frame_CCCT Generic Resource has a capacity greater than 375 MW and therefore would not have satisfied the Selection Criteria. We set the Common Capacity Factor for each Pairing equal to eighty (80) percent which is representative for large coal fired resources and large gas-fired combined cycle resources. This capacity factor is also representative of air quality permit limitations for Craig 1 which limits its capacity factor to 80%.

The combustion turbine Existing Resources have plant capacities ranging from 40 to 70 MW and relatively low historical and expected capacity factors reported by Tri-State. Therefore, each of these resources was paired with a small simple cycle combustion turbine (781_2x40LM6000_eco) Generic Resource. This Pairing satisfied the Selection Criteria. We set the Common Capacity Factor for each Pairing equal to fifteen (15) percent which is representative for combustion turbine resources.

The Rifle Existing Resource is relatively small (81 MW) combined cycle plant. Although a combined cycle plant, Rifle has a historical and expected capacity factor reported by Tri-State that is much lower than typical for combined cycle resource and more typical of a combustion turbine resource. Therefore, the Rifle resource was paired with the same small simple cycle combustion turbine (81_2x40LM6000_eco) Generic Resource used for the combustion turbine Existing Resources. This Pairing satisfied the

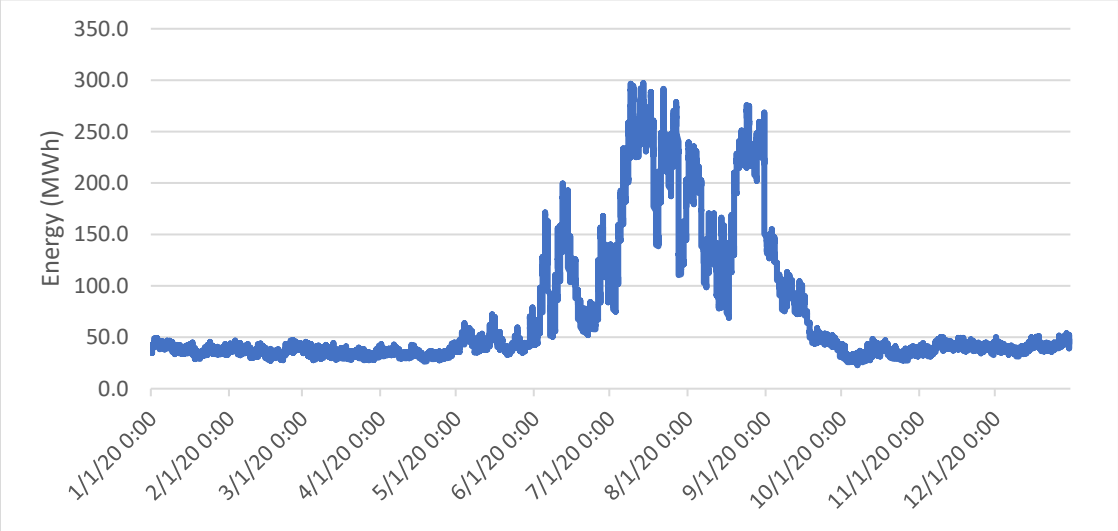
Selection Criteria. We set the Common Capacity Factor for the Pairing equal to fifteen (15) percent which is representative for combustion turbine resources.

The Shafer combined cycle Existing Resource is relatively large (272 MW) with a historical and expected capacity factor reported by Tri-State of approximately thirty five (35) percent. This is relatively low with respect to typical combined cycle resources yet relatively high compared with combustion turbine resources. We decided to pair the Shafer resource with the small gas-fired combined cycle combustion turbine (300_1x1_7FA05_eco) Generic Resource. We felt this was more representative than pairing it with a combustion turbine resource. This Pairing satisfies the Selection Criteria. We set the Common Capacity Factor for the Pairing equal to thirty five (35) percent.

The solar PV Existing Resources were paired with the 100 MW solar PV (CP-1x100PV_eco) Generic Resource. The wind Existing Resources were paired with the 100 MW wind (CP-1x100Wind_eco) Generic Resource. These Pairings satisfy the Selection Criteria, with the exception of the Carousel wind resource. The wind Generic resource has a capacity (100 MW) that is less than the Carousel capacity (150 MW). However, we judged this Pairing reasonable because there is no wind Generic Resource with a capacity greater than 100 MW. We set the Common Capacity Factor for the Pairings equal to the historical capacity factors reported by Tri-State for the Existing Resources.

The Basin West Contract was paired with a Generic Composite consisting of a 230 MW Solar PV resource PPA in eco (CP-1x130PV-eco), a 280 MW Wind resource PPA in eco (CP-1x280Wind-eco) and a 500 MW Li-Ion Battery resource Owned in eco (500MW Li-Ion Battery_eco). The Basin East Contract was paired with a 40 MW Solar PV resource PPA in eco (CP-1x40PV-eco), a 40 MW wind resource PPA in eco (CP-1x40Wind-eco) and a 306 MW RICE resource Owned in eco (306_18x6RICE_eco). It's important to note that a gas-fired dispatchable resource was selected for the Basin East Generic Composite rather than a Li-Ion Battery resource. This was due to the fact that the Basin East Contract energy demand is driven by irrigation loads which are consistently high in the summer and consistently low in the winter (see Figure 1 below). It was judged that a Li-Ion Battery resource with just 4 hours of duration and a relatively high capital cost would have very little utilization over the year and therefore would be less cost-effective than a RICE generating resource with a relatively low capital cost.

Figure 1 – Hourly Energy Profile for the Basin East Contract



Forecasting Methodology and Craig 1 Results

This section provides a detailed description of the methodology used for the forecasting and LCOE and LCOC calculations for Benchmarking of Existing Resources other than the Basin Contracts. As a guide, detailed results for the Craig 1 Pairing are shown below (Table 4 for the Existing Resource and Table 5 for the Generic Resource). Assumptions and results are shown in the upper left portion of the results with the annual cost forecast shown below that. A summary of LCOE and LCOC results for all the Pairings are provided in the subsequent LCOE and LCOC Results section.

Generation for the Existing Resource was forecast to be constant every year based on the Tri-State Modeled Capacity and the Common Capacity Factor for the Existing Resource, and the Tri-State Share and the Common Capacity Factor for the Generic Resource.

For Existing Resources and Generic Resources to be owned by Tri-State, fuel cost was forecast based on the heat rate multiplied by the generation and the first year fuel price (Fuel Cost 2021). For costs in subsequent years the fuel price was escalated at the fuel cost escalation rate which was set equal to the compound annual growth rate of prices observed in the fuel price forecasts provided by Tri-State. Carbon costs were forecast similarly, based on the generation, the carbon emission rate of the resource and the first year Social Cost of Carbon (Social Cost of Carbon 2021) and an escalation rate based on the compound annual growth rate of the Social Cost of Carbon forecast provided by Tri-State. Variable O&M (VOM) was forecast based on generation and the first year variable O&M cost (VOM Cost 2021) and an assumed VOM cost escalation rate. Fuel, carbon and VOM forecasts were not applicable to the resources to be owned by third parties.

For Existing Resources and Generic Resources to be owned by Tri-State, fixed operations and maintenance cost (FOM) and capital expenditures (Capex) were forecast similarly to VOM except in the case of the Existing Resources for which resource-specific forecasts were provided by Tri-State. In order

to ensure equal service lives between the Existing Resource and the Generic Resource, we requested for the purposes of the Benchmarking that Tri-State develop the Existing Resource forecasts assuming that the Existing Resources would operate for the entire study period (through 2040). This ran counter to planned retirement decisions for the Existing Resources, in particular the Craig 1 resource which will be retired by 2025 and Craig 2 and Craig 3 resources which will be retired by 2030, but was necessary to the integrity of the comparison. In addition, Tri-State indicated they would not be expending capex in the final five years of the resource life for the Existing Resources and the Generic Resources. Therefore, the capex costs for the years 2035 through 2040 were assumed to be zero for both the Existing Resources and the Generic Resources. FOM and Capex forecasts were not applicable to the resources to be owned by third parties.

For Existing Resources and Generic Resources to be owned by Tri-State, interest and depreciation were forecast based on the undepreciated capital cost of the resource at the beginning of each year (Capex Balance) multiplied by an assumed debt interest rate and an assumed depreciation rate. The resulting interest and depreciation were deducted from the subsequent year Capex Balance. For the Existing Resources the assumed interest and depreciation rates were provided by Tri-State. For the Generic Resources we assumed the same debt interest rate but a depreciation rate equal to straight line depreciation over a 30 year life. Interest and depreciation forecasts were not applicable to the resources to be owned by third parties.

For Existing Resources and Generic Resources to be owned by Tri-State, we also forecast the liability that Tri-State would incur at the time an Existing Resource owned by Tri-State would reach the end of its depreciation life (the "Accounting Retirement Year"). This liability would occur if and to the extent that the resource is not fully depreciated at the end of the Accounting Retirement Year. We characterized this liability as the "Stranded Cost" of the resource which we set equal to the beginning Capex Balance plus the Capex amount in the year equal to the Accounting Year. The Accounting Year assumption was provided by Tri-State.

For Existing Resources and Generic Resources that are (or would be) owned by third parties, PPA Cost was forecast based on Generation multiplied by a PPA price forecast. For Existing Resources, the PPA price forecast was provided by Tri-State. For Generic Resources, the PPA price forecast was developed by us as part of our Generic Resource Review work.

For calculation of LCOE and LCOC, we first calculated the net present value (NPV) of total costs (Total), fixed costs (Fixed Only), Generation and Capacity by discounting the annual cost values to the year 2020 using a discount rate equal to the debt interest rate. The debt interest rate represents the weighted average cost of capital of Tri-State since Tri-State does not have equity in its capital structure. LCOE was then calculated as the ratio of Total NPV to Generation NPV expressed as $/MWh. LCOC was calculated as the ratio of Fixed Only NPV to Capacity NPV expressed as $/kw-year.

LCOE and LCOC Results

A summary of LCOE and LCOC results for all the Pairings is shown in Table 6. Results broken down by cost component are shown on Figure 2, Figure 3 and Figure 4.

For the coal-fired plant pairings, only LCOE results are relevant. Results show that the Existing Resources are more costly than the Generic Resources due primarily to higher Social Cost of Carbon and higher FOM costs. The difference is greatest for Springerville 3 due to its relatively high interest cost in addition to the Social Cost of carbon and FOM cost differences.

For the Frame CT pairings, only LCOC results are relevant. Results show that the Existing Resources are less costly than the Generic Resources due to lower depreciation, interest, capex and FOM costs. The Existing Resources benefit from very low (highly depreciated) Capex Balance and therefore lower interest and depreciation costs.

For the Shafer Pairing, both the LCOE and LCOC results are relevant. The Common Capacity Factor of 35% is relatively low for a resource that is intended to provide energy (such as a CCCT) and relatively high for a resource that is intended to provide capacity (such as a CT). LCOE results show that Shafer is less costly than the Generic Resource due primarily to very low (highly depreciated) Capex Balance and therefore lower interest and depreciation costs. LCOC results also show Shafer less costly, with the difference due to the same reasons.

For the renewable plant Pairings, only LCOE results are relevant. Results show that the Existing Resources are more costly than the Generic Resources for nearly all the Pairings. This is likely because the Existing Resources were built in prior years when the cost of solar and wind technology was high relative to the costs expected in future years (a declining capital cost curve). The exception is the Twin Buttes wind resource. Its LCOE is less than the Generic Resource. Review of the Twin Buttes PPA price forecast reveals that it has a low price with no escalation which compares favorably to the Generic resource that has a similar first year price but is assumed to escalate at 2% annually thereafter.

For the Basin Contracts, only LCOE results are relevant. Results show that the Basin West Contract is more costly than its Generic Composite. This is primarily because the Basin West Contract has a carbon emission rate and therefore incurs a Social Cost of Carbon whereas the Generic Composite does not (all renewables and battery storage). The impact of the Social Cost of Carbon becomes evident when examining the case where there is no Social Cost of Carbon as described in the Non-Colorado Benchmarking section below. Conversely to the Basin West results, the Basin East Contract results show that the Basin East Contract is less costly than its Generic Composite. The Basin East Contract incurs a Social Cost of Carbon, but so does its Generic Composite along with the relatively high cost of installing and operating a new RICE resource. The net effect is a higher cost for the Generic Composite.

Non-Colorado Benchmarking

In addition to the Benchmarking described above, we also performed a supplemental analysis concerning only the Existing Resources not located in Colorado ("Non-Colorado Resources") to examine how their LCOE and LCOC would change if the Social Cost of Carbon was not applied ("Non-Colorado Benchmarking"). The overall methodology, pairing and forecast methodology was identical to the Benchmarking, except that the Social Cost of Carbon was set to zero for both the Existing Resources and the Generic Resources.

A summary of LCOE and LCOC results for the Non-Colorado Benchmarking is shown in Table 7 below.

LCOE results show that both the Non-Colorado Existing Resources and the Non-Colorado Generic Resources are significantly less costly than under the Benchmarking above. For the thermal resources, although the Existing Resources are still more costly than the Generic Resources the gap in cost is narrowed significantly. This is particularly true for LRS Units 2 and 3 where the cost difference is narrowed to approximately ten (10) percent. LCOE results for the renewable resources are unchanged from the Benchmarking results above since the Social Cost of Carbon does not apply to renewable resources. LCOE results for the Basin Contracts show that each contract is less expensive than its Generic Composite if the Social Cost of Carbon is not applied.

LCOC results are identical to those under the Benchmarking above. This is because the Social Cost of Carbon is a variable cost and therefore is not a component of LCOC which considers fixed costs only.

END OF REPORT

Attachment Vol II 5-6 Ascend Analytics Renewables & Ramping Analysis

Tri-State Generation and Transmission Colorado Energy and Resource Plan Renewables and Ramping Analysis

Summary of work delivered by Ascend Analytics

Overview

Ascend Analytics (Ascend) is pleased to support Tri-State G&T (Tri-State) as it prepares for the 2020 Energy Resource Plan filing with the Colorado Public Utility Commission. Ascend was retained by Tri-State to supplement their in-house modeling capabilities by generating hourly simulation data for renewables and load that capture new market dynamics in the western grid driven by large scale renewable resource deployment. A key limitation of traditional production cost models is the inability to capture weather-driven variability in load and renewable output. A typical approach is to use weather-normalized (e.g. smooth, averaged) input curves for load and renewables. This was not generally a problem when most resources were dispatchable thermal resources. With Tri-State's goal to dramatically increase the amount of variable renewable resources in its portfolio, it becomes critical to capture the inherent variability in loads and resources, because increased volatility drives the need for different types of resources, particularly flexible resources that can provide integration services for system reliability.

Tri-State hired Ascend to use its power system simulation tool PowerSimm to help Tri-State's modeling team better capture the new energy system dynamics with increasing renewable related volatility. This was achieved by providing two deliverables:

1. Simulations of Tri-State member co-op loads and generation of various wind and solar resources between 2021-2030, and
2. An analysis of the effects these variable resources would have on the ramping of system-wide net load.

Tri-State provided historical data on all existing loads and resources for use in training PowerSimm's load and renewable energy simulation modules. Tri-State also provided forecasts of expected future gross load and renewable generation. PowerSimm uses NCDC weather data to generate time-series models that characterize the relationship between weather -> load and weather -> renewable resource behavior. The simulations are internally correlated and consistent within each "sim-rep" or each simulation run of 8760 hours per year over the course of the 10-year study horizon. Ascend delivered 20 such simulated future states. Some or all of these simulated forecasts of Tri-State load and each renewable resource will be input into Tri-State's internal modeling software to solve for resource and portfolio values consistent with an increasingly variable resource portfolio.

Results

Renewable Simulation

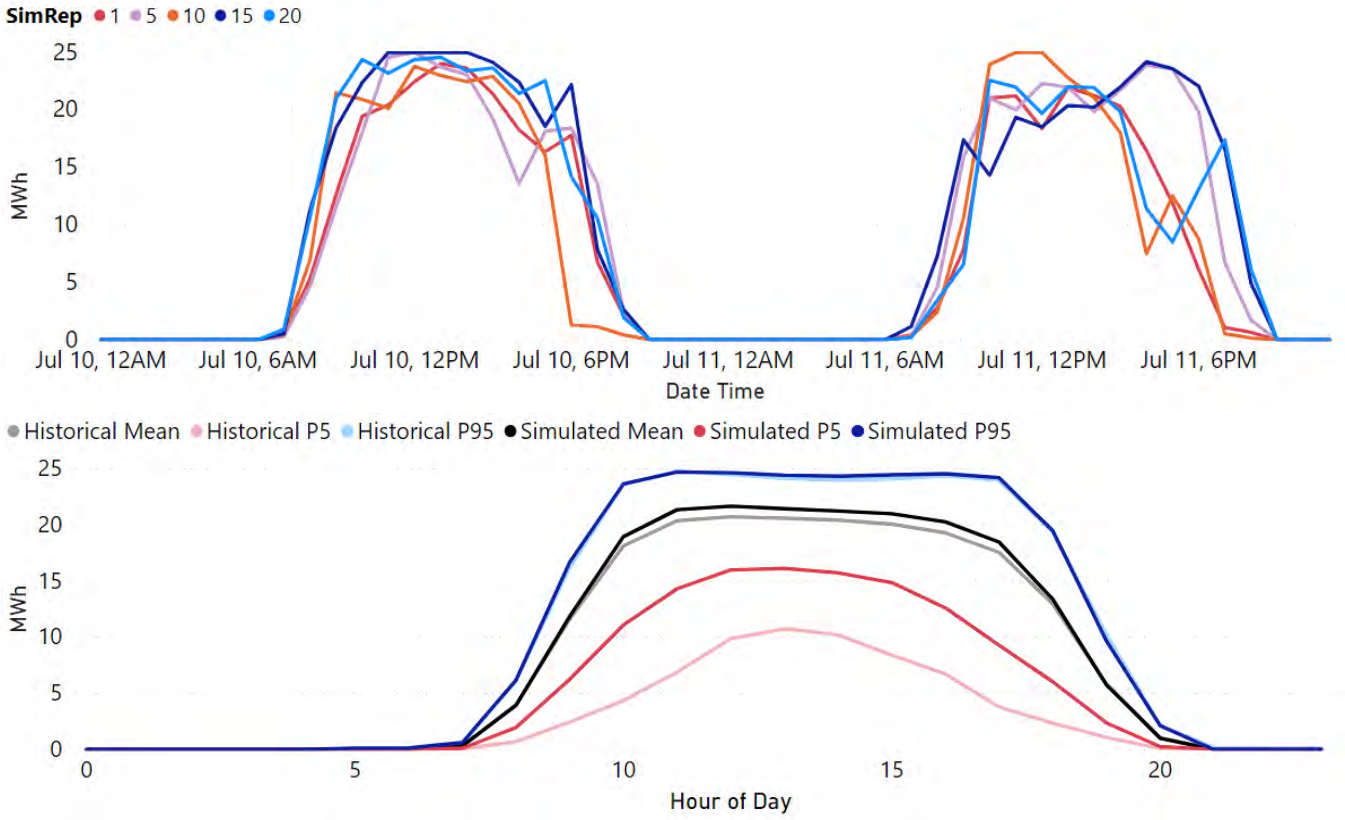
Tri-State provided the following renewable resources to be modeled in PowerSimm:

Resource	Unit Type	Location	State
Alta Luna	Solar	Deming, NM	Existing
Axial	Solar	Moffat County, CO	Under Contract
Carousel	Wind	Burlington, CO	Existing
Cimarron	Solar	Cimarron, NM	Existing
CO Highlands	Wind	Fleming, CO	Existing
Coyote Gulch	Solar	La Plata, CO	Under Contract
Crossing Trails	Wind	Seibert, CO	Under Contract
Dolores	Solar	Dolores County, CO	Under Contract
Kit Carson Wind	Wind	Burlington, CO	Existing
Niyol	Wind	Logan and Washington County, CO	Under Contract
San Isabel Solar	Solar	Trinidad, CO	Existing
Spanish Peaks	Solar	Trinidad, CO	Under Contract
Spanish Peaks Two	Solar	Trinidad, CO	Under Contract
TPE (Escalante)	Solar	McKinley County, NM	Under Contract
Twin Buttes II	Wind	Lamar, CO	Existing

PowerSimm uses historical hourly generation from a resource and correlates that generation against historic weather data to ensure that all behaviors of the resource are captured in the simulation: generation during various meteorological conditions, seasonality, behavior during low-probability weather patterns, etc. Rather than simply repeating historical hourly generation patterns or weather normalized shapes, PowerSimm simulates hourly weather over the modeling time period and uses the historically derived correlations between weather and generation to simulate future hourly generation.

PowerSimm models were set up using historical generation data and expected monthly forecasts provided by Tri-State. The resulting hourly simulations provide statistically robust data on renewable generation across both typical and low-probability conditions, as exemplified in Figure 1 (below) of a sample of five sim-reps (out of 20 simulated) for the Alta Luna solar project.

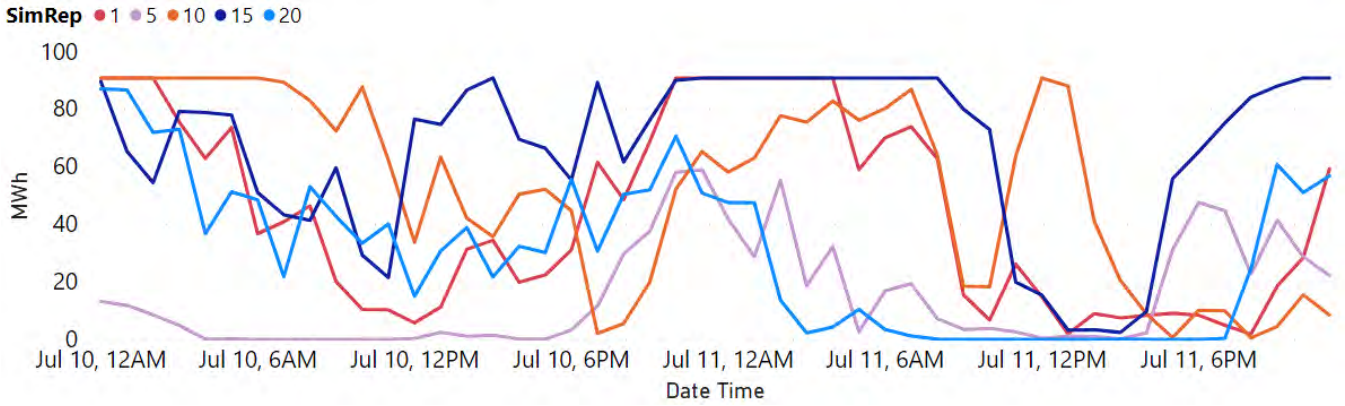
Figure 1: Sample Solar Generation and Validation – Alta Luna

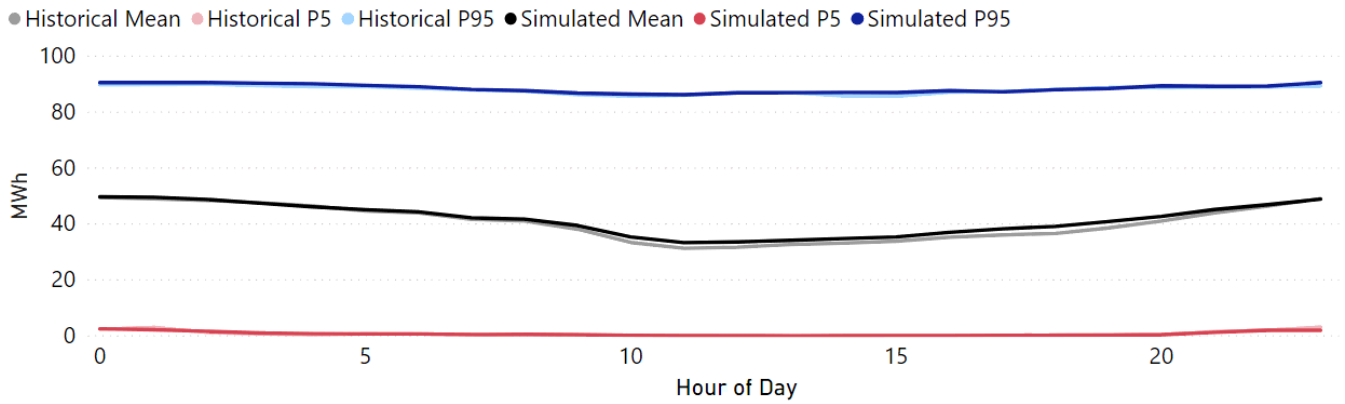


The sim-reps capture a range of variability in the unit's generation. One sim-rep may have max output on one day, while cloud cover on the next day inhibits the unit from outputting at its total capacity as seen in sim-rep 15. For validations (bottom of figure 1) we ensure that the model accurately captures historically observed variations by meeting the mean, P5, and P95 historical observations in the simulations. This approach allows Tri-State to fully understand renewable resource behavior (e.g. wind bursts or droughts, cloudiness, etc.) and risk profiles (e.g. availability during peak load events).

Similarly, Figure 2 shows example generation for five of twenty sim-reps for Tri-States CO Highlands wind unit (top of figure 2).

Figure 2: Sample Wind Generation and Validation – CO Highlands





The sim-reps capture a range of possible variability in the unit's generation. Sim-rep 15 shows generation at max capacity for several hours as the wind resources are plentiful, then a sudden drop off as the wind dies down. Sim-rep 5 demonstrates a different possible weather future where this entire stretch of time shown has relatively low generation. For validations (bottom of figure 2) we ensure that we accurately capture historically present variations by meeting the mean, P5, and P95 historical observations in our simulations.

Load Simulation

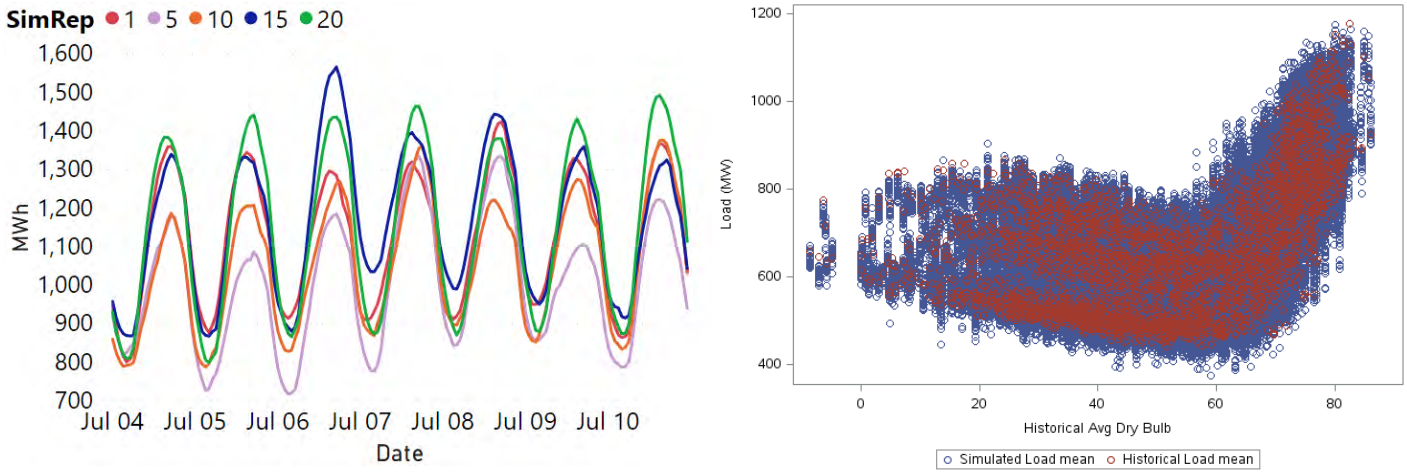
Tri-State provided the following load zones to be modeled in PowerSimm:

Load Zone
East Colorado
Nebraska
New Mexico
West Colorado
Wyoming

The load simulation follows a similar methodology as the renewable simulation. Inputs to the model include hourly historical load volumes as well as a load forecast of expected aggregate growth in demand. The model develops a complex set of correlations based on historical data that considers load, temperature, hour of day, day of week, and time of year. Temporal autocorrelations in the model are also important as each hourly load observation in the simulation is not independent, rather its highly correlated with the observation that came before it.

Figure 3 shows example electric load for five of twenty sim-reps for a week in July (left), showing a variety of possible demand futures. The temporal autocorrelation effects of the model come through, as sim-rep 5 consistently has lower demand than other sim-reps while sim-rep 20 shows consistently higher demand. Weather driven impacts are also visible, as seen in the spike in demand on July 6th for sim-rep 15 indicating a particularly hot day. For load simulations we ensure that we meet the historically present variations by meeting the mean, P5, and P95 historical observations in our simulations. We also ensure that we preserve historically observed temperature-load correlations as shown in the boomerang validation plot to the right. As temperature veers into extreme cold or warm territories we expect load to increase, and we expect our simulations (in blue) to mirror the behavior and cover the full range of historical observations (in red).

Figure 3: Sample Load Simulation and Validation - East Colorado

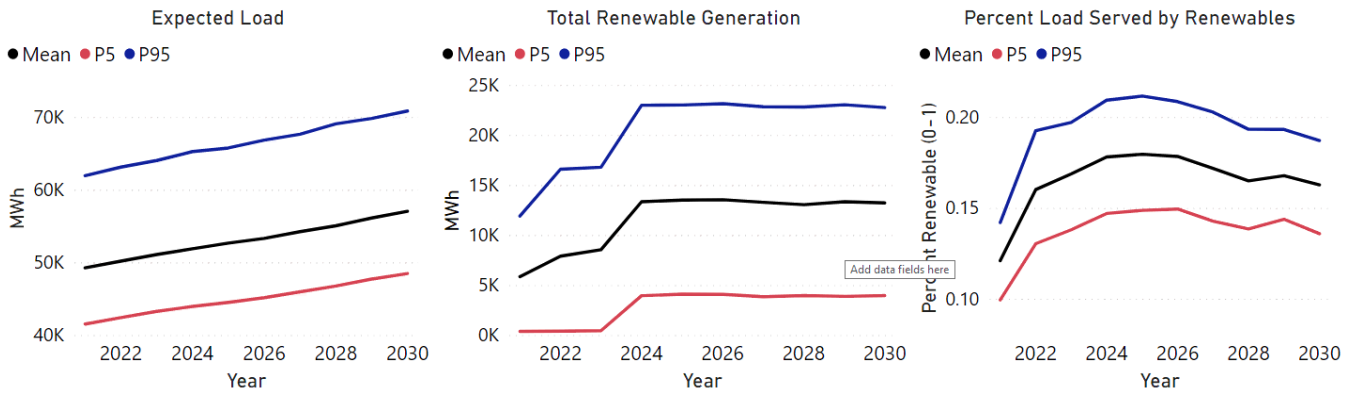


Analysis

Co-simulating Tri-State's load and renewables provides insight on the dynamics in net load, the difference between load and renewable generation, which represents the remaining load to be served by dispatchable resources. Simulating across 20 different possible weather futures, including weather that is considered both "normal" and "extreme," the model captures the interactions of weather, load, and renewable generation and statistically envelopes the most likely future scenario (the mean simulation) while also planning for more extreme possibilities (the P5 and P95 cases).

Figure 4 shows annual trends in load and renewables:

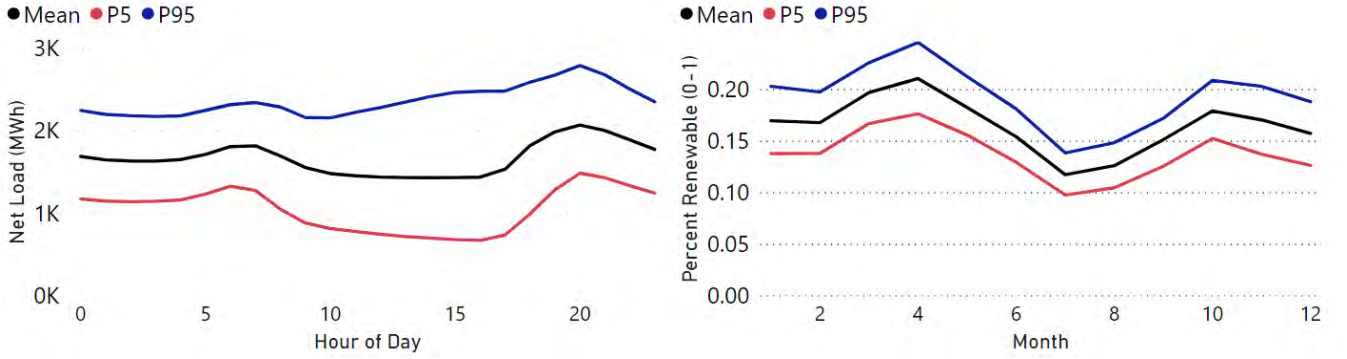
Figure 4: Annual Trends in Load and Renewables



Tri-State's Load (left) across its five load zones grows steadily through time. Renewable generation (middle) grows slowly in the beginning years of the analysis with a big jump in generation in 2024 as new resources come online followed by a leveling out. The resulting percent of load served by renewables (right) grows until 2024 as renewables generation increases followed by a steady decline as the growth in load surpasses the growth in renewable generation.

Figure 5 is a sample of load and renewable generation interaction in 2026.

Figure 5: Net Load (left) and Percent of Load Served by Renewables (right) in 2026



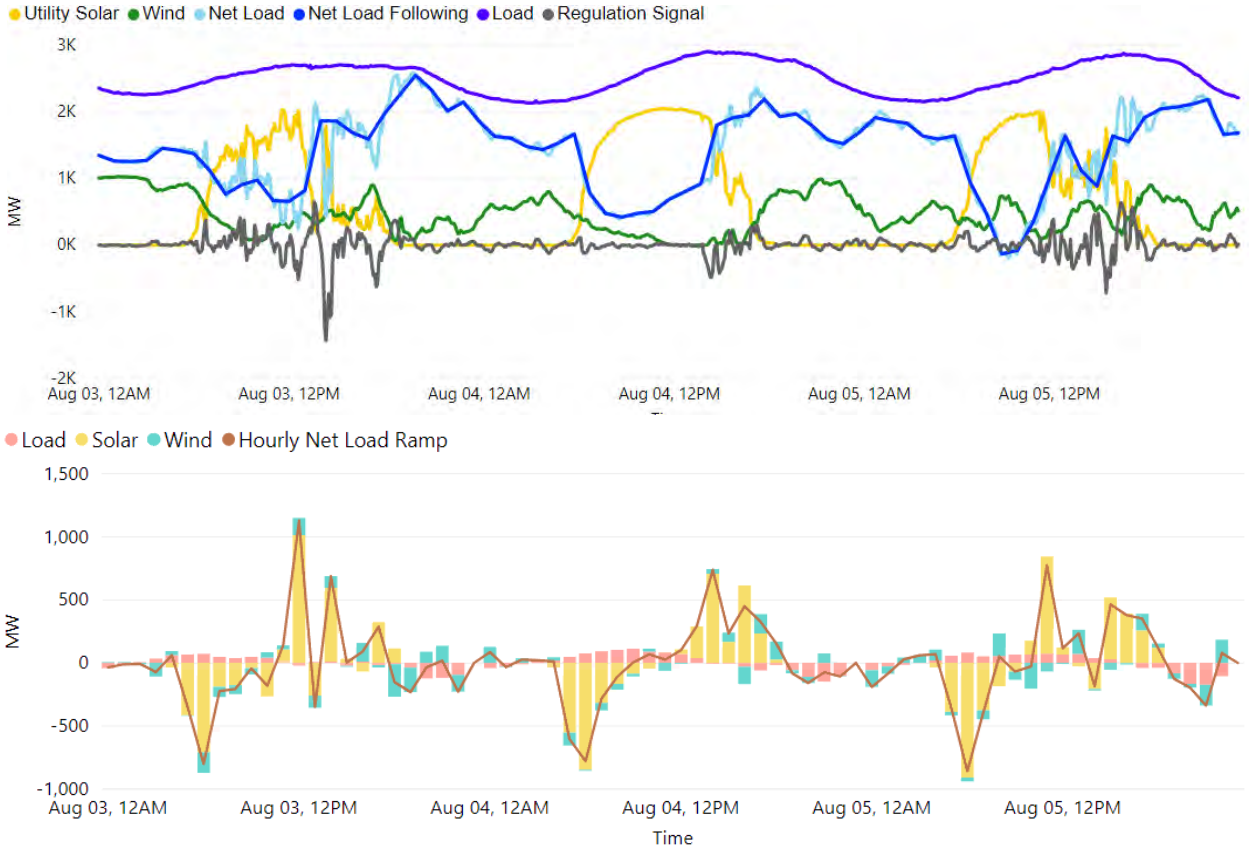
The percent of load served by renewables (right) shows the greatest renewable load share occurs in April and October when loads are low due to moderate temperatures and renewable output tends to peak. Tri-State's solar assets have their peak generation in May, but wind assets have a dual peak in April and October with the April peak being significantly larger. Although there is more solar capacity on the system in 2026 than wind capacity, the wind has a higher capacity factor, more generation, and therefore a stronger influence on total monthly renewable penetration. The hourly weekday Net Load figure (left) shows that Tri-State's net load takes on the "duck" shape, peaking in the morning hours between 6AM and 7AM with a larger peak in the evening at 8PM. Notably, the evening ramp intensity scales inversely with total load with the steepest ramps occurring (on average) during the days with lowest average loads and vice versa.

Ramping Analysis

Ramping analysis was carried out using PowerFlex, an Ascend software tool that analyzes renewable and load behavior on a minute-by-minute timescale to understand the ramping risk of a portfolio on multiple timescales as well as the value of flexible resources and ancillary services required to maintain load balance.

For this study all load and renewable items were input into PowerFlex on a 5-minutely timescale and were scaled up on a yearly basis to match forecasted quantities/capacities. PowerFlex calculated rolling statistics on Net Load (= Load – Total Renewable Generation) to find the largest ramp up and ramp down events in any 5-minute, 15-minute, 30-minute, and 60-minute time period in each month from 2021-2030. Figure 6 below shows a snapshot of the results of this analysis.

Figure 6: Sample PowerFlex Results and Ramping Contributions



The snapshots above shows a sample three-day period of representative load and renewable generation scaled to meet 2030 forecasts; the bottom figure shows the relative ramping contributions of load and renewables. While load takes on a relatively smooth shape, wind and solar profiles have more variability, particularly solar (as seen in the large yellow bars of solar contributions to both positive and negative ramping in the bottom figure). August 3rd shows a very volatile solar generation profile that leads to more dramatic ramping needs mid-day. August 4th has a much smoother solar profile, but we can see from the Ramping Contributions figure (bottom) that even with the smooth profile solar still contributes most to ramping contributions given the nature of solar daily generation patterns.

Table 1 below is a snapshot, based on a typical expansion plan scenario from 2021 to 2030, of what Tri-State's maximum forecasted ramping risk is at different timescales in June throughout the study window.

Table 1: June Ramping Risk for Baseline load/renewable forecasts

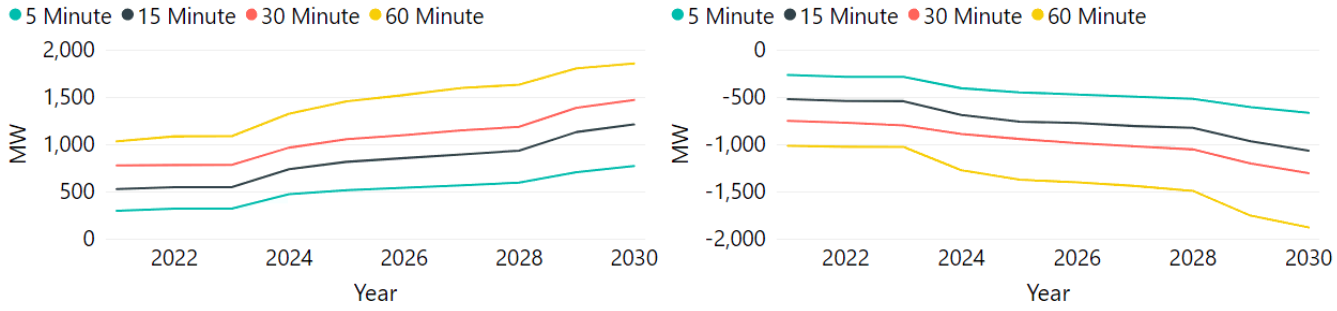
Analysis

As Tri-State increases the capacity of renewable resources over time the net ramping risk increases substantially across all timescales, as shown in Figure 7 below.

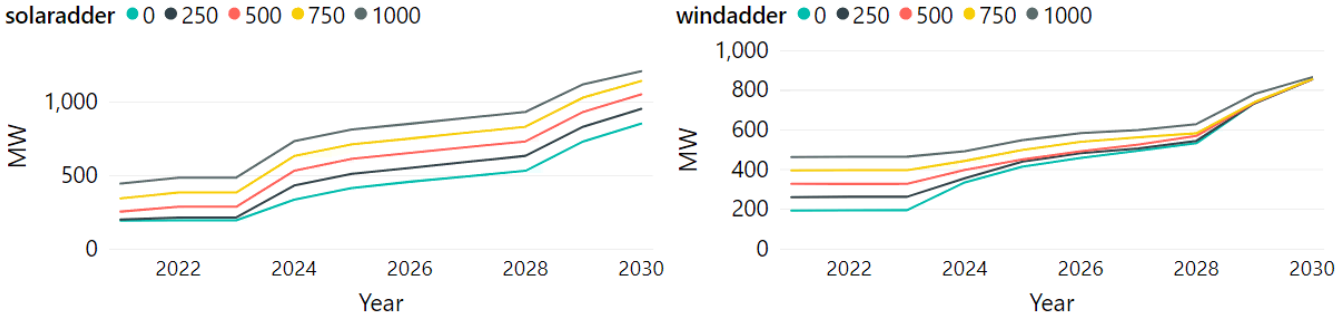
Figure 7: Annual Ramp Up (Left) and Ramp Down (Right) Risk



Ramping requirements grow through time with the ramping requirement increasing more rapidly at longer timescales (e.g. 60-minute ramp risk increases by a larger amount over the 10 year study horizon than 5-minute ramps).

Because of the potential for additional renewables to enter the system that are not currently contracted/planned, Ascend also analyzed ramping risks with solar and wind adders beyond the forecasted quantities to assess the impact of additional intermittent resources on the system. The results of this analysis for an additional 0/250/500/750/1000 MW of added solar/wind capacity (beyond the default forecasted quantity provided by Tri-State) are shown in Figure 8 below.

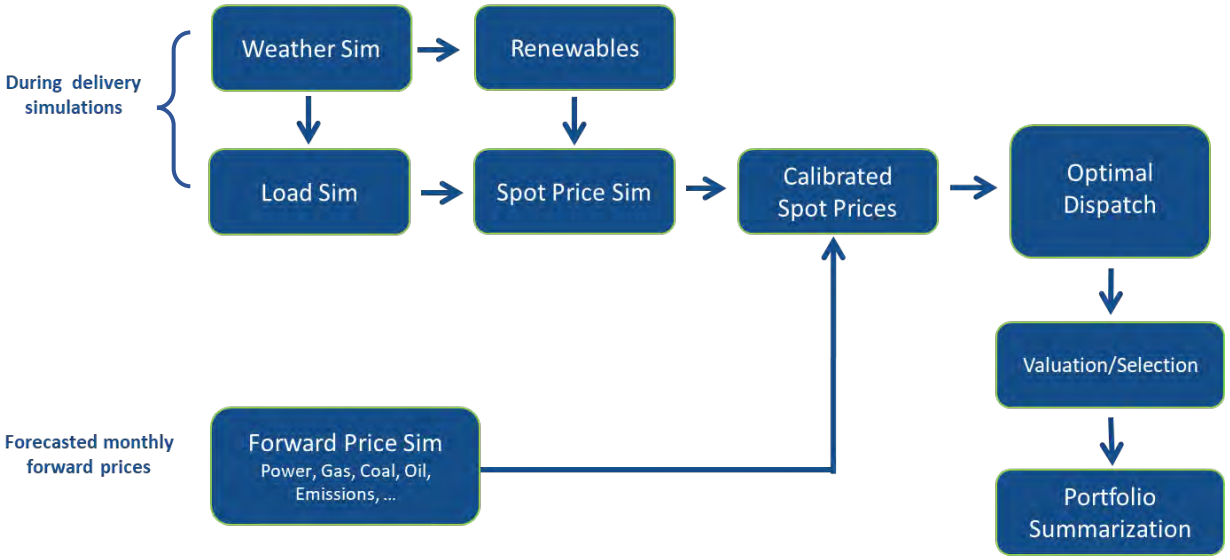
Figure 8: Annual 15 Minute Ramp Up Requirement with Renewable Adders



This analysis suggests that additional solar capacity on the system has a much stronger impact on ramping requirements than additional wind does, which is further supported by the relative ramping contributions of solar shown in Figure 6. Solar has a tendency to be more variable in its generation profile than the wind resources that Tri-State currently has in its portfolio, largely due to the steep ramp-up/ramp-down events that occur daily due to sunrise and sunset and further exaggerated by the effects of clouds and volatile hourly generation.

Appendix: PowerSimm Model Schematic

Figure 7: PowerSimm Modeling Framework



PowerSimm's Sim Engine captures "Meaningful Uncertainty" in weather, load, renewables, and prices

The PowerSimm Resources Planning Suite is a set of software programs consisting of PowerSimm Planner (PowerSimm) production cost model for system operations simulation and PowerFlex for renewable integration planning. The suite is designed and operated by Ascend Analytics for the purposes of Tri-State's2020 ERP. Combined, these tools form a platform for modern resource planning in an era of increasing uncertainty in electricity supply driven by the deployment of renewable generation.

PowerSimm is a dispatch optimization and production cost tool. The tool is comprised of two major elements, the Sim Engine and Dispatch Optimization, that work together to systematically bridge the physical and financial dimensions of electricity provision. PowerSimm uses a simulation-based approach born of the best-in-class techniques to perform decision analysis for portfolio risk management. Managing risk requires characterizing of the volatility in fuel price, power price, renewable generation, and outages. PowerSimm adopts this paradigm into the resource planning context.

The simulation of uncertainty with respect to weather is becoming ever more critical because "weather is the new fuel" in the country's emerging high-renewables system. To capture the changing market dynamics with renewables, PowerSimm simulates weather to capture its effect on renewable output and its effect on energy price formation. We call this "characterizing meaningful uncertainty." It is not simply noise around an arbitrary base scenario, but realistic paths of weather driving renewables, loads, and prices. That means PowerSimm is performing dispatch against system conditions as they really exist, not the idealized system modeled by traditional production cost models with averaged weather patterns, averaged renewable generation profiles, and "expected" load and market conditions. PowerSimm is a stochastic construct and through a multitude of simulations, we probabilistically explore all possible future states through a coherent and appropriately correlated set of data inputs and forecasts. With PowerSimm, resource decision making is supported not only with the mean of the distribution, but also by risk considerations informed by the 5th and 95th percentiles. Therefore, we can solve for the optimal resource portfolio that strikes the best balance between cost and risk.

EXECUTIVE SUMMARY

Project Overview

Mesa Point Energy, along with their subcontractor Brightline Group, (collectively the Mesa Point Team or the Team) performed a beneficial electrification potential study in support of Tri-State Generation and Transmission's (Tri-State) resources planning initiatives. The study is intended to assist Tri-State in developing future Integrated Resource Plans (IRP) and Electric Resource Plans (ERP). The primary objective of this study is to assess the available technical electrification, beneficial electrification, and achievable electrification potential from a variety of fuel-switching electrification measures from 2021 to 2040 for the electric cooperatives served by Tri-State Generation and Transmission (Tri-State).

For the purposes of this study, electrification can be defined as changing the energy source for an end use from a fossil fuel to electricity. In order to achieve "beneficial" electrification a project must meet one or more of the following conditions without adversely affecting the other three:

1. Saves consumers money over the long run
2. Improves quality of life
3. Enables better grid management
4. Reduces negative environmental impacts

The study focuses on beneficial electrification *achievable* potential. It is not a *program* potential study meaning it does not take into consideration the utility's program-level budget and design constraints. Therefore, the study examines what *could be* (i.e., what impacts could accrue from the qualifying beneficial electrification measures considered in this study) but does not account for structural and organizational limitations inherent and unique to the cooperative utility structure where each member distribution system can choose which products and measures from the overall program to offer to their end-use consumers. The study does not select or evaluate specific programs or their costs.

This Executive Summary presents an overview of the analysis approach, key assumptions, and study findings and the main report goes into more detail on methods, results, and findings.

This report is related in several ways to the recent *Demand Side Management and Energy Efficiency Potential Study* for Tri-State completed in May, 2020. The prior report provides an achievable potential assessment for energy efficiency, demand response, and distributed energy resources, and is referenced in sections of this report.

Two separate electronic Reporting Tools are provided with this report. The tools provide the ability to view findings in greater detail by sector, end-use, and region. More detail on the tools, including how they differ from each other, is provided in the main body of the report.

Results

As summarized in Table ES-1, the Mesa Point Team found that the achievable-moderate scenario[1] would result in approximately 2.5 GWh (0.02 percent of baseline sales) of electric load growth from achievable beneficial electrification in 2021 rising to 653 GWh (3.1 percent of baseline sales) of growth through 2040. Using emissions rates based on a forecast of Tri-State's resource mix, the team estimated a lifetime emissions reduction for measures installed in 2021 of 11,414 tons of CO_2, increasing to a lifetime emissions reduction of nearly half a million tons of CO_2 for measures installed in 2040[2]. Over the 20-year study horizon it is estimated that enough fossil fuel consumption could technically be reduced to more than offset the total on-site natural gas consumption in Tri-State's service territory[3].

[1] Four scenarios were modeled, each of which is described later in this Executive Summary and in the methodology section of the body of the report. Results from the achievable-moderate scenario are presented in most portions of this report. That scenario was selected because it represents a balance between aggressive program approaches and a low level of intervention.

[2] Emissions reductions are calculated based on Tri-State's projected resource mix as provided to MPE in March 2020, which was a non-carbon reduced scenario. The actual changes in resource mix over time will impact the net emissions from electrification measures. Updated resource mix projections could be used in future modeling to refine the estimated emissions benefit of electrification over time.

[3] The estimated cumulative reduction in fossil fuel consumption across all measures and baseline fossil fuel types exceeds 631 million therms by 2040 under the technical potential scenario. The study estimates the total annual natural gas consumption by premise-based (non-vehicle) end uses to be approximately 536 million therms at present.

Table ES-1. Portfolio Cumulative Energy Increase and Annual Emissions Reduction by Scenario by Time Horizon

MILESTONE YEAR	TECHNICAL ELECTRIFICA-TION	BENEFICIAL ELECTRIFICA-TION	ACHIEVABLE _MAX	ACHIEVABLE _ AGG	ACHIEVABLE _MOD	ACHIEVABLE _ LOW
Cumulative Electric Energy Load Growth (MWh)						
2021	52,033	5,487	4,875	3,485	2,524	1,957
2025	417,171	84,088	62,069	43,736	30,905	23,583
2030	1,674,758	474,237	278,910	207,716	144,792	105,867
2040	5,513,285	1,907,671	1,044,310	857,810	652,583	486,764
Increase as % of Baseline Sales						
2021	0.34%	0.04%	0.03%	0.02%	0.02%	0.01%
2025	2.54%	0.51%	0.38%	0.27%	0.19%	0.14%
2030	9.41%	2.66%	1.57%	1.17%	0.81%	0.59%
2040	26.19%	9.06%	4.96%	4.07%	3.10%	2.31%
Annual Net CO_2 Emissions Reduction (tons)						
2021	-152,135	21,155	19,370	14,779	11,414	9,755
2025	90,543	160,778	114,249	85,767	65,253	54,071
2030	1,024,508	749,792	450,864	371,263	290,767	238,362
2040	2,408,393	1,391,801	763,155	620,228	506,031	418,796

Figure ES-1 shows the breakdown of projected load growth by sector. The residential sector makes up nearly half of the potential, owing much of that potential to battery and plug-in hybrid electric vehicles[4] followed by space heating and water heating electrification measures. The commercial sector contributes 35 percent of the potential, having a similar breakdown of end uses with electrification potential. In addition to on-road electric vehicles, the commercial sector also has opportunity for off-road electric vehicles such as forklifts and airport ground support equipment, as well as truckstop electrification measures. These electric vehicles and transportation measures make up over 80 percent of the commercial sector electrification potential with the balance being made up primarily by space heating (heat pump) and water heating (heat pump water heater) measures.

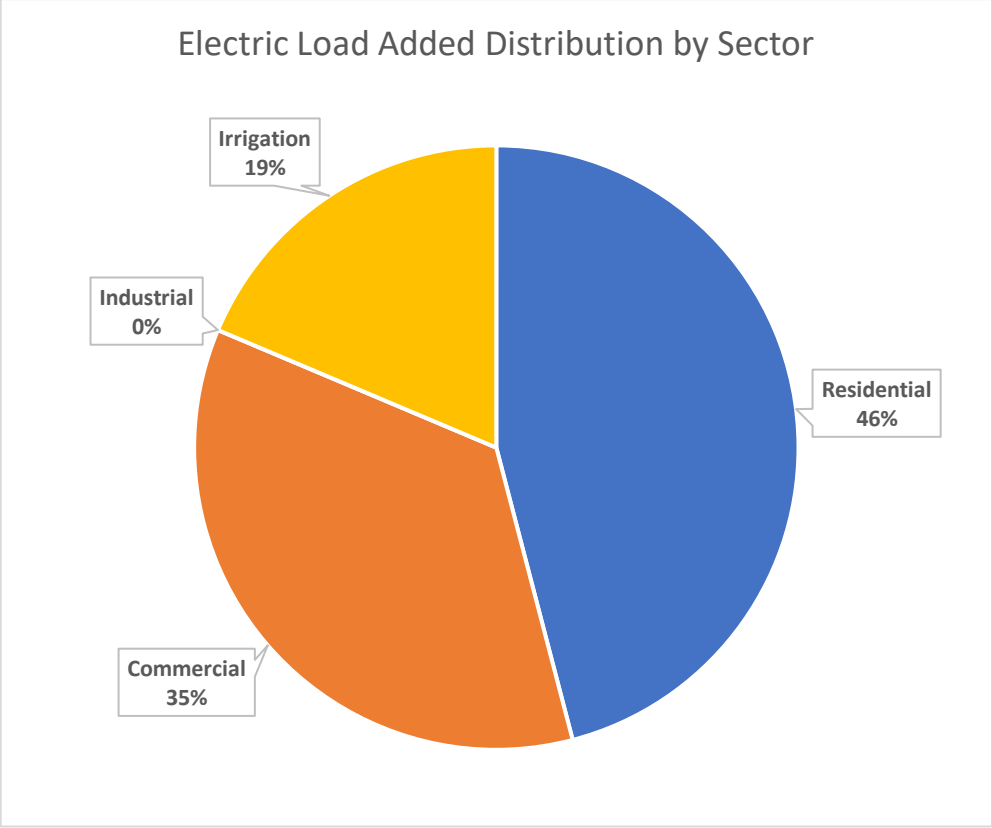
4 As with other electrification measures in this study, electric vehicle potential included in the main body of the report is that directly influenced by Tri-State program activity.

Measures that passed beneficial electrification screening, a process described below and in Section 2.5.2, but contributed a small magnitude towards electrification potential include cooking electrification (electric and induction cooktops) for both the residential and commercial sectors and lawn and garden equipment in the residential sector.

The irrigation sector is estimated to account for nearly 20 percent of the electrification potential in the achievable-moderate scenario by 2040. This potential is made up of the conversion of irrigation pump motors from natural gas, propane, and diesel-driven motors to electric motors.

The industrial sector was shown to have large technical electrification potential from electrification of pipeline compressor stations, but no measure permutation passed the beneficial electrification screening process since each resulted in net emissions increases throughout the 20-year study horizon.

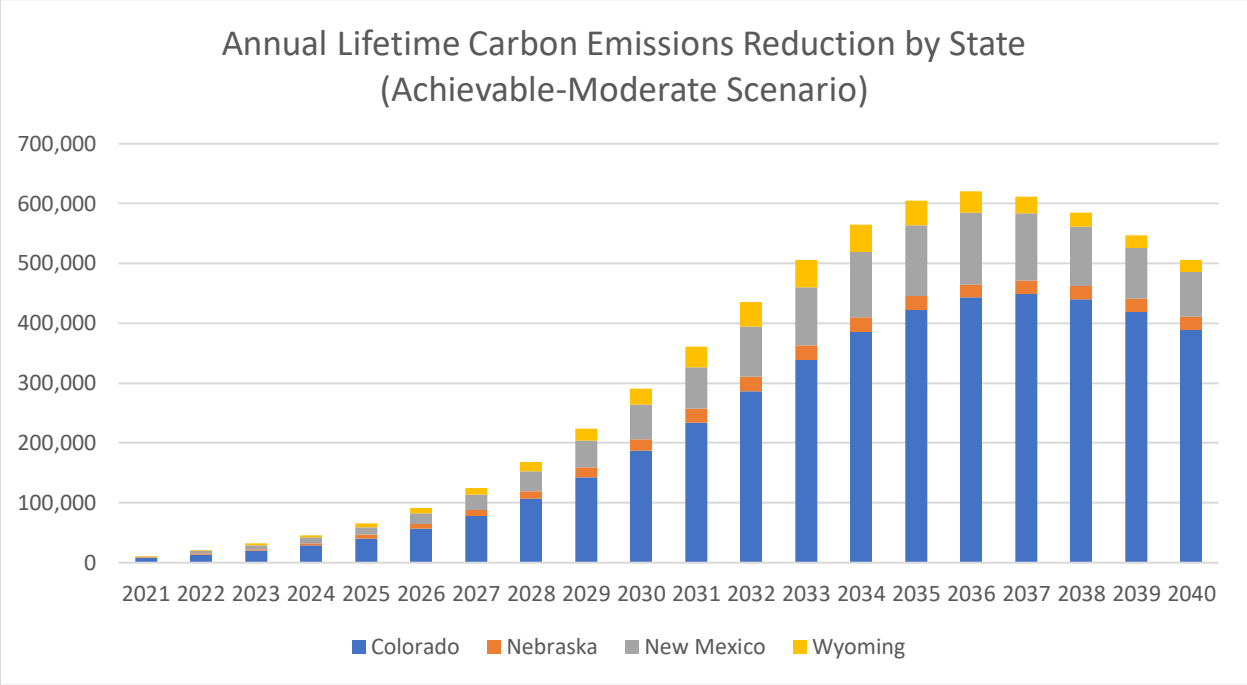
Figure ES-1. Electric Load Added Distribution by Sector (Achievable-Moderate Scenario, 2040)



The estimated emissions reduction associated with beneficial electrification measures under the achievable-moderate scenario, based on Tri-State's forecasted emissions rate as a function of resource mix, is shown in Figure ES-2. The figure represents net emissions expected to be reduced over the lifetime of relevant measures installed in each year of the 20-year study horizon. For some measures analyzed, the net lifetime emissions include both an increase in emissions in the beginning of the measure life and a reduction in emissions later in the life of the measure. This is a function of Tri-State's system-wide emissions rate, measured on a ton/MWh basis, which is expected to decrease over the

study horizon as Tri-State's fuel mix shifts. Other measures represent an immediate emissions reduction in the first year. Figure ES-2 shows the annual carbon emissions reduction estimates broken down by state.

Figure ES-2. Annual Lifetime Carbon Emissions Reduction by State (Achievable-Moderate Scenario)



The commercial sector is expected to make up 58 percent of emissions reduction potential, contributing over 3.7 million tons of CO_2 of the lifetime of measures installed through 2040. The share of emissions reductions as compared to the share of electric load growth potential differs primarily due to energy efficiencies of the baseline and retrofit case equipment. For instance, the commercial sector includes a large portion of emissions reduction from off-road EV measures such as electric forklifts. This type of equipment may contribute a proportionally larger share of emissions reduction potential as compared to its contribution to electric load growth because of the significant efficiency gains realized by switching from internal combustion engines to electric motors.

Table ES-2 summarizes the key cumulative beneficial electrification cost metrics across the portfolio at four time horizons under the achievable-moderate scenario, as well as 20-year averages across the full study time horizon. It is estimated that over the 20-year study horizon approximately 39 GWh of electric load growth is achievable, on average, per year at a cost of $28 million for an acquisition cost of $710/MWh. The 20-year average TRC ratio across the portfolio exceeds 2.0 when considering all achievable measures that pass the beneficial electrification screening.

Table ES-2. Portfolio Electrification Cost Metrics by Time Horizon (Achievable-Moderate Scenario)[5]

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	CUMULATIVE LOAD ADDED (MWH)	ACQUISTION COST ($/MWH)
2021	1.54	$1,941,462	2,524	$769.09
2025	1.61	$25,575,994	30,905	$827.56
2030	1.83	$121,866,050	146,004	$834.68
2040	2.37	$557,671,021	785,329	$710.11
20-year avg.	2.37	$27,883,551	39,266	$710.11

Study Approach and Methods

The study approach undertaken to develop the results presented above consists of three main tasks. These tasks are summarized below and discussed in more detail in Section 2 of this report. The tasks include:

- Customer Segmentation and Forecast Disaggregation
- Measure Impact Research
- Modeling and Data Analysis

Segmentation and forecast: For the market segmentation analysis, the Team first determined the fossil fuel technologies that have an electrical fuel source equivalent, such as water heaters. Next, the Team established the number of fossil fuel technologies per current Tri-State member cooperative customer premise for each customer class and premise segment type. In cases where the electric energy efficiency potential assessment determined the saturations of technologies with an electric fuel source, the saturations of fossil fuel source technologies can be inferred. The study assumes that 100 percent of residential premises have water heating. Using Front Range Colorado as an example, 20 percent of the water heaters have an electric fuel source. This means that 80 percent of the water heaters are fossil fuel based[6]. The final step was to segment fossil fuel technologies into unique fossil fuel types, such as natural gas, propane, diesel, and gasoline. Forecasting this segmentation over the 20-year study horizon followed the forecast developed for the prior DSM potential study, adapting the forecast to estimate fossil fuel segmentation by year instead of electric end use saturation by year.

[5] Program costs are estimates based on several factors and may not align with actual program costs in future years due to structural and organizational limitations that impact portfolio design. This study does not address program design or related drivers of cost.

[6] This breakdown represents Front Range Colorado in year 2020. Each region and year has their own saturation estimates.

Segmentation and forecasting for portions of the electric vehicle beneficial electrification analysis utilized different approaches as some EV technologies cannot be tied to customer premises in a reliable manner. The team used bottom-up and top-down approaches to estimate the forecast for each relevant electric vehicle technology. These methods are described in Section 2 of the report.

Measure impacts: With the market segmentation complete, the Team then characterized a wide variety of electrification measures and their end-use-specific reductions in fossil fuel consumption, added electricity consumption, associated net carbon emissions reduction, costs, and lifetimes. Each measure was assigned to the relevant region(s), sector(s), segment(s), and end use(s) for modeling. Each measure permutation was screened through a four-part beneficial electrification screening process that assessed the measure for customer cost savings, emissions reduction, quality of life, and grid resiliency. The beneficial electrification screening process is described in detail in Section 2.5.2 in the report. The screening involves assessing four criteria of which one or more must exhibit a positive impact while none of the others exhibit a negative impact[7]. The criteria include:

- Saves the customer money
- Reduces emissions
- Improves quality of life
- Fosters grid resiliency

Modeling and data analysis: The Mesa Point Team used industry-standard modeling approaches to estimate the technical electrification, beneficial electrification, and achievable electrification potential and associated costs for the analyzed measures. The projected increase in electricity consumption, reduction in carbon emissions, and associated costs of each measure was forecasted for a 20-year time horizon (2021 – 2040). Four achievable potential scenarios were developed so that varying levels of market opportunities could be assessed given variances in measure incentive levels and aggressiveness of program delivery. Outputs from the modeling were developed to show annual energy load impacts (increase in electric consumption and decrease in fossil fuel consumption), net carbon emission reductions, measure lifetimes, and costs for each measure permutation (by region, sector, segment, end use, and vintage) for each year of the study horizon. It is important to recognize that the carbon emissions reduction estimates are established as a function of Tri-State's forecasted emissions rates (tons of CO_2 per MWh). Tri-State provided the Mesa Point team with a set of projected carbon emissions rates based on projected changes in Tri-State's resource mix. As those projections come to fruition, or change over time, the emissions reduction estimates in this study could be updated to reflect the impacts.

[7] The screening criteria were drawn from the Beneficial Electrification League's definition of BE (https://beneficialelectrification.com).

1. INTRODUCTION

1.1. Background, Project Scope, and Objectives

Tri-State retained Mesa Point Energy, along with their subcontractor Brightline Group, (collectively the Mesa Point Team or the Team) to perform a beneficial electrification (or BE) study in support of the company's resources planning initiatives. The primary objective of this study is to assess the available technical electrification, beneficial electrification, and achievable electrification potential from a variety of measures from 2021 to 2040 for the electric cooperatives served by Tri-State Generation and Transmission (Tri-State).

For the purposes of this study, electrification can be defined as changing the energy source for an end use from a fossil fuel to electricity. For example, electrification could be considered:

- Transportation: Replacement of a gasoline driven vehicle with an electric vehicle
- Space Heating: Replacement of a natural gas fired furnace with a heat pump
- Domestic Water Heating: Replacement of a natural gas water heater with an electric-resistance or heat pump water heater
- Industrial: Use of electrically driven equipment instead of fossil fuel driven equipment in applications such as irrigation pumping and natural gas compressor stations

In order to be "beneficial electrification" a project must meet one or more of the following conditions without adversely affecting the other three:

1. Saves consumers money over the long run
2. Improves quality of life
3. Enables better grid management
4. Reduces negative environmental impacts

In order to *save consumers money*, the electrification measure must reduce the annual cost enough to recover the initial cost of the equipment before the useful life of the electric equipment is reached. *Improved quality of life* may result from enhanced product features, reliability, and other factors. An example of an electrification measure *enabling better grid management* is equipment that allows for some level of demand control by the utility, the customer, or a third-party. An electrification measure *reduces negative environmental impacts* through the elimination of direct emissions in exchange for fewer emissions from the generation of electricity used to power the equipment. This net emissions reduction is examined over the estimated lifetime of the equipment and is based on the projected emissions of the electric generation resources over time.

The beneficial electrification study is intended to assist Tri-State in developing future Integrated Resource Plans (IRP) and Electric Resource Plans (ERP). Tri-State will use the results of this beneficial electrification study to analyze and incorporate potential impacts at various levels of program investment.

The study focuses on beneficial electrification *achievable* potential. As discussed further in Section 2, the study is not a *program* potential study meaning it does not take into consideration program budget and design constraints. Therefore, this report's conclusions and recommendations do not include program-

specific recommendations; rather, the report focuses on identifying market opportunities and costs for electrification initiatives.

Reported emissions reductions in this study rely on information about Tri-State's projected resource mix[8]. Estimated emissions reductions would differ from those presented in this report if Tri-State's generation resource mix forecast changes.

This report is related in several ways to the recent *Demand Side Management and Energy Efficiency Potential Study* for Tri-State completed in May, 2020. The prior report provides an achievable potential assessment for energy efficiency, demand response, and distributed energy resources, and is referenced in sections of this report. Energy efficiency and beneficial electrification are two strategies for achieving demand side management goals. It is important to note that the beneficial nature of electrification measures is substantially impacted by the energy efficiency of the electric equipment being installed. More efficient electric equipment leads to greater emissions reduction over both fossil-fuel equipment and standard electric equipment.

Due to the timing of this report, it is important to note that the assumptions, results, and associated analysis detailed herein do not take into consideration the societal and economic impacts of the COVID-19 virus.

1.2. Achievable v. Planned Potential

This beneficial electrification study examines what *could be* (i.e., what load could be added and emissions reduced from considered beneficial electrification measures) but does not account for structural and organizational limitations to that potential.

Tri-State member cooperatives are responsible for implementing measures and programs on a voluntary basis. Tri-State does not have control over which measures its members choose to offer nor how the measures are bundled into program offerings. Some co-ops may choose not to offer incentive programs, or to incent only a subset of cost-effective measures.

The study only takes into consideration barriers on the market side and does not attempt to predict if and at what levels co-ops will choose to move forward with programs.

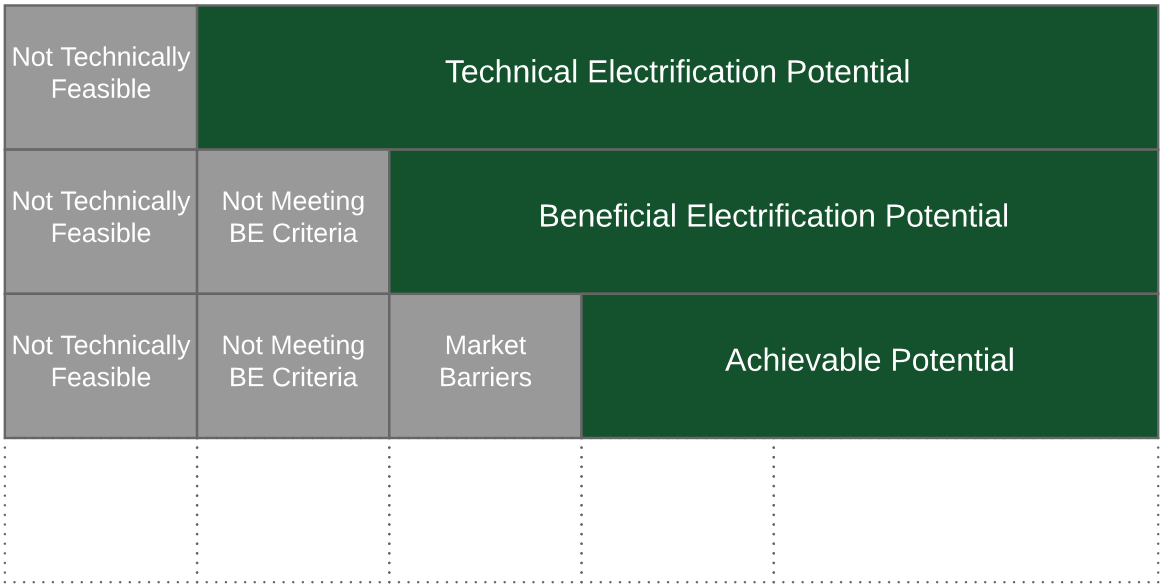
1.3. Study Approach Overview

This study considers measures from the perspective of theoretical maximum benefit, and then accounts for barriers to estimate actual achievable emissions reductions and load growth for the utility.

Specifically, the study begins with *technical electrification potential*, wherein all technically viable measures are included without regard to costs or other barriers. Knowing the technical potential, *beneficial electrification potential* is assessed by estimating costs and reduced emissions associated with implementing measures, and then applying beneficial electrification criteria to the measures. Finally, *achievable potential* is calculated by considering non-economic factors affecting electrification measure implementation. Not considered in the report are factors affecting *program potential*.

[8] Emissions factors were provided by Tri-State based on a resource mix forecast developed in March 2020.

Figure 1: Conceptual Overview of Beneficial Electrification Resource Potential Definitions



- **Technical Electrification Potential** is the theoretical maximum amount of energy load that could be displaced by the replacement of fossil fuel equipment with electric equipment, regardless of cost, emissions impact, and barriers that may prevent the installation or adoption of a measure. Technical electrification potential is only constrained by factors such as technical feasibility and applicability of measures.
- **Beneficial Electrification Potential** represents the amount of emissions reduced, fossil fuel consumption reduced, and associated electric energy and capacity increases that could result from measures that pass beneficial electrification screening criteria. Beneficial electrification screening criteria is described below and in more detail in Section 2.4.2.
- **Achievable Potential** is the energy and emissions impacts that can feasibly be achieved through program and policy interventions. Achievable potential takes into account barriers that hinder consumer adoption of electrification measures such as financial, political and regulatory barriers, and the capability of programs and administrators to ramp up activity over time.
- **Program Potential** reflects the realistic quantity of energy load growth and associated emissions the utility can realize through BE programs during the horizon defined in the study. Potential delivered by programs is often less than achievable potential due to real-world constraints such as program budgets, effectiveness of outreach, and market delays. Program potential would also incorporate go-to-market considerations, such as practical limitations for Tri-State to deliver programs to customers through the rural electric cooperative members. As noted previously and as shown in Figure 1, this study does not address program potential.

1.4. Organization of the Report and Related Deliverables

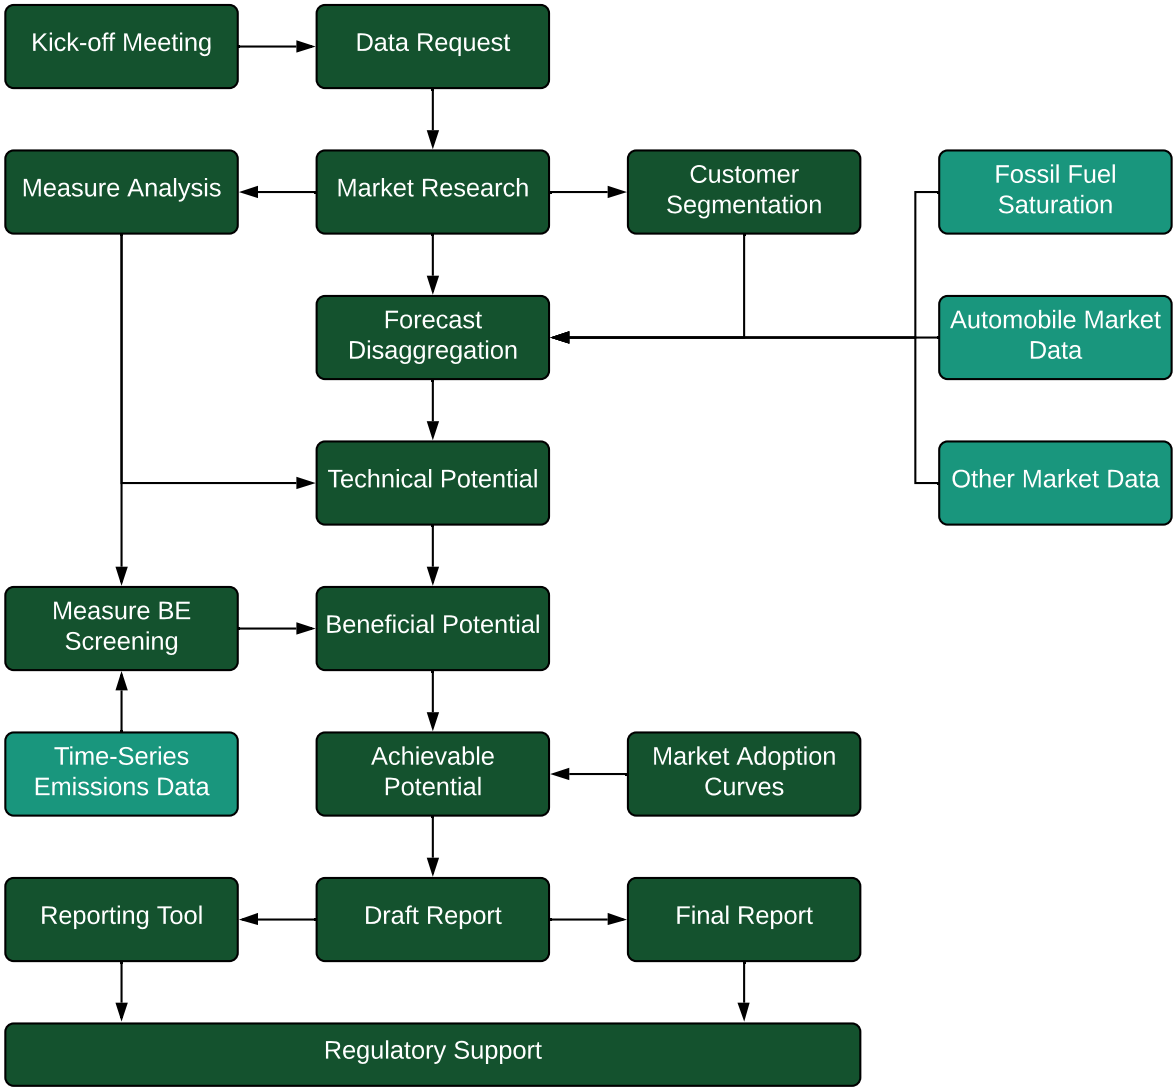
This report presents a summary of the analysis approach, key assumptions, and study findings. Two separate electronic reporting tools are provided with the report, as well as an additional technical appendix spreadsheet that includes select data and input assumptions. The tools provide the ability to view findings by sector, end-use, and region. One reporting tool provides data exclusive of naturally occurring adoption in the EV market, identifying potential that could stem from intervention by Tri-State and its member coops. The main body of this report refers to the results in the version of the tool that excludes naturally occurring adoption. The second reporting tool is inclusive of naturally occurring adoption and is explained further in Appendix C. The intent is for Tri-State and stakeholders to make use of each work product depending on the desired level of detail and perspective.

2. STUDY APPROACH AND METHODS

2.1. Overview

The process shown in Figure 3 depicts the steps taken during a beneficial electrification study.

Figure 2. Approach for Beneficial Electrification Potential Modeling



Each step is described in detail in the sections that follow.

2.2. Customer Segmentation and Forecast Disaggregation

An accurate assessment of achievable beneficial electrification potential requires a thorough characterization of customer technologies. A beneficial electrification study differs from an electric

energy efficiency study as the base forecast represents the technologies that utilize fossil fuels as an energy source and are eligible to switch an electric fuel source. The forecast for a beneficial electrification study differs from an energy efficiency potential assessment forecast, as the BE forecast characterizes the quantity of fossil fuel equipment/technologies eligible for fuel switching and places less importance on the forecast of energy consumption. The forecast characterization of fossil fuel technologies involves the following steps:

- Determine the fossil fuel equipment/technologies that have an electrical fuel source equivalent, such as water heaters.
- Estimate the number of fossil fuel equipment/technologies per current Tri-State member cooperative customer premise for each customer class and premise segment type.
- In cases where the electric energy efficiency potential assessment determined the saturations of technologies with an electric fuel source, the saturations of fossil fuel fuel source technologies can be inferred. For example, if it assumed that 100 percent of residential premises have water heating and 35 percent of the water heaters have an electric fuel source, then it can be assumed that 65 percent of the remaining fuel sources are fossil fuel based.
- Segment fossil fuel equipment/technologies into unique fossil fuel types, such as natural gas, propane, diesel, and gasoline.

To complete these steps the Team relied on a large dataset consisting of:

- The 2020 electric energy efficiency potential study and associated analysis
- Customer forecast from Tri-State member cooperatives
- Market data including fuel shares and equipment saturations
- Technology characteristics including technologies, fuel types, and useful life.

These data were drawn from a combination of primary and secondary research. An overview of the steps involved in forecast characterization process follows.

2.2.1. Customer Segmentation

First, the Team determined the energy and demand loads for each of the geographical regions, sectors, market segments, vintages, and end-uses as follows:

- **Regions**: Sales for rural electric cooperatives were aggregated into regional definitions; including Front Range Colorado, Nebraska, North New Mexico, Wyoming, etc., as shown in Table 1
- **Customer Sectors:** Residential, commercial, irrigation, and industrial (including agricultural)
- **Vintages:** Existing and New Construction
- **End-uses:** Those shown by sector in Table 2

2.2.1.1. Primary Market Research

Primary market research guided the customer segmentation. In 2012, Tri-State distributed a mail-in residential end-use survey requesting information on consumers' residence structure and energy consuming equipment type, age, fuel type, end-uses, and behavior. This data was used to guide the disaggregation of the residential sector load.

The Team also used North American Industry Classification System (NAICS) data that provides business type data on large customers (greater than 250KW) and their associated energy consumption from the Rural Utilities Service (RUS) Form 345. Business type information for energy sales of non-residential customers less than 250KW was not available. Secondary research was necessary to estimate segmentation of business types for customers less than 250KW.

2.2.1.2. Secondary Market Research

The Team utilized secondary resources to complete the customer segmentation, specifically electric versus fossil fuel shares and further segmentation between natural gas and propane. Examples of these resources include the United States Energy Information Administration (EIA) Residential Energy Consumption Survey (RECS) and the EIA Commercial Buildings Energy Consumption Survey (CBECS), among other references, an Environmental Protection Agency-associated technical paper on *National Emissions from Lawn and Garden Equipment*, a U.S. Department of Energy *Energy Storage Technology and Cost Characterization Report*, the U.S. Department of Homeland Security's Homeland Infrastructure Foundation-Level Data (HIFLD) on natural gas compressor stations, among other resources cited throughout this report.

2.2.2. Segmentation of Regions

To accurately characterize Tri-State's large geographic service territory, the Team segmented end-use load profiles and electrification potential by region. Eight (8) regions were defined based on geographic location of the co-ops. Segregating the co-ops by region, instead of producing one set of potential values for all of Tri-State's territory has several advantages:

- Regional segmentation captures variations in equipment end-use saturation and energy intensity. For instance, electric water heater in the residential sector has a higher saturation and energy intensity in Nebraska as compared to Front Range Colorado.
- Barriers to achievable potential may be regionally specific, such as zero emission vehicle encouragement policy within the State of Colorado.

Similar to the electric energy efficiency potential assessment, the Team developed the regional electric cooperative groups shown in Table 1.

Table 1: Tri-State Cooperative Regional Groups

EASTERN COLORADO	FRONT RANGE COLORADO	MOUNTAIN COLORADO	WESTERN COLORADO
Highline	Mountain View	Gunn County	Empire
K.C.	Poudre Valley	Mountain Parks	La Plata
Morgan County	San Isabel	White River	San Luis Valley
Southeast	United		San Miguel
Y-W			Sangre De Cristo
NEBRASKA	**SOUTHERN NEW MEXICO**	**NORTHERN NEW MEXICO**	**WYOMING**
Chimney Rock	Central NM	Cont. Divide	Big Horn
Midwest	Columbus	Jemez Mtns	Carbon
Northwest	Otero County	Mor San Miguel	Garland
Panhandle	Sierra	North. Rio Arriba	High Plains
Roosevelt	Socorro	Southwestern	High West
Wheat Belt		Springer	Niobrara
			Wheatland
			Wyrulec

2.3. End-Use Load Classification

To further disaggregate the load the Team established technology end-use loads within each sector. Table 2 presents a summary of those end-uses.

Table 2: Technology End-Uses for Each Tri-State Sector

RESIDENTIAL	COMMERCIAL	INDUSTRIAL & IRRIGATION
Boilers (Natural Gas Fuel)	Boilers (Natural Gas Fuel)	Pumps (Natural Gas)
Boilers (Propane Fuel)	Boilers (Propane Fuel)	Pumps (Propane)
Furnaces (Natural Gas Fuel)	Furnaces (Natural Gas Fuel)	Pumps (Diesel)
Furnaces (Propane Fuel)	Furnaces (Propane Fuel)	
Water Heating (Natural Gas Fuel)	Water Heating (Natural Gas Fuel)	
Water Heating (Propane Fuel)	Water Heating (Propane Fuel)	
Cooking (Natural Gas Fuel)	Cooking (Natural Gas Fuel)	
Cooking (Propane Fuel)	Fleet Vehicles	
Lawn Equipment	Forklifts	
Garden Equipment	School Buses	
Battery EVs	Transit Buses	
Plug-in Hybrid EVs	Airport Equipment	
	Truck Stop Electrification	

2.4. Electric Vehicle Forecasting

The team used various approaches to estimate the forecast for each relevant electric vehicle technology using both bottom-up and top-down methods of estimation. With the exception of the residential on-road electric vehicle forecast which is derived based on the disaggregated forecast, each technology forecast was constructed outside of the forecasting methods described in this section utilizing the prior DSM potential study as a starting point, as these technologies did not conform with the forecast taxonomy from that study. However, these independent forecasts did follow the same principles and used Tri-State data when applicable. For example, naturally occurring adoption for electric vehicles in Colorado (i.e. adoption independent of Tri-State or member cooperative influence) is expected to be greater relative to non-Colorado regions due to aggressive state policy and funding. This assumption is applied to both the residential on-road forecast and is also carried through to commercial fleets, airport GSE, and forklifts in Colorado, as these are all eligible technologies for Colorado state funding. More detail on forecasting for specific EV technologies is provided in Appendix B.

2.5. Beneficial Electrification Potential Modeling

Drawing on outcomes from the customer segmentation and forecasts the study modeled first technical, then beneficial, and finally achievable electrification potential. Those steps are described in the following sections.

2.5.1. Estimate Technical Electrification Potential

Technical electrification potential is the theoretical maximum amount of energy consumption and capacity added to the grid, along with associated fossil fuel reduction and emissions reduction, associated with electrification measures, disregarding all non-engineering constraints such as cost-effectiveness and the willingness of end-users to adopt the electrification measures. Technical electrification potential is only constrained by factors such as technical feasibility of measures and time. The model applies the measure-level inputs to the disaggregated baseline premise count forecast to estimate technical electric load growth potential, as well as net change in emissions, over the planning horizon.

The core equations used in the technical electrification potential analysis for each individual electrification measure are shown in Equation 1 and Equation 2.

Equation 1. Core Equation for Technical Electrification Potential – Electric Growth

Technical Electricity Consumption Growth Potential of Electrification Measures = Total Number of Premises x Saturation Share x Fuel Share x Remaining Factor x Applicability Factor x Proposed Annual Unit Energy Consumption (kWh)

Equation 2. Core Equation for Technical Electrification Potential – Fossil Fuel Reduction

Technical Fossil Fuel Reduction Potential of Elecrification Measures = Total Number of Premises x Saturation Share x Fuel Share x Remaining Factor x Applicability Factor x Baseline Annual Unit Energy Consumption (therms)

Where:

Total Number of Households: *count of customer households in the subject region.*

Saturation Share: *the fraction of households with fossil fuel equipment for a given end-use in a given market segment. For example, for residential water heating, the saturation share would be the fraction of all residential customers that have fossil fuel water heating in their household.*

Fuel Share*: the fraction of fossil fuel equipment for a particular end-use using a specific type of fossil fuel, either natural gas, propane, gasoline, or diesel. For example, for residential water heating, the fuel share of propane would be the fraction of all residential premises with fossil fuel water heating that use propane as a fuel type.*

Remaining Factor: *the fraction of equipment that is not considered to already be converted from fossil fuel to electric. To extend the example above, the fraction of fossil fuel water heaters that is not already converted to electric.*

Applicability Factor: *the fraction of the applicable units that is technically feasible for conversion to electricity from an engineering perspective—i.e., it may not be possible to install a heat pump water heater in all homes due to air circulation constraints.*

Baseline Annual Unit Energy Consumption: *the annual energy consumption, in therms, of the baseline fossil fuel equipment.*

Proposed Annual Unit Energy Consumption*: the annual energy consumption, in kWh, of the proposed electrically-operated equipment.*

2.5.1.1. Measure Definitions

Once the baseline forecast is disaggregated, the next step to assessing technical electrification potential is to accurately detail the various electrification measures under consideration and estimate their end-use-specific energy impacts, costs, and lifetimes. The Team worked with Tri-State to develop a list of electrification measures to analyze. The list of assessed measure types is included in Table 3, and details on the measure permutations and analysis approach for each measure type, is provided in Appendix A.

Table 3: Measure Types Analyzed

RESIDENTIAL	COMMERCIAL	INDUSTRIAL & IRRIGATION
Heat Pump Water Heating	Heat Pump Water Heating	Electric Irrigation Pumps
Heat Pump Space Heating	Heat Pump Space Heating	Pipeline Compressor Station Electrification
Electric Cooking (Electric Resistance and Induction)	Electric Cooking (Electric Resistance and Induction)	
Electric Lawnmowers	Battery Electric Vehicles	
Electric Snow Blowers	Plug-in Hybrid Electric Vehicles	
Electric Leaf Blowers	Electric Forklifts	
Electric Chainsaws	Electric School Busses	
Electric Trimmers, Edgers, Brush Cutters	Electric Transit Busses	
Battery Electric Vehicles	Electric Public Fleet Vehicles	
Plug-in Hybrid Electric Vehicles	Electric Airport Ground Support Vehicles	
	Electric Parking Spaces	
	Electric Transportation Refrigeration Units	

Upon finalizing the electrification measure list, the Team collected data on energy savings and increases, costs, lifetime, and applicability to determine potential measure impacts. This work involves a multi-step process described here.

Step 1: Define market classifications for application of measures

The Team established market classifications as a framework for documenting applicability of each measure. These classifications were based on factors including region, fuel type, sector, market segment, and end-use as defined in the disaggregated forecast (Section 2.2). Additionally, the Team further defined permutations for each measure based on the following parameters:

- **Climate Zone:** This measure research includes estimates for weather-dependent measures specific to ASHRAE climate zones 4 through climate zone 6
- **Vintage:** Turnover, Early Retirement, New
  - **Replace on Burnout:** Convert equipment to electric when a piece of equipment is at the end of its effective useful life (also referred to as “turnover”)
  - **Early Retirement:** Convert equipment to electric at any time during the life of the equipment

- **New:** Install electric equipment instead of fossil fuel equipment when a new home or building is constructed

Step 2: Screen sectors, segments, and end-uses for applicability

The Team screened market segments and end-uses for applicability of specific electrification measures. For example, certain commercial end-uses, such as cooking, may not be appropriate for segments such as warehouses and therefore were analyzed only in limited market segments.

Step 3: Develop base case impacts and costs

The Team determined base case fossil fuel-burning equipment and practices for each of the electrification measures on the final list and developed a description and rationale for each. This included all base case assumptions and data, such as state building codes (the 2012 International Energy Conservation Code (IECC) in most cases) and federal standards. For each measure, the Team estimated fossil fuel energy consumption for the base equipment, as well as the cost to replace the fossil fuel-burning equipment with a new, similar fossil fuel-burning piece of equipment.

Step 4: Develop electrification measure impacts and costs

The Team developed a description of all electrification (or "change case") measure equipment and practices, including all measure energy consumption assumptions and calculation parameters, such as equivalent full load hours (EFLH). For each measure, the Team estimated electric energy consumption of the proposed equipment, as well as the associated cost to purchase and/or install the equipment.

2.5.2. Estimate Beneficial Electrification Potential

Beneficial electrification potential represents the impacts possible given full adoption of all electrification measures considered to be "beneficial electrification" in that the measures must pass the four BE screening criteria explained below.

To determine whether a measure can be considered beneficial electrification, the Team screened all considered electrification measures using a four-part screening process. This process was established based on the Beneficial Electrification League's (BEL)[9] definition of beneficial electrification as "the application of electricity to end-uses where doing so satisfies at least one of the following conditions, without adversely affecting the others:

- Saves consumers money over time;
- Benefits the environment and reduces greenhouse gas emissions;
- Improves product quality or consumer quality of life; and
- Fosters a more robust and resilient grid.

In order to perform this screening process, each measure was assigned a set of four values, each representing one of the four criteria above. The possible values for each criterion are shown in Table 4.

[9] *Beneficial Electrification League*. (2020). Beneficial Electrification League. https://beneficialelectrification.com/

Table 4: Beneficial Electrification Screening Details

SCREENING CRITERIA	EVALUATION METHOD	PASSING VALUE	FAILING VALUE[10]
Saves consumers money over time	Calculate Participant Cost Test (PCT) for each measure	> 1	< 1
Benefits the environment and reduces greenhouse gas emissions	Calculate net CO_2 emissions reduction for each measure (tons)	> 0	< 0
Improves product quality or consumer quality of life	Identify, qualitatively, whether each measure improves (1), has no impact on (0), or negatively impacts (-1) quality of life	0 or 1	-1
Fosters a more robust and resilient grid	Identify, qualitatively, whether each measure could improve (1), has no impact on (0), or negatively impacts (-1) grid resiliency and flexibility	0 or 1	-1

A value for each of the four criteria was calculated for each measure. Subsequently, a beneficial electrification score (BE score) was calculated for each measure using the following logic: The BE score results in a zero value if any one of the four criteria has a failing value assigned to it. If none of the criteria have a failing value assigned to it, and at least one criterion has a passing value assigned to it, the BE score equals 1.

Measures with a passing BE score of 1 are considered beneficial electrification. Measures with a failing BE score of 0 are screened out of modeling in the beneficial electrification potential scenario and all of the achievable potential scenarios.

2.5.2.1. BE Screening Criteria Descriptions

Approaches to assigning or calculating the score for each BE screening criteria are described in the following sections.

2.5.2.1.1. Criterion 1: Saves the Consumer Money over Time

To evaluate the criterion that a measure saves the customer money, the Team performed a participant cost test on each measure using Equation 3. The PCT considers incentives, tax credit, and the net present value of annual savings on utility bills as benefits and the measure incremental costs,

installation costs, and operation and maintenance costs[11], as costs. Utility bill savings[12] in the context of beneficial electrification is the net savings of reduced fossil fuel costs and increased electricity costs. Annual components of the test inputs are taken to a net present value based on measure life.

Equation 3. Participant Cost Test

$$PCT\ Ratio = \frac{Incentives + Tax\ Credit + Fossil\ Fuel\ Cost\ Savings - Added\ Electric\ Bill\ Costs}{Incremental\ Equipment\ Cost + Installation\ Cost + Maintenance\ Cost}$$

2.5.2.1.2. Criterion 2: Benefits the Environment

To pass this screening criterion, the carbon emissions reduction resulting from reduction of fossil fuel use must be greater than the emissions created from the added electric load. Emission reductions for fossil fuel technologies are a function of the annual consumption, its expected life, and the fuel type.

The emission reduction for the fossil fuels includes transportation to the site from the refining facility, whether that is by pipeline, tanker truck, or other method. This allows a comparison to equivalent emissions added from the electric system, which includes the generation resources emissions and line losses, or the "transportation" to the site from the generation resource. The calculation for added emissions is based on a 20-year forecast of hourly (8760) carbon emissions, with greenhouse gas tons per MWh reducing over time as clean generation resources are expected to be introduced. Consequently, the emission reductions for electric technology are a function of the hourly consumption, its expected life, and the installation. Equation 4, calculated for each year of a measure's life, shows the method to calculate net emissions reductions for each measure.

Equation 4. Net Emissions Reduction Test

$$Net\ Emission\ Reduction = Emissions_{fossil\ fuel} - Emissions_{electrified}$$

Or inserting units,

$$Net\ Emission\ Reduction = \left(\frac{BTU}{year} \times \frac{tons\ CO_2}{BTU}\right) - \left(\sum_{i=0}^{i=8760} \left(kWh_i \times \left(\frac{tons\ CO_2}{kWh}\right)_i\right)\right)$$

Factors used to estimate emissions from the fossil fuel baseline equipment are shown in Table 5.

[11] In many cases for Beneficial Electrical technologies, the Operations and Maintenance costs are negative. Even though this may be presented as a benefit, it is applied a credit to costs within the ratio denominator.

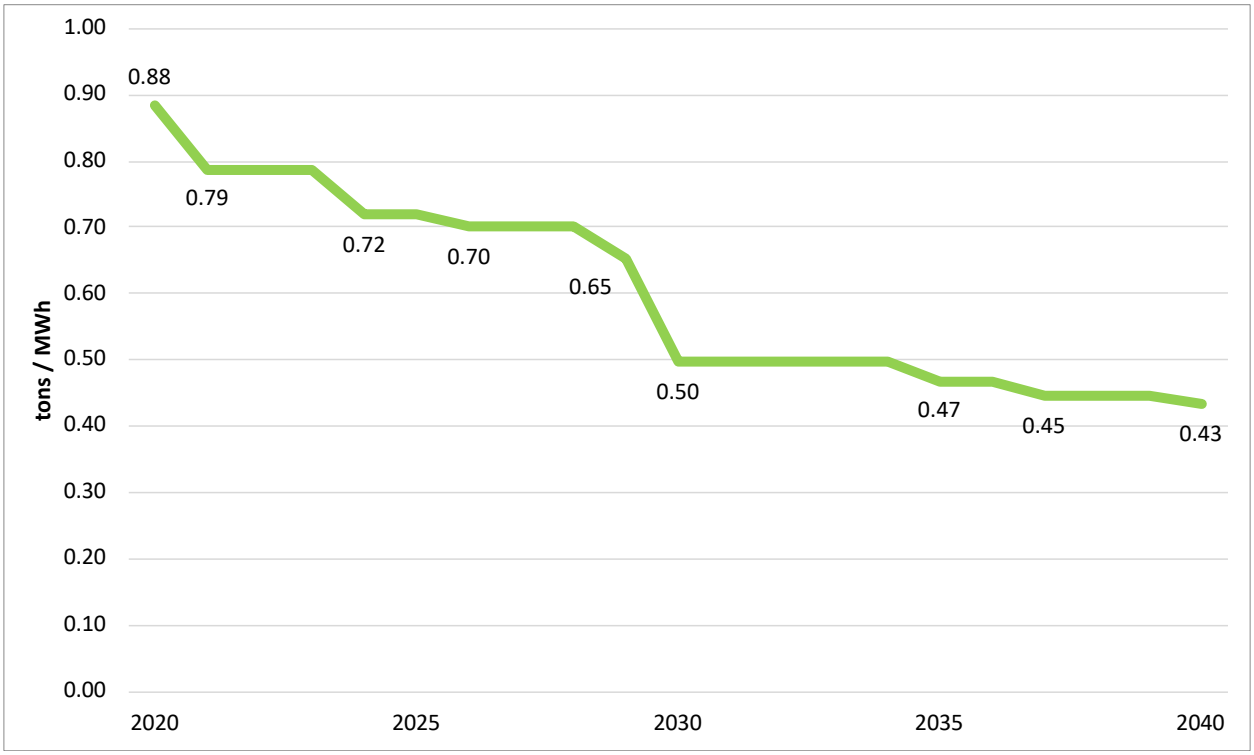
[12] Participant utility bills are based upon the customer rate. Customer rates for this study were generic, not based a specific member cooperative, but were informed by public available, published rates. Generic rates were calculated for each customer segment; residential, commercial, and industrial.

Table 5: Fossil Fuel Carbon Emissions Rates

Fossil Fuel Type	Emissions Rate (tons CO_2/BTU)
Natural Gas	0.00585
Propane	0.00635
Gasoline	0.00971
Diesel	0.00954

Emissions rates used to calculate post/electrified emissions were provided by Tri-State. The rates, measured in tons of CO_2 emissions per megawatt-hour, were provided on an hourly basis for the years 2020 – 2040. The hourly emissions rates were utilized, in conjunction with measure savings and load shape, to calculate the emissions of electrified equipment. The average emissions rates by year are presented in Figure 3, although calculations were done on an hourly basis.

Figure 3: Annual Average Electric Generation Carbon Emission Rates



The emissions rates used in the analysis reflect an individual forecast of Tri-State's resource mix. The forecast could change based on changing regulatory, economic, political, market, and other conditions. Adjustments to Tri-State's resource mix may lead to adjustments in the emissions rates, and therefore adjustments to the emission reduction outcomes. The effects of accelerating or decelerating emissions

rate improvements, or increasing or decreasing the magnitude of the emission rate reductions, would change the post-case emissions and also change which beneficial electrification measures pass the emissions screening criteria.

2.5.2.1.1. Criterion 3: Improves Quality of Life

The Team considered each measure's impact on quality of life in order to assign a value of -1, 0, or 1 to each measure. A value of -1 represents a negative impact, a value of 0 represents no appreciable impact, and a value of 1 represents a positive impact. To assign these values, The Team considered the way in which each measure could improve the quality of life of the customer in terms of comfort, reliability, ease of use, and other aspects. Electrification measures are often associated with these improvements due to the advanced technologies utilized, and reliability of electrically-driven motors, compressors, pumps, etc. Each measures impact on quality of life for the consumer and product quality was carefully considered.

2.5.2.1.2. Criterion 4: Fosters Grid Resiliency

The Team considered whether or not a particular measure may provide an improvement to grid resiliency via potential demand control mechanisms, ability to provide energy storage on the grid, and other aspects. If a particular measure involved a technology that could feasibly provide one of these benefits, the measure received a score of 1 for grid resiliency. If a measure involved a technology that would not feasibly provide these benefits, but would have no negative impact on the grid, the measure received a score of 0 for grid resiliency. If the measure was believed to negatively impact grid resiliency, a score of -1 was assigned to that measure. For example, a heat pump water heater may have the ability to foster grid resiliency by allowing the utility (with customer approval) to adjust the time the unit heats stored water to manipulate the equipment's impact on the system peak demand.

2.5.2.2. Overall Economic Viability

While the beneficial electrification screening process utilized the PCT to screen for cost effectiveness, the Team also assessed the overall economic viability by calculating the Total Resource Cost (TRC) test for each measure. TRC outcomes are presented at the sector and portfolio levels in later sections of this report and at a more granular level in the BE reporting tool. The TRC test is a valuable test to assess measure benefits and costs from the perspective of all the rate payers as a whole. Equation 2 presents the TRC ratio equation.

Equation 5. TRC Ratio

$$TRC\ Ratio = \frac{\left((Avoided\ Electric\ Avoided\ Costs + Avoided\ Fossil\ Fuel\ Costs) \times 10\%\ NEB\ Multiplier\right) + Social\ Cost\ of\ Carbon}{Incremental\ Cost + O\&M\ Costs + Tax\ Credits}$$

The benefits in the TRC test are the net present value of the lifetime avoided energy and capacity costs. The costs in this test are the net present value incremental measure costs.

Specifically, the **benefits** include the net present value of the energy and capacity saved by the measures along with any natural gas or other fossil fuel benefits. The forecast of electric avoided costs of energy

and capacity were obtained from Tri-State[13]. The avoided costs are calculated by applying end-use-specific annual hourly load shapes to measure energy impacts to determine the time-differentiated value of energy and capacity benefits. The annual hourly load shapes were developed from industry-specific energy load profiles, and a peak load window definition of noon to 10 PM during weekday summer months was provided by Tri-State to estimate coincident peak demand.

To accurately value avoided energy impacts for Tri-State, line losses were included. These losses were calculated for each climate zone and reflected the losses from the customer to the co-op and the losses from the co-op to Tri-State. A financial discount rate of 5 percent was applied to value future avoided costs.

Fossil fuel avoided costs were estimated based on various publicly available sources, largely relying upon data contained within natural gas DSM program regulatory filings for the State of Colorado and United State Energy Information Agency (US EIA) annual[14] and short term[15] energy outlooks (AEO) with region adjustments, as available.

The social cost of carbon at $46/ton[16] of CO_2 was incorporated as a benefit of BE in the TRC calculations. This information was provided by Tri-State as a table with values escalated annually over the study time horizon. An additional 10 percent multiplier was applied to the TRC benefits to account for additional non-energy benefits (NEBs) associated with electrification measures such as job creation and societal health benefits. How the NEBs multiplier is calculated is explained in the section below.

The **costs** are the net present value of all costs to implement the measures. These costs include full incremental costs. The full incremental costs include single upfront costs and operational & maintenance costs where applicable. Incentives are not included, because they are transaction between the utility and customer, thus the costs and benefits negate each other. Additionally, state and/or federal tax credits, where applicable were included.

2.5.2.2.1. NEBs Adder

For this study, we used a 10 percent non-energy benefit adder in addition to the monetized cost of carbon to account for health, environmental, and other benefits of electrification. In part, this factor is intended to include the benefit of reduced non-carbon greenhouse gas emissions such as NO_x and SO_x. Additional non-energy benefits to electrification including improved local air quality, improved public and participant health, and compliance (including cost of compliance) with environmental regulations.

To account for benefits beyond cost savings and carbon reduction, some states explicitly monetize the value of health and environmental benefits, while others use a proxy multiplier on the TRC test. This multiplier has the effect of increasing the TRC, potentially allowing for increased BE efforts, inclusion of more measures, and increased program funding.

[13] Because there is added electrical consumption due to beneficial electrification measures, the avoided electric benefits will be **negative**.

[14] *https://www.eia.gov/outlooks/aeo/*

[15] *https://www.eia.gov/outlooks/steo/*

[16] 2020 dollars

Xcel Energy Colorado, in their settlement agreement and DSM plan, uses a TRC modification factor of 20 percent for all non-low income measures and 50 percent for all low income measures, which includes carbon[17].

The BE analysis shows that the monetized cost of carbon increases benefits by about 10 percent. To achieve an overall environmental benefit multiplier of 20 percent, which is in line with Xcel's filings, this analysis adds another 10 percent to account for non-carbon, non-energy benefits.

2.5.3. Estimate of Achievable Potential

The assessment of realistically achievable electrification potential required estimating, among other parameters, the rate at which cost-effective measures can be adopted over time. The Team incorporated individually developed sets of market penetration curves corresponding to implementation scenarios to account for the fact that program implementation scenarios have a direct influence over such market penetration rates. These scenarios were correlated to differing levels of urgency in program implementation, tolerance for rate impacts, macroeconomic conditions, and other situations.

The following are important components in determining achievable potential:

- **Benchmarking.** The amount of participation expected to be achievable through BE programs can be informed by the experience of utilities across the region and nation. For BE measures that have a traditional DSM analog (i.e. heat pump water heaters), program adoption for BE can be informed by traditional DSM program participation rates, adjusting for additional market barriers present for BE measures.
- **Customers' willingness to participate.** The likelihood that customers will participate in electrification programs is a function of several factors, including but not limited to incentive level.
- **Uncertainty.** Planning requirements often necessitate a point-estimate of potential, however, this is not an accurate reflection of the reality of BE programs. The study conceives of achievable potential as a range, or probability distribution, where the point-estimate is the most likely outcome. This distribution defines the lower and upper bounds of expected participation, as well as the most likely value.

Achievable potential electrification impacts were evaluated based on four incentive scenarios as a function of incentive level:

- **Achievable Low**: Incentives below industry standard, with limited administrative expenditures
- **Achievable Moderate**: Incentives and administrative expenditures on par with industry average
- **Achievable Aggressive**: Incentives and administrative expenditures above industry average

[17] Proceeding 17A-0462EG, Xcel Co Settlement Agreement pg 12/34, PSCO DSM plan from Proceeding 18A-0606EG April see pg 333, Proceeding 17A-0462EG decision C18-0417 pg 12 of 45

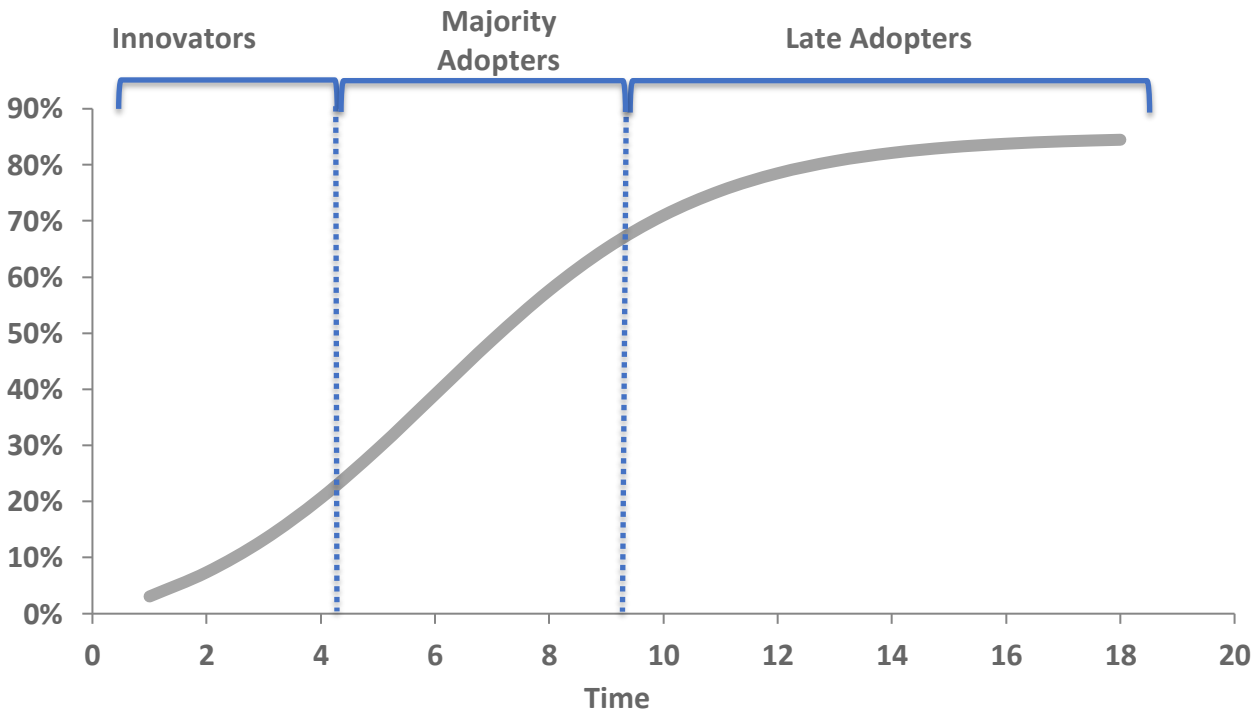
- **Achievable Maximum**: Incentives that cover the full incremental cost of measures, or approximately double industry average, and highly aggressive administrative expenditures

2.5.3.1. Market Adoption Rates

In order to characterize the rate of market adoption for each of the specified scenarios, a quantitative approach was developed based on a Bass Diffusion Model. This method relies on scientific theory and historic program participation data based on Tri-State's experience and other DSM and BE programs in North America.

The Bass Diffusion Model[18] is a mathematical description of how the rate of product diffusion in a market changes over time. When the product is introduced, there is a slow rate of adoption while customers become familiar with the product. When the market accepts a product, the adoption rate accelerates to relative stability in the middle of the product cycle. The end of the product cycle is characterized by a low adoption rate because fewer customers remain that have yet to adopt the product. This concept of forecasting future adoption rates is illustrated in Figure 4.

Figure 4: Typical Product Diffusion in the Marketplace



The rate of adoption in a discrete time period is determined by external influences on the market, internal market conditions, and the number of previous adopters.

[18] Bass, Frank (1969). "A new product growth for model consumer durables". Management Science.

- Initial Year Measure Adoption

First year adoption levels were informed by recent Tri-State historical performance where possible and applicable. For instance, for building-related BE measures, the initial year measure adoption is considered modestly reduced from recent DSM program performance.

- Long-Term Market Adoption Rates

The final adoption scores that resulted from willingness to pay surveys serve as the point-estimate for the long-term market adoption potential for the realistic achievable scenario.

- Adoption Curve Shape

Once the initial year adoption rate (Point A) and long-term adoption rates (Point B) are determined, the remaining step was to determine the rate and duration to get from Point A to Point B.

Unique end-use adoption curves were developed based on the following three parameters:

- **Customer Sector:** Residential, Commercial, and Industrial
- **End-Use Type**: Space Heat, Water Heat, etc.
- **Incentive Level based on Achievable Scenario**: low, moderate, aggressive, maximum

2.5.3.2. Program Costs

To capture the full cost of achievable electrification potential, the Team added program non-incentive costs in the overall assessment of cost-effectiveness. Non-incentive program cost categories included: (1) Administration, (2) Marketing, (3) Technical, and (4) Measurement & Verification and Planning. Program non-incentive costs were calculated on a gross $ per first-year kWh added. Non-incentive costs were developed for each program by sector. The included program cost assumptions are shown in Table 6. These assumed non-incentive costs reflect the same costs used in the recent energy efficiency potential study as program delivery for most BE measures is not expected to take significantly more or less resources to implement.

Table 6: Summary of Non-Incentive Program Costs ($/kWh)

SECTOR	ACHIEVABLE LOW	ACHIEVABLE MOD	ACHIEVABLE AGG
Residential	$0.100	$0.115	$0.150
Commercial	$0.050	$0.058	$0.075
Industrial	$0.100	$0.115	$0.150
Irrigation	$0.050	$0.058	$0.075

For program cost analysis, non-EV incentive costs were developed based on secondary research of existing electrification programs instead of assigning incentives as a percentage of incremental cost. For many electrification measures, the incremental cost is very small or even negative – the electric version of the technology in question costs less than the fossil fuel option. Despite this, incentives or other

motivational elements such as education and outreach, are still required to drive market adoption of BE measures. For the purposes of estimating total program costs, prevailing current incentive amounts were assigned to the achievable-moderate scenario and were scaled up or down in proportion to the incentive level percentages assigned to the other achievable scenarios.

2.5.4. Reporting Tools

A pair of BE Reporting Tools were developed to provide Tri-State staff access to the data outputs from the modeling efforts. The Reporting Tools, presented as Microsoft Excel workbooks, summarize and illustrate the load growth, fossil fuel reduction, and emissions reduction potential and associated costs by sector, year, and scenario enabling the user to select results for a specific region or for the entire service territory. The results are depicted in tabular form and in associated charts that update dynamically based on the selected region. The first of the two files presents results that represent the estimated potential directly associated with interventions by Tri-State and its member coops. The second file presents results that represent estimated potential stemming from both Tri-State's interventions, as well as from naturally occurring adoption. Naturally occurring adoption is expected to be significant in the EV market over the 20-year study horizon. The results presented in the following sections are *exclusive* of naturally occurring adoption. Appendix C provides additional context for the second Reporting Tool that is *inclusive* of naturally occurring adoption in the EV market.

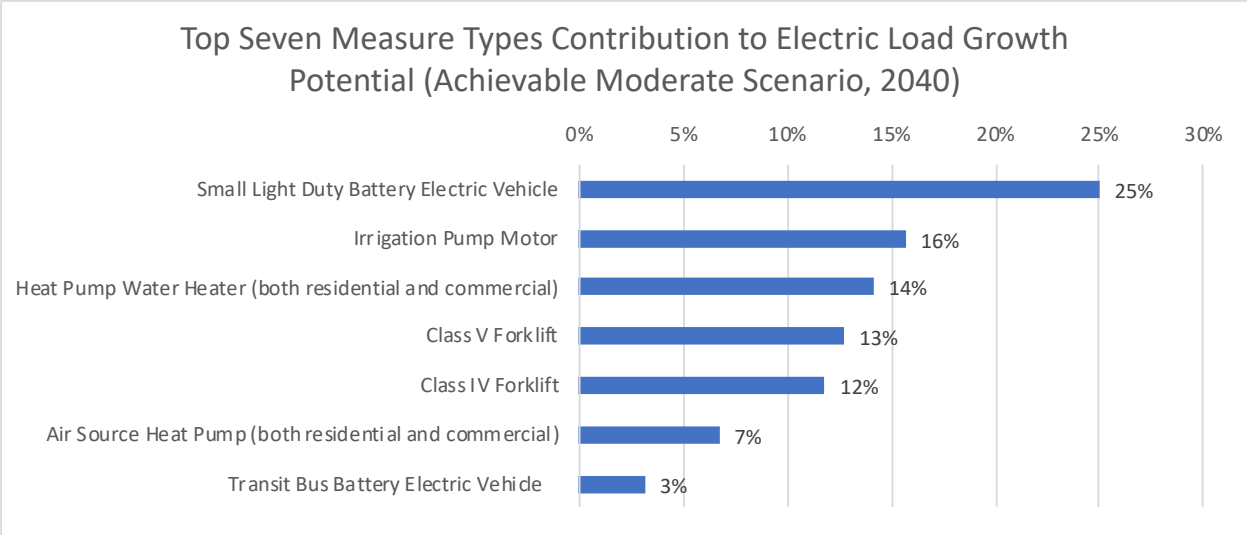
3. PORTFOLIO LEVEL BENEFICIAL ELECTRIFICATION POTENTIAL

3.1. Overview

The study finds that at the portfolio level, in the achievable-moderate scenario, Tri-State can achieve a cumulative reduction of nearly 6.5 million tons CO_2 emissions over the lifetimes of the measures through the electrification of fossil fuel equipment in their service territory. The emissions reduction corresponds to reduction in fossil fuel consumption of nearly 100 million therms (approximately 20 percent of the estimated current on-site natural gas demand in the territory) and an increase in annual electricity consumption of 652,583 MWh, which represents a 3 percent increase in Tri-State's overall load.

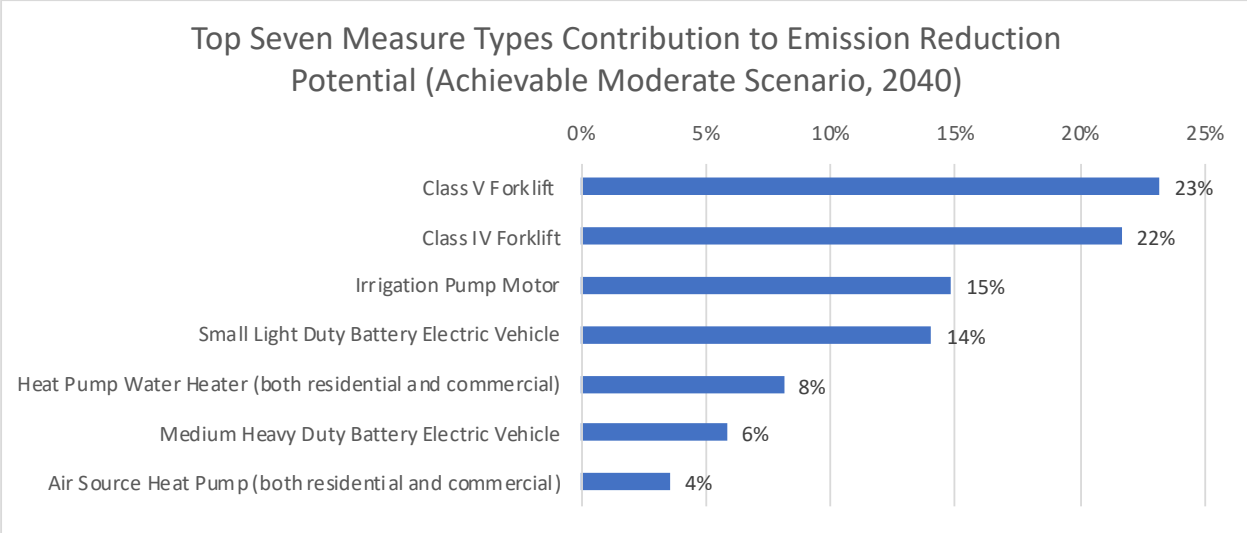
A set of seven measure types constitute nearly 90 percent of the potential load growth from electrification measures. Those seven measures are listed in Figure 5 in order of contribution to electric load growth potential:

Figure 5: Top Seven Measure Types Contribution to Electric Load Growth Potential (Achievable Moderate Scenario, 2040)



A set of seven somewhat overlapping measure types constitute over 90 percent of the cumulative lifetime emissions reduction potential by 2040. Those measure types are listed in Figure 6 in order of contribution to emissions reduction.

Figure 6: Top Seven Measure Types Contribution to Emission Reduction Potential (Achievable Moderate Scenario, 2040)



3.1. Load Growth Potential Results

Table 7 presents portfolio-level potential load growth by time horizon and Figure 7 shows the cumulative growth in electricity consumption potential through 2040. The Achievable-Moderate scenario estimates 2,376 MWh of load growth potential in 2021 rising to 651,520 MWh of cumulative

load growth potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive) could increase cumulative load growth potential by approximately 30 percent. The maximum achievable scenario increases load growth potential by another 23 percent over the aggressive scenario.

Table 7. Cumulative Electric Load Potential (MWh) by Scenario by Time Horizon

MILESTONE YEAR	TECHNICAL ELECTRIFICA-TION	BENEFICIAL ELECTRIFICA-TION	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021	52,033	5,487	4,875	3,485	2,524	1,957
2025	417,171	84,088	62,069	43,736	30,905	23,583
2030	1,674,758	474,237	278,910	207,716	144,792	105,867
2040	5,513,285	1,907,671	1,044,310	857,810	652,583	486,764

Figure 7. Portfolio Electric Load Added by Scenario by Year

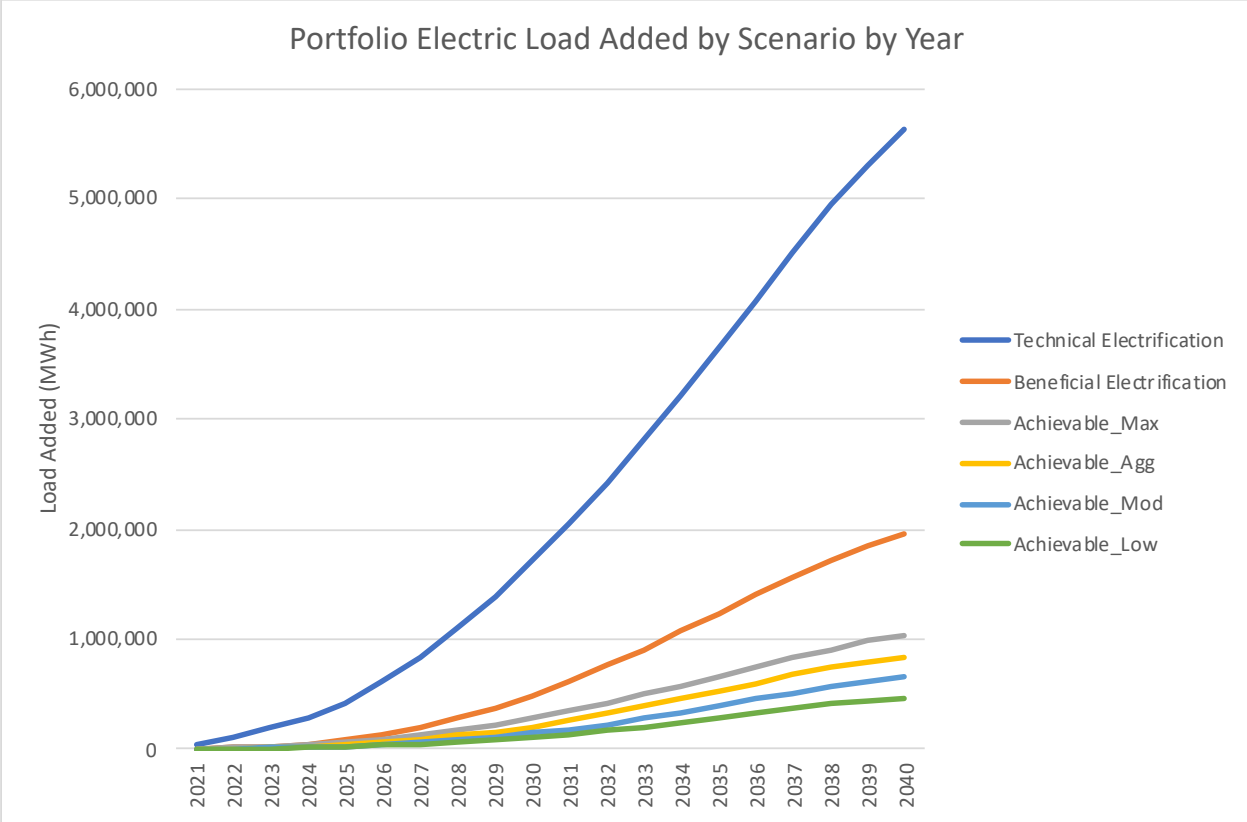


Table 8 shows the impacts of cumulative load growth potential on Tri-State's baseline energy consumption forecast. The cumulative growth associated with the Achievable Moderate scenario would increase Tri-State's baseline forecast consumption by approximately 0.02 percent in 2021. The increase

in baseline energy consumption would grow from 0.19 percent by 2025 to over 3 percent through 2040. The range of potential growth in baseline consumption across the achievable scenarios spans from 2.23 percent (Achievable-Low) to 4.94 percent (Achievable-Max) by 2040.

Table 8. Portfolio Cumulative Load Added as % of Baseline Forecast by Sector by Year

MILESTONE YEAR	TECHNICAL ELECTRIFICA-TION	BENEFICIAL ELECTRIFICA-TION	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021 (first year)	0.34%	0.04%	0.03%	0.02%	0.02%	0.01%
2025	2.54%	0.51%	0.38%	0.27%	0.19%	0.14%
2030	9.41%	2.66%	1.57%	1.17%	0.81%	0.59%
2040	26.19%	9.06%	4.96%	4.07%	3.10%	2.31%

Figure 8 shows the impact of the modeled scenarios on the baseline forecast. Each Achievable scenario would increase Tri-State's overall load growth to some degree. Capturing all technically possible electrification measures considered as part of this study would add over 25 percent to Tri-State's load by 2040.

Figure 8. Impact of Electric Load Added on Baseline Forecast by Scenario by Year

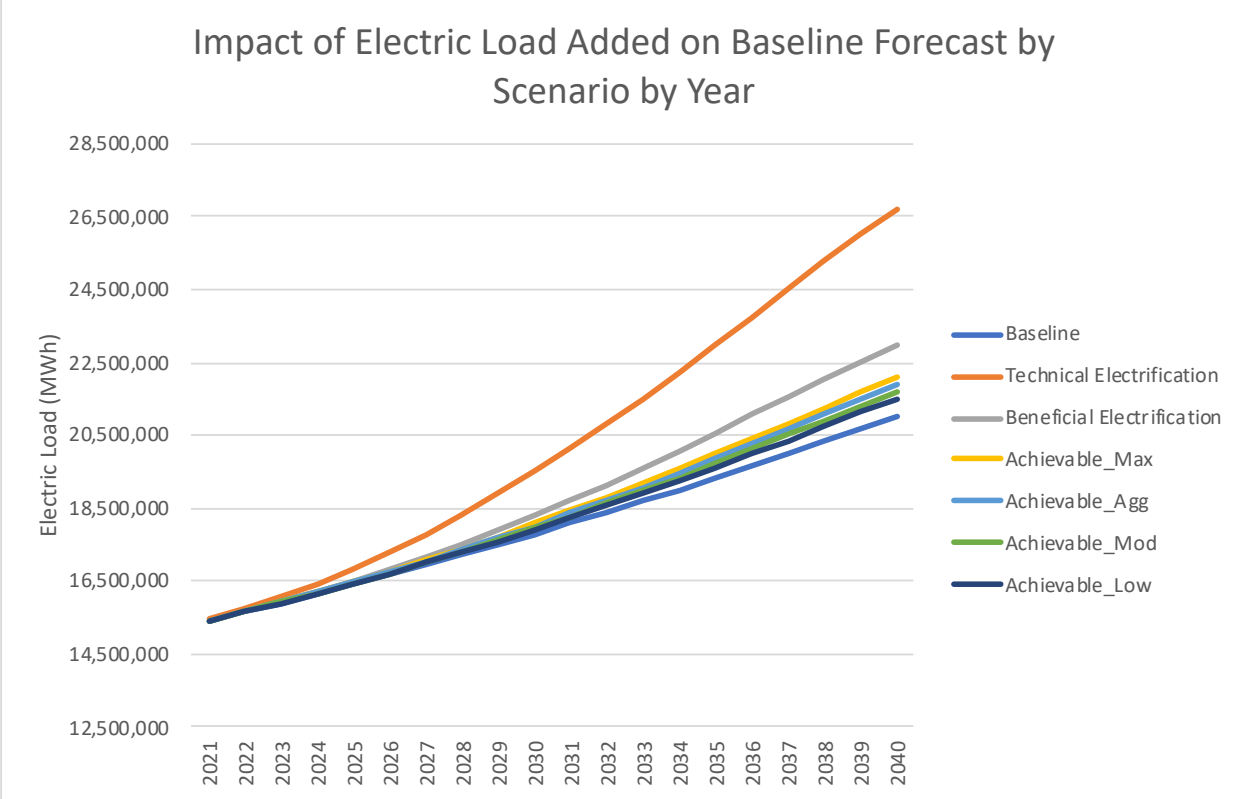

Table 9 presents energy load growth potential by region. Front Range Colorado represents the largest share making up over 42 percent of the total load growth potential. All Colorado regions combined account for nearly three quarters of the load growth potential. The two regions within New Mexico together comprise approximately 15 percent of total potential, while Wyoming accounts for approximately six percent of the total. Nebraska's growth potential is 5 percent of the total. This load growth potential is generally aligned with the distribution of forecast energy load by region. However, Eastern and Western Colorado make up a larger portion of load growth compared to their contribution to the baseline forecast. The outsized contribution to load growth by Eastern Colorado is due, in part, to irrigation pump motor electrification being a highly applicable measure in that region.

Table 9. Cumulative Load Added by Region, Achievable-Moderate Scenario (2040)

STATE / SUB-REGION	POTENTIAL LOAD ADDED (MWH)
Colorado	**460,432**
Eastern	*91,247*
Front Range	*271,902*
Mountain	*32,900*
Western	*64,383*
Wyoming	**38,076**
New Mexico	**118,503**
Northern	*70,475*
Southern	*48,028*
Nebraska	**35,571**
Total	**652,583**

As shown in Figure 9 the residential sector represents the largest opportunity for growth. The residential sector makes up over 45 percent of the total load growth potential, while only accounting for approximately 28 percent of the baseline load. Numerous measures are available to electrify residential energy end uses, with the most substantial growth potential coming from electric vehicles, as discussed further in Section 5. The commercial sector also holds substantial potential load growth at 36 percent of the total growth potential, which is larger than its 17 percent share of the baseline forecast energy consumption. Electric vehicles also contribute a large portion of the growth potential in the commercial sector, at roughly 80 percent of the sector's potential. The irrigation sector contributes less than 20 percent of the achievable electric load growth potential, however that contribution to potential load growth is nearly 3 times the sector's share of the baseline load. Electrification potential in the irrigation sector comes from irrigation pump motor electrification. While the industrial sector comprises nearly 50 percent of the baseline load, the study found no achievable electrification potential for the sector. The study considers pipeline transportation compressor station electrification, which contributes significantly to the technical potential scenario. However, that measure fails the beneficial electrification screen due to increased emissions from electrification over the entire study horizon. More information is presented on the irrigation and industrial sectors in Section 6 and Section 7.

Figure 9. Baseline Forecast and Portfolio Electric Load Added by Sector (2040)

	Forecast %	Load Added %
Irrigation	6.6%	18.6%
Industrial	48.6%	0.0%
Commercial	17.0%	35.4%
Residential	27.9%	45.9%

The portfolio of electrification measures can achieve a cumulative demand growth of 10.6 MW by 2040, as shown in Table 7. The residential sector accounts for the largest share of demand growth, followed by the commercial sector.

Table 10. Portfolio Cumulative Demand Growth Potential by Sector by Year (MW) (Achievable-Moderate Scenario)

MILESTONE YEAR	RESIDENTIAL	COMMERCIAL	INDUSTRIAL	IRRIGATION	TOTAL
2021	0.11	0.11	0.00	0.10	**0.31**
2025	0.48	0.44	0.00	0.25	**1.18**
2030	1.76	2.15	0.00	0.71	**4.61**
2040	6.25	2.69	0.00	1.64	**10.58**

Table 11 presents cumulative and average annual cost, added load, and TRC metrics associated with the Achievable-Moderate scenario. As shown, in the first year Tri-State can achieve 2,524 MWh of energy load growth at a cost of approximately $1.9 million, or $769/MWh. As programs expand and become more established annual costs and energy impacts increase substantially to reach a cumulative program expenditure of over $550 million by 2040 and load growth of 785,329 MWh. The 20-year average annual program costs are approximately $28 million and load growth is 39,266 MWh per year.

Table 11. Portfolio Cost Metrics by Time Horizon (Achievable-Moderate Scenario)

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	CUMULATIVE LOAD ADDED (MWH)	ACQUISTION COST ($/MWH)
2021	1.54	$1,941,462	2,524	$769.09
2025	1.61	$25,575,994	30,905	$827.56
2030	1.83	$121,866,050	146,004	$834.68
2040	2.37	$557,671,021	785,329	$710.11
20-year avg.	2.37	$27,883,551	39,266	$710.11

3.2. Emissions Reduction Results

Net lifetime emissions reductions represent the total negative emissions from implementing a measure minus any added emissions, typically in the early years of that measure's lifetime, if applicable. Due to the shift in Tri-State's fuel mix over time, several measures exhibit emissions increases over the associated fossil fuel equipment early in their measures lives and shift to emissions reductions later. An example of this is shown for a residential heat pump water heater measure in Figure 10. For this particular example, installing a new heat pump water heater in place of an existing natural gas water heater in 2021 nets an emissions increase in 2021, 2022, and 2023. Starting in 2024, the measure begins to exhibit an emissions benefit and continues that emissions reduction through its 12-year measure life.

Figure 10. Residential Water Heater Example Annual Emissions by Fuel Type by Year

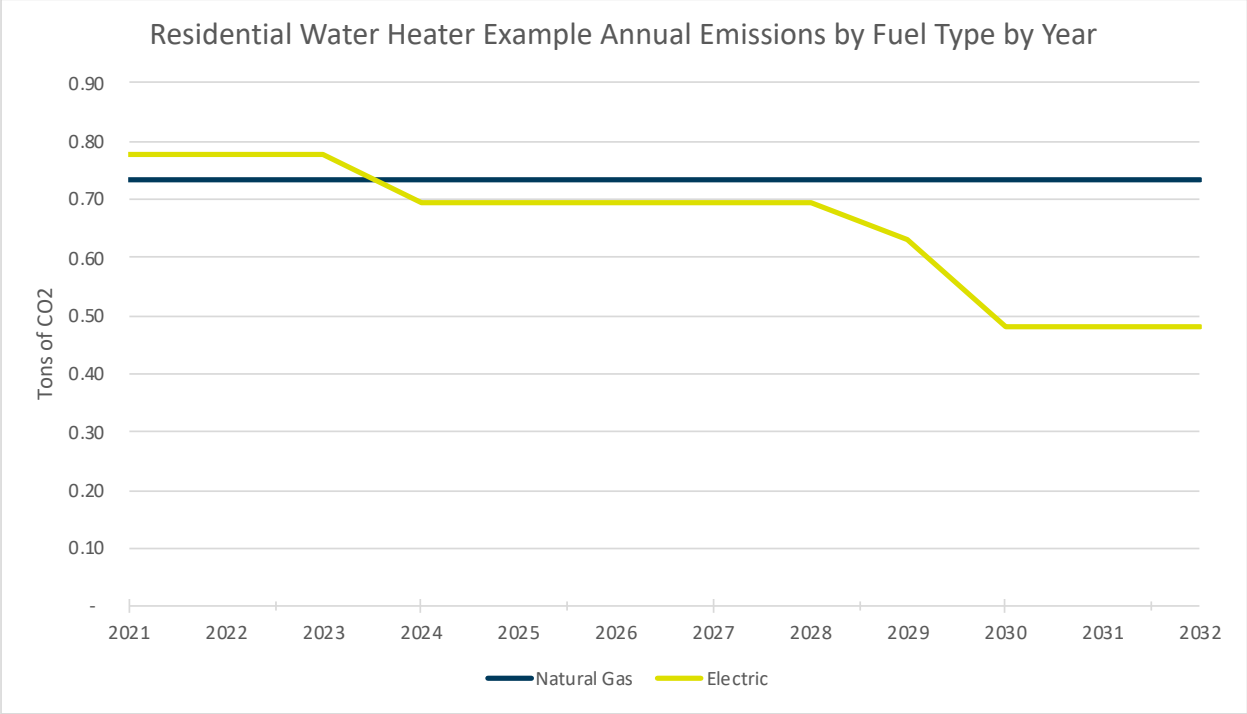

Table 12 shows cumulative net carbon emission reductions by scenario and by time horizon. Since the technical scenario captures all considered electrification measures, that scenario represents measures with lifetime emissions reductions as well as measures that increase emissions.

Table 12. Cumulative Lifetime Carbon Emission Reduction (tons CO_2) by Scenario by Time Horizon

MILESTONE YEAR	TECHNICAL ELECTRIFICA-TION	BENEFICIAL ELECTRIFICA-TION	ACHIEVABLE MAX	ACHIEVABLE AGG	ACHIEVABLE MOD	ACHIEVABLE LOW
2021	(152,135)	21,155	19,370	14,779	11,414	9,755
2025	(255,722)	393,851	301,303	227,915	175,668	147,926
2030	2,483,894	2,787,472	1,773,723	1,399,013	1,075,264	882,236
2040	23,254,798	16,006,011	9,489,083	7,811,346	6,417,877	5,389,333

Figure 11 show the contribution by region to cumulative lifetime emissions reduction in 2040. The bulk of emissions reduction potential is in the Front Range Colorado region.

Figure 11. Cumulative Lifetime Portfolio Carbon Emissions Reduction (Tons CO_2) by Region (2040)

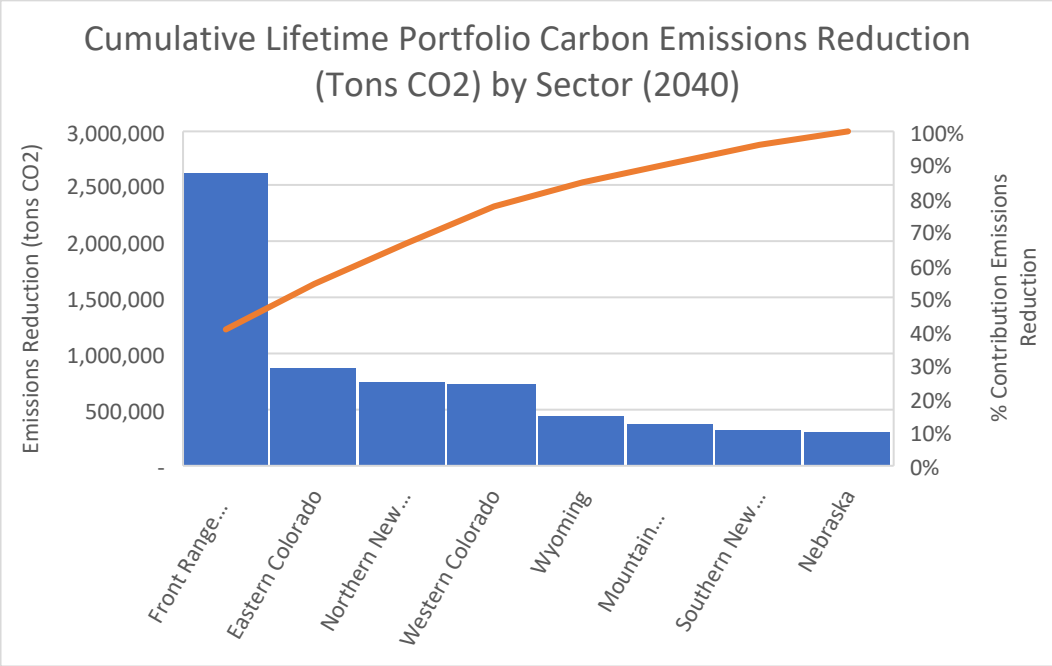

Figure 12 shows the contribution by sector to cumulative lifetime emissions reduction in 2040. The commercial sector makes up over 50 percent of achievable carbon emissions reduction.

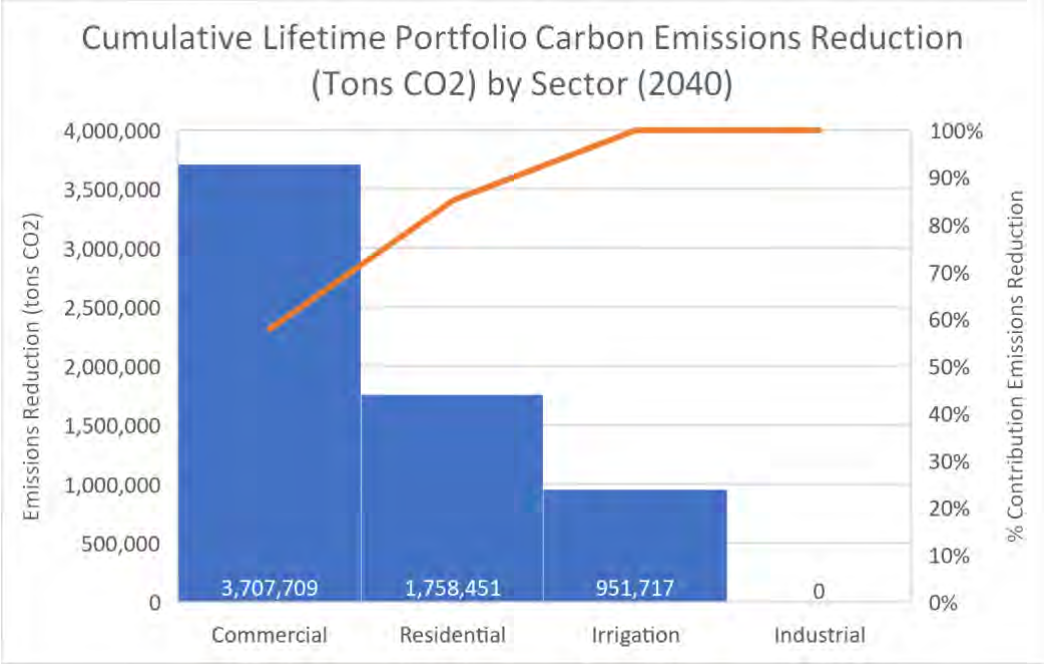
Figure 12. Cumulative Lifetime Portfolio Carbon Emissions Reduction (Tons CO_2) by Sector (2040)



4. RESIDENTIAL BENEFICIAL ELECTRIFICATION POTENTIAL

4.1. Overview

The residential sector accounts for just under one-third of the total baseline forecast energy load, 46 percent of load growth potential, and 27 percent of projected cumulative emissions reduction. Cumulative electric load growth potential for this sector is estimated to be 299,757 MWh through 2040 (Achievable-Moderate scenario) with plug-in hybrids (28 percent) and battery electric vehicles (37 percent) making up nearly two-thirds of the total energy load growth potential. Space heating and water heating are also large components of the residential sector growth potential, contributing 12 percent and 21 percent respectively.

4.2. Detailed Results

Table 13 presents cumulative potential impacts for the residential sector by scenario at various milestones in the analysis period and Figure 13 shows the growth in cumulative added energy consumption potential through 2040. The Achievable-Moderate scenario estimates 1,054 MWh of load growth potential in 2021 rising to 299,757 MWh of cumulative load growth potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive scenario) could increase cumulative load growth potential by approximately 35 percent. The maximum achievable scenario estimates load growth potential approximately 20 percent higher than the aggressive scenario, equating to cumulative increase in electric consumption of an estimated 485,799 MWh through 2040. This equates to an increase of over 8 percent of forecasted sector level baseline sales.

In the achievable-moderate scenario, the residential sector is expected to provide a reduction in carbon emissions of nearly 1.8 million tons of CO_2 by 2040. The achievable-maximum scenario increases that number to nearly 3 million tons of CO_2 by 2040.

Table 13. Cumulative Residential Electrification Impacts

MILESTONE YEAR	TECHNICAL ELECTRIFICA-TION	BENEFICIAL ELECTRIFICA-TION	ACHIEVABLE _MAX	ACHIEVABLE _ AGG	ACHIEVABLE _MOD	ACHIEVABLE _ LOW

2040	11,476,214	4,841,494	2,939,543	2,357,711	1,758,451	1,346,869

Figure 13. Residential Annual Electric Consumption Added by Scenario by Year (MWh)

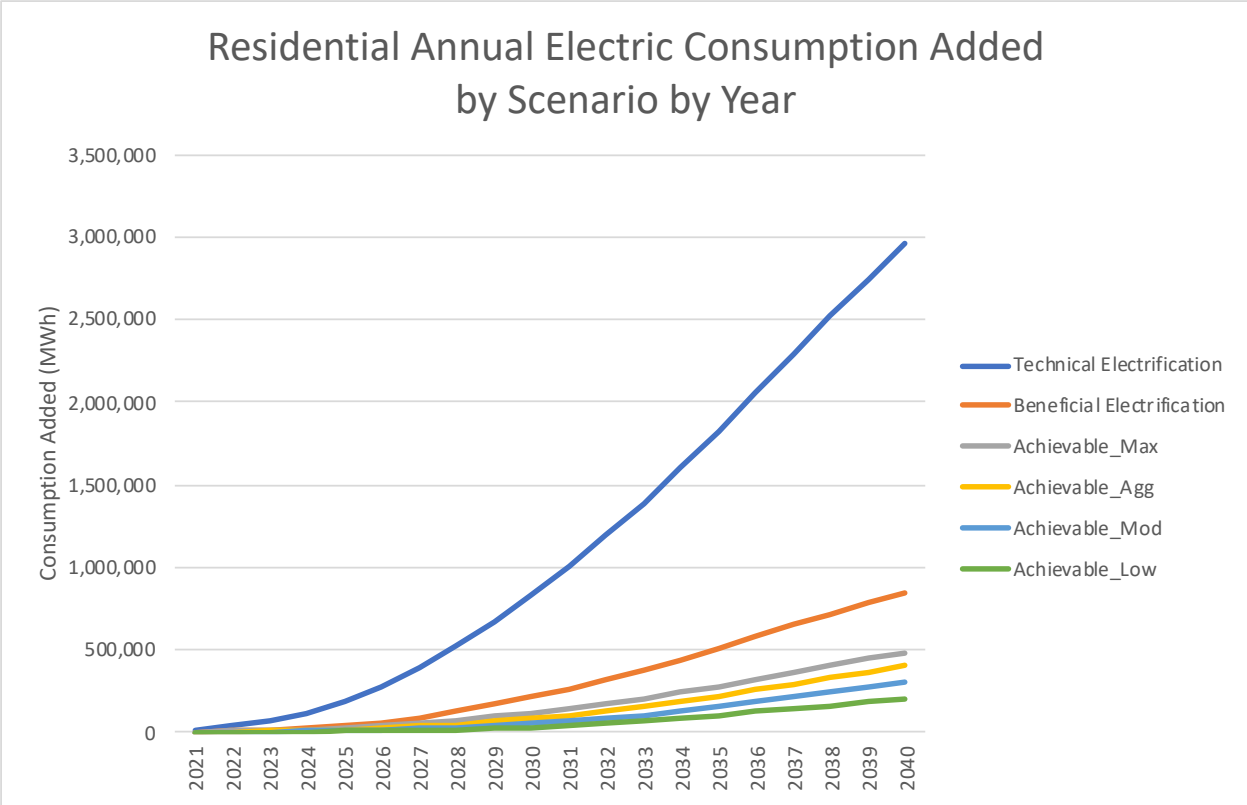

Figure 14 shows the estimated emissions reduction potential by scenario and by year. While in the technical electrification scenario, potential cumulative lifetime emissions reduction is estimated to increase to 11.5 million tons of CO_2 by 2040, the achievable-maximum scenario is estimated to net roughly one-quarter of that amount.

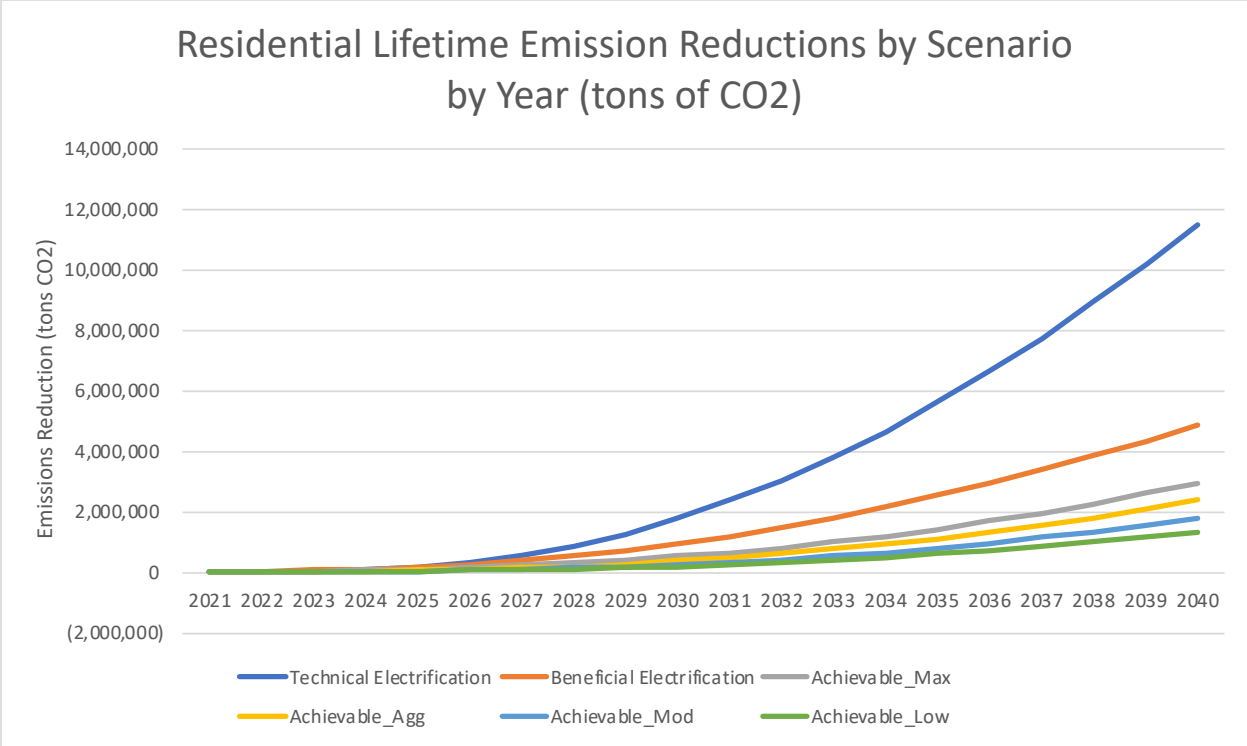
Figure 14. Residential Lifetime Emission Reduction by Scenario by Year (tons of CO_2)



As shown in Figure 15, electric vehicle measures make up approximately two-thirds of the potential electric load growth for the sector. The replacement of fossil fuel space heating equipment (boilers and furnaces) with heat pumps contributes 12 percent to the projected load growth, and heat pump water heaters contribute 21 percent. Less significant measures include electric and induction cooktops and battery-powered electric lawn and garden equipment, together contributing only about 2 percent to the overall project load growth by 2040.

Figure 15. Residential Electric Consumption Added Distribution by End Use

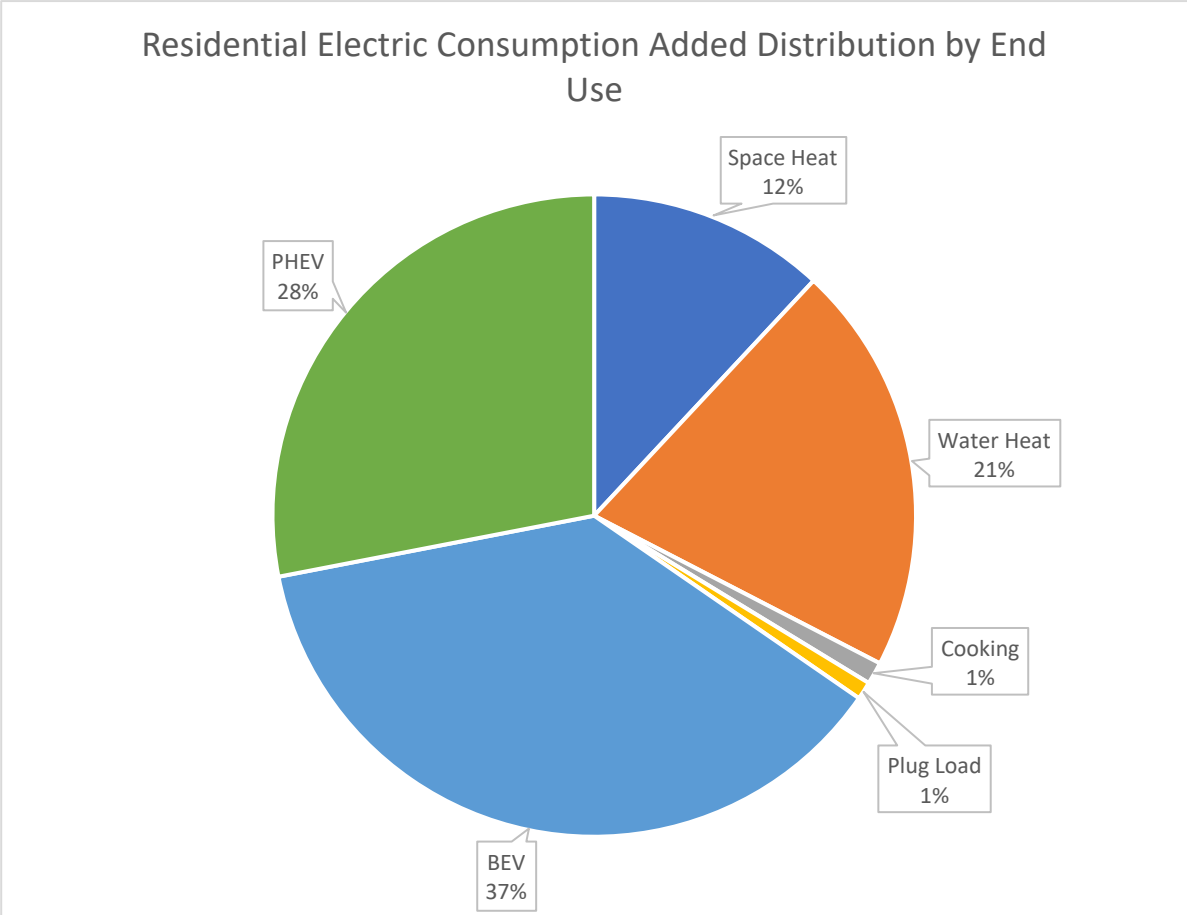


Table 14 presents cumulative program cost metrics by milestone year. As shown, first-year program costs are estimated at $1.4 million, rising to a 20-year average annual cost of approximately $18 million. Acquisition costs decline from $1,370/MWh in 2021 to $1,011/MWh in 2040. At the sector level all residential measures combine to produce TRC ratios of between 1.18 and 1.88 over the study horizon.

Table 14. Residential Sector Electrification Cost Metrics – Achievable-Moderate Scenario

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	CUMULATIVE ADDED CONSUMPTION (MWH)	ACQUISTION COST ($/MWH)
2021	1.18	$1,444,169	1,054	$1,370
2025	1.29	$14,335,776	11,201	$1,280
2030	1.47	$64,035,447	55,246	$1,159
2040	1.88	$368,948,548	365,013	$1,011
20-year avg.	1.88	$18,447,427	18,251	$1,011

5. COMMERCIAL BENEFICIAL ELECTRIFICATION POTENTIAL

5.1. Overview

The commercial sector accounts for 17 percent of the total baseline forecast energy load and accounts for 35 percent of cumulative energy load growth potential and 58 percent of potential emissions reduction by 2040. Cumulative electric load growth potential for this sector is approximately 231 GWh through 2040 (Achievable-Moderate scenario) with battery electric vehicle measures making up over 80 percent of that potential. Space heating and water heating make up the majority of the remaining potential contributing 7 percent and 12 percent of electric load growth, respectively. The Front Range Colorado region has the largest share of load growth potential in the sector at nearly half of the total. Apart from sector-wide EVs, which are applicable across all segments of the commercial sector, other segments with significant potential include restaurants, lodging, and healthcare facilities.

5.2. Detailed Results

Table 15 presents cumulative potential impacts for the commercial sector by scenario at various milestones in the analysis period and Figure 16 shows the growth in cumulative added energy consumption potential through 2040. Figure 17 shows the estimated reduction in carbon emissions by scenario and by year. The Achievable-Moderate scenario estimates 746 MWh of load growth potential in 2021 rising to 231,185 MWh of cumulative load growth potential through 2040. Pursuing an aggressive incentive approach (achievable-aggressive scenario) could increase cumulative load growth potential by approximately 12 percent. The maximum achievable scenario estimates load growth potential approximately 19 percent higher than the aggressive scenario, equating to cumulative increase in electric consumption of an estimated 305,767 MWh through 2040. This equates to an increase of nearly 9 percent of forecasted sector level baseline sales.

In the achievable-moderate scenario, the commercial sector is expected to provide a reduction in carbon emissions of over 3.7 million tons of CO_2 by 2040. The achievable-maximum scenario increases that number to nearly 4.6 million tons of CO_2 by 2040.

Table 15. Cumulative Commercial Electrification Impacts

2030	1,187,433	1,048,762	780,597	723,429	667,686	617,881
2040	9,731,811	7,653,812	4,594,217	3,941,140	3,707,709	3,504,180

Figure 16. Commercial Annual Electric Consumption Added by Scenario by Year

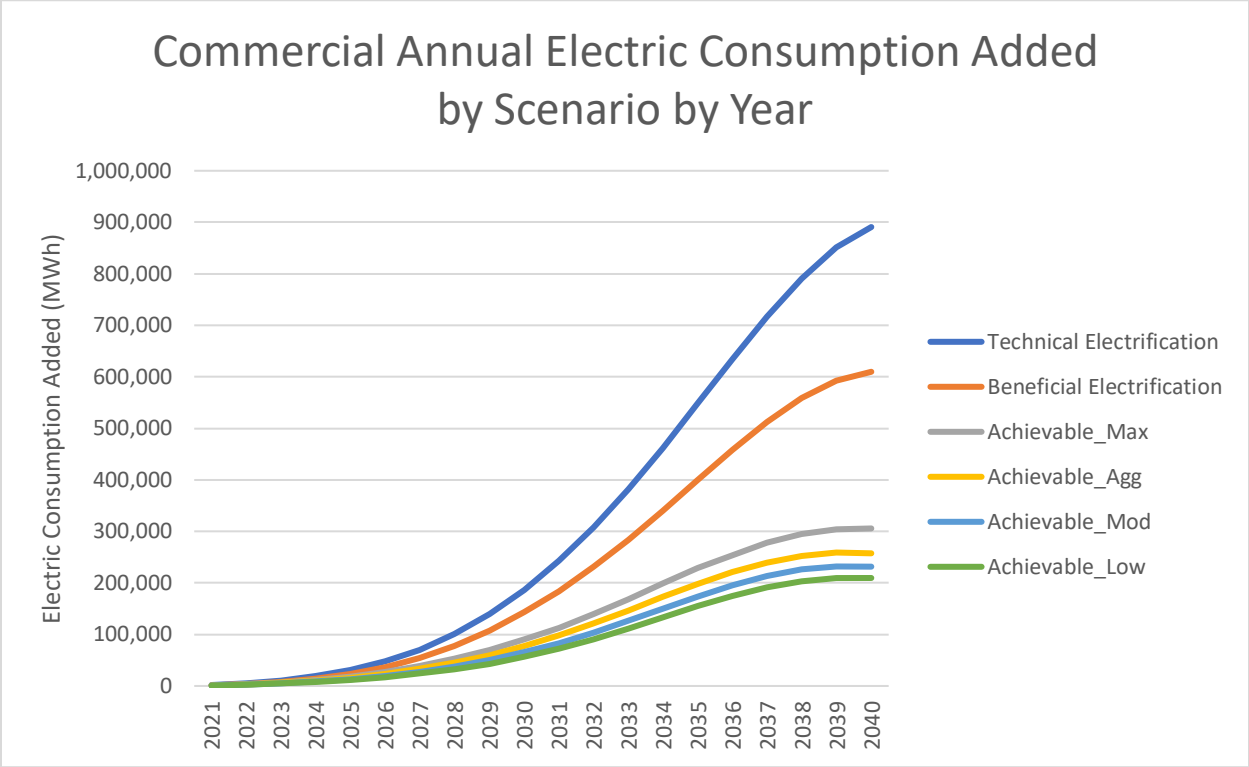

Figure 17. Commercial Lifetime Emission Reductions by Scenario by Year (tons of CO_2)

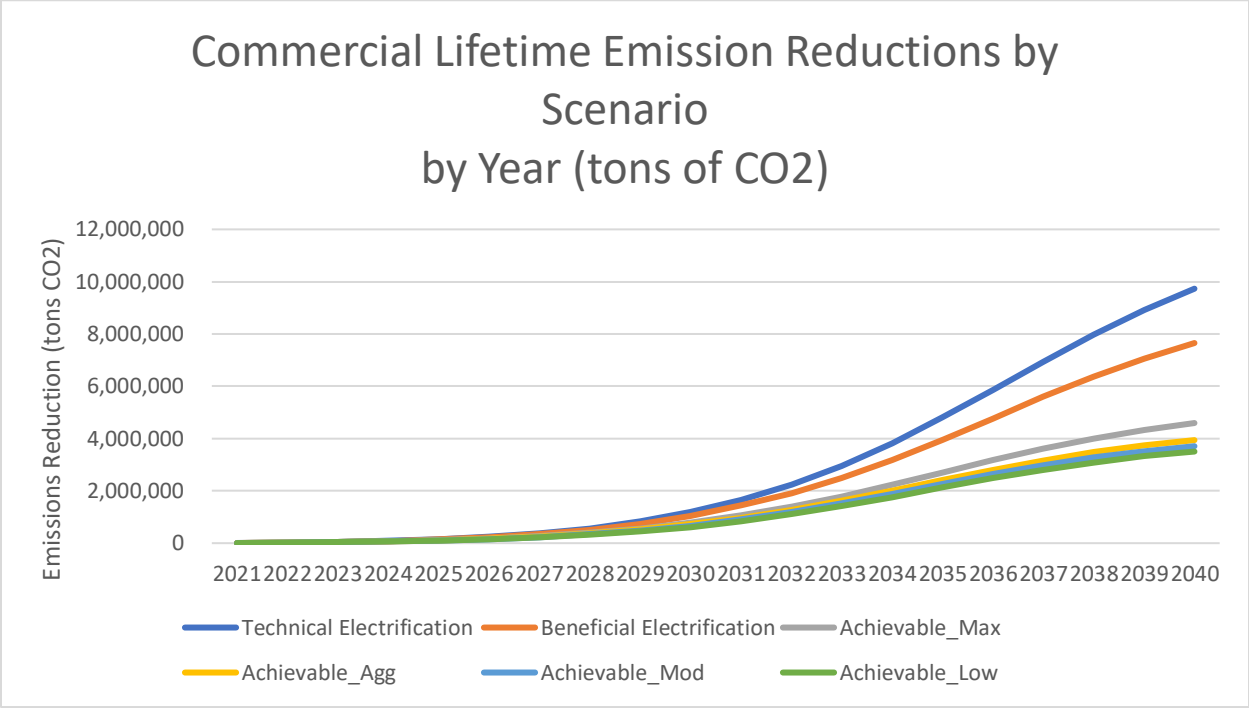

A large majority of both load growth and emissions reduction (over 80 percent in each case) in the commercial sector is attributable to electric vehicle measures. Figure 18 shows the potential increase in electricity consumption in the commercial sector broken down by end use. Apart from electric vehicles, the remaining 20 percent of load growth potential comes primarily from water heating (12 percent) and space heating (7 percent).

Figure 18. Commercial Electric Consumption Added Distribution by End Use

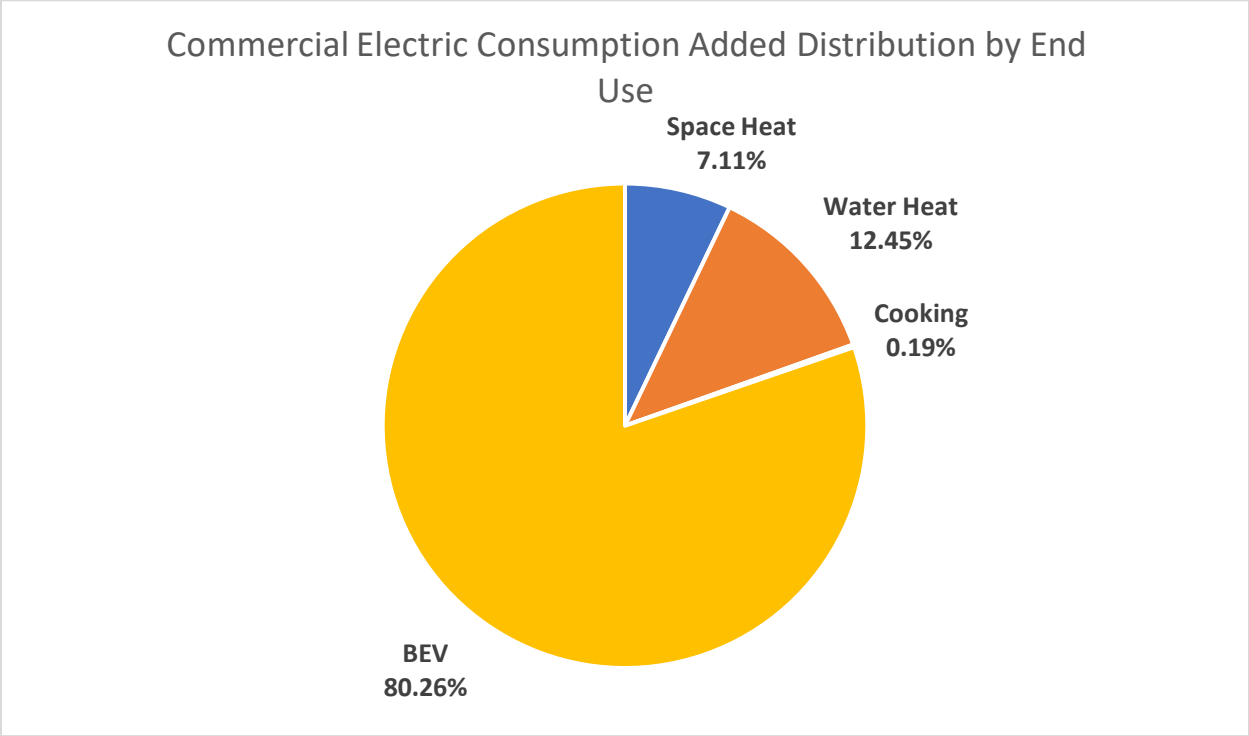

Figure 19 displays the breakdown of electric load growth potential by segment, excluding the sector-wide electric vehicle measures that constitute over 80 percent of the sector's potential. Of the remaining segments, restaurants, lodging, and health facilities contribute the largest shares of load growth potential accounting for 45 percent, 27 percent, and 11 percent of the non-EV potential in the sector, respectively.

Figure 19. Commercial Electric Consumption Added Distribution by Segment (excluding EVs)

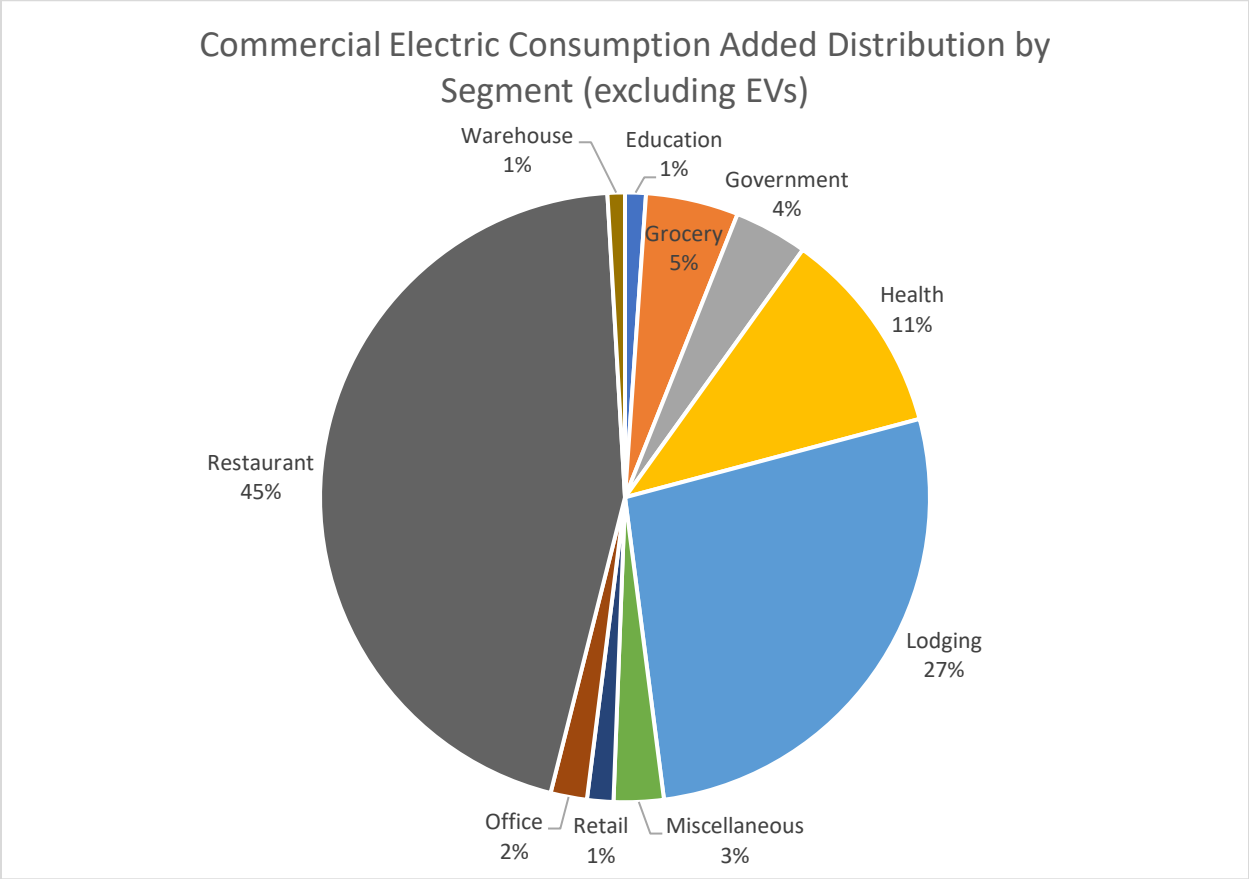

Table 16 presents cumulative program cost metrics by milestone year. As shown, first-year program costs are estimated at $409,700, rising to a 20-year average annual cost of approximately $8.7 million. Acquisition costs shift from $549/MWh in 2021, upward to $834/MWh by 2030, and back down to $585/MWh in 2040. At the sector level all commercial measures combine to produce TRC ratios of between 1.97 and 3.45 over the study horizon.

Table 16. Commercial Sector Electrification Cost Metrics – Achievable-Moderate Scenario

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	CUMULATIVE ADDED CONSUMPTION (MWH)	ACQUISTION COST ($/MWH)
2021	2.71	$409,700	746	$549
2025	1.97	$10,483,573	13,449	$779
2030	2.23	$54,797,334	65,703	$834
2040	3.45	$173,781,926	297,006	$585
20-year avg.	3.45	$8,689,096	14,850	$585

6. INDUSTRIAL BENEFICIAL ELECTRIFICATION POTENTIAL

6.1. Overview

The study analyzed pipeline transportation compressor station electrification to determine the impact of converting natural gas-powered compressor station motors to electric operation. There are estimated to be 68 compressor stations in the Tri-State service territory of which 10 currently operate electrically and 58 use natural gas. These stations have large motors with an average plant horsepower of nearly 15,000 HP. The measure was found to have large technical electrification impacts, having the ability to increase Tri-State's electric sales in the industrial sector by over 11 percent by 2040. This equates to over a 5 percent overall increase in forecasted energy consumption across Tri-State's service territory.

Compressor station electrification failed the BE screening process on the emissions reduction criteria. Many measures analyzed as part of this study passed the emission reduction screen due, in part, to an efficiency gain inherent in the equipment conversion. However, the motor efficiency in a natural gas compressor station represents a relatively small portion of the overall plant efficiency. The conversion from fossil fuel to electric motors improves the motor efficiency significantly, while the other components of compressor station plant efficiency remain unchanged through electrification. The study finds the impact of electrification in this application does not improve emissions reduction over the study horizon.

6.2. Detailed Results

As shown in Table 17, converting natural gas-driven pipeline compressor stations to electrically-driven systems in Tri-State's service territory would add over 1.1 million MWh of cumulative electric consumption by 2040. However, in doing so, an additional 2.2 million tons of CO_2 would be emitted.

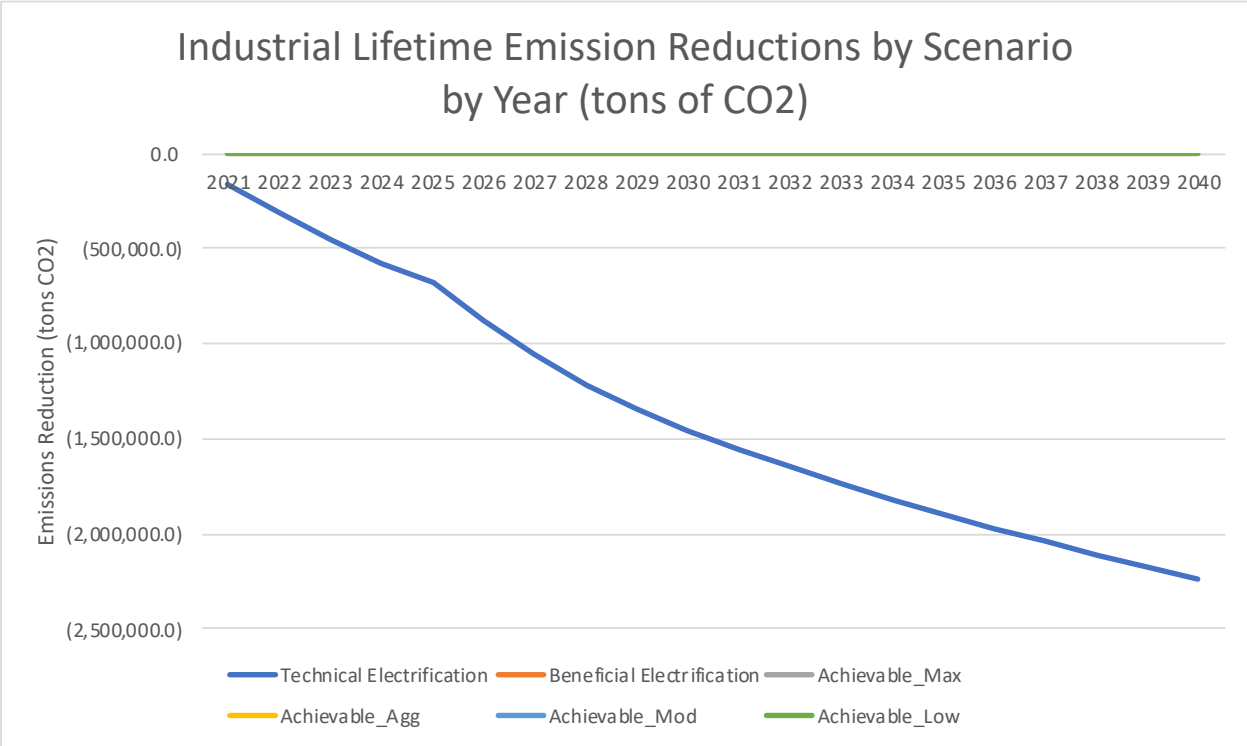
Figure 20 shows the negative emissions reduction (i.e. increased emissions) projected over the study horizon for the technical electrification scenario in the industrial sector.

Figure 20. Industrial Lifetime Emission Reductions by Scenario by Year (tons of CO_2)



7. IRRIGATION BENEFICIAL ELECTRIFICATION POTENTIAL

7.1. Overview

The irrigation sector represents approximately 8 percent of Tri-State's total baseline energy load and is projected to contribute nearly 15 percent of potential emissions reduction due to electrification. The study examined the electrification of irrigation pump motors, examining natural gas, propane, diesel, and gasoline baselines. Cumulative electric consumption growth potential for this sector is estimated at 121,641 MWh through 2040 (Achievable-Moderate scenario). Eastern Colorado represents the greatest potential for the sector, contributing nearly half of load growth and emissions reductions.

7.2. Detailed Results

Table 15 presents cumulative electric consumption growth potential for the irrigation sector by scenario at various milestones in the analysis period and Figure 25 shows the growth in cumulative electric consumption potential through 2040. The Achievable-Moderate scenario estimates 724 MWh of added consumption potential in 2021 rising to approximately 121,641 MWh of cumulative consumption growth potential through 2040. Pursuing an aggressive incentive approach (Achievable-Aggressive scenario) could increase cumulative electrification potential by approximately 50 percent. Energy consumption growth potential increases by an additional 30 percent under the maximum achievable

scenario, equating to a cumulative maximum achievable growth of approximately 252,744 MWh through 2040. This represents over 18 percent growth in the sector over the 20 year study horizon.

Figure 21. Irrigation Annual Electric Consumption Added by Scenario by Year

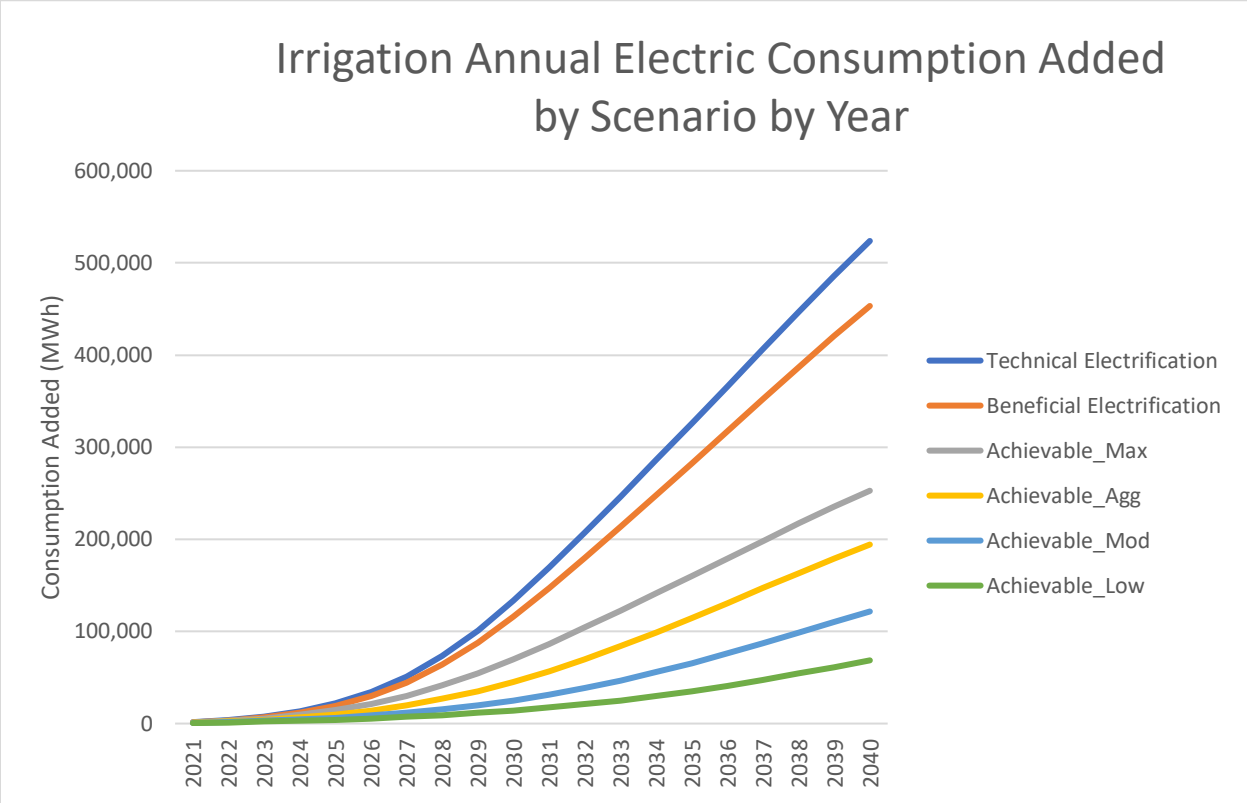

Figure 22 shows the net lifetime emissions reduction potential associated with irrigation electrification. The potential reduction in emissions for the sector approaches 1 million tons of CO_2 by 2040 in the achievable-moderate scenario.

Figure 22. Irrigation Lifetime Emission Reductions by Scenario by Year (tons of CO_2)

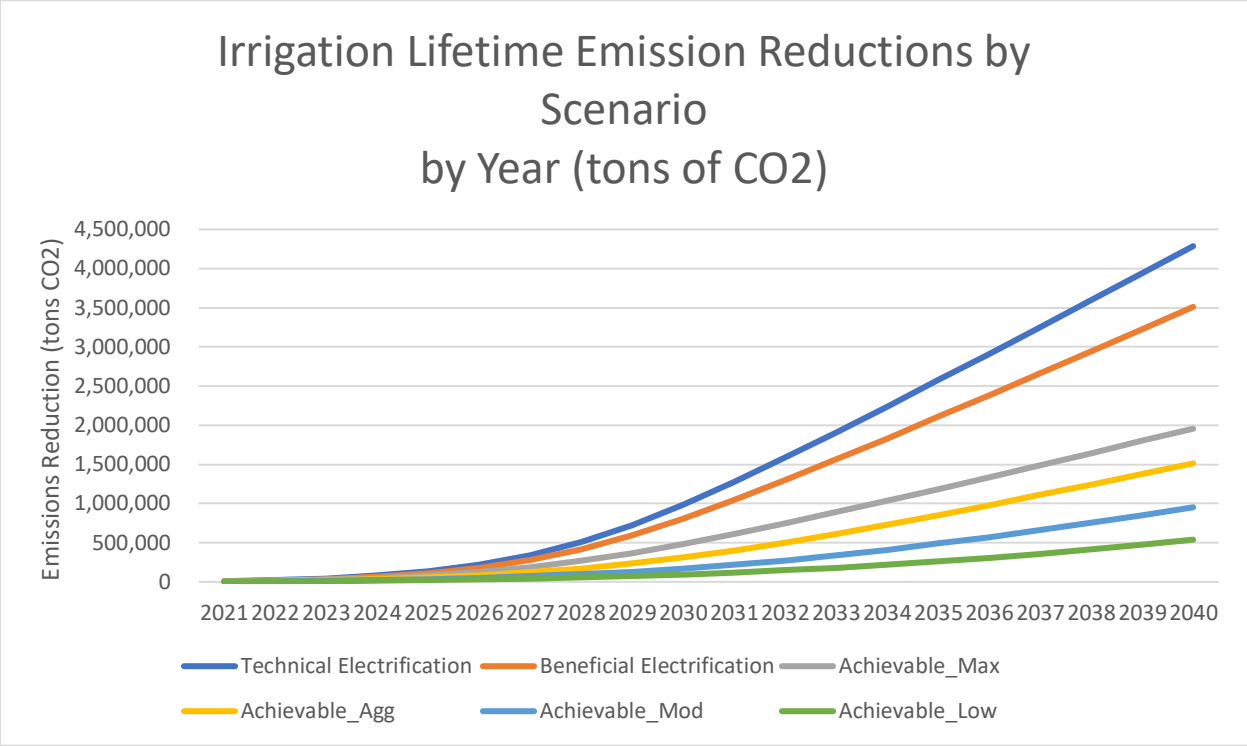

Figure 23 shows the projected breakdown of impacts on electricity consumption in the irrigation sector. Nearly half of the projected load growth is in the Eastern Colorado region, followed by approximately 20 percent contributed by Nebraska and 9 percent by Wyoming.

Figure 24 shows the breakdown of electric consumption impact by segment. In the case of the irrigation sector, and for the purposes of this study, segments refer to the fuel type associated with the baseline irrigation pump motor. The majority of potential comes from converting natural gas pump motors to electric (50 percent). Diesel pump conversions account for 37 percent, while propane pump conversions provide 13 percent of the project electric system growth for the sector.

Figure 23. Irrigation Electric Consumption Added Distribution by Region

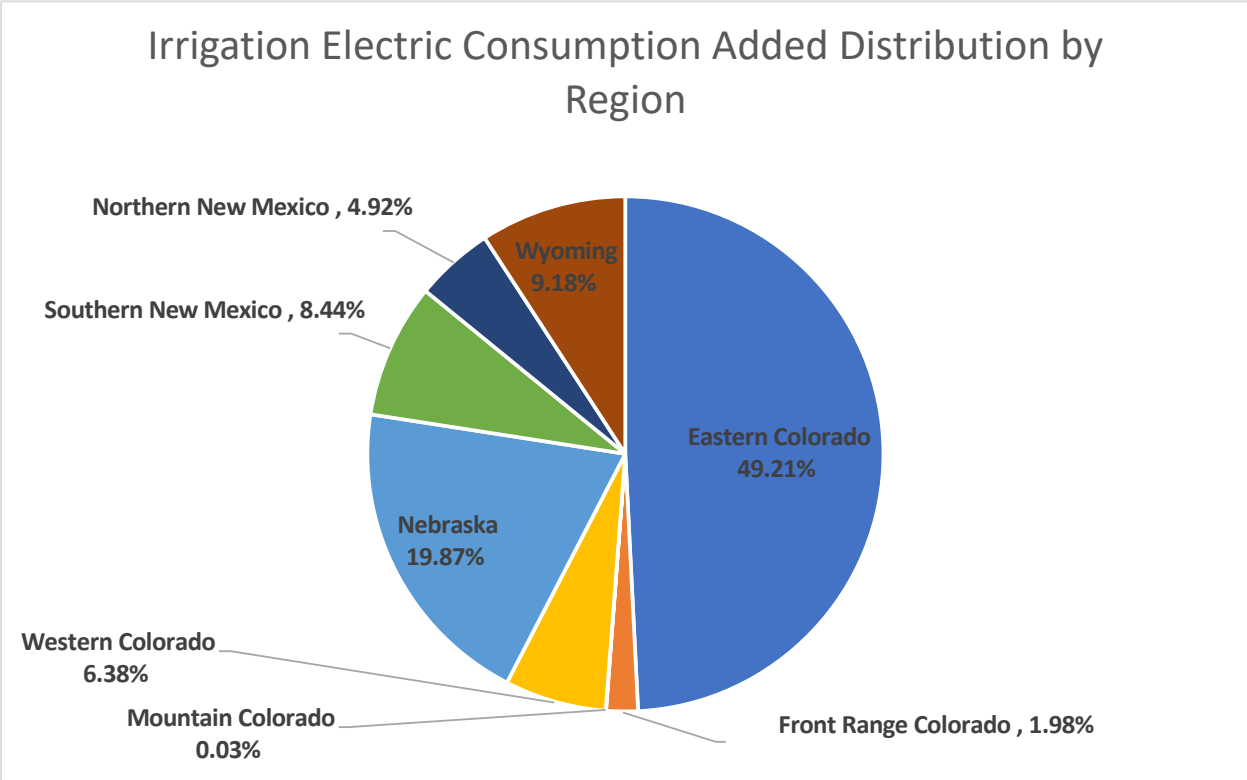

Figure 24. Irrigation Electric Consumption Added Distribution by Segment

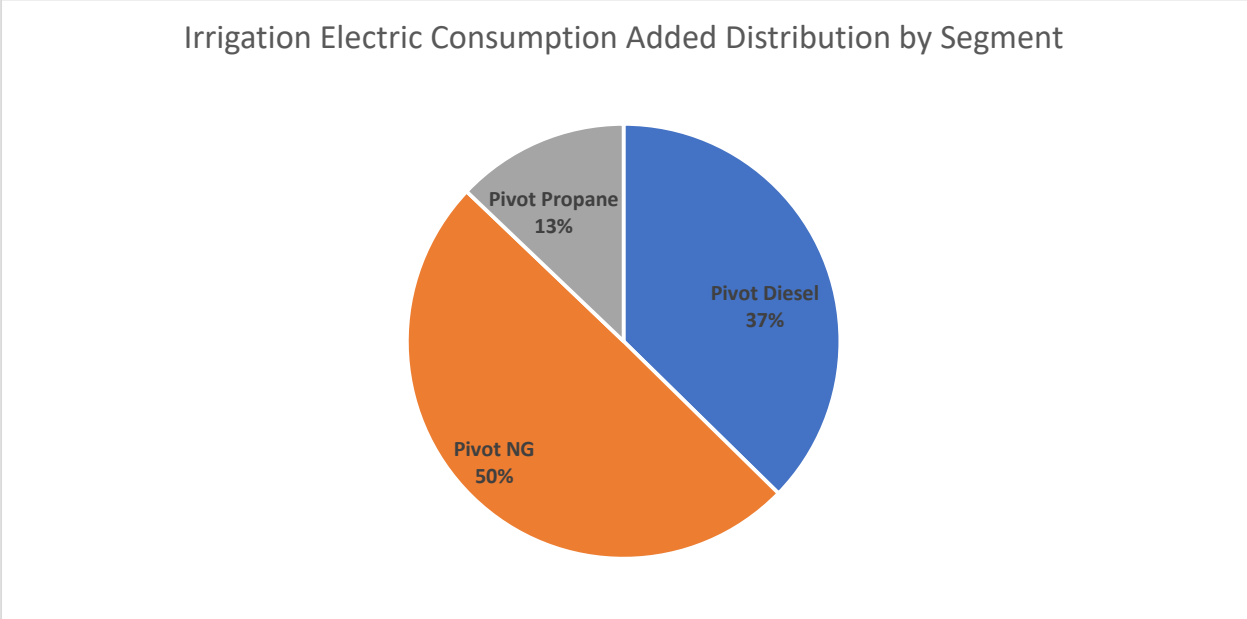

Table 19 presents cumulative and average annual costs, load growth, and TRC metrics associated with the Achievable-Moderate scenario for irrigation electrification measures. As shown, in the first year Tri-State can expect to see an increase in irrigation sector consumption of 724 MWh at a cost of approximately $87,593. As programs expand and become more established annual costs and load impacts increase substantially. The 20-year average annual program costs are approximately $747,027 and the impact on electricity consumption is 6,165 MWh.

Table 19. Irrigation Sector Electrification Cost Metrics – Achievable-Moderate Scenario

MILESTONE YEAR	TRC RATIO	PROGRAM COSTS ($)	CUMULATIVE ADDED CONSUMPTION (MWH)	ACQUISTION COST ($/MWH)
2021	1.20	$87,593	724	$120.95
2025	1.19	$756,645	6,255	$120.97
2030	1.18	$3,033,269	25,055	$121.06
2040	1.18	$14,940,547	123,309	$121.16
20-year avg.	1.18	$747,027	6,165	$121.16

8. KEY FINDINGS AND RECOMMENDATIONS

There are several key findings related to this potential opportunity for Tri-State, some of which are detailed below:

- Over the 20-year period analyzed in this study, Tri-State has the opportunity to reduce carbon emissions in its service territory by over 6 million tons of CO_2 by undertaking the achievable moderate approach to beneficial electrification. This would equate to an associated growth in electricity consumption of over 650 GWh annually, over 3 percent of Tri-State's forecasted baseline load, and a reduction in fossil fuel consumption of nearly 100 million therms across all baseline fuel types. The fossil fuel reduction is estimated to be approximately 20 percent of the total on-site natural gas consumption in Tri-State's service territory.
- Low conversion is a challenge. The difference between the beneficial electrification scenario and the maximum achievable scenario is large, suggesting market adoption is a hurdle to BE potential. Tri-State may benefit from studying innovative ways to increase the saturation level of these beneficial electrification technologies such as implementation strategies, marketing techniques, educational programs, and other techniques.
- Because Tri-State's carbon emissions rate is expected to shift substantially over the study horizon, some measures analyzed result in increased emissions in the early years of their measure life, but provide an emission reduction over the fossil fuel baseline in later years. An example is provided in Figure 10 showing the net emissions by year for a residential water heater measure. Examining the same set of measures over different time horizons and with

different forecasted emissions factors would affect the resulting beneficial electrification potential.

- Equipment load side efficiency gains are integral to passing beneficial electrification screening. As end use efficiency improves, the benefits from electrification also increase. For example air-source heat pumps are much more efficient than electric resistance furnaces, and air-source heat pumps pass BE screening, whereas electric resistance furnaces would not pass under current or forecasted conditions.

- As Tri-State's system-wide emissions rate improves, electrification becomes more beneficial from an emissions reduction standpoint. To continue the example above, were the CO_2 emission rate from Tri-State's generation to approach a range between 0.20 and 0.27 tons/MWh, electric resistance space heating measures would begin to exhibit reduced emissions compared to a fossil fuel baseline. Currently, Tri-State's emission rate is projected to be 0.34 tons/MWh at its lowest over the 20-year study horizon.

- Most measures that passed the beneficial electrification screening also had favorable TRC scores. Even including measures that passed the BE screening, but didn't pass the TRC test, the overall TRC at the portfolio level, and at each sector level, passed at a TRC threshold of 1.0.

- At the measure level, a small number of measures passed BE screening but had TRC scores less than 1. These include electric lawnmowers and leaf blowers, airport bag tractors and pushback tractors, and some permutations of on-road electric vehicles. However, the large majority of measures that exhibit a PCT score greater than 1 also exhibited a TRC score greater than 1. These details can be explored at the measure level in the electronic reporting tool associated with this report.

- When designing traditional DSM programs, energy efficiency measure incentives are often established based on a percentage of the estimated incremental cost of the measure. With BE measures, however, the cost of the electric version of a particular technology is often similar to or lower than the fossil fuel option. Because direct customer incentives are a proven method for driving market adoption of a particular technology, alternative approaches to establishing those incentives may be required for certain measures, such as setting incentives at a percentage of the full measure cost. Additional barriers to adoption may include lack of awareness of electric alternatives to fossil fuel technologies or hesitation to adopt an electric alternative due to lack of knowledge of their operation and reliability. Careful consideration should be taken by Tri-State with respect to the balance between direct customer incentive payments and marketing and outreach efforts.

- There is a large amount of usage in natural gas compressor stations and other pipeline pumping operations but these measures do not pass BE screening at any projected emissions rate. Based upon the Team's calculations, the average electricity consumption of compressor station plants (on an energy per horsepower basis) in the service territory does not represent a significant enough improvement over the natural gas consumption (on an energy per horsepower basis) to result in a net emissions reduction.

- Battery electric vehicles and plug-in hybrid electric vehicles represent the largest opportunity for Tri-State to reduce emissions in the service-territory while increasing electric load on the grid.

- Small light-duty battery-powered electric vehicles provide the largest opportunity for load growth for Tri-State and exhibit a TRC score greater than 3. Of the seven largest contributors to load growth potential, forklifts provide the highest TRC score, greater than 7 for both classes of forklifts.

APPENDIX A. MODELED ELECTRIFICATION MEASURES

A variety of measures were analyzed for input into the beneficial electrification potential model. This Appendix provides additional detail on the measure permutations, energy impacts calculation approach, and resources relevant to each measure.

Electric Lawn and Garden Equipment

The study analyzed several residential lawn and garden measures, including battery-powered:

- Lawnmowers
- Leaf blowers
- Snow blowers
- Chainsaws
- Trimmers, edgers, and brush cutters

Average annual fossil fuel energy consumption for these pieces of equipment was calculated using average equipment horsepower, average annual hours of operation, and brake-specific fuel consumption (BSFC) in gallons per horsepower-hour. Electricity consumption from a battery-powered electric analog was calculated using the output energy estimated for the fossil fuel equipment and applying factors to account for DC/DC roundtrip battery efficiency from charge and discharge cycles, as well as power conversion system efficiency to convert AC to DC at the charger.

Information on average run times, horsepower, and BSFC was drawn from a technical paper associated with the Environmental Protection Agency titled *National Emissions from Lawn and Garden Equipment*[19]. Battery efficiency characteristics were sources from a U.S. DOE paper titled *Energy Storage Technology and Cost Characterization Report*[20].

Heat Pump Water Heating

The study analyzed the conversion of natural gas and propane water heaters to electric heat pump water heaters in the residential sector and applicable segments of the commercial sector. Measures included installation in locations with and without DX cooling and considered the interactive effects on space heating and cooling. Baseline fossil fuel and proposed electricity consumption was calculated adapted from methodologies in Xcel Energy's 2019/2020 DSM Plan's Technical Reference Manual

[19] Banks, J. L., PhD, MS, & McConnell, R. (n.d.). *National Emissions from Lawn and Garden Equipment* (Tech.).

[20] U.S. Department of Energy. (2019, July). *Energy Storage Technology and Cost Characterization Report*. https://www.energy.gov/sites/prod/files/2019/07/f65/Storage%20Cost%20and%20Performance%20Characterization%20Report_Final.pdf

appendix[21]. The calculations relied on inputs including average gallons per day of hot water demand, storage temperature, supply water temperature, draw pattern, and energy factor.

Heat Pump Space Heating

The study analyzed the conversion of natural gas and propane furnaces and boilers to air-source heat pumps in the residential sector and applicable segments of the commercial sector. Measures included installation in locations with and without existing DX cooling and with and without existing ductwork (in the case of a fossil fuel boiler baseline). Baseline fossil fuel and proposed electricity consumption was calculated based on methodologies from Xcel Energy's 2019/2020 DSM Plan's Technical Reference Manual appendix[21]. The calculations relied on inputs including system capacity, baseline fossil fuel efficiency, baseline cooling SEER (if applicable), proposed SEER and HSPF, and heating and cooling equivalent full load hours.

For systems being installed where no ductwork currently exists, the full cost of installing ductwork was taken into account for measure cost estimation.

Electric Cooking

Converting natural gas cooktops to electric resistance and induction type cooktops was analyzed for both the residential and applicable segments of the commercial sector. For residential applications, the Team utilized average annual consumption figures drawn from an Electric Power Research Institute (EPRI) white paper, *Induction Cooking Technology Design and Assessment*[22], for gas, electric, and induction type cooktops. For commercial applications, the Team utilized a methodology from the Minnesota Technical Reference Manual, version 3.0 along with inputs from a D.O.E. Building Technologies Office paper[23], *Energy Savings Potential and Research, Development, & Demonstration Opportunities for Commercial Building Appliances*[24].

Oil and Gas Pipeline Transportation Compressor Stations

The study analyzed the electrification potential for natural gas (or other) pipeline transportation compressor stations in the Tri-State territory. The Team drew from an ArcGIS data set published by the Department of Homeland Security to identify counts of natural gas-driven and electrically-driven

compressor stations in the service territory[25]. There are approximately 68 stations in the region, 10 of which currently operate off of electricity. Data was drawn from the data set to estimate the average annual consumption per horsepower, in natural gas or electricity, for the specific plants in the territory. That data was used, along with average plant total horsepower, to establish the annual consumption by fuel type for these large plants. Cost data was also available from this resource.

Irrigation Pumping Electrification

To identify fossil fuel consumption and electricity consumption for the relevant types of irrigation pump motors, the Team drew from a University of Nebraska report on energy use in irrigation pumping[26]. The resource identified typical water-horsepower-hours per fuel unit which was used to determine average therms of natural gas, propane, diesel, and gasoline per water-horsepower-hour. To determine average pump motor runtime, the Team analyzed Tri-State-specific consumption data for irrigation accounts in each region to determine an average pump run time by region. The therms per water-horsepower-hour values were multiplied by the regional pumping hours figures, as well as by the stipulated horsepower determined by the measure definition, to determine fossil fuel baseline consumption. A kWh per water-horsepower-hour value was used similarly to determine the electricity consumption in the proposed case.

On-road vehicles

The potential study defined on-road vehicle measures based on gross vehicle weight rating (GVWR) according the Federal Highway Administration classification system:

- Light-duty vehicles – GVWR <10,000 pounds
- Medium-duty vehicles – GVWR 10,001 – 26,000 pounds
- Heavy-duty vehicles – GVWR >26,001 pounds

Light-duty vehicles represented the largest sample of analyzed vehicles, and the team stratified light-duty vehicles as small, medium, large passenger vehicles and light-duty trucks. These strata are approximate to vehicle Class 1 (small and medium light-duty vehicles) and Class 2a (large light-duty vehicles and light-duty trucks). Medium-duty vehicles are represented as delivery step vans for the purpose of this potential study. Finally, heavy-duty vehicles are represented as school bus and transit bus vehicles.

Off-road vehicles

Airport Ground Support Equipment

Airports are serviced by various forms of ground support equipment (GSE) to assist in air travel operations. Among the various GSE, the team reviewed the following technologies as opportunities for electrification:

- Pushbacks
- Tow tractors
- Belt loaders

These three GSE are typically operated as ICE vehicles; however, the aviation industry has begun adopting electric counterparts for these GSE over the past decade. The transition has been gradual with market estimates of approximately 10 percent electric GSE market saturation.

Electric Forklifts

Forklifts are categorized based on multiple classes that span Class I through Class VII with each class forklift intended for specific abilities and operation in specific environments. Class IV and V forklifts are most prevalently ICE vehicles. However, research conducted by EPRI[27] on behalf of Tri-State found the market offers electric equivalent forklift models for all class IV forklifts and 80 percent electric equivalent forklift models for class V forklifts. Class IV forklifts are characterized as counterbalanced with cushioned or solid tires designed for indoor usage whereas and Class V forklifts are characterized as counterbalanced with pneumatic tires intended for outdoor usage.

Electric Parking Space Infrastructure: *Truck Stop Electrification*

Electric parking space technologies considered in this analysis included truck stop electrification (TSE) and electric transport refrigeration units (eTRU). These systems allow truck drivers to shut down their diesel engines while at truck stops by relying on electricity rather than the truck's engine to provide power for necessities such as cab plug loads or HVAC as well as cargo refrigeration. For TSE, the team reviewed on-board electrification commonly known as shore power in which truck stops are equipped with parking spaces with electric infrastructure that provides a pedestal providing electric power that the truck is able to connect to via a heavy duty extension plug. A competing TSE technology known as off-board electrification is available and provides amenities to trucks such as cooling, heating, plug load, internet, etc. via a module that connects to the truck's cab side window. However, these systems are less prevalent relative to the shore power option due to higher installation costs, operating costs, and market trends at time of reporting. For these reasons, only shore power TSE technology was considered in the potential analysis.

eTRU technology is broadly defined in this report as trailers that have the ability to be powered by grid-supplied electricity. Various TRU technologies are available on the market; however, for the purposes of

[27]EPRI Electrification Initiative. Tri-State Generation and Transmission Association, Inc. Case Study Report, 2016.

this report, we focus on eTRUs that have the option to be powered via shore power when parked at a truck stop. These eTRUs are connected to pedestals like the TSE described above but provide three phase 480 volt power supply to the eTRU. In doing so, the truck driver is able to rely on the electricity provided through the grid rather than on the eTRU generator powered by the truck's diesel engine.

APPENDIX B. EV POTENTIAL ASSESSMENT APPROACH ADDITIONAL DETAILS

As mentioned several times in the body of the report, the assessment of electrification potential for electric on-road and off-road vehicles and related electric parking infrastructure measures involved alternate approaches to several aspects of the study. EV measures are less related to customer premise counts and forecasts than the other measures analyzed as part of the study which can be readily tied to buildings/premises. Some ways in which the approach to analyzing EV measures differed were identified in the body of this report. Additional details on those methods are described in this Appendix.

Beneficial Electrification Screening

As discussed in Section 2.5.2, the team screened each electric vehicle technology against a set criteria qualifying beneficial electrification including impacts on the environment, quality of life, cost savings for the end user, and grid resiliency. As noted, this screening process is largely qualitative to assess if the beneficial electrification technology can successfully contribute a neutral or positive impact within each category. Similar to building technologies, the team assessed electric vehicles based on greenhouse gas and criteria pollutant net emission impacts, technology capital and O&M costs, as well as the technology's ability to reduce stress on the grid. The findings of this screening exercise are discussed in this section.

Cost Effectiveness Screening

As presented in Section 2.5.2, the team calculated PCT cost effectiveness for each measure based on net cost savings for the customer, tax credits, and incentives (benefits) and incremental cost, installation cost, and maintenance costs (costs). TRC cost effectiveness for each measure was based on benefits including reduced net emissions and net O&M savings, while costs were based on initial incremental capital costs and avoided energy costs. Discussed below are the processes used to estimate incremental costs for each EV technology assessed in this potential study.

Incremental Costs (Capital and O&M)

The team performed cost research on a variety of sources ranging from current market data to literature review of secondary research. Our approach to assessing incremental costs included review of capital costs for the purchase of the electric vehicle and its ICE equivalent as well as the incremental cost of operation and maintenance (O&M) between the two technologies. O&M costs are typically negative as electric vehicles usually have lower fuel costs and reduced maintenance requirements[28]. These parameters informed the cost effectiveness analysis to determine the various benefit-cost ratios.

Of the technologies reviewed, data for on-road vehicles was most prevalent. Incremental capital costs were gleaned primarily from manufacturer websites that had both ICE and equivalent electric vehicle models; however, certain information for measures such as the heavy-duty vehicle were sourced from secondary studies. We additionally developed permutations of on-road vehicles in the residential sector that included and excluded the cost of purchasing and installing charging equipment in a home. The team defined fuel costs for on-road vehicles based on fuel economy rates (both electric and gasoline

[28] Vehicle and/or equipment depreciation was not included as an O&M cost as part of this study.

mileage rates) provided by the Environmental Protection Agency (EPA) and annual vehicle miles travelled (VMT) provided by the Federal Highway Administration (FHA) and the Argonne National Laboratory's Alternative Fuel Life-Cycle Environmental and Economic Transportation (AFLEET) model. Maintenance cost estimates were based on various secondary studies and data that provided information on the lifetime costs associated with repairs and general maintenance for ICE vehicles and their electric counterparts.

We assessed incremental costs for off-road technologies based on the same parameters outlined above for on-road vehicles. Each category of off-road vehicles – forklifts, airport GSE, and TSE – were reviewed using secondary data sources. The team leveraged prior research conducted by EPRI[29] on behalf of Tri-State to develop capital and O&M costs for forklifts and charging equipment. To assess costs for the various airport GSE, the team used the Idaho National Laboratory's GSE Cost Model v1.1 which provides capital and operating costs for ICE and electric bag tractors, belt loaders, pushbacks as well as GSE charging equipment. Finally, TSE costs were defined based on literature reviews of various TSE pilot programs.

Estimate Load Growth Potential

Load growth is characterized as the increased electricity consumption resulting from the replacement of ICE vehicles to electric vehicles. For the purposes of this analysis, the team assumed a one-for-one substitution between the ICE and electric vehicles thereby assuming that each technology operates for the same number of miles driven or hours operated. Load growth estimation begins with understanding the expected forecast of ICE vehicle stock across the study timeframe and estimating the portion of that stock that can and will be converted to electric technology as characterized as technical and achievable potential, respectively. Due to the various electric vehicle technology types, the team completed independent analyses to estimate overall load growth.

Technology Forecasts

The team used various approaches to estimate the forecast for each relevant electric vehicle technology using both bottom-up and top-down methods of estimation. With the exception of the residential on-road electric vehicle forecast which is derived based on the disaggregated forecast, each technology forecast was constructed outside of the forecasting methods described in Section 2.2, as these technologies did not conform with the forecast taxonomy. However, these independent forecasts did follow the same principles described in that section and used Tri-State data when applicable. For example, naturally occurring adoption for electric vehicles in Colorado is expected to be greater relative to non-Colorado regions due to aggressive state policy and funding. This assumption is applied to both the residential on-road forecast and is also carried through to commercial fleets, airport GSE, and forklifts in Colorado, as these are all eligible technologies for Colorado state funding. Forecast methods for each EV technology are described in this section.

[29] EPRI Electrification Initiative. Tri-State Generation and Transmission Association, Inc. Case Study Report, 2016.

On-road Electric Vehicles

The on-road vehicles are comprised of both the residential and commercial sectors. To estimate the residential on-road vehicle stock and forecast, the team was able to leverage the existing residential forecast of households across the Tri-State territory. We applied a multiplier to each household to serve as a proxy for the number of vehicles owned per household. The team assumed an average of 1.9 vehicles per household[30]. After applying the multiplier to estimate the total residential vehicle stock, we extrapolated the forecast based on residential growth rate for each Tri-State region derived from the disaggregated forecast. To calculate the percentage of these stock forecasts that serve as potential for conversion to either plug-in hybrids (PHEV) or battery electric vehicles (BEV), the team applied various electric vehicle sales forecasts by state to estimate the amount of naturally occurring adoption. For the states of New Mexico, Wyoming, and Nebraska, the natural occurring adoption was considered less aggressive due to minimal state policy and was modeled based on the US Energy Information Agency's 2020 Annual Energy Outlook base case sales scenario. Colorado, however, has very aggressive policies oriented at electric vehicle adoption and charging infrastructure build out. To estimate this natural occurring adoption, the team used a Colorado-specific electric vehicle sales forecast which reflects near-term investments planned by the state[31]. The remaining vehicle stock net of natural occurring adoption serves as the basis for the technical and achievable potential analysis for residential on-road electric vehicles.

Unlike the residential vehicle stock, the commercial vehicle stock is considered to be far more heterogeneous insofar as vehicles in the commercial sector serve a wider range of customers and segments. The team narrowed its commercial on-road vehicle forecast analysis to the following vehicle types and categories:

- Public fleets
  - Municipalities, counties, school districts
    - Transit buses, school buses, light-duty vehicles
- Private fleets
  - Company fleets
    - Medium-duty vehicles

To estimate the public fleet forecasts, the team conducted a linear regression analysis based on municipal fleet size relative to the associated population based on various locations throughout Tri-State's Colorado territory. We subsequently applied the regression model to the populations of each non-Colorado cooperative served by Tri-State to estimate public fleet sizes for those locations. As many public fleets are comprised of both vehicles and equipment, we estimated approximately 40 percent of fleet units are vehicles based on select municipal data. Having established the estimated number of public fleet vehicles within each Tri-State region eligible for conversion to electric, the team calculated

[30] US Bureau of Transportation Statistics.

[31] Colorado Energy Office, June 2019.

the fleet forecast based on weighted average growth rates across the residential and commercial sectors derived from the disaggregated forecast discussed in Section 2.2.

The analysis of private fleets focused on medium-duty ground delivery and freight vehicles. To derive the forecast for each vehicle type, our analysis relied on data from private fleets owned by United Parcel Service (UPS) and FedEx. The team located all UPS and FedEx customer centers and shipment centers for ground delivery and service centers for freight in Tri-state's territory based on maps and company inventories. Using a national average number of vehicles per facility, we estimated the total private fleet base size within Tri-State's territory. The forecast across the study timeframe is based on the disaggregated forecast growth rates.

The team estimated the total number of transit buses based on the population locations within Tri-state service area. Our analysis excluded cities and towns with a population fewer than 2,000 with the exception of specific towns that have low populations but high visitation from non-residents which consequently support the presence of a transit bus system. We assumed the average number of buses per 1,000 people as 0.5 to 1.2 based on research provided by the World Bank Group and PPIAF[32]. With these data, we estimated the number of transit buses based on each Tri-State region's population and extrapolated the forecast across the study horizon using weighted residential and commercial growth rates from the disaggregated forecast.

Lastly, school buses were forecasted based on K-12 enrollment in all school districts within Tri-state service area. We assumed 55 percent of students will ride the bus to school[33]. To determine school bus capacity, we classified school districts into urban, rural and small rural designation. School buses in rural districts are assumed to have a smaller capacity as they travel a longer distance compared with those in urban areas. Based on the reported number of students, we estimated the total expected demand for school buses across Tri-State's service territory. The forecast growth rates are based on the residential sector disaggregated forecast.

Each of the above-described forecasts for public and private fleets as well as transit and public buses within the state of Colorado were further adjusted to reflect possible naturally occurring adoption. Specifically, we adjusted the forecast downward based on Colorado's Beneficiary Mitigation Plan[34] which may provide grant funding for the conversion of these vehicles from ICE to electric technology. These funds are expected to be administered from 2021 – 2023 but no indication of the level of funding to cities and towns within Tri-State's territory was available at the time of reporting. The team ultimately applied a conservative adjustment of five percent to each forecast for these three years. However, we do note that future policy and/or funding may further increase naturally occurring adoption such as a zero emissions vehicle standard for medium- and heavy-duty vehicles which was under consideration of adoption by the state of Colorado at the time of reporting.

[32] "Number of Buses per 1,000 Population." Urban Bus Toolkit, ppiaf.org. Accessed 8 July 2020.

[33] "School Bus." *Amalgamated Transit Union*, www.atu.org/work/school. Accessed 8 July 2020.

[34] Colorado Beneficiary Mitigation Plan Volkswagen, Audi, and Prosche Clean Air Act Settlements, September 2019.

Off-road Electric Vehicles

The team used various data sources and approaches to estimate stock forecasts for the off-road vehicle technologies analyzed in the potential study. The categories of off-road vehicles examined did not conform to the potential study's taxonomy described in Section 2.2. Therefore, the team developed custom forecasts similarly to how on-road commercial fleet vehicles were assessed.

Airport GSE reviewed in the analysis include pushbacks, tow tractors, and belt loaders. Our analysis of GSE centered on commercial airports within Tri-State's territory of which five were identified across the Western Colorado and Mountain Colorado regions. The team's approach to estimate the stock of existing GSE used data from each airport to estimate the number of pushbacks and derived ratios of the number of tow tractors and belt loaders to pushbacks based on secondary research. The average forecast growth rate for the GSE is based on the commercial operations forecasts cited in each airport's master plan. The GSE forecast was further adjusted to reflect possible naturally occurring adoption based on Colorado's Beneficiary Mitigation Plan[35] which makes grant funding available through 2023 for converting GSE from ICE to electric technology. Consequently, the forecast from 2021-2023 was adjusted downward by five percent.

Forklift forecasts are based on prior research conducted by EPRI[36] on behalf of Tri-State that provided an estimate of total forklift shipments to facilities within Tri-State's territory for Class I, II, III, IV, and V forklifts. We focused our analysis on Class IV and V forklifts as these technologies are typically built as ICE vehicles and eligible to be converted to electric technology. Leveraging data from the disaggregated forecast, the team allocated total forklift shipments to each state and region based on energy consumption. Growth rates associated with the disaggregated forecast were used to estimate increases in forklift shipments by state through 2040. To estimate total potential stock available for conversion, the team made adjustments to the forklift forecasts to account for technological constraints as well as possible naturally occurring adoption. Based on research completed by EPRI, it is assumed all ICE Class IV forklifts have an electric equivalent while 80 percent of ICE Class V forklifts have an electric equivalent. Therefore, the Class V forecast was reduced to account for this market technological constraint. The Class IV forklift forecast was also adjusted to reflect technical constraints of businesses and facilities that cannot accommodate charging schedules and/or infrastructure within their facility. As noted earlier, we further reduced the Colorado forecast for both classes of forklifts to account for Colorado's Beneficiary Mitigation Plan[37] which has set aside funding for forklift conversion to electric technology. These funds are expected to be administered from 2021 – 2023; the team adjusted the shipment counts for these years accordingly by five percent. These adjusted forecasts provided the basis for the technical potential assessment.

Electric Vehicle Infrastructure

Truck stop electrification (TSE) forecasts are based on prior research conducted by EPRI on behalf of Tri-State and secondary research. As TSE measures analyzed are associated with the availability of

[35] ibid.

[36] EPRI Electrification Initiative. Tri-State Generation and Transmission Association, Inc. Case Study Report, 2016.

[37] Colorado Beneficiary Mitigation Plan Volkswagen, Audi, and Porsche Clean Air Act Settlements, September 2019.

commercial truck stops, the forecasts assess the growth of existing truck stops across the project timeframe. EPRI's research identified all truck stops and associated parking spaces within Tri-State's territory. The team used this research to establish the number of truck stops within each state and Tri-State region. Forecasted growth of truck stops to 2040 was based on secondary research on demand for truck stop capacity[38]. Because there are currently no existing codes or standards nor known policies directly incenting the installation of TSE measures, the team did not adjust the forecast for any natural occurring adoption.

Technical Potential

The beneficial electrification study assessed potential for both load growth resulting from the conversion of transportation technologies to electric as well as the consequent reduction in use of transportation fuels and associated emissions. The team estimated these impacts by analyzing consumption of each measure technology based on various data sources as discussed below.

The on-road measures were comprised of various light-duty, medium-duty, and heavy-duty vehicles. The team calculated energy consumption based on vehicle miles travelled (VMT) and the efficiency of each vehicle based on miles per gallon for ICE technologies and miles per kWh for electric vehicles. The product of the vehicle efficiency and annual VMT determined the annual energy impact for the measure. For example, using the EPA-published miles per gallon and miles per kWh efficiencies for various light-duty vehicles with a GVWR less than 5,000 pounds, the team found an average ICE vehicle miles per gallon of 35.8 and an average kWh per mile of 3.5. Based on an annual VMT of 13,252 miles for the state of New Mexico, the expected avoided annual gasoline consumption was estimated at approximately 370 gallons while estimated electricity consumption was approximately 3,824 kWh. The team applied this approach to each on-road measure.

The team relied on various sources to estimate the impacts for off-road vehicles. Impacts associated with forklifts and TSE/eTRU were estimated based on primary research completed by EPRI[39] on behalf of Tri-State. The EPRI analysis provided data on electricity and fuel usage for these technologies. The team used these data in conjunction with other studies to validate, and if necessary, adjust parameter assumptions used in the EPRI study to estimate the impacts of forklifts and TSE/eTRU equipment. Airport GSE estimates were also based on secondary sources. Specifically, the team used data from an EPRI study (not specific to Tri-State) as well as data from the Idaho National Laboratory's GSE Cost Model (version 1.1) to estimate the electric and fuel impacts for each GSE technology type.

Achievable Potential

The approach to assessing achievable potential for electric vehicles followed the same logic and methods as outlined in Section 2.5.3. Similar to the analysis used for building measures, the Team defined adoption curves based on a Bass diffusion model. The data informing the adoption curves were based on two key parameter inputs:

[38] Estimating the Supply and Demand for Commercial Heavy Truck Parking on Interstate Highways. Virginia Transportation Research Council and Federal Highway Administration, December 2002.

[39] EPRI Electrification Initiative. Tri-State Generation and Transmission Association, Inc. Case Study Report, 2016.

- Maximum estimated number of vehicles and/or units eligible to be converted to electric
- Adoption rates based on customer willingness to participate

The team estimated the first parameter based on the technology forecast, i.e., the summation of units available for conversion to electric after accounting for naturally occurring adoption and any technical constraints. The second parameter of customer adoption is based on secondary data collected from the Midwest that surveyed both residential and non-residential customers. The team used data from residential customers who were asked their willingness to purchase an electric vehicle based on rebate values that covered a percent of the incremental cost. The survey did not ask non-residential customers specifically about converting existing vehicles and equipment to electric; therefore, the team used non-residential customers' response to willingness to install solar PV on their facility based on the number of years of investment payback as a proxy adoption rate. While the team acknowledges the disparity between solar PV and electric vehicles, we assumed this data as a proxy due to the fact that the adoption is based on investment payback which focuses decision making from an economic perspective and that both solar PV and electric vehicles are newer disruptor technologies. Future studies would benefit from primary data collection throughout Tri-State's territory. With these parameters defined, the Team developed Bass diffusion curves to approximate adoption at various incentive levels. Innovation and imitation coefficients were defined based on literature review of electric vehicle adoption models.

Estimate Emissions Reduction

Environmental Life Cycle Analysis

In order to estimate the CO_2 emission impacts resulting from the replacement of ICE vehicles with electric vehicles, the team defined analogous boundaries on the value chain for each energy source. We defined these boundaries beginning at the production of each energy source and ending with the energy consumption. For the fossil fuel-derived energy sources, including gasoline and diesel, the team conducted an environmental life cycle analysis to estimate the emissions associated with all processes beginning with the refining of crude oil to gasoline and/or diesel, delivery to distribution locations and retail stations, and combustion in end user vehicles. Similarly, we estimated emission impacts for the generation of electricity based on Tri-State's generation mix and transmission and distribution to charging infrastructure. No CO_2 emissions are associated with consumption of the electricity after being delivered to the electric vehicle.

The team used data from Argonne National Laboratory's AFLEET model to provide parameter estimates of CO_2 emissions resulting from the production, distribution, and combustion of conventional gasoline and conventional diesel. The AFLEET model provided parameters for upstream emissions (fuel refining and distribution to retail stations) and downstream emissions (combustion in ICE). The team used these data to develop emission factors per gallon of fuel consumed. Upstream CO_2 emissions comprise 16 percent of the total emissions for the value chain. To estimate CO_2 emissions associated with electric vehicles, we applied the hourly emissions forecast data provided by Tri-State (see Section 2.2) to the energy consumption of the electric vehicle inclusive of line losses.

APPENDIX C. NATURALLY OCCURRING ADOPTION OF ELECTRIC VEHICLES

As discussed in Appendix B, the Team reviewed and applied applicable naturally occurring adoption to most of the technologies in the electric vehicle study. Naturally occurring adoption was applied to technology forecasts with the purpose of calculating the total stock available of fossil fueled vehicles that could be converted to electric based on a Tri-State program intervention. The adjustment to the forecast for naturally occurring adoption is a standard process in potential study modeling which effectively isolates the potential opportunity a utility has to achieve its goals above and beyond a business-as-usual scenario. While energy efficiency potential studies typically represent naturally occurring adoption based on codes and standards, this beneficial electrification potential study bases naturally occurring adoption primarily on existing policies that incent uptake of electric vehicles.

While this study presents electric vehicles with naturally occurring adoption removed, the Team also assessed the impacts for electric vehicles inclusive of the vehicle stock that is expected to be converted through naturally occurring adoption. The purpose of this exercise is to present the overall load increase Tri-State could expect beyond any form of program intervention. The naturally occurring adoption adjustments made by the Team applied mostly to the Colorado regions due to significant state-level policies currently in place that provide various incentives for both the residential and commercial sectors to adopt electrified vehicles (conservative natural occurring adoption was also applied to on-road vehicles for non-Colorado regions). To include these impacts, the Team conducted separate model runs based on technology forecasts that did not adjust for naturally occurring adoption. This resulted in a larger available stock for conversion; however, in certain cases, the larger stock requires more years before reaching maximum market adoption. Of the two Reporting Tools provided with this report, and described in Section 2.5.4, one provides results *exclusive* of naturally occurring adoption of EVs and the other provides results *inclusive* of naturally occurring adoption of EVs.

Notes:

1 Project is not registered with WREGIS
2 Contract expired
3 For WAPA Colorado River Storage Projects (CRSP) and the Loveland Area Projects (LAP) the 5 year average REC allocation was used rather then actual generation because generation data is not differentiated by size.
4 RECs for Basin include 2019 MRETs accrual with estimates of known projects (207.58MW Prevailing Wind & 142MW Aurora Wind 2021, 200MW Northern Divide 2022, 128MW Wild Springs Solar 2023, 150MW Cabin Creek Solar 2024) (50% CF for wind and 25% CF for solar)
5 Colorado load determined by deducting 16% of Highline load and adding 17% of High West.
6 2% deducted from NM Load because RPS is based on Retail Sales
Generation from Member Net-Metering programs are not included

80% Carbon Reduction Version 1

Colorado Compliance

(current RPS as it pertains to a QWU and energy provided at wholesale)

Notes:

1 Project is not registered with WREGIS

2 Contract expired

3 For WAPA Colorado River Storage Projects (CRSP) and the Loveland Area Projects (LAP) the 5 year average REC allocation was used rather then actual generation because generation data is not differentiated by size.

4 RECs for Basin include 2019 MRETs accrual with estimates of known projects (207.58MW Prevailing Wind & 142MW Aurora Wind 2021, 200MW Northern Divide 2022, 128MW Wild Springs Solar 2023, 150MW Cabin Creek Solar 2024) (50% CF for wind and 25% CF for solar)

5 Colorado load determined by deducting 16% of Highline load and adding 17% of High West.

6 2% deducted from NM Load because RPS is based on Retail Sales
Generation from Member Net-Metering programs are not included

80% Carbon Reduction Version 2

Colorado Compliance

(current RPS as it pertains to a QWU and energy provided at wholesale)
