EXECUTIVE SUMMARY

Testimony of Mike Monasmith

INTRODUCTION

This Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) is a joint document being published by the U.S. Bureau of Land Management (BLM) and the California Energy Commission (CEC). It is in the interest of the BLM and the Energy Commission to share in the preparation of a joint environmental analysis of the proposed project to avoid duplication of staff efforts, to share staff expertise and information, to promote intergovernmental coordination at the local, state, and federal levels, and to facilitate public review by providing a joint document and a more efficient environmental review process. Additionally, both the National Environmental Policy Act of 1969 (NEPA) and the California Environmental Quality Act (CEQA) have provisions to promote the efficient preparation of joint documents in order to save resources and benefit the public.

This SA/DEIS contains U.S. Bureau of Land Management and Energy Commission staff (hereafter jointly referred to as staff) independent evaluation of the Genesis Solar LLC (applicant) Genesis Solar Energy Project (GSEP) application, which was filed with the BLM and CEC. The application filed with BLM is the BLM Application for a Right of Way Grant on BLM-administered land (CACA 048880), and the application filed with the Energy Commission is the Application for Certification (09-AFC-8). The SA/DEIS examines engineering, environmental, public health, and safety aspects of the GSEP, based on the information provided by the applicant and other sources available at the time the SA/DEIS was prepared. The SA/DEIS will also include for BLM a Draft Land Use Plan Amendment (Draft PA) to the BLM's California Desert Conservation Area Plan (1980) (as Amended).

The applicant has also applied for the American Recovery and Reinvestment Act (ARRA) Renewable Energy Grant Program. Two goals of the ARRA Renewable Energy Grant Program are to enhance America's energy independence and create near-term employment opportunities for Americans. To be eligible for these ARRA funds, the applicant must begin construction on the GSEP by the end of 2010.

This SA/DEIS serves as staffs' analysis of the engineering, environmental, public health and safety aspects of the proposed project, based on the information provided by the applicant and other sources available at the time the SA/DEIS was prepared. The SA/DEIS contains all analyses normally contained in an Environmental Impact Report (EIR) as required by the California Environmental Quality Act (CEQA), as well as all analyses required as part of an EIS prepared under the National Environmental Policy Act (NEPA). The SA/DEIS will be available for a 90-day public comment period beginning on April 9, 2010. The Notice of Availability (NOA) (published by the U.S. Environmental Protection Agency in the *Federal Register*) initiates the 90-day public review and comment period.

When considering a power plant project greater than 50 Megawatts (MWs) for licensing, the Energy Commission is the lead state agency under CEQA, and its process is

functionally equivalent to the preparation of an EIR. Similarly, BLM is the lead Federal agency for the NEPA review of the proposed Right-of-Way and possible Land Use Plan Amendment. The Energy Commission and the BLM are engaging in concurrent review processes. The following explains in more detail the steps each agency will take to complete review.

In support of its certification process, the Energy Commission staff has the responsibility to complete an independent assessment of the project's engineering design and its potential effects on the environment, on the public's health and safety, and whether the project conforms with all applicable laws, ordinances, regulations and standards (LORS). The staff also recommends measures to mitigate potential significant adverse environmental effects and conditions of certification for construction, operation, maintenance and eventual decommissioning of the project.

This SA/DEIS is not the decision document for these proceedings nor does it contain findings of the Energy Commission related to environmental impacts or the project's compliance with local/state/federal legal requirements. The SA/DEIS will serve as staff's testimony in evidentiary hearings to be held by the Committee of two Commissioners overseeing this case. The Committee will consider the recommendations presented by staff, the applicant, all parties, government agencies, and the public prior to proposing its decision. The entire Energy Commission will make a final decision, including findings after the Committee's publication of its proposed decision. The Commission's final decisions on power plant AFCs greater than 50 MWs are subject to judicial review by the Supreme Court of California (Pub. Res. § 25531.)

In support of the processing of the Right-of-Way (ROW) Application and land use plan amendment processes, the BLM has the responsibility to evaluate the environmental impacts of the proposed action, the No Action alternative, and other alternatives that may meet the purpose and need for the proposed project.

The BLM has determined that the proposed site for the Genesis project is not identified in the California Desert Conservation Area (CDCA) Plan as associated with power generation or transmission. The requested ROW cannot be granted unless such a grant would be consistent with the terms of the CDCA Plan. Therefore, BLM must amend the Plan to allow power generation and transmission at the proposed site as a prerequisite to granting the ROW. As part of the DEIS, BLM identify its preferred alternative and will also present a potential Draft PA to the CDCA Plan to allow for the project if a ROW is granted.

Following the 90-day public comment period, BLM and CEC staff will review and develop responses to comments provided by the public and other agencies and plan to publish the responses in August, 2010. Responses to the comments and other relevant information identified during the comment period will be incorporated into the Supplemental Staff Assessment/Final Environmental Impact Statement (SSA/FEIS), which will also identify for BLM a Proposed Land Use Plan Amendment (Proposed PA). The NOA (published by the EPA in the *Federal Register*) will initiate a 30-day protest period on the Proposed PA to the Director of the BLM. Protests regarding the Proposed PA must be sent in writing to the Director of the BLM and comply with the protest procedures described in 43 CFR § 1610.5-2.

Following resolution of any protests regarding proposed CDCA Plan amendments, BLM may then publish an Approved Plan Amendment and a Record of Decision (ROD) on the Project Application. The decision regarding the ROW grant is appealable to the Interior Board of Land Appeals upon issuance of the ROD.

PROPOSED PROJECT LOCATION AND DESCRIPTION

The GSEP is located approximately 25 miles west of the city of Blythe, California, on BLM-administered lands. The project area is south of the Palen/McCoy Wilderness Area and north of Ford Dry Lake and Interstate 10, and can be viewed in **Project Description Figures 1** and **2**. The proposed GSEP is entirely on Federal land. A summary legal description of the BLM ROW application is provided in the following Table.

Section	Aliquot	Estimated Acres
Township 6S, Range 19E, San Bernardino Base & Meridian		
4	S ½ except wilderness	260
5	All except wilderness	550
6	SE ¼	160
7	N ½ NE ¼	80
8	NE ¼, N ½ NW ¼	240
9	N ½	320
10	All except wilderness	580
11	SW ¼	160
13	NW ¼ except wilderness; SW ¼	280
14	N ¾, NW ¼, N ¾, NE ¼	240
15	N ½ NW ¼ , N ½ NE ¼	160
24	W ½ N ½	160
	Subtotal, T 6 S, R 19 E:	3,190
Township 6S, Range 18E, San Bernardino Base & Meridian		
1	S ½ except wilderness	290
2	S ½ except wilderness	260
3	S ½	320
4	All except wilderness	580
	Subtotal, T 6S, R18 E:	1,450
	Total, Modified ROW, 1/4/08	**4,640**

Source: BLM, Plan of Development, September 2009

The applicant is seeking a Right-of-Way grant with BLM for approximately 4,640 acres of lands. (The ROW application for the GSEP was originally 19,000 acres when filed in 2007). Construction and operation of the project would disturb a total of about 1,800 acres. As such, any difference between the total acreage listed in the Right-of-Way application (4,640) and the total acreage required for project construction and operation (approx. 1,800) would not be part of the ROW grant, if BLM decides to approve the project.

The Project area is located in east central Riverside County, where land use is characterized predominantly by open space and conservation and wilderness areas. The western portion of the county accounts for most of the developed area of the county, including urban areas and agricultural areas. The southeastern corner of the

county to the east of the Project also contains limited agricultural areas and rural development (Riverside County, 2003). The following Riverside County Assessor's Parcel Number's apply to the parcels within the overall ROW and linear corridor boundary: 810290005-810290008, 810410013, 810410019, 810410014, 810410026, 810410002, 810410021, 810410015, 810410022, 810410023, 810410027-810410029, 810420012, 818040010, 818070001-818101003, 818111008, 818112004,879020025.

The area designated within the Palo Verde Valley Area Plan occurs to the east of the Project and encompasses the developed and agricultural area in eastern Riverside County. The portion of the Palo Verde Valley Area Plan in the vicinity of the Project consists mainly of sparsely populated desert and mountain areas. The more populated and agricultural areas occur farther east of the GSEP in the vicinity of Blythe.

The Project is also located within the BLM California Desert Conservation Area Plan (CDCA Plan) (BLM, 1980), and is shown in **Project Description Figure 3**. The CDCA Plan establishes a number of conservation areas under the Wilderness Review Program. The Project is located adjacent to the southern boundary of the Palen/McCoy Wilderness Area. The Chuckwalla Mountains and Little Chuckwalla Mountains Wilderness Areas are also located farther south-southwest of the Project.

The Genesis project will utilize solar parabolic trough technology to generate electricity. With this technology, arrays of parabolic mirrors collect heat energy from the sun and refocus the radiation on a receiver tube located at the focal point of the parabola. A heat transfer fluid (HTF) is heated to high temperature (750°F) as it circulates through the receiver tubes. The heated HTF is then piped through a series of heat exchangers where it releases its stored heat to generate high pressure steam. The steam is then fed to a traditional steam turbine generator where electricity is produced.

MAJOR COMPONENTS OF THE PROPOSED PROJECT

The following items are some of the major components of GSEP. For a more exhaustive list, please see Section B.1.2., in the **Project Description** section.

Project Construction

Project construction is expected to occur over a total of 39 months. Project construction will require an average of 646 employees over the entire 39-month construction period, with labor requirements peaking at approximately 1,085 workers in Month 23 of construction. The construction workforce will consist of laborers, craftsmen, supervisory personnel, support personnel, and management personnel.

Temporary construction parking areas will be provided within the power plant site adjacent to the laydown area. The plant laydown area will be utilized throughout the build out of the two solar units. If approved, project construction would begin in the fourth quarter of 2010, with commercial operation commencing in the second quarter of 2013.

Operation and Maintenance

While electrical power is to be generated only during daylight hours, GSEP will be staffed 24 hours a day, seven days per week. A total estimated workforce of 40-50 full time employees will be needed once the GSEP is fully operational.

Transmission System

The GSEP generation tie-line would use the existing pole structures of the BEPTL to interconnect with Southern California Edison's proposed Colorado River Substation, to be located south and west of the city of Blythe, California.

Transmission Line Route

Project proposed new transmission line, along with a new access road and new natural gas pipeline will be co-located in one linear corridor to serve the main GSEP facility. This corridor would exit the facility to the south and would be approximately 6.5 miles long. The generation tie-line would cross Interstate 10 (I-10), and tie into the Blythe Energy Project Transmission Line (BEPTL), which is currently under construction.

Fuel Supply and Use

The auxiliary boiler will be fueled by natural gas supplied from a new six-mile, eight-inch pipeline connected to an existing Southern California Gas pipeline located north of I-10. The maximum estimated natural gas usage is expected to be 60 million standard cubic feet per year, for a maximum of 60,000 million British thermal units per year.

Water Use

The GSEP proposes to use a wet cooling tower for power plant cooling. Water for cooling tower makeup, process water (steam) makeup, and other industrial purposes uses such as mirror washing would be supplied from onsite groundwater wells, and stored in several on-site tanks. Storage tanks would contain raw water (500,000 gallons), treated water (1,250,000 gallons) and wastewater (250,000 gallons). Project cooling water blowdown would be piped to lined, onsite evaporation ponds (two 30-acre ponds that will be covered by nets to discourage migratory and local bird usage). After used project water has gone through the evaporation process, the solids that settle at the bottom of the evaporation pond will be periodically tested by the applicant, and removed to a licensed, non-hazardous waste disposal facility.

Water Requirements

The GSEP proposes to utilize approximately 1,644 acre-feet of ground water per year (AFY) for its operation. Staff is recommending a Water Conservation Plan, which has several options to reduce water use.

Water Source and Quality

The GSEP water needs will be met by use of groundwater pumped from one of two wells on the plant site. Water for domestic uses by project employees will also be provided by onsite groundwater treated to potable water standards. Groundwater modeling testing data indicates that the onsite groundwater has varying levels of totally dissolved solids (TSD) that range from 3,000 to 5,000 mg/l.

Solar Mirror Washing Water

Water from the primary desalination process (reverse osmosis (RO) water), will be deionized and used to clean the solar collectors and to facilitate dust and contaminant removal. The collectors would be cleaned once or twice per week, determined by the reflectivity monitoring program. This mirror washing operation would be done at night and involves a water truck spraying treated water on the mirrors in a drive-by fashion. The applicant expects that that the mirrors will be washed weekly in winter and twice weekly from mid-spring through mid-fall. Because the mirrors are angled down for washing, water does not accumulate on the mirrors; instead, it would fall from the mirrors to the ground and, due to the small volume (two acre-feet/year), is expected to soak in with no appreciable runoff. Any remaining rinse water from the washing operation would be expected to evaporate on the mirror surface.

PROPOSED PROJECT OBJECTIVES

The specific objectives of GSEP are:

- To develop a utility-scale solar energy project utilizing parabolic trough technology;
- To construct and operate an environmentally friendly, economically sound, and operationally reliable solar power generation facility that will contribute to the State of California's renewable energy goals;
- To locate the project in an area with high solar insolation (i.e., high intensity of solar energy);
- To interconnect directly to the CAISO Grid through BEPTL and the SCE electrical transmission system; and
- To fulfill Governor Schwarzenegger's and Secretary Salazar's Memorandum of Understanding to expedite renewable energy development in California.

SUPPORT FOR PROPOSED PROJECT

NEPA guidance published by the Council on Environmental Quality (CEQ) states that an environmental impact statement Purpose and Need section "shall briefly specify the underlying purpose and need to which the agency is responding in proposing the alternatives including the proposed action" (40 CFR §1502.13). The following discussion sets forth the purpose of, and need for, the project as required under NEPA.

BLM PURPOSE AND NEED

The BLM's purpose and need for the GSEP is to respond to Genesis Solar, LLC's application under Title V of Federal Land Policy and Management Act, FLPMA (43 U.S.C. 1761) for a ROW grant to construct, operate, and decommission a solar thermal facility on public lands in compliance with FLPMA, BLM ROW regulations, and other Federal applicable laws. The BLM will decide whether to approve, approve with modification, or deny issuance of a ROW grant to Genesis Solar, LLC for the proposed GSEP. The BLM's actions will also include consideration of amending the CDCA Plan concurrently. The CDCA Plan (1980, as amended), while recognizing the potential compatibility of solar generation facilities on public lands, requires that all sites associated with power generation or transmission not identified in that plan be

considered through the plan amendment process. If the BLM decides to approve the issuance of a ROW grant, the BLM will also amend the CDCA Plan as required.

In conjunction with FLPMA, BLM authorities include:

- Executive order 13212, dated May 18, 2001, which mandates that agencies act expediently and in a manner consistent with applicable laws to increase the "production and transmission of energy in a safe and environmentally sound manner."
- The Energy Policy Act 2005, which requires the Department of the Interior (BLM's parent agency) to approve at least 10,000 MW of renewable energy on public lands by 2015.
- Secretarial Order 3285, dated March 11, 2009, which "establishes the development of renewable energy as a priority for the Department of the Interior."

The Federal government and the State of California have established the need for the nation and State to increase the development and use of renewable energy in order to enhance the nation's energy independence, meet environmental goals, and create new economic and employment growth opportunities. GSEP would help meet these needs by:

- Assisting California in meeting its Renewable Portfolio Standard goals of 20% of retail electric power sales by 2010 under existing law (Senate Bill 1078 – Chapter 516, Statutes of 2002) and 33% of electrical power retail sales by 2020 under pending legislation;
- Supporting U.S. Secretary of the Interior Salazar's Orders 3283 and 3285 making the production, development and delivery of renewable energy top priorities for the United States;
- Supporting Governor Schwarzenegger's Executive Order S-14-08 to streamline California's renewable energy project approval process and to increase the State's Renewable Energy Standard to 33% renewable power by 2020;
- Supporting the greenhouse gas reduction goals of Assembly Bill 32 (California Global Warming Solutions Act of 2006); and.
- Sustaining and stimulating the economy of California by helping to ensure an adequate supply of renewable electrical energy, while creating additional construction and operations employment and increased expenditures in many local businesses.

DOE PURPOSE AND NEED

The Applicant has applied to the Department of Energy (DOE) for a loan guarantee under Title XVII of the Energy Policy Act of 2005 (EP Act), as amended by Section 406 of the American Recovery and Reinvestment Act of 2009, P.L. 111-5 (the Recovery Act). DOE is a cooperating agency on this EIS pursuant to a MOU between DOE and BLM, signed in January 2010. The purpose and need for action by DOE is to comply with its mandate under EP Act by selecting eligible projects that meet the goals of the Act.

The EP Act 2005 established a Federal loan guarantee program for eligible energy projects, and was amended by ARRA to create Section 1705. That section authorizes a new program for rapid deployment of renewable energy projects and related manufacturing facilities, electric power transmission projects, and leading edge biofuels projects. The primary purposes of ARRA are to promote job preservation and creation, infrastructure investment, energy efficiency and science, assistance to the unemployed, and State and local fiscal stabilization. The Section 1705 Program is designed to address the current economic conditions of the nation, in part, through renewable energy, transmission, and leading edge biofuels projects.

CEQA FUNCTIONAL EQUIVALENT AND NEPA PROCESSES

The Bureau of Land Management (BLM) and the Energy Commission have executed a Memorandum of Understanding concerning their intent to conduct a joint environmental review of the project in a single National Environmental Policy Act (NEPA)/California Environmental Quality Act (CEQA) process. It is in the interest of the BLM and the Energy Commission to share in the preparation of a joint environmental analysis of the proposed project to avoid duplication of staff efforts, to share staff expertise and information, to promote intergovernmental coordination at the local, state, and federal levels, and to facilitate public review by providing a joint document and a more efficient environmental review process.

Under federal law, BLM is responsible for processing a Right-of-Way application for a proposed project, and associated transmission lines and other facilities, to be constructed and operated on land it administers. In processing applications, BLM must comply with the requirements of NEPA, the President's Council on Environmental Quality (CEQ) Regulations For Implementing The Procedural Provisions Of The National Environmental Policy Act (NEPA) (40 CFR Parts 1500 – 1508), and BLM's NEPA Handbook (H-1790-1). Agency specific NEPA procedures require that federal agencies reviewing projects under their jurisdiction consider the environmental impacts associated with the proposed project construction and operation before making a decision.

As the lead state agency under CEQA, the Energy Commission is responsible for reviewing and ultimately approving or denying all applications to construct and operate thermal electric power plants, 50 MW and greater, in California. The Energy Commission's facility certification process carefully examines public health and safety, environmental impacts, and engineering aspects of proposed power plants and all related facilities, such as electric transmission lines and natural gas and water pipelines.

The GSEP Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) includes all analyses normally contained in an Environmental Impact Report (EIR) as required by the California Environmental Quality Act (CEQA). When issuing a license, the Energy Commission is the lead state agency under CEQA, and its process is functionally equivalent to the preparation of an EIR.

The SA/DEIS is a joint CEQA (equivalent) and NEPA document drafted to meet and satisfy the regulatory needs of the CEC and BLM. As such, this document may not look like a traditional CEQA document or a traditional EIS-level NEPA document. However,

this document has been prepared under the joint effort of the Energy Commission and BLM and meets the needs and criteria of each agency from both a regulatory and analytical perspective.

To help facilitate the review of this joint document, some of the major distinctions between CEQA and NEPA are provided below:

	CEQA	**NEPA**
Purpose	Contains a substantive mandate that public agencies refrain from approving projects with significant environmental effects if there are feasible alternatives or mitigation measures that can substantially lessen or avoid those effects. Mountain Lion Foundation v. Fish and Game Commission (1997) 16 Cal.4th 105.	"NEPA procedures must ensure that environmental information is available to public officials and citizens before decisions are made and before actions are taken." (40 CFR 1500.1(b)) "NEPA's purpose is not to generate paperwork – even excellent paperwork – but to foster excellent action. The NEPA process is intended to help public officials make decisions that are based on understanding of environmental consequences, and take actions that protect, restore and enhance the environment." (40 CFR 1500.1(c))
Application	To all governmental agencies at all levels in California, including local agencies, regional agencies, and state agencies, boards, districts and commissions.	To all federal agencies.
Activities	All approvals or discretionary projects, which have not been exempted from CEQA by statute or regulation, that may result in either a direct, indirect, or cumulatively considerable physical change in the environment.	Include in every recommendation or report on proposals for legislation or other major Federal actions significantly affecting the quality of the human environment.
Regulation	Resources Agency adopted CEQA Guidelines at Public Resources Code §§ 21000 et seq. Public agencies must adopt implementing procedures.	The President's Council on Environmental Quality (CEQ) Regulations For Implementing The Procedural Provisions Of The National Environmental Policy Act (NEPA) (40 CFR Parts 1500 – 1508). Also, BLM has adopted its own NEPA procedures; see the BLM NEPA Handbook (H-

		1790-1).
Documents	Full analysis includes an EIR, which must be certified by the lead agency. In addition, the lead agency must make certain independent substantive "findings," based on substantial evidence, that potential impacts have been reduced to a level below significance, or otherwise issue a statement of overriding conditions.	All major federal actions that may result in significant impact(s) on the environment require the preparation of an EIS. The federal agency decision on the action analyzed in an EIS is announced in a Record of Decision (ROD).
Baseline	Must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time of the preparation of the environmental analysis.	The baseline under NEPA is the description of the Affected Environment. The EIS shall succinctly describe the environment of the area(s) to be affected by the alternatives under consideration (40 CFR 1502.15). The affected environment describes the environmental conditions and trends at the time the action would occur.
Analysis	Must determine whether there are potentially adverse significant effects on the environment. Lead agencies are given broad latitude in determining what is "significant" according to locally adopted "thresholds of significance." Must analyze direct, indirect and cumulative impacts.	Must analyze direct and indirect effects (see 40 CFR 1508.8), and cumulative impacts (see 40 CFR 1508.7) of the proposed action and alternatives. Include, for the Proposal, unavoidable adverse impacts, the relationship between short-term use and long-term productivity, and any irreversible or irretrievable commitments of resources (40 CFR 1502.16).
Lacking Science	No requirements to use anything other than the evidence in the record before the lead agency, unless a "fair argument" can be made that there are potentially significant impacts.	Must acknowledge whether there is incomplete or unavailable information regarding reasonably foreseeable significant adverse impacts. Must obtain such information, with original research if necessary, unless costs of obtaining it are "exorbitant" or the "means to obtain it are unknown." If unavailable, EIS must evaluate the impacts based

		on theoretical approaches generally accepted in the scientific community. (40 CFR 1502.22)
Economic and Social Impacts	Does not require any analysis of social or economic impacts, except where any such impact has a direct or indirect physical effect on the environment. Physical effects do not include economic or social impacts without any accompanying impact on the environment.	Must analyze the positive and negative economic and social effects of each alternative analyzed, where any such impact has a related physical or human impact. Human impacts may include economic, social or health impacts. In fulfillment of Environmental Justice requirements, identify any disproportionate adverse effect on low-income or minority populations associated with one or more alternatives.
Alternatives	EIR must consider "a range of reasonable alternatives" that achieves the objectives of the project, in "meaningful detail," which has been interpreted as less onerous than NEPA's "substantial treatment" standard. Need not be exhaustive of all conceivable alternatives. One must be the "no project" alternative.	An EIS must rigorously explore and objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated. Devote substantial treatment to each alternative considered in detail. Include alternatives not within the jurisdiction of the lead agency. Include the alternative of no action. Identify the agency preferred alternative. (40 CFR 1502.14)
Mitigation Measures	Lead agency must adopt feasible mitigation measures to lessen environmental impacts, or must make a statement of overriding consideration based on substantial evidence.	EIS must include appropriate mitigation measures not already included in the proposed action or alternatives. (see 40 CFR 1502.14(f)) Also see the CEQ definition of Mitigation at 40 CFR 1508.20.

AFFECTED ENVIRONMENT

The BLM has developed the Guidance for Processing Applications for Solar Power Generation Facilities on BLM-administered land in the California Desert District (2008). Cumulatively, the BLM guidance states a "reasonably foreseeable development scenario should be developed using an 'areawide' approach selected specifically for the individual project and surrounding area. The appropriate land area to cover in analyzing

cumulative impacts may vary by resource." The BLM California Desert District, Palm Springs-South Coast Field Office -- the Federal lead agency for GSEP -- provided the area to consider for the cumulative impact analysis for the Project in pre-application meetings in July 2009. **Cumulative Impacts Figure 2** reflects the extent of the area considered in the cumulative impact analysis, which accounts for other solar projects proposed within an approximately 30-mile radius for GSEP. In accordance with BLM guidance, cumulative impacts are evaluated for each of the technical disciplines addressed in this document.

PUBLIC NOTICES, OUTREACH, AND PUBLIC AND AGENCY INVOLVEMENT

PUBLIC COORDINATION

The Energy Commission and the BLM have collaborated in their efforts to facilitate robust public participation in their joint regulatory review of the GSEP. To reach this goal, Energy Commission staff with assistance from BLM staff conducted ten discovery workshops to publicly discuss technical issues related to the proposed project, and determine if GSEP should be approved for construction and operation, and if so, under what set of conditions. These workshops formed the basis of discovery for the proceeding, and provided the public as well as local, state, and federal agencies the opportunity to ask questions about, and provide input on, the proposed project.

The Energy Commission issued notices for these workshops at least 10 days prior to the meeting. BLM provides public participation opportunities consistent with the President's Council on Environmental Quality Regulations for Implementing the Procedural Provisions of the NEPA (40 CFR Parts 1500 – 1508), BLM Planning Regulations (43 CFR Part 1600), and respective BLM Handbooks (H-1790-1 and H-1601-1). The Bureau of Land Management and Energy Commission's outreach efforts are an ongoing and collaborative throughout the entire proceeding.

BLM'S INITIAL PUBLIC NOTICE AND OUTREACH

The Notice of Intent was published in the *Federal Register (Volume 74, No. 224)* on November 23, 2009. On December 10, 2009, the CEC, with participation from BLM, held a publicly-noticed Informational Hearing at Blythe City Hall Council Chambers in Blythe, California. On December 11, 2009, BLM held its formal Scoping Meeting at the University of California-Riverside, Palm Desert Campus. A draft scoping report was released for public review and comment in January 2010. A full listing of comments, organized by technical discipline, are included in the **Introduction** to this document.

ENERGY COMMISSION STAFF'S PUBLIC OUTREACH

Energy Commission staff provides formal notices to property owners within 1,000 feet of the proposed site and within 500 feet of a linear facility (such as transmission lines, gas lines and water lines). Staff mailed the public notices on October 6, 2009, informing the public, agencies, and elected officials of the Commission's receipt and availability of the application 09-AFC-8. Each notice contained a link to a Commission-maintained project website (http://www.energy.ca.gov/sitingcases/genesis_solar/index.html).

Libraries

On September 29, 2009, the Energy Commission staff also sent copies of the GSEP AFC to the following libraries:

Riverside Main Library 3581 Mission Inn Avenue Riverside, CA 92501	Palo Verde Valley District Library 125 West Chanslor Way Blythe, CA 92225-1245

In addition to these local libraries, copies of the AFC were also made available at the Energy Commission's Library in Sacramento, the California State Library in Sacramento, as well as, state libraries in Eureka, Fresno, Los Angeles, San Diego, and San Francisco.

Energy Commission's Public Adviser's Office

The Energy Commission's outreach program is also facilitated by the Public Adviser's Office (PAO). The PAO requested public service announcements at a variety of organizations including *The Desert Independent,* Blythe City Council, three separate Chambers of Commerce, and local (Palm Springs) television and radio stations. These notices informed the public of the Commission's receipt of the GSEP Application for Certification (AFC), and invited the public to attend the Public Site Visit (of the proposed GESP site) and Informational Hearing/BLM Scoping Meeting on December 10, 2009 in Blythe, CA.

BLM AND CEC PUBLIC WORKSHOPS

Staff from the Energy Commission and the BLM held Data Request, Data Response, and Issues Resolution Workshops in the following California communities: Blythe, Palm Desert, Palm Springs, and Sacramento. These ten (10) workshops were conducted on the following days: November 23 and 24, 2009; December 10, 18 and 31, 2009; January 6, 11 and 12, 2010; and, February 10 and 18, 2010. During each of these workshops, specific time for public participation was allocated, and public comment was taken. These workshops provided a public forum for the applicant, interveners, staff and cooperating agencies to interact regarding project issues.

Policy Level and Programmatic Agency Coordination

On August 8, 2007, the California Energy Commission and the Bureau of Land Management signed a Memorandum of Understanding (MOU) for the purpose on agreeing to prepare joint environmental documents for proposed, solar thermal projects which fall under the jurisdiction of both agencies. The MOU outlines roles and responsibilities of the cooperative process.

On October 12, 2009, California's Governor, Arnold Schwarzenegger, signed an MOU with the U.S. Department of the Interior's Secretary, Ken Salazar. The purpose of the MOU "is to direct California Agencies and Department of the Interior Agencies…to take the necessary actions to further the implementation of the Governors Executive Order S-14-08 and the Secretary's Order 3285 in a cooperative, collaborative, and timely manner". The agencies identified to in the MOU are the California Department of Fish

and Game (CDFG), California Energy Commission (CEC), Bureau of Land Management (BLM) and the U.S. Fish and Wildlife Service (FWS). The MOU also outlined specific objectives.

On January 26, 2010, the U.S. Department of the Interior's Bureau of Land Management signed a Memorandum of Understanding (MOU) with the U.S. Department of Energy's (DOE) Loan Guarantee Program (LGP) office. The purpose of the MOU is to provide a framework for the BLM and the LPG to cooperate in preparing Environmental Assessments, Environmental Impact Statements for renewable energy project's that require federal actions be taken by both the BLM and the LGP.

Project Specific Agency Coordination

On October 6, 2009, the Energy Commission staff sent a notice of receipt and a copy of the GSEP Application for Certification to all local, state, and federal agencies that might be affected by the proposed project. Staff continues to seek cooperation and or comments from regulatory agencies that administer LORS which may be applicable to proposed project. These agencies may include, as applicable, the U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service (FWS), U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, California Coastal Commission, Colorado River Board of California, California Department of Transportation, State Water Resources Control Board/Colorado River Regional Water Quality Control Board, California Department of Fish and Game (CDFG), and the California Air Resources Board/Mojave Desert Air Quality Management District, among others. Additionally, staff notified agencies on November 9, 2009, informing them of the availability of supplemental information for the 09-AFC-8 proceeding.

Staff, particularly the **Biological Resources** staff, worked closely with the CDFG and the FWS to evaluate the proposed GSEP, and provide analysis contained within this SA/DEIS. Both CDFG and the FWS attended and participated in public workshops to address the wildlife issues and related "Incidental Take Permits" required for the proposed GSEP. Additionally, staff has benefited from the cooperation of the CDFG in evaluating the proposed streambed alteration agreements that would normally fall under CDFG's jurisdiction if not for the Energy Commission's "in lieu" permitting authority.

Government to Government Consultation - Notification of the Local Native American Communities

BLM staff first sent letters to various tribes on November 26th 2007. The letter provided an initial briefing on the project and a request for consultation. The letters were mailed to the following fourteen (14) recipients:

1. Mr. Richard Milanovich, Tribal Chair; Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

2. Ms. Patricia Tuck, Tribal Historic Preservation Officer, Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

3. Ms. Bridget Nash-Chrabascz, Tribal Historic Preservation Officer, Quechan Indian Tribe, Ft. Yuma Indian Reservation P.O. Box 1899, Yuma, AZ 85366-1899

4. Mr. Robert Martin, Chairman; Morongo Band of Mission Indians. 12700 Pumarra Rd. Banning, CA 92220

5. Ms. Sherry Cordova, Chair, Cocopah Tribal Council. County 15th and Ave,G. Somerton, AZ 85350

6. Mr. Eldred Enas, Chairman, Colorado River Tribal Council. 26600 Mojave Rd. Parker, AZ 85344

7. Mr. Darrell Mike, Chairman, Twenty-Nine Palms Band of Mission Indians. 46-200 Harrison Place, Coachella, CA 92236

8. Mr. John James, Chairman; Cabazon Band of Mission Indians. 84245 Indio Springs Rd. Indio, CA 92203-3499

9. Ms. Maryann Green, Chairperson, Augustine Band of Mission Indians. P.O. Box 846 Coachella, CA 92236

10. Mr. Timothy Williams, Chairman; Fort Mojave Tribal Council. 500 Merriman Ave. Needles, CA 92363

11. Mr. Charles Wood, Chairman; Chemehuevi Tribal Council. P. O. Box 1976 Havasu Lake, CA 92363.

12. Mr. Michael Jackson, Sr., President, Fort Yuma Quechan Tribe. P.O. Box 1899, Yuma, AZ 85366-1899

13. Mr. James Ramos, Chairman; San Manuel Band of Mission Indians. P.O. Box 266, Patton, CA 92369

14. Ms. Mary Resvaloso, Chairwoman; Torres-Martinez Desert Cahuilla Indians. P.O. Box 1160, Thermal, CA 92274-1160

Replies were received from the following three (3) Tribes requesting reports, expressing concerns, or referring to neighboring groups whom may have an interest in the project area.

1. Ms. Patricia Tuck, Tribal Historic Preservation Officer, Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

2. Ms. Bridget Nash-Chrabascz, Tribal Historic Preservation Officer, Quechan Indian Tribe, Ft. Yuma Indian Reservation P.O. Box 1899, Yuma, AZ 85366-1899

3. Mr. Britt W. Wilson, Project Manager-Cultural Resources; Morongo Band of Mission Indians. 12700 Pumarra Rd. Banning, CA 92220

A second set of letters were mailed to tribes on November 23, 2009, identifying the Notice of Intent (NOI) and requesting for comments and/or specific concerns. The letter also designated the deadline for the comment period (December 23, 2009). These letters were sent to the same aforementioned fourteen (14) addressees.

On February 22, 2010, the BLM sent an update letter containing information about project review; CEC-BLM workshops that were held in December, 2009 and January/February, 2010; Native American input; the upcoming release of the SA/EIS; cultural resources surveys from summer 2009 and winter 2010; as well as invitations for tribes to consult on eligibility evaluations of archeological sites and the Programmatic Agreement (PA) being prepared by BLM, the State Historic Preservation Office (SHPO), and the Advisory Council on Historic Preservation (ACHP).

SUMMARY OF SCOPING COMMENTS IN RESPONSE TO THE BLM'S NOTICE OF INTENT

Summary of the Scoping and Draft Comment Process

The Notice of Intent for GSEP was published in the *Federal Register (Volume 74, No. 224)* on November 23, 2009. On December 10, 2009 the CEC with participation from BLM held a publicly-noticed Informational Hearing at Blythe City Hall, Council Chambers in Blythe, California. On December 11, 2009, BLM held its primary Scoping Meeting at the University of California-Riverside, Palm Desert Campus. A draft scoping report was released for public review and comment in January 2010.

Original scoping comment letters submitted by members of the public (letters from both individuals and letters submitted by groups on behalf of members) may be reviewed upon request at the BLM Palm Springs-South Coast Field Office,1201 Bird Center Drive, Palm Springs, California, 92262.

These scoping comment issues were identified by reviewing the comment documents received. Many of the comments identified similar issues; all of the public comment documents were reviewed and the **Introduction** section of this document provides a complete summary of the issues, concerns, and/or questions raised. Issues are grouped into one of the three following categories:

- Issues or concerns that could be addressed by effects analysis;
- Issues or concerns that could develop an alternative and/or a better description or qualification of the alternatives;
- Issues or concerns outside the scope of the Environmental Impact Statement

The matrix below reflects specific issues articulated by non-profit and community-based organizations representing members of the public interested in a wide-array of issues related to the construction and operation of the Genesis Solar Energy Project. These organizations (and others) submitted Notice of Intent (NOI) comment letters on or before December 23, 2009. Many of the NOI comments and scoping comments identified similar issues. The matrix below was developed to provide a general sense of issues articulated by these organizations. Issue-by-issue descriptions for all scoping comments are listed by technical area in the **Introduction** section of this SA/DEIS.

ENVIRONMENTAL JUSTICE

Executive Order 12898, "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations," focuses federal attention on the environment and human health conditions of minority communities and calls on federal agencies to achieve environmental justice as part of this mission. The Order requires the United States Environmental Protection Agency (US EPA) and all other federal agencies to develop strategies to address this issue. The agencies are required to identify and address any disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority or low-income populations. Some agencies have also interpreted this Order as applying to state agencies that receive federal funding. Energy Commission staff assumes that the Order applies, and conducts the appropriate analysis accordingly.
This analysis is also necessary to satisfy BLM's obligations under Executive Order 12898. In considering environmental justice in energy facility siting cases, staff uses a demographic screening analysis to determine whether a low-income and/or minority population exists within the potentially affected area of the proposed site. The demographic screening is based on information contained in two documents: "Environmental Justice: Guidance Under the National Environmental Policy Act" (Council on Environmental Quality, December, 1997) and "Guidance for Incorporating Environmental Justice Concerns in EPA's Compliance Analyses" (U.S. Environmental Protection Agency, April, 1998).

The Environmental Justice screening process relies on Year 2000 U.S. Census data to determine the presence of minority and below-poverty level populations. Environmental Justice: Guidance Under the National Environmental Policy Act, defines minority individuals as members of the following groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic origin; or Hispanic. A minority population is identified when the minority population of the potentially affected area is:

1. greater than 50%; or

2. present in one or more US Census blocks where a minority population of greater than 50% exists.

In addition to the demographic screening analysis, staff follows the steps recommended by the U.S. EPA's guidance documents in regard to outreach and involvement; and if warranted, a detailed examination of the distribution of impacts on segments of the population.

Staff has followed each of the above steps for the following eleven (11) sections in the SA/DEIS: **Air Quality, Hazardous Materials, Land Use, Noise, Public Health, Socioeconomics, Soils and Water, Traffic and Transportation, Transmission Line Safety/Nuisance, Visual Resources,** and **Waste Management**. Over the course of the analysis for each of these eleven technical disciplines, staff considered potential impacts and mitigation measures, and whether there would be a significant impact on an environmental justice population. Staff determined that the remaining technical areas did not involve potential environmental impacts that could contribute to a

disproportionate impact on an environmental justice population, and so did not necessitate further environmental justice analysis for those areas.

PROJECT'S COMPLIANCE WITH LAWS, ORDINANCES, REGULATIONS, AND STANDARDS (LORS)

Based upon the information provided, discovery achieved and analysis completed to date, staff has concluded that with just two exceptions, the implementation of its recommended mitigation measures – described in the conditions of certification – will mitigate all potential environmental impacts of the GSEP to a level of less than significant. Therefore, the project analysis complies with the requirements of the California Environmental Quality Act (CEQA) and the National Environmental Policy Act (NEPA). For a detailed review of potentially significant impacts and the related mitigation measures (conditions of certification), please refer to each chapter of this SA/DEIS.

Within the technical areas of **Air Quality** and **Transmission System Engineering,** additional information is necessary and required in regard to specific issues that are described in the sections' summary of conclusions. These are outstanding issues that will be resolved through the course of the Staff Assessment (SA) Workshops and subsequent filings, and will be reflected in a Supplemental Staff Assessment (SSA).

As noted in the **Land Use** and **Visual Resources** sections, cumulative impacts would be significant and would not be mitigated to less than significant levels. Therefore, if this project were to be approved, an override consideration may be necessary.

Staff also concludes that with implementation of staff's recommended mitigation measures described in each technical section's conditions of certification, GSEP would comply with all applicable laws, ordinances, regulations, and standards (LORS), except as described in the **Soil and Water Resources** section.

Specifically, the state of California has expressed a strong interest in developing its solar energy resources. However, the construction and operation of solar energy facilities requires the use of water, which state policy also protects. The Energy Commission must balance the state's interest in promoting solar energy development with its interest in conserving and protecting the state's water resources. GSEP proposes to use water for power plant cooling, which staff believes is contrary to the state's long term interest in maximizing solar power generation and minimizing adverse environmental impacts.

This will be an especially critical issue in the renewable development areas that will be identified in the joint state/federal Renewable Energy Action Team's Desert Renewable Energy Conservation Plan (DRECP). Therefore, staff proposes that the project prepare a Water Conservation Plan that outlines the actions necessary to bring the project cooling water use into compliance with the state's water policies. Later this year, Energy Commission staff plans to file a request for an Energy Commission Order Instituting an Informational Proceeding to address the overall issue of water use (particular groundwater use) by solar thermal power plants. For a more detailed discussion of

water policy and related LORS, see staff's technical analysis in the **Soil and Water Resources** section of this SA/DEIS.

SUMMARY OF ENVIRONMENTAL IMPACTS AND RELATED MITIGATION (FOR ENERGY COMMISSION AND CEQA PURPOSES)

With the exception of the technical areas identified below, Energy Commission staff believes that as currently proposed, including the applicant's and the staff's proposed mitigation measures and the staff's proposed conditions of certification, the proposed GSEP would comply with all applicable laws, ordinances, regulations, and standards (LORS).

Summary of Genesis Solar Energy Project SA/DEIS Technical Analyses

Technical Area	Complies with LORS	Impacts Mitigated
Air Quality	Yes	Yes
Alternatives	Not Applicable	Not Applicable
Biological Resources	Yes	Yes
Cultural Resources	Yes	undetermined
Cumulative	Yes	Yes
Efficiency	Not Applicable	Not Applicable
Facility Design	Yes	Yes
Geology and Paleontology	Yes	Yes
Hazardous Materials	Yes	Yes
Land Use	Yes	**No***
Noise and Vibration	Yes	Yes
Public Health	Yes	Yes
Reliability	Not Applicable	Not Applicable
Socioeconomic Resources	Yes	Yes
Soil and Water Resources	**No**	Yes
Traffic and Transportation	Yes	Yes
Transmission Line Safety/Nuisance	Yes	Yes
Transmission System Engineering	Yes	Yes
Visual Resources	Yes	**No***
Waste Management	Yes	Yes
Worker Safety and Fire Protection	Yes	Yes

*cumulative impacts

SUPPLEMENTAL STAFF ASSESSMENT

Based on Staff Assessment (SA) workshops and written comments, staff may refine its analysis, correct errors, and finalize conditions of certification to reflect areas where agreements have been reached with the parties, and will then publish a Supplemental Staff Assessment/Final Environmental Impact Statement (SSA/FEIS). The SSA/FEIS will be a limited document representing revisions and additions to technical areas

discussed below, rather than a document including discussion for each technical section.

Air Quality

Staff will need to receive/review a Final Determination of Compliance (FDOC) from the Mojave Desert Air Quality Management District (MDAQMD), including the review and incorporation of revisions made by MDAQMD to address staff and other party comments on the Preliminary Determination of Compliance. This analysis will likely require revisions to both staff and MDAQMD-recommended conditions of certification.

Cultural Resources

Issue discussions in the SSA will include the following:

- Mitigation for project impacts to cultural resources that will be handled in a Programmatic Agreement (PA) negotiated among all stakeholders -- federal, state, and private – including critically important resources, with ongoing input for Native American organizations. Development of the PA by the BLM and the State Historical Preservation Office is underway.
- The data compilation for the cumulative analysis is also ongoing, and that analysis will be included in the SSA.
- BLM is compiling information on its consultation with Native Americans, required by NHPA Sec. 106. An account of this consultation will be included in the SSA.

With the finalization and implementation of the PA, staff expects all project impacts will be mitigated. Staff is expecting no additional information from the applicant.

Land Use

Staff concluded that the GSEP (and its alternatives) would combine with other past and reasonably foreseeable future projects to substantially reduce scenic values of wilderness areas and recreational resources in the Chuckwalla Valley and southern California desert region and therefore, would result in a significant and unavoidable cumulative land use impact. These cumulative visual impacts would be significant in terms of CEQA, and would not be mitigated to less than significant levels. Therefore, if this project were to be approved, an override consideration would be necessary

Soil & Water Resources

Final completion of staff's analysis of the proposed project is subject to the following:

- Submittal of a Water Conservation Plan.
- Submittal of the following to the Colorado River Regional Quality Control Board (RWQCB) and County of Riverside for review and comment and to the Energy Commission for approval:
  - Engineering design detail and groundwater monitoring plans for the proposed wastewater evaporation ponds;
  - Engineering design detail and groundwater monitoring plans for the proposed Heat Transfer Fluid (HTF) fluid bioremediation units;

- Characterization of the anticipated waste streams proposed to be discharged into the evaporation ponds and bioremediation units;
- A description of the frequency and chemical analysis of waste and a plan that describes actions that will be taken in case of a detectable release;
- A closure plan for the evaporation ponds and bioremediation units; and
- Demonstration that the proposed project would be in compliance with Order 2009-0009-DWQ Storm Water requirements that take effect July 1, 2010.

- Submittal of the applicant's final, 100 percent engineering and design for GSEP's storm water diversion channel(s) will need to be reviewed for final comment and approval by the Energy Commission.

Transmission System Engineering

The applicant will need to provide environmental information for downstream congestion management improvements in order for staff to finalize their analysis on proposed, necessary transmission improvements. Such improvements will be stipulated in a forthcoming (Fall 2010) Phase II Interconnection Study.

Visual Resources

Staff concluded that the proposed project would result in a substantial adverse cumulative impact to existing scenic resource values as seen from several wilderness viewing areas and Key Observation Points north of the project in the vicinity of the McCoy and Palen Mountains. These cumulative visual impacts would be significant in terms of CEQA, and would not be mitigated to less than significant levels. Therefore, if this project were to be approved, an override consideration would be necessary.

BLM'S PREFERRED ALTERNATIVE (FOR BLM AND NEPA PURPOSES)

BLM's objective is to select an alternative that is inclusive of the purpose and need of the project and adequately addresses the environmental issues while still maintaining the proposed project output. Currently, the BLM has identified the Proposed project with dry cooling as the preferred alternative in the SA/DEIS. As the BLM and CEC progress through the process, analysis of both public and agency comment will weigh heavily in the selection of the final preferred alternative that will presented in the SSA/FEIS.

RECOMMENDATIONS

The SA/DEIS is a document of the Energy Commission staff that has been developed and written with staff from the Bureau of Land Management. Accordingly, by its very nature, the conclusions and recommendations presented herein are considered staff's analysis of the project, and its testimony hereto. In summary, this SA/DEIS finds that with one exception, the Genesis Solar Energy Project is in conformance with all LORS. Where Project impacts were identified, BLM and Energy Commission staff recommends mitigation to offset direct, indirect, and cumulative impacts and to assure compliance with state and federal laws such as the federal and state endangered species acts. With

implementation of staff's proposed conditions of certification, Project impacts would be reduced to less than significant levels.

CONCLUSIONS

Staff will work to resolve any outstanding issues and update the SA/DEIS prior to Evidentiary Hearings, which are scheduled to commence on July 19, 2010 in Blythe, California. Based on Staff Assessment (SA) workshops planned for early May, 2010, written comments and input from the public, agencies and other parties to this proceeding, staff may refine its analyses, correct errors, and finalize conditions of certification to reflect areas where agreements have been reached with the parties. All these updates to the SA/DEIS, coupled with responses to public comments, will be reflected in the BLM/Energy Commission Supplemental Staff Assessment /Final Environmental Impact Statement (SSA/FEIS) for GSEP, currently scheduled for publication in late August, 2010.

A. - INTRODUCTION

Mike Monasmith

This Staff Assessment /Draft Environmental Impact Statement (SA/DEIS) is a joint document being published by the U.S. Bureau of Land Management (BLM) and the California Energy Commission (CEC). It is in the interest of the BLM and the Energy Commission to share in the preparation of a joint environmental analysis of the proposed project to avoid duplication of staff efforts, to share staff expertise and information, to promote intergovernmental coordination at the local, state, and federal levels, and to facilitate public review by providing a joint document and a more efficient environmental review process.

This SA/DEIS contains U.S. Bureau of Land Management and Energy Commission staffs' (hereafter jointly referred to as staff) independent evaluation of the Genesis Solar, LLC (applicant) Genesis Solar Energy Project (GSEP) application, which was filed with the BLM and CEC. The application filed with BLM is the BLM Application for a Right-of-Way Grant on BLM-administered land (CACA 048880) and the application filed with the Energy Commission is the Application for Certification (09-AFC-8). The SA/DEIS examines engineering, environmental, public health and safety aspects of the Genesis Solar Energy Project (GSEP), based on the information provided by the applicant and other sources available at the time the SA/DEIS was prepared. For the BLM, the SA/DEIS will also include a Draft Land Use Plan Amendment (Draft PA) to the California Desert District Plan (1980) as Amended.

The applicant has also applied for the American Recovery and Reinvestment Act (ARRA) Renewable Energy Grant Program. Two goals of the ARRA Renewable Energy Grant Program are to enhance America's energy independence and create near-term employment opportunities for Americans. To be eligible for the ARRA funds, the applicant must begin construction on GSEP by the end of 2010.

This SA/DEIS serves as staffs' analysis of the engineering, environmental, public health and safety aspects of the proposed project, based on the information provided by the applicant and other sources available at the time the SA/DEIS was prepared. The SA/DEIS includes analyses normally contained in an Environmental Impact Report (EIR) as required by the California Environmental Quality Act (CEQA), as well as analyses required as part of an EIS prepared under the National Environmental Policy Act (NEPA). The SA/DEIS is available for a 90-day public comment period beginning April 9, 2010. The Notice of Availability (NOA) (published by the EPA in the *Federal Register*) will initiate the 90-day public review and comment period.

When considering a project for licensing, the Energy Commission is the lead state agency under CEQA, and its process is functionally equivalent to the preparation of an EIR. Similarly, BLM is the lead Federal agency for the NEPA review of the proposed Right-of-Way and possible Land Use Plan Amendment. The Energy Commission and the BLM are engaging in concurrent review processes. The following explains in more detail the steps each agency will take to complete review.

In support of its certification process, the Energy Commission staff has the responsibility to complete an independent assessment of the project's engineering design and its potential effects on the environment, on the public's health and safety, and whether the project conforms with all applicable laws, ordinances, regulations and standards (LORS). The staff also recommends measures to mitigate potential significant adverse environmental effects and conditions of certification for construction, operation, maintenance and eventual decommissioning of the project..

This SA/DEIS is not the decision document for these proceedings, nor does it contain findings of the Energy Commission related to environmental impacts or the project's compliance with local/state/federal legal requirements. The SA/DEIS will serve as staff's testimony in evidentiary hearings to be held by the Energy Commission's Genesis Solar Energy Project Committee, consisting of two Commissioners overseeing this case. The Committee will hold evidentiary hearings and will consider the recommendations presented by staff, the applicant, all parties, government agencies, and the public prior to proposing its decision. The entire Energy Commission will make a final decision, including findings, after the Committee's publication of its proposed decision. The Commission's final decisions on power plant AFCs are subject to judicial review by the Supreme Court of California (Pub. Res. § 25531.)

In support of the processing of the Right-of-Way (ROW) Application and CDCA Plan Amendment processes, the BLM has the responsibility to evaluate the environmental impacts of the proposed action, the No Action alternative, and other alternatives that may meet the purpose and need for the proposed project or identify the need for additional planning amendments that could mitigate cumulative effects.

The BLM has determined that the proposed site for the Genesis project is not identified in the California Desert Conservation Area (CDCA) Plan as associated with power generation or transmission. The requested ROW cannot be granted unless such a grant would be consistent with the terms of the CDCA Plan. Therefore, BLM must amend the Plan to allow power generation and transmission at the proposed site as a prerequisite to granting the ROW. As part of the DEIS, BLM will identify its preferred alternative and will also present a potential Draft Plan Amendment to the CDCA Plan to allow for the project if a ROW is granted.

Following the 90-day public comment period, BLM and CEC staff will review and develop responses to comments provided by the public and other agencies, and plan to publish the response in August, 2010. The responses to the comments, and other relevant information identified during this period, will be incorporated into the Supplemental Staff Assessment/Final EIS (SSA/FEIS), which will also identify for BLM a Proposed Land Use Plan Amendment (Proposed PA). The NOA (published by the EPA in the *Federal Register*) will initiate a 30-day protest period on the Proposed PA to the Director of the BLM. Protests regarding the Proposed PA must be sent in writing to the Director of the BLM and comply with the protest procedures described in 43 CFR § 1610.5-2. Following resolution of any protests regarding proposed CDCA Plan Amendments, BLM may then publish an Approved Plan Amendment and a Record of Decision (ROD) on the Project Application. The decision regarding the ROW grant is appealable to the Interior Board of Land Appeals upon issuance of the ROD.

A.1 AGENCY AUTHORITIES AND RESPONSIBILITIES

Energy Commission certification is in lieu of any permit required by state, regional, or local agencies and by federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). However, both the Commission and BLM typically seek comments from and work closely with other regulatory agencies administering LORS that may be applicable to the proposed project. The following paragraphs describe the agency coordination that has occurred throughout this joint SA/EIS process.

A.1.1 U.S. BUREAU OF LAND MANAGEMENT (BLM)

The Bureau of Land management's authority for the proposed action is the Federal Land Policy and Management Act (FLPMA) of 1976 [43 United States Code (U.S.C.) 1701 et seq.], The proposed action is consistent with Section 211 of the Energy Policy Act (EP Act) of 2005 (119 Stat. 594, 600), and BLM's Solar Energy Development Policy of April 4, 2007. The FLPMA authorizes BLM to issue right-of-way grants for renewable energy projects. Section 211 of the Energy Policy Act of 2005 states that the Secretary of the Interior should seek to have approved a minimum of 10,000 megawatts of renewable energy generating capacity on public lands by 2015.

A.1.2 CALIFORNIA ENERGY COMMISSION (CEC)

The Energy Commission has the exclusive authority to certify the construction, modification, and operation of thermal electric power plants 50 megawatts (MW) or larger in the state. The Energy Commission certification is in lieu of any permit required by state, regional, or local agencies and by federal agencies to the extent permitted by federal law (Pub. Resources Code, § 25500). The Energy Commission must review power plant AFCs to assess potential environmental impacts including potential impacts to public health and safety, potential measures to mitigate those impacts (Pub. Resources Code, § 25519), and compliance with applicable governmental laws or standards (Pub. Resources Code, § 25523 (d)). The Energy Commission staff's analyses were prepared in accordance with Public Resources Code, sections 25500 et seq.; Title 20, California Code of Regulations, sections 1701 et seq.; and CEQA (Pub. Resources Code, §§ 21000 et seq.).

A.1.3 US FISH AND WILDLIFE SERVICE (USFWS) AND THE CALIFORNIA DEPARTMENT OF FISH AND GAME (CDFG)

U.S. Fish and Wildlife Service

The U.S. Fish and Wildlife Service (USFWS) has jurisdiction to protect threatened and endangered species under the Endangered Species Act (ESA). Formal consultation with the USFWS under Section 7 of the ESA is required for any federal action that is likely to adversely affect a federally-listed species. This consultation will be initiated through the preparation and submittal of a Biological Assessment (BA) which describes the proposed project to the USFWS. Following review of the BA, the USFWS may issue a Biological Opinion (BO) which will specify mitigation measures that must be implemented for any protected species.

California Department of Fish and Game

The California Department of Fish and Game (CDFG) has the authority to protect water resources of the state through regulation of modifications to streambeds, under Section 1602 of the Fish and Game Code. The Energy Commission, BLM, and the applicant have provided information to CDFG to assist in their determination of the impacts to streambeds, and identification of permit and mitigation requirements. The applicant filed a Streambed Alteration Agreement with CDFG. The requirements of the Streambed Alteration Agreement will be included as a recommended Condition of Certification/Mitigation Measure.

CDFG also has the authority to regulate potential impacts to species that are protected under the California Endangered Species Act (CESA). Accordingly, the applicant for the Genesis Solar Energy Project has filed the appropriate incidental take permit applications. The requirements of the Incidental Take Permits will be included as a recommended Condition of Certification/Mitigation Measure discussed in the Biological Resources section of this document.

A.1.4 OTHER AGENCIES WITH AUTHORITY

U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (USACE) has jurisdiction to protect water quality and wetland resources under Section 404 of the Clean Water Act. Under that authority, USACE reviews proposed projects to determine whether they may impact such resources, or are subject to a Section 404 permit. Throughout the SA/DEIS process, the Energy Commission and BLM have provided information to the USACE to assist them in making a determination regarding their jurisdiction and need for a Section 404 permit.

Mojave Desert Air Pollution Management District

The project site is located in the Mojave Desert Air Basin[1] and is under the jurisdiction of the Mojave Desert Air Quality Management District (District). Based upon the authorities in 40 Code of Federal Regulations (CFR) Part 52 and 40 CFR Part 60, the District is responsible for issuing the federal New Source Review (NSR) permit and has been delegated enforcement of the applicable New Source Performance Standard (Subpart IIII).

California Department of Transportation

The department of transportation has jurisdiction over encroachments to Caltrans facilities and related easements and rights-of way.

Riverside County

The County of Riverside has jurisdiction to issue building permits to the GSEP. Building permits issued by the county are considered ministerial in nature. The county also has

[1] The Mojave Desert Air Basin lies inland southeast of the San Joaquin Valley Air Basin, and northeast of the South Coast Air Basin. The desert portions of Kern, San Bernardino, Riverside, and Los Angeles counties are within its boundaries.

jurisdiction to issue discretionary approvals for any easements, rights-of-way and or encroachment permits where county facilities are concerned.

Other Agencies

For a comprehensive review of all agencies and their corresponding permits, licenses, and other LORS conformance for specific areas, see staff's technical analyses in the SA/DEIS.

A.2 CASE AND PROPERTY DESCRIPTION

The Genesis Solar Energy Project (GSEP) is located approximately 25 miles west of the city of Blythe, California, on BLM-administered land. The project area is south of the Palen/McCoy Wilderness Area and north of Ford Dry Lake and Interstate 10.

The proposed GSEP is entirely on BLM-administered land located in Township 6S Range 18E and Township 6S Range 19E, San Bernardino Base and Meridian. A summary legal description for the BLM ROW application is provided in the following Table.

The applicant is seeking a right-of-way grant for approximately 4,640 acres of land administered by the BLM. Construction and operation of the project would disturb a total of about 1,800 acres. As such, any difference between the total acreage listed in the Right-of-Way application (4,640) and the total acreage required for project construction and operation (approx. 1,800) would be excluded from the ROW grant, if BLM decides to approve the project.

The Project area is located in eastern Riverside County, where land use is characterized predominantly by open space and conservation and wilderness areas. The western portion of the county accounts for most of the developed area of the county, including urban areas and agricultural areas. The southeastern corner of the county to the east of the Project also contains limited agricultural areas and rural development (Riverside County, 2003). The following Riverside County Assessor’s Parcel Number’s apply to the parcels within the overall ROW and linear corridor boundary: 810290005-810290008, 810410013, 810410019, 810410014, 810410026, 810410002, 810410021, 810410015, 810410022, 810410023, 810410027-810410029, 810420012, 818040010, 818070001-818101003, 818111008, 818112004,879020025. 810410002, 810410021, 810410015, 810410022, 810410023, 810410027-810410029, 810420012, 818040010, 818070001-818101003, 818111008, 818112004,879020025.

A.3 BLM LAND USE PLAN CONFORMANCE

The principal land use plan affecting this proposed project is the U.S. Bureau of Land Management’s California Desert Conservation Area (CDCA) Plan of 1980, as amended.

The BLM has determined that a Land Use Plan Amendment is required because the proposed site for the GSEP is not identified in the California Desert Conservation Area (CDCA) Plan as associated with power generation or transmission lines greater than 161kV. The requested ROW grant cannot be approved unless it would be consistent

with the terms of the CDCA Plan or subsequent amendments. Therefore, the BLM must consider amending the CDCA Plan to allow power generation and transmission at the proposed GSEP site as a prerequisite to granting the ROW. As part of this DEIS, the BLM will identify its preferred alternative and will also present a potential Draft PA to the CDCA Plan to allow for the project if a ROW is granted.

These Land Use Plan Amendments could further address minimizing the cumulative effects of large scale renewable projects along the I-10 Corridor. Proposed Land Use Plan Amendments are depicted in Alternatives Appendix B and include consideration of those areas, both inside and outside the project footprint, that could be managed specifically for ROW avoidance or exclusion areas, habitat conductivity and targeted acquisition areas that would function for compensatory mitigation for sensitive species.

In the CDCA Plan, the location of the proposed BSPP facility includes land that is classified as Multiple-Use Class L (Limited Use). The Plan states that solar power facilities may be allowed within Limited Use areas after NEPA requirements are met. This DEIS acts as the mechanism for complying with those NEPA requirements. Because solar power facilities are an allowable use of the land as it is classified in the CDCA Plan, the proposed action does not conflict with the Plan. However, Chapter 3, "Energy Production and Utility Corridors Element" of the Plan also requires that newly proposed power facilities that are not already identified in the Plan be considered through the Plan Amendment process. The proposed BSPP facility is not currently identified within the Plan, and therefore a Plan Amendment is required to include the facility as a recognized element within the Plan.

Planning Criteria (BLM)

The CDCA Plan planning criteria are the constraints and ground rules that guide and direct the development of the Plan Amendment. They ensure that the Plan Amendment is tailored to the identified issues and ensure that unnecessary data collection and analyses are avoided. They focus on the decisions to be made in the Plan Amendment, and will achieve the following:

"Sites associated with power generation of transmission not identified in the Plan will be considered through the Plan Amendment process."

Because the proposed facility is not currently identified within the CDCA Plan, an amendment to identify the proposed facility within the Plan is hereby proposed. As specified in Chapter 7, Plan Amendment Process, there are three categories of Plan Amendments, including:

- Category 1, for proposed changes that will not result in significant environmental impact or analysis through an EIS
- Category 2, for proposed changes that would require a significant change in the location or extent of a multiple-use class designation; and
- Category 3, to accommodate a request for a specific use or activity that will require analysis beyond the Plan Amendment Decision.

Based on these criteria, approval of the proposed project would require a Category 3 amendment. This section summarizes the procedures necessary to evaluate the proposed Plan Amendment, as well as the procedures required to perform the environmental review of the ROW application.

Statement of Plan Amendment

The Implementation section of the Energy Production and Utility Corridors Element of the CDCA Plan lists a number of Category 3 amendments that have been approved since adoption of the Plan in 1980. An additional amendment is proposed to be added to this section of the Plan, and would read "Permission granted to construct solar energy facility (proposed BSPP Project)."

Plan Amendment Process

The Plan Amendment process is outlined in Chapter 7 of the Plan. In analyzing an applicant's request for amending or changing the Plan, the BLM District Manager, Desert District, will:

1. Determine if the request has been properly submitted and if any law or regulation prohibits granting the requested amendment.

2. Determine if alternative locations within the CDCA are available which would meet the applicant's needs without requiring a change in the Plan's classification, or an amendment to any Plan element.

3. Determine the environmental effects of granting and/or implementing the applicant's request.

4. Consider the economic and social impacts of granting and/or implementing the applicant's request.

5. Provide opportunities for and consideration of public comment on the proposed amendment, including input from the public and from federal, State, and local government agencies.

6. Evaluate the effect of the proposed amendment on BLM management's desert-wide obligation to achieve and maintain a balance between resource use and resource protection.

Decision Criteria for Evaluation of Proposed Plan Amendment

The Decision Criteria to be used for approval or disapproval of the proposed amendment require that the following determinations be made by the BLM Desert District Manager:

1. The proposed amendment is in accordance with applicable laws and regulations;

2. The proposed amendment will provide for the immediate and future management, use, development, and protection of the public lands within the CDCA.

The BLM Desert District Manager will base the rationale for these determinations on the principles of multiple uses, sustained yield, and maintenance of environmental quality as required in FLPMA.

Decision Criteria for Evaluation of Application

In addition to defining the required analyses and Decision Criteria for Plan Amendments, the Plan also defines the Decision Criteria to be used to evaluate future applications in the Energy Production and Utility Corridors Element of Chapter 3. These Decision Criteria include:

1. Minimize the number of separate rights-of-way by utilizing existing rights-of-way as a basis for planning corridors;
2. Encourage joint-use of corridors for transmission lines, canals, pipelines, and cables;
3. Provide alternative corridors to be considered during processing of applications;
4. Avoid sensitive resources wherever possible;
5. Conform to local plans whenever possible;
6. Consider wilderness values and be consistent with final wilderness recommendations;
7. Complete the delivery systems network;
8. Consider ongoing projects for which decisions have been made; and
9. Consider corridor networks which take into account power needs and alternative fuel resources.

Factors to be Considered

The Plan also states that, in the evaluation of proposed power plants, BLM will use the same factors affecting the public lands and their resources as those used by the Energy Commission. These factors are the environmental information requirements defined in the California Code of Regulations (CCR) Title 20, Appendix B, and include:

- General (Project Overview)
- Cultural Resources
- Land Use
- Noise
- Traffic and Transportation
- Visual Resources
- Socioeconomics
- Air Quality
- Public Health

- Hazardous Materials Handling
- Worker Safety
- Waste Management
- Biological Resources
- Water Resources
- Soils
- Paleontological Resources
- Geological Hazards and Resources
- Transmission System Safety and Nuisance
- Facility Design
- Transmission System Design
- Reliability
- Efficiency

The specific determinations required for the Plan Amendment evaluation are discussed in detail below. This DEIS acts as the mechanism for evaluating the proposed project Application for Consideration to the CEC, the application for grant of Right of Way (ROW) to the BLM, and the proposed CDCA Plan Amendment by the BLM. The factors specified in CCR Title 20, Appendix B are included within the scope of the analysis presented in the DEIS.

Results of CDCA Plan Amendment (BLM)

Required Determinations:

1. Determine if the request has been properly submitted and if any law or regulation prohibits granting the requested amendment. The applicant's request for a ROW was properly submitted, and this DEIS acts as the mechanism for evaluating and disclosing environmental impacts associated with that applications. No law or regulation prohibits granting the amendment.

2. Determine if alternative locations within the CDCA are available which would meet the applicant's needs without requiring a change in the Plan's classification, or an amendment to any Plan element. The CDCA Plan does not currently identify any sites as solar generating facilities. Therefore, there is no other location within the CDCA which could serve as an alternative location without requiring a Plan Amendment. The proposed project does not require a change in the Multiple-Use Class classification for any area within the CDCA.

3. Determine the environmental effects of granting and/or implementing the applicant's request. This DEIS acts as the mechanism for evaluating the environmental effects of granting the ROW and the Plan Amendment.

4. Consider the economic and social impacts of granting and/or implementing the applicant's request. This DEIS acts as the mechanism for evaluating the economic and social impacts of granting the ROW and the Plan Amendment.

5. Provide opportunities for and consideration of public comment on the proposed amendment, including input from the public and from federal, State, and local government agencies. A Notice of Intent (NOI) to amend the CDCA Plan was published in the Federal Register October 17, 2008, Vol. 73, No. 202 Fed. Reg.61902-61903. The U.S. Environmental Protection Agency provided comments during the 30-day NOI scoping period. In accordance with the NOI, issues identified during the scoping period are placed in the comment categories below.

6. Issues to be resolved in the plan amendment: Several comments were received with concerns over the loss of open space and recreational lands if the plan was amended to allow industrial use. This comment is being resolved through this Plan Amendment.

7. Issues to be resolved through policy or administrative action: All other comments received addressed specific environmental impacts and mitigation measures that each commenter requested be analyzed in the SA/DEIS. These comments are being resolved by being considered within this DEIS.

8. Issues beyond the scope of this plan amendment: No comments were received that were outside of the scope of this Plan Amendment.

9. Evaluate the effect of the proposed amendment on BLM management's desert-wide obligation to achieve and maintain a balance between resource use and resource protection.

The balance between resource use and resource protection is evaluated within the DEIS. Title VI of the FLPMA, under CDCA, provides for the immediate and future protection and administration of the public lands in the California desert within the framework of a program of multiple use and sustained yield, and maintenance of environmental quality. Multiple use includes the use of renewable energy resources, and through Title V of FLPMA, the BLM is authorized to grant ROWs for generation and transmission of electric energy. The acceptability of use of public lands within the CDCA for this purpose is recognized through the Plan's approval of solar generating facilities within Multiple-Use Class L.

The purpose of the DEIS is to identify resources which may be adversely impacted by approval of the proposed project, evaluate alternative actions which may accomplish the purpose and need with a lesser degree of resource impacts, and identify mitigation measures and Best Management Practices (BMPs) which, when implemented, would reduce the extent and magnitude of the impacts and provide a greater degree of resource protection.

Conformance of ROW Application with Decision Criteria (BLM)

1. Minimize the number of separate ROWs by utilizing existing ROWs as a basis for planning corridors: The proposed project assists in minimizing the number of separate ROWs by being proposed largely within existing Corridor N. Electrical transmission associated with the proposed project will occur within these existing corridors, and placement of the facility adjacent to these corridors minimizes the length of new corridors necessary for transmission of natural gas to the site.

2. Encourage joint-use of corridors for transmission lines, canals, pipelines, and cables: Placement of the proposed project within existing Corridor N maximizes the joint use of this corridor for natural gas and electrical transmission.

3. Provide alternative corridors to be considered during processing of applications: This decision criterion is not applicable to the proposed project. Placement of the proposed facility adjacent to existing corridors does not require designation of alternative corridors to support the proposed project.

4. Avoid sensitive resources wherever possible: The extent to which the proposed project has been located and designed to avoid sensitive resources is addressed throughout the DEIS. BLM and other Federal regulations that restrict the placement of proposed facilities, such as the presence of designated Wilderness Areas or Desert Wildlife Management Areas were considerations in the original siting process used by the applicant to identify potential project locations. The project location and configurations of the boundaries were modified in consideration of mineral resources. The alternatives analysis considered whether the purpose and need of the proposed project could be achieved in another location, but with a lesser effect on sensitive resources.

5. Conform to local plans whenever possible: The extent to which the proposed project conforms to local plans is addressed within the Land Use section of the DEIS. The proposed project is in conformance with the RiversideCounty General Plan.

6. Consider wilderness values and be consistent with final wilderness recommendations: The proposed project is not located within a designated Wilderness Area or Wilderness Study Area.

7. Complete the delivery systems network: This decision criterion is not applicable to the proposed project.

8. Consider ongoing projects for which decisions have been made: This decision criterion is not applicable to the proposed project. Approval of the proposed project would not affect any other projects for which decisions have been made.

9. Consider corridor networks which take into account power needs and alternative fuel resources: This decision criterion is not applicable to the proposed project. The proposed project does not involve the consideration of an addition to or modification of the corridor network. However, it does utilize facilities located within Corridor N,

which were designed with consideration of both power needs and locations of alternative fuel resources

A.4 CEQA PROJECT OBJECTIVES

CEQA guidelines require a clearly written statement of objectives to guide the lead agency in developing a reasonable range of alternatives and aid decision-makers in preparing findings or a statement of overriding considerations. CEQA specifies that the statement of objectives should include the underlying purpose of the project (Section 15126.6(a)).These objectives reflect the applicant's objectives and the BLM's stated purpose and need of the project and will be considered in the comparison of alternatives, as required under both NEPA and CEQA. The Energy Commission developed the following objectives for the project:

- To construct and operate an environmentally and economically sound, and operationally reliable solar power generation facility that will contribute to the State of California's renewable energy goals;
- To locate the project in an area with high solar insolation (i.e., high intensity of solar energy);
- To fulfill Governor Schwarzenegger's and Secretary Salazar's Memorandum of Understanding to expedite renewable energy development in California.

The specific objectives and purpose of GSEP as identified by the applicant are:

- To develop a utility-scale solar energy project utilizing parabolic trough technology;
- To construct and operate an environmentally friendly, economically sound, and operationally reliable solar power generation facility that will contribute to the State of California's renewable energy goals;
- To locate the project in an area with high solar insolation (i.e., high intensity of solar energy);
- To interconnect directly to the CAISO Grid through the SCE electrical transmission system; and
- To commence construction in 2010 to qualify for the American Recovery and Reinvestment Act (ARRA) of 2009's Renewable Energy Grant Program.

The applicant has proposed this project in light of the recently enacted State of California legislation and goals, which includes Senate Bill 1078, passed in 2002, establishing the California Renewable Portfolio Standard (RPS). It requires utilities to increase their sale of electricity produced by renewable energy sources, including solar facilities, by a minimum of one percent per year with a goal of 20 percent of their total sales by 2017. However, the California Public Utilities Commission, Energy Commission and the California Power Authority adopted the Energy Action Plan (EAP), which pledged that the agencies would meet an accelerated goal of 20% by the year 2010. The California Senate then passed Senate Bill 107 to be consistent with the EAP and accelerated the implementation of RPS, requiring utilities to meet the goal of 20 percent renewable energy generation by 2010. In November 2008, California's Governor

instituted Executive Order S-14-08, which establishes an updated RPS goal that all retail sellers of electricity shall serve 33% of their load with renewable energy by 2020.

GSEP would be built in an area with high potential for solar resource development. The project would allow California utilities to increase the percentage of renewable resources in their energy portfolio and aid the utilities in reaching the goals set forth by the RPS.

A.5 BLM PURPOSE AND NEED

The BLM's purpose and need for the GSEP is to respond to the applicant's application under Title V of the FLPMA (43 USC 1761) for a Right-Of-Way (ROW) Grant to construct, operate and decommission a concentrated solar thermal electric generating facility, and associated infrastructure, in compliance with FLPMA, BLM ROW regulations, and other applicable federal laws. The BLM will decide whether to approve, approve with modification, or deny issuance of a ROW grant to the applicant for the proposed GSEP.

In addition, there are no existing roads suitable for vehicular access to, or around, the project site. Thus, site access will also be analyzed and, if the project is approved or approved with modification, any new or existing roads required for construction, operation, or decommissioning of the project will be designated as either open, limited, or closed to off-road vehicles, consistent with criteria established in 43 CFR 8342.1.

BLM's action will also include concurrent consideration of amending the California Desert Conservation Plan of 1980, as amended (CDCA). The decision the BLM will make is whether or not to grant a ROW and if so, under what terms and conditions, (and whether to amend the CDCA).

A.6 PROJECT EVALUATION AND APPROVAL PROCESS

This Staff Assessment /Draft Environmental Impact Statement (SA/DEIS) is a joint document being published by the U.S. Bureau of Land Management (BLM) and the California Energy Commission (CEC). It is in the interest of the BLM and the Energy Commission to share in the preparation of a joint environmental analysis of the proposed project to avoid duplication of staff efforts, to share staff expertise and information, to promote intergovernmental coordination at the local, state, and federal levels, and to facilitate public review by providing a joint document and a more efficient environmental review process.

This SA/DEIS contains staff's independent evaluation of the applicant's applications which were filed with the BLM and CEC. The application filed with BLM is the BLM Right-of-Way Application (CACA 048880) and the application filed with the Energy Commission is the Application for Certification (09-AFC-8). The SA/DEIS examines engineering, environmental, public health and safety aspects of Genesis Solar Energy Project (GSEP), based on the information provided by the applicant and other sources available at the time the SA/DEIS was prepared.

This SA/DEIS is not the decision document for these proceedings nor does it contain final findings of the BLM or Energy Commission related to environmental impacts or the project's compliance with local/state/federal legal requirements. Following a 90-day public comment period on the SA/DEIS, the SA/DEIS will be supplemented by staff's Supplemental Staff Assessment/Final Environmental Impact Statement (SAE/FEIS), which will serve as staff's final testimony.

A.6.1. BLM EVALUATION AND APPROVAL PROCESS

The SA/DEIS will also include for BLM a Draft Land Use Plan Amendment (Draft PA) to the California Desert District Plan (1980) as Amended. A 90-day public review and comment period will be provided on the SA/DES (initiated by the NOA published by the U.S. EPA in the *Federal Register*). The SSA/FEIS will include, for BLM, a Proposed Land Use Plan Amendment (Proposed PA). That NOA (published by the EPA in the *Federal Register*) will initiate a 30-day protest period on the Proposed PA to the Director of the BLM. Following resolution of any protests BLM may then publish an Approved Plan Amendment and a Record of Decision (ROD) on the Project Application.

Under the NEPA process, the significance of the impacts are developed based on the definition of "significantly" provided in NEPA regulations Section 1508.27. This evaluation includes both the context of the action with respect to the affected resources, as well as the intensity of the effect on those resources. The following are considered in evaluating the intensity:

- Whether the impact is beneficial or adverse;
- The degree to which the proposed action affects public health or safety;
- Unique characteristics of the geographic area, including parks, farmlands, wetlands, wild and scenic rivers, or ecologically critical areas;
- The degree to which the effects are likely to be highly controversial;
- The degree to which the effects are highly uncertain or involve unique or unknown risks;
- The degree to which the action may establish a precedent for future actions;
- Whether the action may be individually insignificant, but cumulatively significant when combined with other actions;
- Whether the action is related to other actions with individually insignificant but cumulatively significant impacts The degree to which the action may adversely affect significant scientific, cultural, or historical resources;
- The degree to which the action may adversely affect an endangered or threatened species or its habitat; and
- Whether the action threatens a violation of federal, State, or local law or requirements imposed for the protection of the environment.

As outlined in CEQ NEPA regulations 40 CFR 1502.16, the analysis also includes a discussion of both direct and indirect effects and their significance, adverse environmental effects which cannot be avoided, the relationship between short-term

uses of man's environment and the maintenance and enhancement of long-term productivity, and any irreversible or irretrievable commitments of resources.

The decisions to be made by the agencies (licensing by the Energy Commission, and right-of-way grant by BLM) are independent of each other.

A.6.2. CEC EVALUATION AND APPROVAL PROCESS

The Energy Commission's siting regulations require staff to independently review the AFC and assess whether the list of environmental impacts contained is complete and whether additional or more effective mitigation measures are necessary, feasible, and available (Cal. Code Regs., tit. 20, §§ 1742 and 1742.5(a)).

In addition, staff must assess the completeness and adequacy of the measures proposed by the applicant to ensure compliance with health and safety standards and the reliability of power plant operations (Cal. Code Regs., tit. 20, § 1743(b)). Staff is required to develop a compliance plan (coordinated with other agencies) to ensure that applicable laws, ordinances, regulations, and standards are met (Cal. Code Regs., title 20, § 1744(b)).

Staff conducts its environmental analysis in accordance with the requirements of the California Environmental Quality Act (CEQA). No additional Environmental Impact Report (EIR) is required because the Energy Commission's site certification program has been certified by the California Resources Agency as equivalent to meeting all requirements of a certified regulatory program (Pub. Resources Code, § 21080.5 and Cal. Code Regs., title 14, § 15251 (j)).

Staff's impact assessment, including the recommended conditions of certification, is only one piece of evidence that the Committee assigned to oversee the Genesis Solar Energy Project AFC will consider in reaching a decision on the proposed project and making its recommendation to the full Energy Commission for its ultimate consideration and action. At the public evidentiary hearings, all parties will be afforded an opportunity to present evidence and to rebut the testimony of other parties, thereby creating a hearing record on which a decision on the project can be based. The hearing before the assigned Committee also allows parties to argue their positions on disputed matters, if any, and it provides a forum for the Committee to receive comments from the public and other governmental agencies.

Following the hearings, the Committee's recommendation to the full Energy Commission on whether to approve the proposed project will be contained in a document entitled the Presiding Members' Proposed Decision (PMPD). Following its publication, the PMPD is circulated in order to receive written public comments. At the conclusion of the comment period, the Committee may prepare a revised PMPD. At the close of the comment period for the revised PMPD, the PMPD is submitted to the full Energy Commission for a decision.

A.6.3. JOINT NEPA/CEQA PROCESS

The BLM and the Energy Commission have executed a Memorandum of Understanding concerning their intent to conduct a joint environmental review of the project in a single

National Environmental Policy Act (NEPA)/California Environmental Quality Act (CEQA) process. It is in the interest of the BLM and the Energy Commission to share in the preparation of a joint environmental analysis of the proposed project to avoid duplication of staff efforts, to share staff expertise and information, to promote intergovernmental coordination and collaboration at the local, state, and federal levels, and to facilitate public review and participation by providing a joint document and a more efficient environmental review process.

A.6.4. AGENCY COORDINATION

The Energy Commission and BLM seek comments from, and work closely with, other regulatory and wildlife agencies that administer LORS applicable to proposed project. These agencies may include as applicable, the U.S. Environmental Protection Agency, U.S. Fish and Wildlife Service, U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, California Coastal Commission, California River Board of California, California Department of Transportation, State Water Resources Control Board/Colorado River Regional Water Quality Control Board, California Department of Fish and Game, the California Air Resources Board and the Mojave Desert Air Quality Management District. On October 6, 2009, the Energy Commission staff sent the GSEP AFC to all local, state, and federal agencies that might be affected by the proposed project. Additionally, on November 9, 2009, staff mailed agencies a subsequent letter informing them of receipt and availability of supplemental information for the 09-AFC-8 application.

A.7 PUBLIC COORDINATION

SUMMARY OF THE SCOPING AND DRAFT COMMENT PROCESS

PUBLIC COORDINATION

The Energy Commission and the BLM have collaborated in their efforts to facilitate robust public participation in their joint regulatory review of the GSEP. As a means towards this goal, a number of public workshops and hearings have occurred on the proposal to determine whether the proposed project should be approved for construction and operation, and if so, under what set of conditions. These workshops and hearings provided the public, as well as local, state and federal agencies, the opportunity to ask questions about and provide input on the proposed project. The Energy Commission issued notices for these workshops and hearings at least 10 days prior to the meeting. BLM will provide public participation opportunities consistent with the President's Council on Environmental Quality Regulations for Implementing the Procedural Provisions of the NEPA (40 CFR Parts 1500 – 1508), BLM Planning Regulations (43 CFR Part 1600), and respective BLM Handbooks (H-1790-1 and H-1601-1).

The Bureau of Land Management and Energy Commission's outreach efforts are an ongoing process that, to date, has involved the following efforts:

BLM SCOPING MEETING

The Notice of Intent was published in the *Federal Register (Volume 74, No. 224)* on November 23, 2009. On December 10, 2009 the CEC with participation from BLM held a publicly-noticed Informational Hearing at Blythe City Hall, Council Chambers in Blythe, California. On December 11, 2009, BLM held its primary Scoping Meeting at the University of California-Riverside, Palm Desert Campus. A draft scoping report was released for public review and comment in January 2010.

Issues were identified by reviewing the comment documents received. Many of the comments identified similar issues; all of the public comment documents were reviewed and the following section provides a summary of the issues, concerns, and/or questions raised. The comments and questions are organized to reflect the structure of the SA/DEIS, and are listed for review as follows:

Purpose and Need

- The purpose and need statements should not be narrowly defined to rule out feasible alternatives
- The project should be discussed in the context of the larger energy market; identify potential purchasers of the power produced; discuss how the Project will assist in meeting its renewable energy portfolio standards and goals
- The purpose and need statements must address the true nature of the Project without simply adopting the applicant's purpose

Project Description

- What utility company is partnering with this project?
- What will the natural gas line be used for?

Air Resources (Airsheds)

- Greenhouse gas emissions/climate change impacts on plants, wildlife, and habitat
- Planning for species adaptation due to climate change
- Discussion of how projected impacts could be exacerbated by climate change
- Quantify and disclose anticipated climate change benefits of solar energy
- Discussion of trenching/grading/filling and effects on carbon sequestration of the natural desert
- Discussion of ambient air conditions, NAAQS, and criteria pollutant nonattainment areas in all areas considered for solar development
- Estimation of emissions of criteria pollutants
- Description and estimation of emissions from potential construction activities
- Specify the emission sources by pollutant from mobile sources, stationary sources, and ground disturbance

- Discuss the need for an Equipment Emissions Mitigation Plan
- Discuss the need for Fugitive Dust Control Plan

Soils Resources

- Impacts to desert soils
- Increased siltation during flooding and dust
- Impacts to crypto-biotic crust
- Preparation of a drainage, erosion, and sediment control plan

Water Resources (Surface and Groundwater)

- Discuss the amount of water needed for the proposed Project, where this water will be obtained, and the amount and source of power that would be needed to move the water to the facility
- Identify impacts to jurisdictional waters of the US and California
- Effects of additional groundwater pumping in conjunction with other groundwater issues
- Impacts to groundwater, surface water, and wetlands
- Effects of diversion of water from ephemeral streams
- Water supply impacts related to dust control, fire prevention and containment, vegetation management, sanitation, equipment maintenance, construction, and human consumption
- Description of water conservation measures to reduce water demands
- Effects of climate change on water supply
- Discussion of potential effects of Project discharges on surface and groundwater quality
- Disposal of wastewater or other fluids
- Determination if Project requires a Section 404 permit under the Clean Water Act (CWA)
- Description of natural drainage patterns, Project operations, identify whether any component of Project is within 50 or 100-year floodplain
- Provide information on CWA Section 303(d) impaired waters, if any, and efforts to develop and revise total maximum daily loads
- Describe of the water right permitting process and the status of water rights within the basin, including an analysis of whether water rights have been over-allocated
- Describe any water right permits that contain special conditions; measures to mitigate direct, indirect, and cumulative impacts; and provisions for monitoring and adaptive management.
- Discuss whether it would be feasible to use other sources of water

- Discuss whether it is possible to recycle the water that would be sent to the evaporation ponds
- Identify the storm design containment capacity of the evaporation ponds, explain how overflow in larger storm events will be managed, and discuss potential environmental impacts (drainage channels affected, water quality, biological resources) in the event of overflow
- Discuss whether the evaporation pond lining will adequately prevent leakage into the ground water
- Discuss how water will be purified on-site
- Discuss how dissolved solids will be handled
- Discuss how the Project will recharge ground water
- Discuss lack of rainfall in the Project area
- Discuss how soil erosion on low fill slopes and steeply graded areas could result in sedimentation of water bodies
- Discuss impacts affecting surface springs
- Analyze potential connectivity between deep, medium and shallow groundwater aquifers
- Discuss potential adverse affects on residential wells
- Analyze potential adverse impacts affecting the watershed of the Palen and McCoy Mountains

Biological Resources

- If there are threatened or endangered species present, recommend BLM consult with USFWS and prepare a Biological Opinion under Section 7 of the ESA
- Consider adopting a formal adaptive management plan
- Impacts to all known species, not just special status, should be analyzed to assure ecosystem level protection
- Maximize options to protect habitat and minimize habitat loss and fragmentation
- Impacts due to increased shade in the desert environment
- Seasonal surveys should be performed for sensitive plant and animal species
- Analyze the effects of ponded water or bioremediation areas on wildlife, particularly migratory waterfowl
- Acquisition of lands for conservation should be part of mitigation strategy
- Impacts regarding habitat fragmentation and loss of connectivity
- Discuss the biological value of brackish groundwater and the Project's associated impacts
- Analyze potential harm to the Ford Dry Lake ecosystem (vernal pools that provide rare and endemic plants and fairy shrimp populations)

- Include surveys to account for unidentified plant species that have not yet been discovered
- Analyze impacts affecting the Palen-McCoy wilderness area and the Multiple Species Wildlife Habitat Management Plan
- Consider that the linear footprint of the Project poses a greater threat to wildlife movement (wildlife corridors) than would a more compact polygon
- Consider scientific studies pertaining to wildlife corridors and habitat linkages in the California deserts
- Identify and quantify critical habitat that might be directly, indirectly, or cumulatively affected by each alternative
- Analysis of impact and mitigation on covered species should include:
  - Baseline conditions of habitats and populations of the coved species
  - A clear description of how avoidance, mitigation and conservation measures will protect and encourage the recovery of the cove species and their habitats in the Project area
  - Monitoring, reporting and adaptive management efforts to ensure species and habitat conservation effectiveness
- Identify potential impacts of construction, installation, operation, and maintenance activities on habitat and threatened and endangered species
- Describe the condition of the land selected for the proposed Project and disclose whether the land is classified as disturbed or impaired
- Discuss the impact associated with construction fences around the Project site, and consider whether there are options that could facilitate better protection of covered species
- Discuss the effects the evaporation ponds will have on birds and wildlife
- Consider conducting biological surveys for wet years
- Discuss impacts affecting wilderness areas
- Provide detailed vegetation and wildlife maps to facilitate public input
- Discuss impacts affecting the Eastern Colorado and Northern Colorado Recovery Units
- Analyze the Project's potential to foreclose future conservation options
- Address impacts to all known species in the Desert Renewable Conservation Plan, so as to assure ecosystem level protection
- Confidentiality agreements should not be allowed for the surveys in support of the proposed Project
- Discuss effects of erosion on dune habitats

Vegetation Resources (Vegetative communities, priority and special status species)

- Identify all petitioned and listed threatened and endangered species and critical habitat that might occur within the Project area
- Include a full floral inventory of all species encountered on-site
- Seasonal surveys should be performed for sensitive plant species—lack of fall surveys may under represent onsite plants
- If transplantation is to be a part of the mitigation strategy, a detailed plan must be included as part of the EIS/SA
- Discuss impacts affecting Unusual Plant Assemblages (UPA)
- Vegetation maps should be at scale that is useful for evaluating impacts
- Impacts due to non-native invasive species
- Inclusion of an invasive plant management plan
- Assess Project impacts affecting plant taxa occurring within the Project area that are considered rare within California but more common elsewhere
- Impacts to existing plant communities

Wildlife Resources (Priority species, special status species)

- Address impacts to both individual and intergeneration movement
- Impacts to the following species:
  - Desert Tortoise
  - Burrowing owl
  - Desert bighorn sheep
  - Mojave fringe-toed lizard
  - Mule deer
  - American badger
  - Northern harrier
  - Swainson's hawk
  - Loggerhead shrike
  - Purple martin
  - Migratory birds
  - Golden eagles
  - Kit Fox
- Impacts to wildlife movement corridors
- Preserve large landscape-level migration areas

- Before passive relocation of burrowing owl is enacted, consider the location of the substitute burrows. If burrows are on site, the owls will move there and will have to be removed again

Cultural Resources

- Has a 100 percent archaeological inventory been conducted pursuant to Section 106 of the National Historic Preservation Act and BLM Manual 8100?
- Have archaeological sites been evaluated pursuant to the National Register of Historic Places criteria?
- Has consultation with Native Americans take place?
- Evaluate impacts affecting Sacred Sites
- Describe the process and outcome of government-to-government consultation between BLM and each of the tribal governments within the Project area, issues that were raised (if any), and how those issues were addressed in the selection of the proposed alternative
- Evaluate potential impacts on archeological, cultural, and historical resources in the vicinity of the Project, including, but not limited to: (1) Native American resources, burial sites, and artifacts; and (2) historical mining operations and related artifacts.
- Assuming the Project site has cultural resources, it is critical to have a “Treatment Plan” or an Historic Preservation plan
- Analyze impacts affecting the Palen Mountains, which are very sacred to the Uto-Aztecan
- Evaluate the sacredness and lack of water

Visual Resources

- Baseline for visual resources has not been categorized
- Visual impacts to wilderness areas
- Avoid impacts affecting visually sensitive areas
- Analyze the Project’s aesthetic and visual impacts that could affect tourism in the area
- The benefits which the Project will provide may well outweigh the costs of visual impacts

Land Use/Special Designations (ACECs, WAs, WSAs, etc.)

- Discuss impacts affecting Multi-Species Wildlife Habitat Management Area (WHMA)
- Evaluation of consistency with land use and regulatory plans, including Executive Order 11644, which allows for use of off-road vehicles on public lands
- Describe reasonably foreseeable future land uses and associated impacts resulting from additional power supply

- Consider direct and indirect effects of the inter-connecting transmission line
- Discuss how the Project would support or conflict with existing land use plans

Public Health and Safety

- Disclose any potentially toxic or hazardous wastes that may be associated with Project construction, operation, and maintenance including pesticides and herbicides
- Discuss how toxic wastes will be disposed
- Identify fire prevention BMPs due to use of high temperature liquids
- Discuss if bioremediation areas are to be used for soil contaminated by heat transfer fluid
- Discuss the generation of concentrated, dewatered solid waste associated with evaporation ponds and describe whether this waste product will be transported off site for disposal
- Discuss the effect the evaporation ponds will have on human safety
- Address potential direct, indirect, and cumulative impacts of hazardous waste from construction and operation of the proposed Project
- Discuss hazards that could occur in the event of an earthquake or explosion
- Address the effects that each alternative may have on wildfire risks

Noise/Vibration

- Consider wildlife as sensitive receptors

Recreation (RMAs, facilities, LTVAs, dispersed recreation opportunities, etc.)

- Evaluation should include impacts regarding off-highway vehicle use (OHV), camping, photography, hiking, wildlife viewing, and rockhounding
- Evaluation should include number of users, value of affected land for recreational purposes, and need to locate and acquire replacement venues for lands lost
- Evaluate indirect impacts caused by displacing recreational users

Social and Economic Setting

- Evaluation of economic impacts due to construction, implementation, and operation
- Economic impacts regarding loss of commerce due to recreational use losses

Environmental Justice (minority and low-income communities)

- Evaluate whether diminished recreational access would be placed disproportionately on minorities and low-income communities
- Include an evaluation of environmental justice populations within the geographic scope of the Project

Cumulative Impacts

- Identify impacts from other projects occurring in the vicinity, including solar, wind, geothermal, roads, transit, housing, ORV use, military maneuvers, and other development
- The cumulative analysis area should encompass the Sonoran/transition desert areas of the California desert at a minimum
- Some reasonably foreseeable Projects in the vicinity include all the solar and wind applications along I-10
- Identify cumulative impacts affecting wildlife and vegetation
- Include discussion of cumulative impacts to ground water supply
- In the introduction to the Cumulative Impacts Section, identify which resources are analyzed, which ones are not, and why
- Analyze the potential for development and population growth to occur in those areas that receive the generated electricity
- describe the reasonably foreseeable future land use and associated impacts that will result from the additional power supply
- Examine the potential for ecosystem fragmentation associated with the cumulative effects of large-scale industrial development occurring in the California Desert areas
- Analyze the Project's cumulative impacts affecting biological resources
- The cumulative impacts analysis should address species migration needs and other ecological processes that maybe caused by global climate change

Alternative Development and/or Alternative Design Criteria

- Project description should not be narrowly defined to rule out feasible alternatives
- Describe how each alternative was developed, how it addresses each Project objective, and how it would be implemented
- The preferred alternative should consider conjunctive use of disturbed private land in combination with adjacent lower value federal land
- Consider reduced Project size
- Alternatives should include: sites not under BLM jurisdiction; Project extent and electrical power generation that differ from proposal; use of different technology; benefits associated with the proposed technology
- Alternatives should describe rationale used to determine whether impacts of an alternative are significant or not
- Consider reconfiguration alternatives proposed by CEC in their Dec. 7, 2009 data request—to minimize impacts to wildlife movement and sensitive biological resources
- Discuss feasibility of using residential and wholesale distributed generation, in conjunction with increased energy efficiency, as an alternative

- Consider cost of energy for different technologies
- Consider large-scale rooftop photovoltaic
- Established power purchase agreements should not affect decisions made on alternatives
- Consider alternative technologies that require significantly less water
- Consider the no-action alternative
- Consider Dry Cooling as an alternative
- Consider moving the project off of all sand areas

LIBRARIES

On October 6, 2009, the Energy Commission staff sent the GSEP AFC to both the Riverside Main Library in Riverside, California, and the Palo Verde Valley District Library in Blythe, California.

In addition, to these local libraries, copies of the AFC are also available at the Energy Commission's Library in Sacramento, the California State Library in Sacramento, as well as public libraries in Eureka, Fresno, Los Angeles, San Diego, and San Francisco.

PUBLIC OUTREACH EFFORTS

Energy Commission staff provides formal notices to property owners within 1,000 feet of the proposed site and within 500 feet of a linear facility (such as transmission lines, gas lines and water lines). Staff mailed the public notices on October 6, 2009, informing the public, agencies, and elected officials of the Commission's receipt and availability of the application, 09-AFC-8. Each notice contained a link to a Commission-maintained project website (http://www.energy.ca.gov/sitingcases/GENESIS_SOLAR/index.html).

DATA REQUEST, DATA RESPONSE & ISSUES RESOLUTION WORKSHOPS

Staff from the Energy Commission and the BLM held Data Requests, Data Response and Issues Resolution Workshops in the following California communities: Blythe, Palm Desert, Palm Springs, and Sacramento. These workshops were conducted on the following days: November 23 and 24, 2009; December 10, 18 and 31, 2009; January 6, 11 and 12, 2010; and, February 10 and 18, 2010. During each of these workshops, specific time for public comment was allocated, and participation was encouraged. These workshops provided a public forum for the applicant, intervenors, staff and cooperating agencies to interact regarding project issues.

NOTIFICATION TO THE LOCAL NATIVE AMERICAN COMMUNITY

The BLM staff first sent letters to various Native American tribes regarding this project on November 26th 2007. The letter provided an initial briefing on the project and a request for any comments and concerns and was mailed to the following fourteen (14) recipients:

1. Mr. Richard Milanovich, Tribal Chair; Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

2. Ms. Patricia Tuck, Tribal Historic Preservation Officer, Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

3. Ms. Bridget Nash-Chrabascz, Tribal Historic Preservation Officer, Quechan Indian Tribe, Ft. Yuma Indian Reservation P.O. Box 1899, Yuma, AZ 85366-1899

4. Mr. Robert Martin, Chairman; Morongo Band of Mission Indians. 12700 Pumarra Rd. Banning, CA 92220

5. Ms. Sherry Cordova, Chair, Cocopah Tribal Council. County 15th and Ave,G. Somerton, AZ 85350

6. Mr. Eldred Enas, Chairman, Colorado River Tribal Council. 26600 Mojave Rd. Parker, AZ 85344

7. Mr. Darrell Mike, Chairman, Twenty-Nine Palms Band of Mission Indians. 46-200 Harrison Place, Coachella, CA 92236

8. Mr. John James, Chairman; Cabazon Band of Mission Indians. 84245 Indio Springs Rd. Indio, CA 92203-3499

9. Ms. Maryann Green, Chairperson, Augustine Band of Mission Indians. P.O. Box 846 Coachella, CA 92236

10. Mr. Timothy Williams, Chairman; Fort Mojave Tribal Council. 500 Merriman Ave. Needles, CA 92363

11. Mr. Charles Wood, Chairman; Chemehuevi Tribal Council. P. O. Box 1976 Havasu Lake, CA 92363.

12. Mr. Michael Jackson, Sr., President, Fort Yuma Quechan Tribe. P.O. Box 1899, Yuma, AZ 85366-1899

13. Mr. James Ramos, Chairman; San Manuel Band of Mission Indians. P.O. Box 266, Patton, CA 92369

14. Ms. Mary Resvaloso, Chairwoman; Torres-Martinez Desert Cahuilla Indians. P.O. Box 1160, Thermal, CA 92274-1160

Replies were received from the following three (3) Tribes requesting reports, expressing concerns, or referring to neighboring groups whom may have an interest in the project area.

1. Ms. Patricia Tuck, Tribal Historic Preservation Officer, Agua Caliente Band of Cahuilla Indians, 5401 Dinah Shore Drive, Palm Springs, CA 92264

2. Ms. Bridget Nash-Chrabascz, Tribal Historic Preservation Officer, Quechan Indian Tribe, Ft. Yuma Indian Reservation P.O. Box 1899, Yuma, AZ 85366-1899

3. Mr. Britt W. Wilson, Project Manager-Cultural Resources; Morongo Band of Mission Indians. 12700 Pumarra Rd. Banning, CA 92220

On February 22, 2010, the BLM sent an additional letter that provided an update on the CEC-BLM workshops that were held in December, 2009 and January and February, 2010 and on Native American input that was received. The letter invited tribes to consult on eligibility evaluations of archeological sites and invited tribes to consult on the Programmatic Agreement (PA) being prepared by BLM, the State Historic Preservation Office (SHPO), and the Advisory Council on Historic Preservation (ACHP).

ENERGY COMMISSION'S PUBLIC ADVISER'S OFFICE

The Energy Commission's outreach program is also facilitated by the Public Adviser's Office (PAO). The PAO also requested public service announcements at a variety of organizations including the Blythe City Council, local newspapers, three separate Chambers of Commerce, local (Palm Springs) television and (Palm Springs and Blythe) radio stations. These notices informed the public of the Commission's receipt of the GSEP application 09-AFC-8, and invited the public to attend the Public Site Visit (to the proposed GSEP site) and Informational Hearing/BLM Scoping Meeting on December 10, 2009 in Blythe, CA.

ORGANIZATION OF THE STAFF ASSESSMENT/DRAFT ENVIRONMENTAL IMPACT STATEMENT (SA/DEIS)

The SA/DEIS contains an Executive Summary, Introduction, Project Description, and Project Alternatives. The environmental and engineering analyses of the proposed project are contained in a discussion of nineteen (19) separate technical areas.

ENVIRONMENTAL ANALYSIS

- Air Quality
- Biological Resources
- Cultural Resources and Native American Values
- Hazardous Materials Management
- Public Health and Safety
- Soil and Water Resources
- Land Use, Recreation, and Wilderness
- Noise and Vibration
- Socioeconomics and Environmental Justice
- Traffic and Transportation
- Transmission Line Safety and Nuisance
- Visual Resources
- Waste Management

- Worker Safety and Fire Protection

ENGINEERING ANALYSIS

- Facility Design
- Geology, Paleontology, and Minerals
- Power Plant Efficiency
- Power Plant Reliability
- Transmission System Engineering

Each technical area is addressed in a separate chapter. These chapters are followed by a discussion of alternatives, facility closure, project construction and operation compliance monitoring plans. Among other things, each technical area assessment will include a discussion of:

- laws, ordinances, regulations, and standards (LORS);
- the regional and site-specific setting;
- project specific and cumulative impacts;
- mitigation measures;
- closure requirements;
- conclusions and recommendations; and
- conditions of certification for both construction and operation

Cumulative Impacts

An understanding of potential cumulative impacts is important, particularly in light of the recent and rapid development of proposed renewable energy projects in the southeast region of California and the BLM California Desert District. Historically, the desert has seen little change or human development largely due to the adverse climatic conditions. The introduction of large utility scale solar facilities will reduce the amount of previously undisturbed desert area. The intensity of the proposed development at this time depends on actual development; however, many proposed projects are undergoing environmental review.

Federal and State of California regulations guide the analysis of cumulative impacts as part of environmental review under the National Environmental Policy Act (NEPA) and the California Environmental Quality Act (CEQA). At the Federal level, the Council of Environmental Quality regulations for implementing NEPA define cumulative impact as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time" (40 Code of Federal Regulations [CFR] Section 1508.7).

California state regulations have adopted similar language to define cumulative impacts as “the change in the environment which results from the incremental impact” of the Genesis Solar Energy Project (the Project) when “added to other closely related past, present, and reasonably foreseeable probable future projects.” Cumulative impacts can result from “individually minor but collectively significant projects taking place over a period of time” (California Code of Regulations, Title 14 Division 6, Chapter 3, Section 15355).

This overview of the past, present, and reasonably foreseeable future projects provides the data for the cumulative impacts analysis of each environmental resource evaluated in the AFC. Factors that have been considered in developing the past, present, and reasonably foreseeable scenarios include Federal and State goals for renewable energy development; long-term transmission plans; local land use planning documents; and applications filed with Federal, State, and local agencies, including the Bureau of Land Management (BLM), the CEC, and Riverside County.

Affected Environment

The BLM has developed “Guidance for Processing Applications for Solar Power Generation Facilities on Bureau of Land Management Administered Public Lands in the California Desert District” (2008). The BLM guidance states “the reasonably foreseeable development scenario should be developed using an ‘areawide’ approach selected specifically for the individual project and surrounding area. The appropriate land area to cover in analyzing cumulative impacts may vary by resource.” The BLM California Desert District, Palm Springs-South Coast Field Office, the Federal lead agency on the Project, provided the area to consider for the cumulative impact analysis for the Project.

Environmental Setting, Past and Present Actions

The Project area is located in eastern Riverside County, where land use is characterized predominantly by open space and conservation and wilderness areas. The western portion of the county accounts for most of the developed area of the county, including urban areas and agricultural areas. The southeastern corner of the county to the east of the Project also contains agricultural areas and limited rural development (Riverside County, 2003).

The Riverside County General Plan divides areas of the county into regional planning areas (Riverside County, 2003). The Project is located within the Eastern Riverside County Desert Areas (Non-Area Plan), which encompasses lands in the eastern portion of the county not located within a specific area plan. The General Plan land use policy is to “preserve the character of the Eastern Riverside County Desert Area” (Riverside County, 2003).

The area designated within the Palo Verde Valley Area Plan occurs to the east of the Project and encompasses the developed and agricultural area in eastern Riverside County. The portion of the Palo Verde Valley Area Plan in the vicinity of the Project consists mainly of sparsely populated desert and mountain areas. The more populated and agricultural areas occur farther east of the Project in the vicinity of Blythe.

The Project is also located within the BLM California Desert Conservation Area Resource Management Plan (CDCA Plan) (BLM, 1980). The CDCA Plan establishes a number of conservation areas under the Wilderness Review Program. The Project is located adjacent to the southern boundary of the Palen/McCoy Wilderness Area. The Chuckwalla Mountains and Little Chuckwalla Mountains Wilderness Areas are also located farther south-southwest of the Project.

Reasonably Foreseeable Future Actions

The State of California has issued a number of executive and legislative measures that have created a need in California for the development of solar and other renewable energy sources. The California Renewables Portfolio Standard (RPS) currently calls for the State's utilities to procure 20 percent of their retail electricity sales from renewable energy by 2010, as specified in Senate Bill 107, passed in 2006 and effective as of January 1, 2007.

The current RPS represents a more aggressive goal from the original RPS goal of 20 percent by 2017, originally established by Senate Bill 1078 in 2002. Governor Schwarzenegger's Executive Order of November 2008 (S-14-08) and California Energy Action Plan (2005) have also set the goal at 33 percent by 2020.

In response to the growing demand for renewable energy sources in California, the BLM and the CEC have received applications for the development of solar and other renewable energy facilities throughout California. Several planning initiatives have been established to programmatically review California's natural and social resources and identify areas most suitable for development of renewable energy resources. For the purposes of the cumulative impacts discussion, the proposed projects and public planning initiatives are considered present and reasonably foreseeable future actions that are included in the cumulative impacts analysis.

B. DESCRIPTION OF THE PROPOSED PROJECT AND ALTERNATIVES

B.1 - DESCRIPTION OF PROPOSED PROJECT AND ALTERNATIVES

Mike Monasmith and Susan V. Lee

B.1 PROPOSED PROJECT

B.1.1 INTRODUCTION

On August 31, 2009, the California Energy Commission received an Application For Certification (AFC) from the applicant Genesis Solar, LLC to construct and operate the Genesis Solar Energy Project (GESP) in eastern Riverside County, approximately 25 miles west of the Arizona-California border city of Blythe, California. Following the augmentation of the AFC with additional data and information in Supplements, the AFC was deemed complete by the Energy Commission on November 4, 2009, beginning staff's analysis of the proposed project.

This section provides a description of the proposed project and three (3) project alternatives being considered by the Energy Commission and the U.S. Bureau of Land Management (BLM). Under NEPA, both the proposed project ***and*** the three project alternatives are all considered alternatives to each other. The alternatives range in size from 850 acres up to 1,800 acres.

Two of the three project alternatives being described herein are the same size. The remaining alternative is a significantly smaller version of the proposed project (approximately 50 percent smaller). This smaller alternative is being considered because of its ability to avoid environmental impacts to groundwater resources (the impetus behind the "dry cooling" alternative as well).

All three of the project alternatives would use the same solar electric technology and therefore have a common description of equipment, systems, processes, resource inputs, operations, closure plans and general location. As such, in order to avoid redundancy, this section will present a single project description that identifies the elements that are common to each alternative and then separately identify the elements that are unique to each alternative.

B.1.2 DESCRIPTION

The Genesis Solar Energy Project at the Ford Dry Lake site is proposed for development in the Sonoran Desert approximately 25 miles west of Blythe, California. The total area in the BLM ROW application is 4,640 acres. The actual proposed facility would be located on approximately 1,800 acres. Surrounding land uses include the McCoy Mountains to the east, the Palen Mountains (including the Palen Mountains Wilderness Area) to the north, and the Blythe Airport about 15 miles to the east. Interstate 10 (I-10) is located about 2 miles south of the southernmost border of the proposed ROW area.

The project will require two separate units consisting of a total of 1,760 solar collector assemblies (SCAs) arrayed in rows, or piping loops, with four assemblies in each loop.

Each SCA will consist of individually mounted mirror modules approximately 40 feet long, for a total length of 492 feet with an approximate mirror area of 8,795 square feet. The mirrors to be used for the project will have an aperture of 18.9 feet and focal length of 5.6 feet.

The overall site layout and generalized land uses are characterized as follows:

- 250-MW facility, including solar generation facilities, on-site substation, administration, operations and maintenance facilities: approximately 1,800 acres;
- Evaporation ponds: up to 50 acres (located within the 1,800-acre site);
- Surface water control facilities for storm water flow and discharge; and
- Temporary construction laydown area(s) will be accommodated within the larger site footprint. No additional laydown areas outside the eventual project footprint are contemplated.

The following sections describe the site arrangement and the processes, systems, and equipment that constitute the generation facilities. All plant facilities will be designed, constructed and operated in accordance with applicable laws, ordinances, regulations and standards (LORS). All generating facilities would be located within the fence line of each of the alternative projects. **Project Description Figure 1** illustrates the regional setting for the proposed project. Project related, linear facilities (approximately 6.5 miles in length) located outside the project fence line are limited to a new 230-kV transmission line, access road, and the 8-inch natural gas pipeline, and can be viewed in **Project Description Figure 2**.

Major Facilities and Site Arrangement

Overall project facilities include the following major components:

- Solar field(s);
- Power block;
- Access road from I-10 (Wiley Wells exit) to onsite office;
- Office and parking;
- LTU (Land Treatment Unit) for bioremediation of HTF-contaminated soil;
- Maintenance buildings and laydown area; and,
- Onsite transmission facilities including switchyard.

Each 125 MW power plant (one for the eastern solar field, and one for the western solar field) consists of:

- STG (Steam Turbine Generator);
- SSG (Servicing Scenario Generator) heat exchangers;
- Surface condenser;
- Feedwater pumps;
- Deaerator

- Feedwater heaters
- Wet cooling tower
- Evaporation ponds
- Natural gas-fired boilers
- Solar thermal collection field

The plant's power cycle is the Rankine-with-reheat thermodynamic cycle. A preliminary heat balance diagram for the process is included in Figure 3.4-6. The thermal input is via heated HTF from the parabolic trough solar field at a temperature of approximately 740F.

Overall annual availability for each 125 MW facility is expected to be between 96 to 98 percent of possible operating hours (between 3,000 and 3,200 hours per year). Each plant's capacity factor will depend on the local solar insolation, but has been estimated to be approximately 27 percent, or approximately 300,000 MWh/year. Each 125 MW plant will use the Rankine thermodynamic cycle with reheat described as follows:

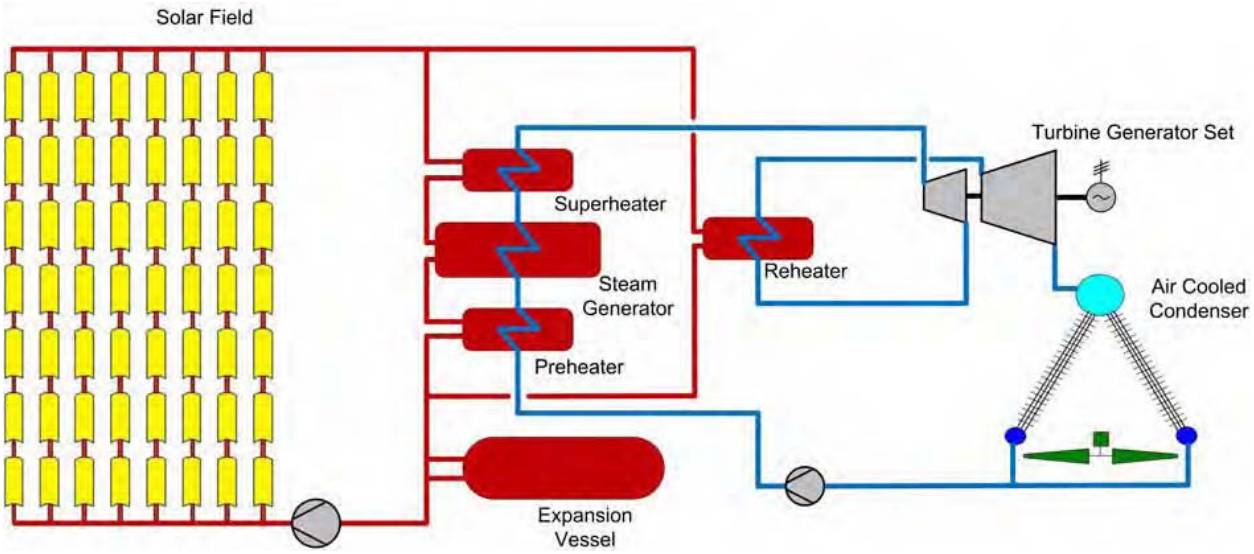
Process 1: The working fluid (water) is pumped from low to high pressure. During this process, steam extracted from the STG is used to preheat the water prior to entering the SSG system, which increases overall cycle efficiency.

Process 2: The high pressure liquid enters the SSG system where it is heated theoretically at constant pressure by the HTF to become superheated steam.

Process 3: The superheated steam expands through the high pressure section of the steam turbine, turning the generator to produce electricity. This steam is then reheated in different vessels that are part of the SSG system and sent to the reheat section of the steam turbine. The reheat exhausts into the low pressure (LP) section of the steam turbine.

Process 4: The wet steam from the LP section then enters the surface condenser where it is cooled at a constant low pressure to become a saturated liquid. The condensed liquid returns to Process 1.

As the HTF is circulated from the SSG to the solar field, it absorbs solar energy and provides a high temperature (740^{o}F) energy source for the Rankine cycle. Waste heat is rejected in Process 4. As the turbine exhaust is condensed, the heat is transferred to the cool circulating water. The warm circulating water carries the heat to the wet cooling tower to be rejected.



Power Generation Process

The power generating facility is composed of the following major components:

- Deaerator,
- Feedwater pumps,
- Feedwater heaters,
- SSG,

- Steam superheater,
- Steam reheater,
- STG,
- ACC,
- Between 850 acres and approximately 1,700 acres of parabolic trough solar collection fields, and HTF piping, pumping, and conditioning system – depending on which alternative is approved.

The thermodynamic cycle is illustrated in the diagram below and described in the steps that follow:

Red lines on the diagram represent HTF piping. Hot HTF flows from top to bottom in the figure, arriving from the solar fields (having captured the sun's energy) and transferring this heat from the sun to the superheater and reheater; from where it then moves the heat energy to the steam generator; and, lastly the HTF flows to the preheater before returning to the solar fields to be heated once again in a continual cycle of renewable, clean energy. The blue lines represent steam and water piping. Feedwater, the portion of the blue line between the ACC and the preheater, is heated in a series of feedwater heaters by steam turbine extractions at various pressure levels.

Solar Energy Conversion Facilities Description

This section describes the major energy conversion components of the Project, including the solar collection system, SSG, STG, auxiliary boilers, and HTF freeze protection heat exchanger. The Project will consist of two, single-unit parabolic trough solar fields (125 MW each) that feed a single power plant having a combined, nominal output of 250 MW. The plant will consist of a conventional steam Rankine-cycle power block, two parabolic trough solar fields, an HTF and steam generation system, as well as a variety of ancillary facilities, such as conventional water treatment, electrical switchgear, administration, warehouse, and maintenance facilities.

Individual Components of the Proposed Project

Solar Collector Assemblies - The project's SCAs are oriented north-south to rotate east-west to track the sun as it moves across the sky throughout the day. The SCAs collect heat by means of linear troughs of parabolic reflectors, which focus sunlight onto a straight line of heat collection elements (HCEs) welded along the focus of the parabolic "trough".

Heat Transfer Fluid - Therminol™ (VP-1), an aromatic hydrocarbon, biphenyl-diphenyl oxide manufactured by Solutia, is currently being considered as the HTF for the Project. Therminol is a special high-temperature oil that has an excellent operating history and is used in many heat transfer processes. Dowtherm A, an essentially chemically identical product manufactured by Dow, is being considered as an alternative to Therminol™ (VP-1).

Parabolic Trough Collector Loop - Each of the collector loops consist of two adjacent rows of SCAs, each row is about 1,300 feet long. The two rows are connected by a crossover pipe. HTF is heated in the loop and enters the header, which returns hot HTF from all loops to the power block where the power generating equipment is located.

Mirrors - Low-iron glass mirrors are mounted on the SCA. These mirrors are reliable components that have shown no long-term degradation in reflective quality. Twenty-year-old mirrors can be cleaned and brought back to like-new reflectivity. Long-term endurance of the mirror, as measured by the experience at Solar Electric Generating Station (SEGS), indicates mirror life of 30 years or more can be expected for the Project. Flexible mirror reflectivity monitoring procedures using demineralized water for mirror washing is critical. The periodic monitoring of mirror reflectivity provides a valuable quality control tool for mirror washing and helps to optimize wash labor.

Solar Steam Generator System - The SSG system design is similar to any "kettle boiler" shell and tube heat exchanger in that the hot HTF is circulated through tubes and the steam is produced on the shell side. The SSG system includes heat exchangers for preheating the condensate, superheating the steam, and reheating steam, in addition to the boiler vessels.

HTF Freeze Protection Heat Exchanger - The HTF freezes at temperatures below 54 °F. To eliminate the problem of HTF freezing, steam-fed shell and tube heat exchangers will be used to keep the HTF above 100 °F whenever the facility is offline. As discussed above, the auxiliary boilers will supply the heat for this process as well as performing the function of a startup boiler. This dual-use configuration reduces the number of individual emission sources.

HTF Expansion Tank - Expansion tanks are required to accommodate the volumetric change that occurs when heating the HTF to the operating temperature. Nitrogen will be used to blanket the headspace of the tanks. The nitrogen purge prevents oxidation or contamination of the HTF by reducing its exposure to atmospheric air.

HTF Ullage/Flash System - During plant operation, HTF will degrade into components of high and low boilers (substances with boiling points higher and lower than the HTF). The low boilers are removed from the process as vapors through the ullage system. The high boilers are removed from the process as liquid and sediment through the HTF flash system.

Auxiliary Boiler - The auxiliary boiler will be fueled by natural gas and will provide steam for maintaining steam cycle equipment vacuum over night and for startup. Sealing steam is used to prevent air from entering the steam turbine while the condenser is under vacuum. This method reduces startup time for the plant compared to relying on solar-generated steam as the sealing steam source. Unlike a gas-fired power plant, a solar thermal plant must wait for the sun to rise in the morning to start generating steam and has a finite time to generate electricity (i.e., the number of sunlight hours). If the plant does not have a secondary source of steam, plant startup is delayed (and thus total daily electrical generation reduced), while solar heat alone generates sealing steam and vacuum is established in the condenser. Once the plant begins generating electricity for delivery to the electrical grid, the fired auxiliary boiler is no longer needed and is held in stand-by mode until auxiliary heat is again required after plant shutdown. The maximum estimated natural gas usage for the auxiliary boiler is expected to be 60 million standard cubic feet per year, for a maximum of 60,000 British thermal units per year.

Major Electrical Systems and Equipment

This section describes the major electrical systems and equipment. Roughly 10 percent of the STG output will be used on-site for plant auxiliary loads such as motors, heaters, control systems, and general facility loads including lighting and heating, ventilation, and air conditioning (HVAC). Some of the power needed for on-site uses will be converted

Power will be generated by the STG (size and generation voltage is depending on the final generator selection) and stepped up by a fan-cooled generator step-up transformer (GSUT). Start-up power will be back-fed through the GSUT. Once the STG is running, it will supply the plant auxiliary power through a generator bus tap and the unit auxiliary transformer (UAT). The plant stand-by electrical power requirements will be back-fed through the GSUT and UAT. There will also be an alternate back-feed power source to the main auxiliary switchgear. This will be key-interlocked with the main auxiliary power source to prevent both sources from operating simultaneously.

Grounding - The electrical system is susceptible to ground faults, lightning, and switching surges that can pose hazards to site personnel and electrical equipment. The station grounding system provides an adequate path to ground to permit the dissipation of current created by these events. The station ground grid will be designed for adequate capacity to dissipate ground current.

Bare conductors will be installed below-grade in a grid pattern throughout the power block area. Each junction of the grid will be bonded together by an exothermic weld or compression connection. Ground resistivity readings will be used to determine the necessary numbers of ground rods and grid spacing to ensure safe step and touch potentials under severe fault conditions. Grounding stingers will be brought from the

ground grid to connect to building steel and non-energized metallic parts of electrical equipment.

Electrical Generation - As shown in the key one line diagram, Figure 3.4-7, the Project's STGs will tie into a 230 kV on-site switchyard. The STGs generate electricity at 13.8 kV that will connect to the switchyard at 230 kV via a generator circuit breaker (GCB) and a GSUT. The GCB will be rated at 8000 Amperes (A) and will include 8000/5 A current transformers and 14.4-0.12 kV voltage transformers for generator bus duct and UAT protection. A disconnect switch will be included with the generator circuit breaker for generator disconnect and transformer maintenance. An 8000 A isolated phase bus duct will connect the generator to the GCB and the GCB to the GSUT. The GSUTs will be 150 megavolt-amps (MVA), 230-13.8 kV, two-winding, delta-wye grounded, and fan-cooled (using oil-immersed natural circulation, multi-stage, forced air cooling). The neutral point of high-voltage winding will be solidly grounded. The main step-up transformer will have metal oxide surge arrestors connected to the high-voltage terminals and will have manual de-energized ("no-load") tap changers located in high-voltage windings to allow for a nominal voltage plus or minus five percent with a 2.5 percent differential to allow for generator output voltage variations. The GSUT will rest on a concrete pad with a perimeter berm designed to contain the transformer non-polychlorinated biphenyl (PCB) insulating oil in the event of a leak or spill.

The plant site switchyard will be located near the unit two power blocks, as shown in Figure 3.4-3, and will require an overhead 795 thousand circular mils (kcmil) size, steel-reinforced, aluminum conductor unit tie line for the connection to both unit's GSUTs. The switchyard will consist of 230 kV switchyard circuit breakers with 230 kV, 1200 A disconnect switches on each side of the breaker for breaker maintenance. The switchyard breakers will be of the dead tank design with 1200/5 multi-ratio current transformers on each bushing and 230-0.12 kV coupling capacitor voltage transformers located near the breaker control cabinet for protection of the gen-tie line during normal operation of the GSUT and the UAT during back-feed. The switchyard breakers will also be coordinated with the GCBs and 4.16 kV station service switchgear main breakers for bus duct, GSUT, UAT, and unit tie line protection and will also be used for generator synchronizing.

A disconnect switch will be located at the gen-tie line termination within the switchyard for line isolation. The switchyard will be equipped with metering accuracy instrument transformers. Lightning arresters will be provided in the area of the takeoff towers to protect against surges due to lightning strikes. Tubular aluminum alloy bus will be used in the switchyard. Cable connections between the tube bus and equipment will be aluminum or aluminum alloy type cable. Electrical faults will be detected, isolated, and cleared in a safe and coordinated manner as soon as practical to ensure the safety of equipment, personnel, and the public. Protective relaying will meet Institute of Electrical and Electronic Engineers (IEEE) requirements and will be coordinated with the utility.

Fuel Supply and Use - As shown in Figure 3.4-1 and discussed in Section 3.4, the auxiliary boilers will be fueled by natural gas supplied from a new six-mile, eight-inch pipeline connected to an existing Southern California Edison (SCE) pipeline located north of I-10. Natural gas delivered to the Project site will flow through a revenue quality flow meter, pressure regulation station, and filtering equipment, and will provide gas to

the auxiliary boilers for each 125 MW power plant. Safety pressure relief valves are provided downstream of the pressure regulation valves. The estimated natural gas usage for each auxiliary boiler is 30 million British thermal units per hour (MMBtu/hr) or a total of 60 MMBtu/hr for the Project. The maximum annual natural gas usage is expected to be 60 million standard cubic feet per year (MMSCF/yr) for a maximum of 60,000 MMBtu/year. Table 3.4-1 shows the typical composition of the natural gas used to fuel the Project's auxiliary boilers.

Water Supply and Consumptive Requirements - The Project's various water uses include makeup for the circulating water system, makeup for the SSG, water for solar collector mirror washing, service water, potable water, and fire protection water.

Water Treatment - The raw water, circulating water, process water, and mirror washing water all require on-site treatment and this treatment varies according to the quality required for each of these uses. The power plant's design consists of a pre-treatment system upstream of the cooling tower, and a post-treatment system downstream of the cooling tower.

Water is cycled in the cooling tower until the concentration of chemical constituents rises to levels where it becomes unusable and it is blown down as a waste stream. The number of cycles undertaken are called cycles of concentration (COC). The number of COCs in the cooling tower is limited by the incoming water chemistry and the behavior of chemistry constituents as the concentration increases. Without any pre-treatment of the raw water ("makeup water") from groundwater on site, the calcium concentration would limit the process to about five COCs due to the potential to form calcium carbonate ($CaCO_3$) scale, and silica would limit the process to 10 COCs due to the formation of silica (SiO_2) and magnesium silicate scale. Because of the limitation of these constituents in the process, pre-treatment of the makeup water is desirable to reduce the quantity of makeup water required. The pre-treatment design for the Project takes into account the relatively high concentrations of chloride and sodium present in the makeup water to the site. As aforementioned, there are several tanks on site which will contain the raw water, treated water, and wastewater, which will have the following capacity:

- Raw Water/Fire Water Storage Tank: 500,000 gallons
- Treated Water Storage Tank: 1,250,000 gallons
- Wastewater Storage Tank: 250,000 gallons

Tanks were sized to provide sufficient water to support operation of the plant during peak operating conditions, as well as provide a 12-hour storage capacity to enable continued operation when a failure interrupts water or wastewater treatment capabilities. The tanks also allow the plant to levelize water supply requirements on a 24-hour basis and eliminate midday demand peaks. The Raw Water/Fire Water Storage Tank provides water for plant operation and fire protection, as discussed in the **Worker Safety** section of this document.

Water Source and Quality – Project water for Genesis will come from pumping groundwater from wells to be installed at the Project site. These wells will pump groundwater from the Bouse Formation and/or underlying Fanglomerate within the Chuckwalla Valley Groundwater Basin. The characteristics and yield of the aquifer that is proposed for the Project water supply, and the long-term effect of pumping of the groundwater system, are discussed in more detail in the **Soil and Water Resources** section of this document.

Steam Cycle Process Water - Makeup water for the steam cycle must meet stringent specifications for suspended and dissolved solids. To meet these specifications, water from the treated water storage tank is sent to a DI makeup water tank, and then processed through a demineralized water makeup system consisting of mixed-bed demineralizers and a 40,000 gallon demineralized water storage tank. Water produced by this system will also be used for the mirror washing described below. Additional conditioning of the condensate and feedwater circulating in the steam cycle is provided by means of a chemical feed system. To minimize corrosion, an oxygen scavenger for dissolved oxygen control, and an alkaline solution for pH control, are fed into the condensate. To minimize scale formation in the SSG, a solution of disodium phosphate (DSP) and tri-sodium phosphate (TSP) may be fed into each feedwater system. The chemical feed systems include an oxygen scavenger feed tank, an alkaline solution (amine) feed tank, and a phosphate solution feed tank. The feed tanks are provided with two full-capacity metering pumps.

A steam cycle sampling and analysis system monitors the water quality at various points in the plant's steam cycle. The water quality data are used to guide adjustments in water treatment processes and determine the need for other corrective operational or maintenance measures. Steam and water samples are routed to a sample panel where steam samples are condensed and the pressure and temperature of all samples are reduced as necessary. The samples are then directed to automatic analyzers for continuous monitoring of conductivity and pH. All monitored values are indicated at the sample panel and critical values are transmitted to the plant control room. Grab samples are periodically obtained at the sample panel for chemical analyses that provide information on a range of water quality parameters.

Solar Mirror Washing Water - To facilitate dust and contaminant removal, deionized (demineralized) water from the demineralized water storage tank is used to spray clean the solar mirrors on a periodic basis, determined by the reflectivity monitoring program. This operation is generally done at night and involves a water truck spraying deionized water on the mirrors in a drive-by fashion. The deionized water production facilities, already in place for SSG makeup water, will be sized to accommodate the additional solar mirror washing demand of about two acre-feet per year and is shown on the water balance diagrams. Water from the washing operation is expected to mostly evaporate on the mirror surface with no appreciable runoff.

Cooling Systems - Each power plant includes two cooling systems: 1) the steam cycle heat rejection system (*e.g.,* cooling tower); and 2) the closed cooling water system (equipment cooling), each of which is discussed below.

Steam Cycle Heat Rejection System - The cooling system for heat rejection from the steam cycle consists of a surface condenser, circulating water system, and wet cooling tower. The surface condenser receives exhaust steam from the LP section of the STG and condenses it to liquid for return to the SSG. The surface condenser is a shell-and-tube heat exchanger with wet, saturated steam condensing on the shell side and circulating water flowing through the tubes to provide cooling. The warmed circulating water exits the condenser and flows to the cooling tower to be cooled and reused.

The circulating water is distributed among multiple cells of the cooling tower, where it cascades downward through each cell and then collects in the cooling tower basin. The mechanical draft cooling tower employs electric motor-driven fans to move air through each cooling tower cell. The cascading circulating water is partially evaporated, and the evaporated water is dispersed to the atmosphere as part of the moist air leaving each cooling tower cell. As discussed in Section 5.10, Visual Resources, because of climatic conditions at the site, visible moisture plumes are expected to occur relatively infrequently and largely in winter months, and no need is expected for a plume-abated cooling tower.

The circulating water is cooled primarily through partial evaporation and secondarily through heat transfer with the air. The cooled circulating water is pumped from the cooling tower basin back to the surface condenser and auxiliary cooling water system.

Auxiliary Cooling Water System - The auxiliary cooling water system uses water from the cooling tower for the purpose of cooling equipment including the STG lubrication oil cooler, the STG generator cooler, steam cycle sample coolers, large pumps, etc. The water picks up heat from the various equipment items being cooled and rejects the heat to the cooling tower.

Waste Management - Project wastes include wastewater, non-hazardous solid waste, hazardous solid waste, and hazardous liquid waste. Project waste streams and management details are discussed in Section 5.4, Water Resources and Section 5.13, Waste Management.

Wastewater - Wastewater would be segregated into two separate collection systems, one for industrial streams and one for sanitary wastes. Industrial wastewater from both the pre-treatment and post-treatment systems will be piped to three 8-acre evaporation ponds for disposal. The evaporation ponds make up a total combined area of 24 acres for each 125 MW unit (48 acres of pond for both 125 MW units). There are three primary and one occasional waste streams discharging into the evaporation ponds:

- Pre-cooling tower water treatment MMF waste stream
- Post-cooling tower water treatment MMF waste stream
- Post-cooling tower water treatment
- 2nd stage Reversed Osmosis (RO) waste stream

Occasionally, storm water may accumulate in the proposed Land Treatment Unit (LTU) that will be used to treat soil affected by spills of HTF, and will be transferred to the evaporative ponds.

On an annual average, blowdown to the evaporation ponds will be approximately 90,000 gallons per day for each unit, increasing to approximately 140,000 gallons per day for each unit during peak summer conditions. The Project's sanitary system will collect wastewater from sanitary facilities such as sinks and toilets. This waste stream will be sent to an on-site sanitary waste septic system designed and permitted in accordance with Riverside County Department of Health Services standards.

Evaporation Ponds - As noted above, it is expected each 125 MW unit will have three double-lined evaporation ponds. Each pond will have a nominal surface area of eight acres resulting in a total of 24 acres of evaporation ponds for each unit or a total of 48 acres of ponds for both 125 MW units. The ponds will be designed and permitted as Class II Surface Impoundments in accordance with Colorado River Regional Water Quality Control Board (CRRWQCB) requirements, as well as the requirements of the California Integrated Waste Management Board (CIWMB). Multiple ponds are planned to allow plant operations to continue in the event a pond needs to be taken out of service for some reason, *e.g.,* needed maintenance. Each pond will have enough surface area so the evaporation rate exceeds the cooling tower blowdown rate at maximum design conditions and annual average conditions
.
The average pond depth is eight feet and residual precipitated solids will be removed approximately every seven years to maintain a solids depth no greater than approximately three feet for operational and safety purposes. The precipitated solids will be sampled and analyzed to meet the characterization requirements of the receiving disposal facility.

On-site Bioremediation Land Treatment Unit - The Project will include a bioremediation LTU to treat soil impacted by incidental spills and leaks of HTF at various concentrations. The unit will be designed and permitted as a Class II LTU in accordance with CRRWQCB and CIWMB requirements. The LTU will cover an area of approximately 600 feet by 725 feet, including the staging area, and will cater for both 125 MW units. The LTU will be constructed with a prepared base consisting of two feet of compacted, low permeability, lime treated material and be surrounded on all sides by a minimum two foot high compacted earthen berm with slopes of approximately 3:1 (horizontal:vertical). Based on available operation data from other sites, it is anticipated approximately 750 cubic yards (on average) of HTF-affected soil may be treated per year. Larger or smaller quantities could be generated during some years, depending on the frequency and size of leaks and spills.

Other Non-Hazardous Solid Waste - Construction, operation, and maintenance of the Project will generate non-hazardous solid wastes typical of power generation or other industrial facilities (see Section 5.13, Waste Management). These wastes include scrap metal and plastic, insulation material, paper, glass, empty containers, and other miscellaneous solid wastes. These materials will be disposed by means of contracted refuse collection and recycling services.

Hazardous Solid and Liquid Waste - Small quantities of hazardous wastes will be generated during Project construction and operation. Hazardous wastes generated during the construction phase will include substances such as paint and primer, thinners, and solvents. Hazardous solid and liquid waste streams generated during

Project operations include substances such as used hydraulic fluids, oils, greases, filters, etc., as well as spent cleaning solutions and spent batteries. To the extent possible, both construction and operation-phase hazardous wastes will be recycled. Tables 5.13-2 (construction phase) and 5.13-3 (operations phase) in Section 5.13, Waste Management, summarize Project hazardous waste streams in terms of quantities, origin and composition, and management method(s).

Hazardous Material Management - There will be a variety of hazardous materials used and stored during construction and operation of the Project. The **Hazardous Materials Management** section of the SA/DEIS provides additional data on the hazardous materials that will be used during construction and operation, including quantities, associated hazards and permissible exposure limits, storage methods, and special handling precautions. Hazardous materials that will be used during construction include gasoline, diesel fuel, oil, lubricants, and small quantities of solvents and paints. All hazardous materials used during construction and operation will be stored on site in storage tanks, vessels and containers that are specifically designed for the characteristics of the materials to be stored; as appropriate, the storage facilities will include the needed secondary containment in case of tank/vessel failure.

Engineering Controls - Engineering controls help to prevent accidents and releases (spills) from moving off site and affecting communities by incorporating engineering safety design criteria in the design of the project. The engineered safety features proposed by the applicant for use at the GSEP project include:

- storage of small quantity hazardous materials in original, properly labeled containers;
- construction of secondary containment areas surrounding each of the bulk hazardous materials storage areas, designed to contain accidental releases that might happen during storage or delivery plus the volume of rainfall associated with a 25-year, 24-hour storm;
- physical separation of stored chemicals in isolated containment areas in order to prevent accidental mixing of incompatible materials, which could result in the evolution and release of toxic gases or fumes;
- installation of a fire protection system for hazardous materials storage areas; and
- continuous monitoring of HTF piping system by plant staff and by automatic pressure sensors designed to trigger isolation valves if a leak is detected.

Air Emissions Control and Monitoring - Installation and operation of the Project will result in a change in the emissions signature for the site. Criteria pollutant emissions from the proposed auxiliary boilers, fire pump engines, emergency generator engines, and cooling towers are discussed in the **Air Quality** and **Public Health** section of this analysis. Operation of the Project will result in emissions to the atmosphere of both criteria and toxic air pollutants from the proposed auxiliary boilers, fire pump engines, emergency generator engines, and cooling towers, and fugitive losses from the HTF system. Construction-related emissions are associated with site disturbance resulting from site preparation and with the typical emissions and associated construction-related activities encountered at any construction site.

Fire Protection - Fire protection systems are provided to limit personnel injury, property loss, and Project downtime resulting from a fire. The systems include a fire protection water system and portable fire extinguishers.

Each 125 MW power plant's fire protection water system will be supplied from a dedicated 360,000-gallon portion of the 500,000-gallon raw water storage tank located on the plant site. One electric and one diesel-fueled backup firewater pump, each with a capacity of 3,000 gallons per minute, will deliver water to the fire protection water-piping network for each plant. A smaller electric motor-driven jockey pump will maintain pressure in the piping network. If the jockey pump is unable to maintain a set operating pressure in the piping network, the diesel fire pump starts automatically.

The piping network will be configured in a loop so a piping failure can be isolated with shutoff valves without interrupting the supply of water to a majority of the loop. The piping network will supply fire hydrants located at intervals throughout the power plant site, a sprinkler deluge system at each unit transformer, HTF expansion tank and circulating pump area, and sprinkler systems at the STG, and in the operations and administration buildings. Portable fire extinguishers of appropriate sizes and types will be located throughout the plant site.

Fire protection for the solar field will be provided by zoned isolation of the HTF lines in the event of a rupture that results in fire. As vegetation or other combustible materials will not be allowed in the solar field, the HTF will be allowed to extinguish itself naturally, since the remainder of the field is of nonflammable material (aluminum, steel, and glass) (see Section 5.14, Worker Safety, for additional discussion of on- and off-site fire protection measures).

Plant Auxiliary Systems

The following plant auxiliary systems control, protect, and support the power plant and its operation.

Distributed Control System - The Distributed Control System (DCS) provides control, monitoring, alarm, and data storage functions for power plant systems. These include:

- Control of the STG, SSG system, and balance-of-plant systems in a coordinated manner
- Monitoring of operating parameters from plant systems and equipment
- Visual display of the associated operating data to control operators and technicians
- Detection of abnormal operating parameters and parameter trends
- Provision of visual and audible alarms to apprise control operators of such conditions
- Storage and retrieval of historical operating data

The DCS is a microprocessor-based system. Redundant capability is provided for critical DCS components such that no single component failure will cause a plant outage. The DCS consists of the following major components:

- Computer monitor-based control operator interface (redundant)
- Computer monitor-based control engineering work station
- Multi-function processors (redundant)
- Input/output processors (redundant for critical control parameters)
- Field sensors and distributed processors (redundant for critical control parameters)
- Historical data archive
- Printers, data highways, data links, control cabling, and cable trays

The DCS is linked to the control systems furnished by the STG supplier and the solar field controls. These datalinks provide STG control, monitoring, alarm, and data storage functions via the control operator interface and control technician workstation of the DCS.

Lighting System - The Project's lighting system will provide operations and maintenance personnel with illumination in both normal and emergency conditions. The system will consist primarily of AC lighting, but will include DC lighting for activities or emergency egress required during an outage of the plant's AC electrical system. The lighting system will also provide AC convenience outlets for portable lamps and tools. Lighting will be designed to provide the minimum illumination needed to achieve safety and security objectives and will be shielded and oriented to focus illumination on the desired areas and minimize additional nighttime illumination in the site vicinity.

Cathodic and Freeze Protection Systems - Cathodic protection systems protect against electrochemical corrosion of underground metal piping and structures. Underground metal piping structures will have cathodic protection as necessary based on soil conditions. Freeze protection systems (heat tracing) will be employed to protect small water and condensate piping systems that cannot be easily drained. Also due to the high freezing temperature of the solar field's HTF (54°F), steam-fed HTF freeze protection heat exchangers will be provided to protect the system during the night hours and colder months.

Service Air and Instrument Air Systems - The service air system supplies compressed air to hose connections located at intervals throughout the power plant. Compressors deliver compressed air at a regulated pressure to the service air-piping network. The instrument air system provides dry, filtered air to pneumatic operators and devices throughout the power plant. Air from the service air system is dried, filtered, and pressure regulated prior to delivery to the instrument air-piping network.

HTF Leak Detection - Leak detection of HTF will be accomplished in a combination of ways. Small leaks, possibly at ball joints or other connections, will be located based on daily inspection of the solar field. Those small leaks can then be corrected via repacking of joints or valves or by minor repairs if needed. The ability to isolate loops and sections

of the field will allow for quick repairs. In order to identify and react to larger sudden leaks quickly, the Project is considering a combination of remote pressure sensing equipment and remote operating valves that would allow for isolation of large areas of the field, or possibly the entire field. Such features will be developed as part of the detail design process.

POWER PLANT CIVIL/STRUCTURAL FEATURES

The following subsections describe civil/structural features of the Project, as illustrated in the power block arrangements presented in Figures 3.4-2 and 3.4-3. The power plant will be designed in conformance with 2007 California Building Code and the applicable wind and seismic criteria for site location. As noted earlier, sensitive Project facilities (*e.g.,* power block, evaporation pond) will be placed at specific on-site locations that avoid mapped AP fault zones.

SSG System, STG and Associated Equipment - The SSG system, STG, and condenser will be located outdoors and supported on reinforced concrete mat foundations. The STG foundation will include a reinforced concrete pedestal that supports the STG above the surface condenser. The one step-up transformer and GSUT will be supported on reinforced concrete mat foundations. Balance-of-plant (BOP) mechanical and electrical equipment will be supported on individual reinforced concrete pads. BOP components/materials include piping, valves, cables, switches, etc. that are not included with major equipment and are generally installed or erected onsite.

Solar Array Support Structures - Each solar collector array will be supported by structures (stands) that connect the parabolic troughs to the drive mechanism. Each array will be supported by multiple individual foundations with a foundation located approximately every 40 feet along the array. Foundation design will be based on site-specific geotechnical conditions to ensure the solar array stands are able to support all loading conditions (including wind loading) at the Project site.

Buildings - The Project will include a common administration building and warehouse between the two 125 MW power plants. A control building will be located in each power block. The design and construction of the administration building and warehouse will be consistent with normal building standards. Other plant site “buildings” will include the water treatment building, as well as a number of pre-engineered enclosures for mechanical and electrical equipment. Building columns are supported on reinforced concrete mat foundations or individual spread footings and the structures rest on reinforced concrete slabs. The total square footage of the various Project buildings and pre-engineered enclosures (*e.g.,* control rooms, administration building, warehouse, electrical equipment enclosures, fire pumps, and diesel generators) is approximately 39,000 square feet.

Water Storage Tanks - There will be a number of covered water tanks on site for each 125 MW power plant. For each plant, there will be a 500,000-gallon raw water storage tank for short-term backup cooling water supply, with a portion (360,000 gallons) dedicated to the plant’s fire protection water system; a 1,250,000-gallon treated water storage tank; and a 250,000 waste water storage tank. There also will be a 40,000-gallon storage tank for storage of demineralized water. Water storage tanks will be

vertical, cylindrical, field-erected steel tanks supported on foundations consisting of either a reinforced concrete mat or a reinforced concrete ring wall with an interior bearing layer of compacted sand supporting the tank bottom.

Roads, Fencing, and Security - The Project site is located in a remote section of eastern Riverside County, about four miles north of I-10, and approximately 25 miles west of Blythe. All vehicular traffic approaching the site will use I-10. Only a small portion of the overall plant site will be paved, primarily the site access road and portions of each power block (paved parking lot and roads encircling the STG and SSG areas). The entire site will be fenced appropriately to restrict public access during construction and operations. In order to ensure that the facility site is not the target of unauthorized access, staff has required the implementation of site security measures that are discussed in the **Hazardous Material Management** section of this document. These measures would provide appropriate levels of security to protect electrical infrastructure from malicious mischief, vandalism, or domestic/foreign terrorist attacks.

Site Drainage - As discussed in the **Soil & Water** section under the Drainage Erosion and Sediment Control Plan (DESCP), natural drainage across the site is episodic, shallow, and occurs over a broad area primarily as sheet flow or in shallow washes. In desert regions, the catchment boundaries and distribution of drainage may shift over time based on the ground conditions, intensity of the storm event, velocity of the flow, and sediment transportation including USGS quadrangle maps and aerial images. The watershed boundary and sub-basin boundaries selected for this Project site were based on existing information. The total watershed modeled encompasses 93,182 acres of which 91,696 acres are off-site.

Under post-developed conditions, it is proposed to divert the off-site watershed in three channels:

- Runoff from sub-basin 1 (north-western) will be diverted through a channel on the west side of the west 125 MW unit.
- Runoff from sub-basin 2 (north) will be diverted through a channel between the two 125 MW units.
- Runoff from sub-basin 3 (north-eastern) will be diverted though a channel along the east side of the east 125 MW unit.

Consultation with the CDFG resulted in a determination on jurisdiction of state waters, which is discussed in the **Biological Resources** and **Soil & Water Resources** sections of this document.

These three main channels and associated diversion berms on the down slope sides will divert flows downstream of the site following their existing drainage paths, causing no impact to the site. The channels and diversion berms will be sized sufficiently to pass the anticipated flows and entrained sediment volumes; will be armored as necessary for erosion protection using natural gravel derived during site grading activities; and will be

maintained periodically or after major storm events as needed to sustain their proper function. The main purposes of the diversion are to prevent interaction with off-site storm water and on-site storm water which will:

- Allow natural groundwater recharge of the off-site storm water with no contact with the changed flow conditions of the on-site water.
- Protect the site infrastructure from flash flood events, which have the potential to damage the solar parabolic troughs.
- Control treatment of the on-site flows from the solar collector array (location of HTF within the solar parabolic troughs).
- Protect the site from upstream sediment loading.
- Control on-site flows in detention basins to ensure there is no increase in post developed flow discharging from the site, minimize the impact on downstream drainage features (lake playas, etc).
- Maximize the developable area within the solar field.

On-site storm water management for the completed facility will be provided through the use of source control techniques, site design, and treatment control. The Project will employ a comprehensive system of management controls, including site-specific Best Management Practices (BMPs), to minimize storm water contact with contaminants and thus minimize pollutants in storm water. These management controls include:

- Erosion Control
- Sediment Control
- Wind Erosion
- Tracking Control
- Non-stormwater discharges
- Waste Management

Earthwork - Solar fields have fairly stringent grading requirements as parabolic troughs must be almost level along their troughs and grades perpendicular to the troughs are generally benched to two percent or less. Under pre-developed conditions, each 125 MW module generally slopes from the northeast to the southwest. Grading for post-developed conditions will slightly modify the existing contours to provide a surface level appropriate for the parabolic troughs. The preliminary grading is designed to ensure the run-off from solar fields is directed into the appropriate drainage channel, and the power block, evaporation ponds, and land farm units are protected in the 100-year, 24-hour storm event.

TRANSMISSION FACILITIES

Interconnection to Substation - The Genesis switchyard will contain three breakers and three line takeoff structures. It will have space for a future breaker and line takeoff structure. Air insulated structures will be utilized giving the switchyard a size of approximately 270 feet by 400 feet. The switchyard and interconnections will be built for

230 kV and will operate at that nominal voltage. Instrument transformers (current and capacitive voltage transformers) will be included for protection. Shield wires and lightning arrestors will be included to protect substation equipment and personnel against lightning strikes. The switchyard arrangement is shown in the power block layout general arrangement for unit two.

The generated electrical power from the Project switchyard will be transmitted through a generation-tie (gen-tie) line that will be routed in a southeasterly ROW eventually connecting to the proposed Southern California Edison (SoCal Edison) 500-230 kV Colorado River substation via the Blythe Energy Project Transmission Line (BEPTL). Please see **Project Description Figure 4**.

Interconnection Design Considerations - The gen-tie line will be constructed for operation at 230kV, the nominal operating voltage of the regional transmission system. The use of 230 kV as the targeted design voltage in the AFC is consistent with the industry use of the 230-kV term to describe the nominal voltage for this class of system. Each circuit will be supported by mono-pole structures at approximately 800 feet intervals with final heights as determined during detailed design. The lines will be insulated from the poles using porcelain insulators engineered for safe and reliable operation at a worst-case voltage of 241.5 kV (nominal, plus five percent). Shield wires will be included along the length of the lines to protect against lightning strikes (see Figure 4.2-1 in Section 4, Safety and Reliability). The pole designs were engineered to provide conceptual design limits for purposes of the electrictromagnetic field (EMF) studies and in accordance with the current Blythe-Julian Hinds structures.

- **Transmission System Upgrades -** The Project will require an interconnection upgrade at the Colorado River Substation. All impacts, and appropriate mitigation, have not been fully identified at this point in terms of the forthcoming Phase II Interconnection study of 2,200 MW of generation. However, 9,690 MW of generation in the Genesis cluster Phase I Interconnection study indicated that the project interconnection to the grid would not result in downstream transmission impacts.

PROJECT CONSTRUCTION

Power Generation Facility - Major milestones of the planned Project construction schedule are as follows:

- Begin construction Unit 1: Month 1
- Startup and test Unit 1: Month 21
- Commercial operation Unit 1: Month 25
- Begin construction Unit 2: Month 12
- Startup and test Unit 2: Month 33
- Commercial operation Unit 2: Month 39

Project construction is expected to occur over a total of 39 months. Project construction will require an average of 650 employees over the entire construction period, with labor requirements peaking at approximately 1100 workers in Month 23 of construction. The

construction workforce will consist of laborers, craftsmen, supervisory personnel, support personnel, and construction management personnel. Please see the **Socioeconomics and Environmental Justice** section of this document for a detailed discussion and breakdown of the construction workforce, by skill, over the entire construction period. Construction of each 125 MW Unit is expected to take approximately 25 months with each unit being phased by 12 months.

Temporary construction laydown and parking areas will be provided within the power plant site (see Figure 3.4-1). Construction power will be provided by the local distribution system and routed to the site along wood poles within the 230 kV ROW. Due to the size of the plant site, the solar field laydown area will be relocated periodically as the solar field is built out. The construction sequence for power plant construction includes the following general steps:

Site Preparation: this includes detailed construction surveys, mobilization of construction staff, grading, and preparation of drainage features. Grading for the solar field, power block, and rerouted wash will be completed during the first nine months of the construction schedule.

Foundations: this includes excavations for large equipment (STG, SSG, GSUT, cooling tower, etc.), footings for the solar field, and ancillary foundations in the power block.

Major Equipment Installation: once the foundations are complete, the larger equipment will be installed. The solar field components will be assembled in an on-site erection facility and installed on their foundations. Equipment and materials will be delivered to the Project plant site by truck; large components (*e.g.,* STG) will be brought by rail to a rail siding in the town of Blythe and then are expected to be trucked to the site on I-10.

BOP: with the major equipment in place, the remaining field work will be piping, electrical, and smaller component installations.

Testing and Commissioning: testing of subsystems will be done as they are completed. Major equipment will be tested once all supporting subsystems are installed and tested. ‘

Civil Works - The construction sequence for civil works includes the following general steps:

Site Disturbance: Once all areas are appropriately staked and signed and access to the site has been established, grading activities will occur over an extensive portion of the site. Grading will commence with rough grading activities, including grubbing, clearing, moisture conditioning, bulk grading, and initial compaction. The first ground-disturbing activities to take place will be the initial clearing and grading to prepare the site for the storm water drainage, construction, and equipment foundation pads. Temporary drainage ditches and berms will also be designed around construction work areas, soil stockpile areas, and excavation areas to minimize the amount of potential pollutant or sediment-laden surface water runoff.

Site Grading: The solar pad grading of the site will have an average slope of one to three percent on the north-south direction. Each solar pad will be graded with the intent of balancing the cut-and-fill as much as possible to minimize earth movement on the site. Drainage diversion channels and protective berms will also be developed with a balance of cut and fill earthwork.

Site Drainage: The post-development sediment/retention basin at the discharge points will provide storm water pollution prevention BMP controls, along with retention time to reduce the peak off-site discharge to match pre-development conditions. The road berm will also be constructed to provide site protection from storm water run-on during a 100-year return storm event. The toe of the western protective berm slope may be armored with soil cement cover and rip rap to provide for slope erosion protection during a heavy storm event.

Internal Road System: A primary access road will be constructed to the power block area. This road will be 24 feet wide and paved with approximately 3,000 tons of imported asphalt concrete material. Auxiliary roads will be 24 feet wide and use compacted native materials or gravel surface.

Restoration of Temporary Disturbance: All temporarily disturbed areas will be restored to their preconstruction conditions, as required by the BLM. Temporary access roads used during construction will also be regraded and restored to pre-existing function and grade. BLM-approved seed mixes will be applied to temporarily disturbed areas, as required. No fertilizer will be used during stabilization or rehabilitation activities unless authorized by the BLM. No vegetation will be restored or encouraged within the solar field because of the fire hazard. Vegetation within the LTU area will be controlled to prevent containment from being compromised. When construction of storm water management structures is complete, contours will be carefully restored to the extent feasible.

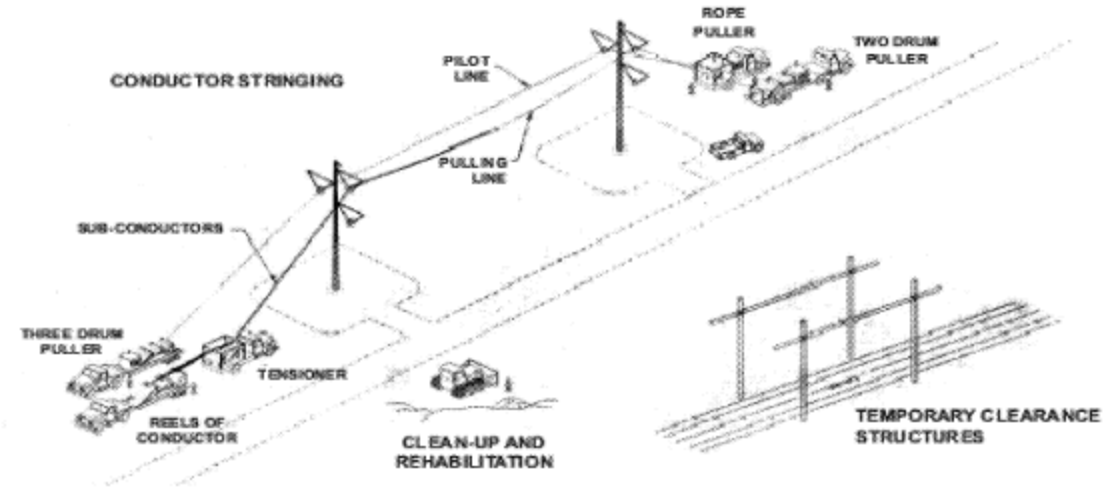
Generator Tie Line - The gen-tie line will be constructed with crews working continuously along the ROW, with construction of the entire gen-tie line requiring a peak workforce of approximately 34 workers. Gen-tie line construction will include the following activities:

- Preparation of marshalling yards
- Access road and spur road construction
- Clearing and grading of pole sites
- Foundation preparation and installation of poles
- Conductor installation
- Cleanup and site reclamation

Various construction activities would occur during the construction process with several construction crews operating simultaneously at different locations. The following subsections describe in more detail the construction activities associated with the Project gen-tie line.

Marshalling Yards: Construction staging/laydown and parking areas are proposed for two locations: 1) within the Project site, and 2) at the Wiley Well Rest area. Construction materials such as concrete, wire and cable, fuels, and small tools and consumables would be delivered to the staging/laydown areas by truck. Mobile trailers or similar suitable facilities (for example, modular offices) would be used for construction offices to be located at the Project staging/laydown areas.

Road Work: The construction, operation, and maintenance of the proposed gen-tie line would require that heavy vehicles access structure sites along the road. The Project proposes to use the newly constructed site access road and Wiley Well Road for all construction, operation, and maintenance activities associated with the gen-tie line. If required, new spur roads, approximately 14 feet wide and averaging 70 feet in length, would be constructed from the access roads to the structure sites. Each spur road would lead to a construction pad for a pole structure.



Pole Pads: At each site, a work area would be required for the structure footing location, structure assembly, and the necessary crane maneuvers. The work area would be cleared of vegetation only to the extent necessary and the construction pad would be leveled to facilitate the safe operation of equipment such as construction cranes.

Pole Erection: Transmission line pole structure foundation excavations would be made with power drilling equipment. A vehicle-mounted power auger or backhoe would be used to excavate for the structure foundation. Although not expected, in some instances blasting could be necessary because of specific geologic conditions. In the unlikely event blasting is necessary, conventional or plastic explosives would be used. Safeguards (*e.g.* blasting mats) would be employed when adjacent areas require protection. ‘

Conductor Installation: Typical conductor stringing activities are illustrated below. Crossing structures would consist of H-frame wood poles placed on either side of an obstacle. These structures would prevent ground wire, conductors, or equipment from falling on an obstacle and would be removed following the completion of conductor installation. Equipment for erecting the crossing structures would be the same as the equipment discussed above for transmission pole installation. Crossing structures may not be required for small roads or other areas where suitable safety measures such as barriers, flagmen, or other traffic controls could be used.

Pilot lines would be pulled (strung) from structure to structure and threaded through the stringing sheaves at each structure. This phase of work may be accomplished through the use of helicopters to minimize or otherwise eliminate the need to traverse the ROW along the ground from structure to structure. Following the pilot lines, a larger diameter stronger line would be attached to the conductors to pull

them onto the structures. This process would be repeated until the ground wire or conductor is pulled through all sheaves.

Source: AFC, page 3-30.

Pulling Sites: The shield wire and conductors would be strung using powered pulling equipment at one end and powered braking or tensioning equipment, approximately one mile apart. Tensioners and/or pullers, line trucks, wire trailers, and tractors needed for stringing and anchoring ground wire or conductor would be necessary at each pulling site. The tensioner, in concert with the puller, would maintain tension on the shield wires or conductors while they would be pulled through the structures. There will be approximately 25 pulling sites required to install the conductors along this segment of the gen-tie line. The sites will be accessed from the Project access roads or Wiley's Well Road.

Clean up and Site Reclamation: Construction sites, material storage yards, and access roads would be kept in an orderly condition throughout the construction period. Approved enclosed refuse containers would be used throughout the Project. Refuse and trash would be removed from the sites and disposed in an approved manner. Oils or chemicals would be hauled to a disposal facility authorized to accept such materials. Open burning of construction trash would not be acceptable.

The post-construction ROW would be restored as required by the BLM. All practical means would be made to restore the land to its original contour and restore the natural drainage patterns along the ROW. Because re-vegetation would be difficult in many areas of the Project because of low amounts of precipitation, it would be important to minimize disturbance during construction.

Natural Gas Pipeline - Construction of the gas pipeline will be the responsibility of SoCal Gas (SCG) and is expected to take three to six months with a peak workforce of approximately 46 workers. Provisions for construction contractor employee parking for the pipeline construction will be accommodated by the Applicant at the plant site, except for those supervisory contractor employee and agency inspection vehicles which must be temporarily parked along the route while construction takes place. Most major pieces of pipeline construction equipment will remain along the pipeline ROW during

construction with storage and staging of equipment and supplies either located at the Project plant site or other acceptable site selected by SCG at the time construction is underway. Excavated earth material would be stored within the construction ROW. During nonworking hours, any open trench will be covered with wood or other material of sufficient strength to support wildlife.

Trenching: The optimal trench will be approximately 48 inches wide and 4 to 10 feet deep. With loose soil, a trench up to eight feet wide at the top and three feet wide at the bottom may be required. The trench depth will provide a minimum cover of 36 inches.

Stringing: The pipeline components will be staged along the trench on wooden skids in preparation for installation.

Installation: Installation consists of bending, welding, and coating the weld-joint areas of the pipe after it has been strung, padding the ditch with sand or fine spoil, and lowering the pipe string into the trench following non-destructive testing of all welds.

Backfilling: consists of returning spoil back into the trench around and on top of the pipe, ensuring the surface is returned to its original grade or level. The backfill will be compacted to protect the stability of the pipe and minimize subsequent subsidence.

Trenchless construction methods may be used for short crossings under existing water lines or other buried pipelines. Boring pits will be dug on each side of the crossing to accommodate the process. Cleanup consists of restoring the surface of the roadway or ROW by removing any construction debris, grading to the original grade and contour, and revegetating or repairing where required.

FACILITY OPERATION

The Project will have a moderate sized workforce during operation; an estimated total workforce of 40 to 50 full time equivalent personnel will be needed to staff the facility 24 hours per day/seven days per week. When the solar facility is not operating (i.e. generating electricity), personnel will nonetheless be present for necessary maintenance, start-up, and/or site security.

FACILITY CLOSURE

Facility closure can occur on either a temporary or permanent basis. Temporary closure is a cessation of facility operations for a period of time greater than would be required for routine maintenance, overhaul, or replacement of major plant equipment. Temporary closures may be caused by damage to the facility from events such as fire, earthquake, or other natural occurrences, or by short-term economic considerations.

Permanent closure is a cessation of facility operations with no intent to restart. Permanent closure may result from a combination of facility age and economic considerations, or from damage considered beyond repair or other reasons. Temporary and permanent facility closures are both discussed in detail in the **Joint Conditions of Certification** section of this document.

Temporary Closure - In the case of a temporary closure, security for the Project facilities will be maintained on a 24-hour basis and the CEC and other responsible agencies will be notified. The course of action that will be followed will depend on whether or not the temporary closure involves a release of hazardous materials.

If there is no actual or threatened release of hazardous materials, a contingency plan will be implemented for the temporary halting of facility operations. The purpose of this contingency plan, to be developed prior to the beginning of operations, is to ensure compliance with all applicable Laws, Ordinances, Regulations, and Standards (LORS) and appropriate protection of public health, safety, and the environment. Depending on the expected duration of the temporary shutdown, the contingency plan may include the draining and proper disposal of chemicals from storage tanks and other facility equipment, the safe shutdown of all plant equipment, and various other measures to protect onsite workers, the public, and the environment.

If the temporary closure involves an actual or threatened release of hazardous materials to the environment, procedures will be implemented as provided in a Hazardous Materials Business Plan that will be developed for the Project (see Section 5.12, Hazardous Materials Handling). Procedures will include, but not be limited to, the following:

- Measures to control the release of hazardous materials.
- Requirements for notifying the appropriate agencies and the public.
- Emergency response procedures.
- Training requirements for Project personnel in hazardous materials release response and control.

Once the hazardous materials release has been resolved, temporary closure will proceed as described above for temporary closure without a hazardous materials release.

Permanent Closure - The planned operational life of the Project is 30 years, but the Project facility conceivably could operate for a longer or shorter period depending upon economic considerations or other circumstances. For example, if the Project facility remains economically viable, it could operate for more than 30 years, which would defer environmental impacts associated with closure and with the development of replacement power generating facilities. However, if the facility were to become economically non-viable before 30 years of operation, it could be closed permanently at an earlier time.

Regardless of when permanent closure occurs, a decommissioning plan specifying the appropriate closure procedures will be developed and implemented. As in the case of a temporary closure, security for the Project facility will be maintained on a 24-hour basis. During permanent closure, the Energy Commission and other responsible agencies including the BLM will be notified of the decommissioning schedule and plans.

The procedures provided in the decommissioning plan will be designed to ensure public health and safety, environmental protection, and compliance with applicable LORS.

Prior to the beginning of permanent closure activities, the decommissioning plan will be submitted to the CEC for review and approval.

Depending on conditions at the time of closure, the closure measures may range from extensive “mothballing” to the complete removal of Project equipment and other structures. In general, the decommissioning plan for the Project will address the following:

Proposed decommissioning measures for the power plant and all associated facilities constructed as part of the Project, designation of equipment and appurtenances to be removed or that may remain in place, as applicable.

- Activities necessary for site reclamation.
- Provisions for recycling facility components, collection and disposal of wastes, and resale of unused chemicals back to suppliers or other parties.
- Decommissioning alternatives other than full restoration of the site.
- Costs associated with the proposed decommissioning and reclamation activities and the source of funds to implement these activities.
- Conformance with applicable LORS and with local/regional plans.

As it is not possible to predict at present the conditions that will exist at the time decommissioning decisions must be made, decommissioning details will be developed and provided to the CEC when the time for permanent closure is closer and more information is available.

If the evaporation ponds or LTU require temporary closure, the Closure and Post-Closure Maintenance Plan shall be implemented. A Preliminary Closure and Post-Closure Maintenance Plan for both waste management units will be submitted to the Colorado River Regional Water Quality Control Board with the application for a Report of Waste Discharge (RoWD) (please see the **Waste Management** section of this document for a more detailed discussion).

ALTERNATIVES RETAINED FOR ANALYSIS

Three alternatives are retained for analysis within each discipline’s section:

- Reduced Acreage Alternative
- Dry Cooling Alternative
- No Project/No Action Alternative

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would essentially be Unit 1 of the proposed project, including a 125 MW solar facility located within the boundaries of the proposed project as defined by NextEra (applicant). This alternative is analyzed for two major reasons: (1) it eliminates about 50 percent of the proposed project area so all impacts are reduced, and (2) by eliminating the eastern solar field, it would reduce the water

required for wet cooling by 50 percent. The boundaries of the Reduced Acreage Alternative are shown in **Alternatives Figure 1**.

The Reduced Acreage Alternative would have a net generating capacity of approximately 125 MW and would occupy approximately 900 acres of land. This alternative would retain 50 percent of the proposed project's generating capacity, and would affect 50 percent of the land affected by the proposed project. Specifically, the alternative would retain the Unit 1 solar field, including the construction parking, construction trailers, and temporary construction laydown area; the administration building and warehouse; the solar collector assembly area; the western evaporation pond area (approximately 24 acres); and the land farm area (approximately 10 acres). The alternative would require relocating the switchyard from the Unit 2 power block to the Unit 1 power block. The eastern evaporation pond area (approximately 24 acres) that corresponds with Unit 2 would not be included in the Reduced Acreage Alternative. This area could be used for the relocated gas yard if needed.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the Colorado River Substation. It would require infrastructure, including groundwater wells, transmission line, road access, an administration building, and evaporation ponds. The required infrastructure and transmission line for the Reduced Acreage Alternative would follow the routes defined for the proposed project, even though Unit 1 would not be constructed. The linear facilities would require approximately 90 acres. The gas pipeline would be approximately 1 mile longer than for the proposed project.

Dry cooling is being evaluated as an alternative to the proposed project and could also be used with this configuration; however, if wet cooling were retained, approximately 822 acre-feet per year would be pumped during operations.

DRY COOLING ALTERNATIVE

Description of the Process and Equipment Required

There are two types of dry cooling systems: direct dry cooling and the less-used indirect dry cooling. In both systems, fans blow air over a radiator system to remove heat from the system via convective heat transfer (instead of once-through cooling or evaporative heat transfer). In the direct dry cooling system, also known as an air-cooled condenser (ACC), steam from the steam turbine exhausts directly to a manifold radiator system that rejects heat to the atmosphere, condensing the steam inside the radiator. Direct dry cooling is analyzed as an alternative to the wet cooling proposed by NextEra for the Genesis Solar Energy Project.

Dry cooling is the best choice of cooling technologies for a steam power plant to conserve water and minimize wastewater. However, this technology can create both environmental and economic concerns, depending on the location and specific situation. These concerns are evaluated for the GSEP site specifically in Sections C and D of each individual technical discussion of this SA/DEIS.

Advantages and Disadvantages of Dry Cooling

The following is a general list of the general advantages and disadvantages of dry cooling.

Advantages of Dry Cooling Systems

- Dry cooling allows a power plant location to be independent of a water source. It has essentially no water intake or water discharge requirements.
- Dry cooling minimizes the use of water treatment chemicals.
- Dry cooling minimizes the generation of liquid and solid wastes.
- Dry cooling does not generate visible plumes that are commonly associated with wet cooling towers.
- Dry cooling eliminates impacts to aquatic biological resources.
- Dry cooling eliminates the need for discharge permits.
- Dry cooling eliminates the need for disturbance of wetland/aquatic substrate habitat.

Disadvantages of Dry Cooling Systems

- Dry cooling requires air-cooled condensers that could have negative visual effects.
- Compared to once-through cooling, dry cooling requires the disturbance of a larger area for the air-cooled condensers than that required for cooling towers.
- Dry cooling can have noise impacts that are greater than once-through or wet cooling systems because of the number of fans and the considerably greater total airflow rate. New quieter fans and other mitigation measures are available to reduce these impacts.
- Using dry cooling, the power plant steam cycle efficiency and output can be slightly reduced, depending on site conditions and seasonal variations in ambient conditions. Also, extra power is needed to operate the cooling fans.
- Capital costs for building air-cooled condensers are generally higher than capital costs for once-through cooling.

Description of the Air Cooled Condensers

In order to compare the performance and impacts of a dry cooling system or ACC with that of the wet-cooled system, the operating conditions at a common design point must be established. The design and operation of an ACC are highly dependent upon the ambient conditions at a specific site.

Size, Configuration, and Layout

The size of an ACC is a function of the heat load from the steam turbine generator and the ambient conditions. The ACC is composed of tube bundles with fins attached to the tubes to enhance heat transfer to the air. These bundles are grouped together and mounted in an A-frame configuration on a steel support structure. These A-frame tube bundles are aligned in rows or bays. Steam is ducted directly from the steam turbine exhaust to the ACC where it enters in a parallel flow into the tubes across the top of the

bays. Air is blown from below across the finned tube bundles by a series of large fans, which are located beneath the A-frame tube bundles. Each fan is considered a module. To accommodate the large mass of air required for cooling the steam, the A-frame tube bundles are elevated on top of an open structure. As the steam passes down through the tube bundles, it is condensed and drains by gravity flow into a tank from which it is pumped back to the steam turbine. Since the steam is exhausted directly from the steam turbine generator after it has expanded through the turbine, it is at both a very low pressure and large volume. This condition limits the distance that the ACC can be located from the steam turbine generator, due to the drop in pressure that results during the transport of the steam; this limitation must be taken into consideration when configuring the plant layout.

Staff has not developed and analyzed detailed layouts for the ACC system. However, it is assumed that the ACC system would be located where the cooling towers are currently proposed. **Alternatives Figure 2** illustrates the approximate size and location of the ACC on the power block layout.

Approximately 18 ACC fans would be required for cooling each 125 MW power block when the ambient temperature is above 50 degrees Fahrenheit (GSEP 2009f). The 18 ACC fans described in the GSEP cooling study would have a length of approximately 279 feet, a width of approximately 127 feet, and a height of 98 feet (GSEP 2009f). However, based on the ACC preliminary designs for nearby solar thermal projects in similar ambient temperatures, an additional 11,690 square feet could be required for siting of the fans and the fans would be up to 120 feet in height. In addition to the ACC fans, NextEra would use a small Wet Surface Air Cooler when needed to provide auxiliary cooling during extremely hot days (GSEP 2009f). The proposed wet cooling towers and associated equipment occupy an area of about 420 feet long by 60 feet wide. While the ACCs would require about 40 to 50 percent more land area than the proposed wet cooling towers, from the site layout, it appears that such a system would fit in the approximate current location of the cooling tower as there is unused space between the power block and the solar collector assembly (GSEP 2009a). This unused space would have been previously graded as it is designed to be used for construction parking and construction trailers. An environmental assessment of the impacts of using dry-cooling instead of wet-cooling is presented in each individual technical discussion (Sections C and D) for each resource element.

NO PROJECT/NO ACTION ALTERNATIVE

CEQA No Project Alternative

The No Project Alternative under CEQA defines the scenario that would exist if the proposed Genesis Solar Energy Project were not constructed. The CEQA Guidelines state that “the purpose of describing and analyzing a ‘no project’ alternative is to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project” (Cal. Code Regs., tit. 14 § 15126.6(i)). The No Project analysis in this SA/DEIS considers existing conditions and “what would be reasonably expected to occur in the foreseeable future if the project were not approved.” (Cal. Code Regs, tit. 14 § 15126.6, subd. (e)(2)).

If the No Project Alternative were selected, the construction and operational impacts of the Genesis Solar Energy Project would not occur. There would be no grading of the site, no loss of resources or disturbance of desert habitat, and no installation of power generation and transmission equipment. The No Project Alternative would also eliminate contributions to cumulative impacts on a number of resources and environmental parameters in Riverside County and in the Sonoran Desert as a whole. **Project Description 3** provides a depiction of proposed solar energy application developments provided by BLM's Palm Springs – South Coast Filed Office.

In the absence of the Genesis Solar Energy Project, however, other power plants, both renewable and non-renewable, may have to be constructed to serve the demand for electricity and to meet the California Renewable Portfolio Standard (RPS). The impacts of these other facilities may be similar to those of the proposed project because these technologies require large amounts of land like that required for the Genesis Solar Energy Project. The No Project/No Action Alternative may also lead to siting of other non-solar renewable technologies to help achieve the California RPS.

Additionally, if the No Project/No Action Alternative were chosen, additional gas-fired power plants may be built, or existing, older and inefficient gas-fired plants, many of which rely on Once-Through Cooling (OTC), may operate longer. Importantly, if the proposed Genesis project were not built, California would not benefit from the reduction in greenhouse gases that this facility would provide, and California utilities would not receive the 250 MW contribution to their renewable state-mandated energy portfolio.

NEPA No Action Alternatives

Under NEPA, the No Action Alternative is used as a benchmark of existing conditions by which the public and decision makers can compare the environmental effects of the proposed action and the alternatives. Like the No Project Alternative described above, under the No Action Alternative, the impacts of the Genesis Solar Energy Project (GSEP) would not occur.

BLM is considering two separate actions (whether to approve a plan amendment and whether to approve the proposed project or an alternative). BLM's "action alternative" would be to amend the CDCA Plan to include GSEP (250 MW), and to approve the project as proposed. If the GSEP and ancillary facilities are approved, a ROW grant would be issued, and the CDCA Plan would be amended to include Genesis' generation facilities and transmission line as an approved site under the Plan. Similarly, BLM could amend CDCA Plan to include one of the alternatives fully analyzed in this Draft EIS (the Dry-Cooling Alternative or Reduced Acreage Alternative), and approve the construction and operation of those alternatives. The alternative and ancillary facilities would be approved, a ROW grant for the appropriate acreage would be issued, and the CDCA Plan would be amended to include the alternative power generation facilities and transmission line as an approved site under the Plan.

BLM's alternatives related to the No Action Alternative and the Plan amendment are the following:

- **No Action on project but amend the CDCA plan to make the area available for future solar development.** The Genesis Solar Energy Project is not approved

(project denied), and no ROW grant is issued, but the CDCA plan is amended to make the project area available for large scale renewable energy development under a future project proposal.

- **No Action on project and amend the CDCA plan to make the area unavailable for future solar development.** The Genesis Solar Energy Project is not approved (project denied), and no ROW grant is issued, and the CDCA plan is amended to make the project area unavailable for large scale renewable energy development.
- **No Action on project application and no land use plan amendment**. The Genesis Solar Energy Project is not approved (denied), no ROW grant is issued, and no CDCA Plan amendment is approved. There is no consideration of information that would allow approval of a CDCA Plan amendment that would make the land available for large scale energy development in the future.

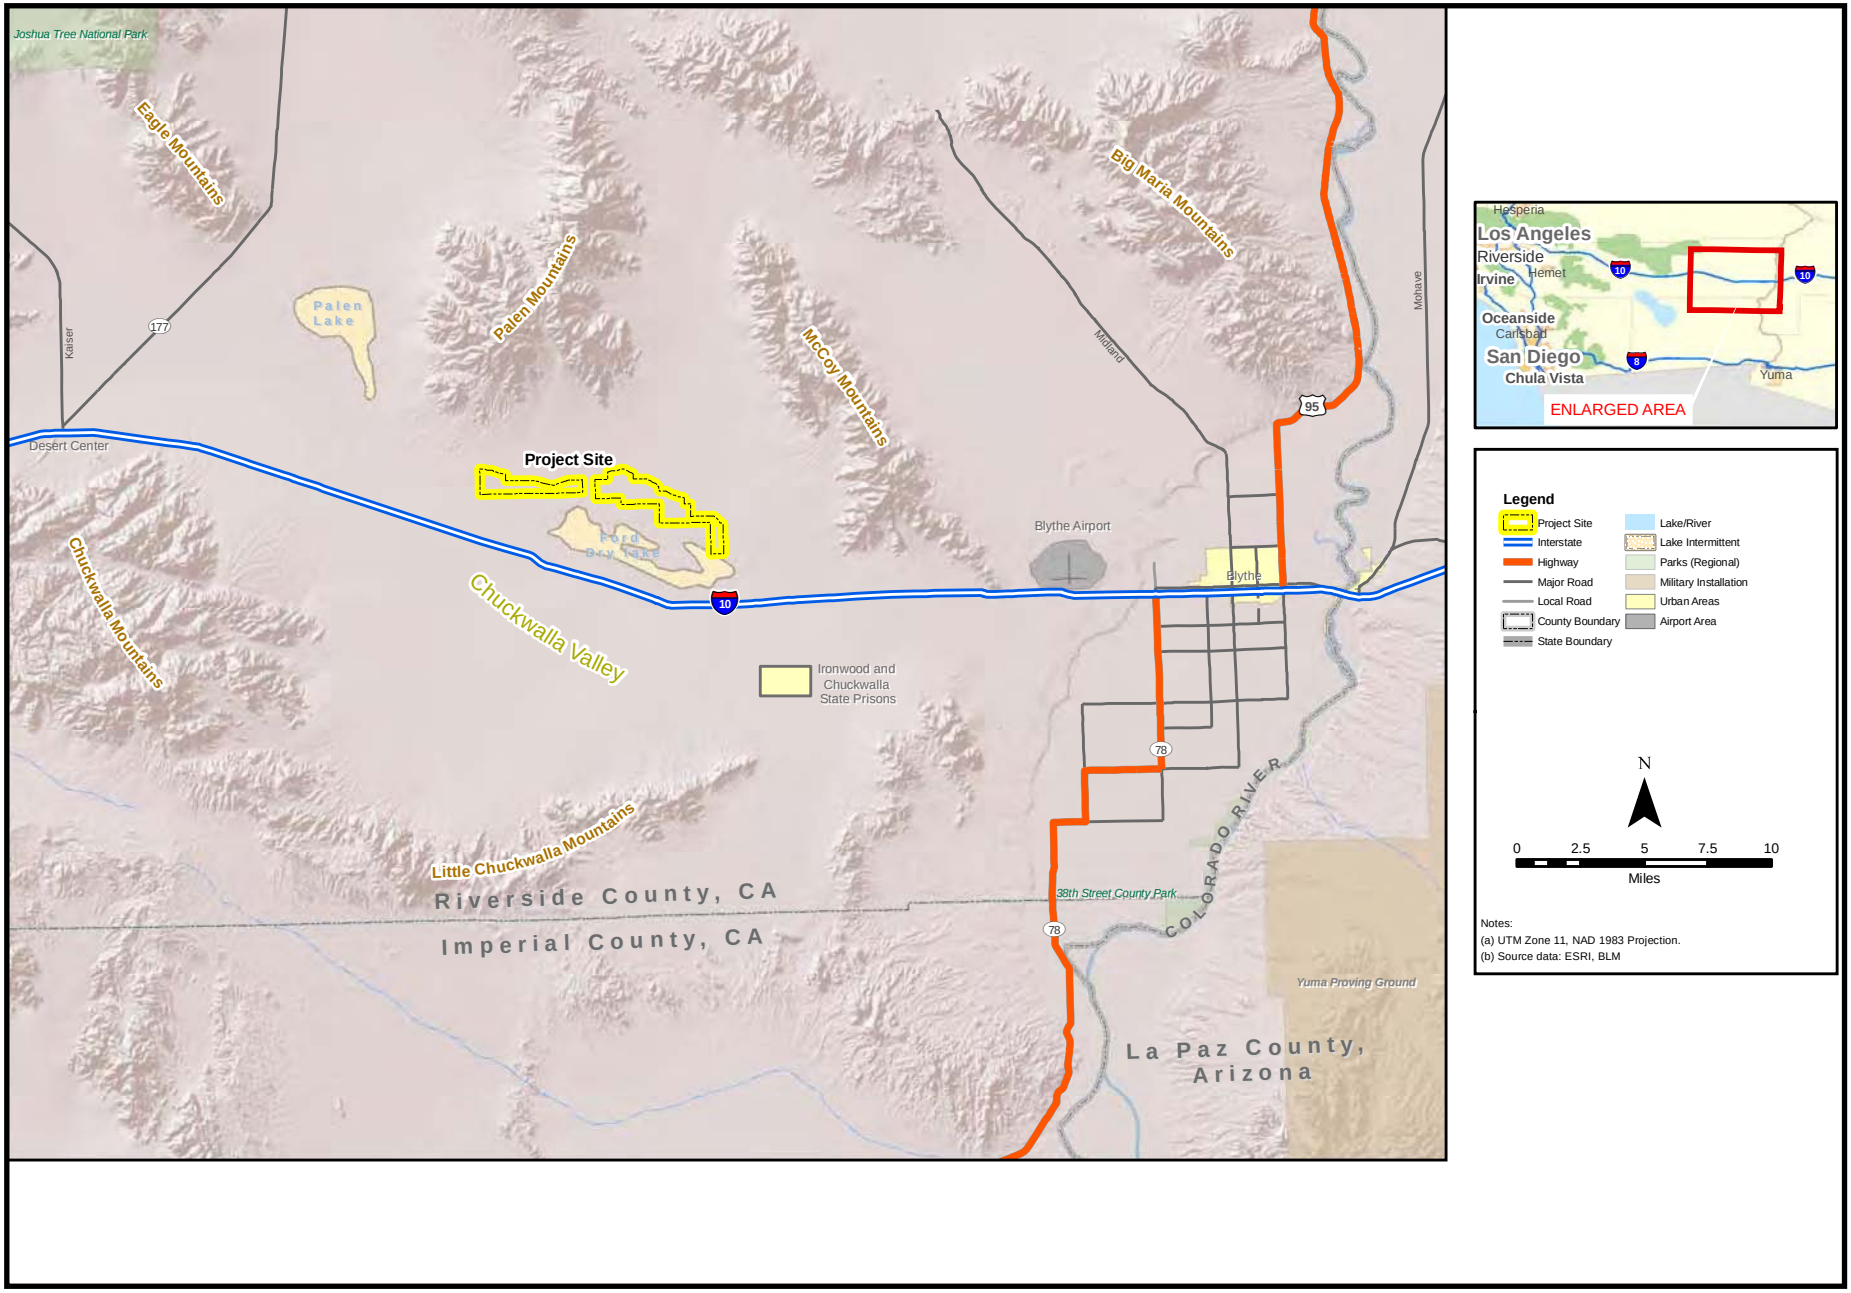
Each of these No Action Alternatives is addressed under each resource element technical discussion (Sections C and D) of this SA/EIS.

Project Objectives

The Project objectives, as indicated by the applicant, are as follows:

- To construct, operate and maintain an efficient, economic, reliable, safe and environmentally sound solar powered generating facility throughout its useful life to help: (i) achieve the State of California objectives mandated by SB 1078 (California Renewable Portfolio Standard Program), (ii) AB 32 (California Global Warming Solutions Act of 2006), and (iii) other local mandates adopted by the State's municipal electric utilities to meet the requirements for the long-term, wholesale purchase of renewable electric energy for distribution to their customers;
- To develop a site with an excellent solar resource;
- To develop a site with close proximity to transmission infrastructure in order to minimize associated environmental impacts;
- To develop a new utility-scale solar energy project using proven concentrated solar trough technology; and,
- To develop a site with available degraded ground water resources to allow wet cooling in order to maximize power generation, optimize efficiency, and reduce the delivered cost of electricity to customers.

B.1.5 DECOMMISSIONING AND RESTORATION



The planned operational life of the project is 30 years, but the facility conceivably could operate for a longer or shorter period depending on economic or other circumstances. If the project remains economically viable, it could operate for more than 30 years. However, if the facility were to become economically non-viable before 30 years of operation, permanent closure could occur sooner. In any case, a Decommissioning Plan will be prepared and put into effect when permanent closure occurs. The J**oint Conditions of Compliance** section of this document discusses this issue.

The procedures provided in the decommissioning plan will be developed to ensure compliance with applicable LORS, and to ensure public health and safety and protection

of the environment. The Closure Plan will be submitted to the CEC and BLM for review and approval prior to a planned closure. Depending on conditions at the time, permanent closure measures may range from extensive “mothballing” to the complete removal of project equipment and other structures.

B.2 – ALTERNATIVES EVALUATED

Testimony of Susan V. Lee

B.2.1 SUMMARY OF CONCLUSIONS

In this analysis of the Genesis Solar Energy Project, 25 alternatives to the project have been developed and evaluated. These include six alternative site locations or configurations, a dry cooling alternative, a range of different solar and renewable technologies, generation technologies using different fuels, and conservation/demand-side management. Of the 25 alternatives, two alternatives were determined to be reasonable and feasible by the Bureau of Land Management and the Energy Commission and have the potential to result in reduced impacts in comparison with the proposed project: the Reduced Acreage Alternative and the Dry Cooling Alternative. Both alternatives would also include and be complimentary to the proposed land use plan decisions located in Appendix B. Those areas that have studied and found to be unsuitable for development would be managed as future rights of way exclusion areas. In addition to the proposed action, the agencies considered three No Project/No Action Alternatives that would vary in their approach to considering the land use plan amendment.

The Reduced Acreage Alternative would be half as large as the proposed project and was found to reduce the impacts of the proposed GSEP by approximately 50 percent. It would affect substantially less Mojave fringe-toed lizard habitat, would substantially reduce the geomorphic impacts, and would create no impacts to the Chuckwalla and Palen-McCoy sand corridors. However, as highlighted in the Section C.1 (Air Quality), the Reduced Acreage Alternative would reduce the benefits of the proposed GSEP by approximately 50 percent. While the Reduced Acreage Alternative would meet most project objectives, it is uncertain whether the Reduced Acreage Alternative is economically feasible.

The Dry Cooling Alternative was found to have impacts similar to the proposed project for most resource elements. However, because it would use less water, it would reduce impacts to groundwater-dependent ecosystems and reduce impacts of the visible vapor plumes that the proposed project would create with use of cooling towers. The Dry Cooling Alternative was found to reduce the efficiency of the steam power cycles, which would slightly reduce the total amount of power generated. As a result, the benefits of the GSEP in replacing gas-fired power plants and associated greenhouse gases would be reduced. At this time, dry-cooling appears to be a feasible alternative to the GSEP's use of wet-cooling.

The No Project/No Action Alternative is not superior to the proposed project because it would likely delay development of renewable resources or shift renewable development to other similar areas, and could lead to increased operation of existing power plants that use non-renewable technologies.

One site alternative was evaluated in detail by the Energy Commission under the California Environmental Quality Act only: the Gabrych Alternative, which was presented by the applicant. While the impacts of the Gabrych Alternative site would be similar to those of the proposed site in many resource elements, it is likely to have less

severe biological resources and cultural resources impacts, as it is located on disturbed lands used for agriculture. The Gabrych Alternative would be located on some active and some previously farmed agriculture land, resulting in a significant impact to agriculture.

Alternative solar thermal technologies (Stirling engine, solar power tower, utility scale solar photovoltaics, and linear Fresnel) are also evaluated. As compared with the proposed solar trough technology, these technologies would not substantially change the severity of visual impacts, biological resources impacts and cultural impacts, though land requirements and water use vary among the technologies. Distributed solar photovoltaic facilities would likewise require extensive acreage, although because it can be installed on existing buildings, it would minimize the loss of undisturbed open space. However, increased deployment of distributed solar photovoltaics faces challenges in manufacturing capacity, cost, and policy implementation.

Other generation technologies (wind, geothermal, biomass, tidal, wave, natural gas, and nuclear) are also examined as possible alternatives to the project. These technologies would either be infeasible at the scale of the Genesis Solar Energy Project, or would not reduce or eliminate significant impacts caused by the Genesis Solar Energy Project without creating their own significant impacts in other locations. A natural gas plant would contribute to greenhouse gas emissions and would not meet the project's renewable generation objective. Construction of new nuclear power plants is currently prohibited under California law. Other renewable generation technologies are not required to be analyzed by the BLM because they fall outside BLM's purpose and need for the proposed action, which is to is to respond to NextEra's application under Title V of FLPMA (43 U.S.C. 1761) for a ROW grant to construct, operate, and decommission a solar thermal facility on public lands in compliance with FLPMA, BLM ROW regulations, and other Federal applicable laws.

Conservation and demand side management programs would likely not meet the state's growing electricity needs that would be served by the Genesis Solar Energy Project. In addition, these programs would not provide the renewable energy required to meet the California Renewable Portfolio Standard requirements. Wave and tidal technologies are not yet commercially available in the United States.

Staff's analysis of renewable energy technology options indicates that contributions from each commercially available renewable technology will be needed to meet California's Renewable Portfolio Standard requirements and to achieve the statewide renewable energy target for 2020. Therefore, the combined contribution of the alternatives of wind, distributed solar photovoltaic, geothermal, and biomass is needed to complement rather than substitute for the Genesis Solar Energy Project solar thermal contribution to meeting statewide renewable energy requirements. The table below indicates that each of these four alternative technology options when considered individually is insufficient to meet the project objectives related to the Renewable Portfolio Standard.

Alternatives Table 1 lists the alternatives retained for analysis in this SA/DEIS and those eliminated, and summarizes the rationale for each conclusion.

Alternatives Table 1. Summary of Alternatives Retained and Eliminated

Alternative	Rationale for Retention or Elimination
Alternatives Retained for CEQA and NEPA Analysis	
Proposed Project/Action - 250 MW	Evaluated as the applicant's proposal.
Reduced Acreage Alternative - 125 MW	Evaluated in the SA/DEIS because it would substantially reduce impacts of the Genesis Solar Energy Project and meet the BLM purpose and need.
Dry Cooling Alternative	Evaluated in the SA/DEIS because it would substantially reduce impacts of the Genesis Solar Energy Project and meet the BLM purpose and need.
No Project/No Action Alternative	Required under CEQA and NEPA. Note that additional NEPA No Action Alternatives are described below under Land Use Plan Amendment Alternatives.
Land Use Plan Amendment Alternatives Evaluated Only under NEPA	
Authorize Genesis Solar Energy Project through a CDCA Land Use Plan Amendment	Action required under the CDCA Plan of 1980, as amended.
Amend CDCA Land Use Plan for a reduced size project or project including dry cooling within the proposed project's boundaries (125 MW)	A smaller project or a project including dry cooling reduces impacts; site location is an action for which an amendment to the CDCA Plan of 1980, as amended, is required.
Do not approve the ROW grant and do not amend the CDCA Land Use Plan of 1980, as amended.	The first No Action Alternative: deny the ROW application and do not amend the CDCA Land Use Plan of 1980.
Do not approve the ROW grant and amend the CDCA Land Use Plan of 1980, as amended, to make the area unavailable for future solar development.	The second No Action Alternative: deny the ROW application and amend the CDCA Land Use Plan of 1980 to make the site unavailable for any future solar development.
Do not approve the ROW grant and amend the CDCA Land Use Plan of 1980 to make the area available for future solar development.	The third No Action Alternative: deny the ROW application but amend the CDCA Land Use Plan of 1980 to make the site available for future solar development.
Site Alternative Evaluated Under CEQA	
Gabrych Alternative	Would substantially reduce impacts of the Genesis Solar Energy Project while meeting most project objectives.
Alternatives Eliminated from Detailed Analysis	

Alternative	Rationale for Retention or Elimination
McCoy	Would not substantially reduce impacts of the Genesis Solar Energy Project; pending right-of-way grant application for the site, therefore not considered a viable alternative.
Desert Center 1	Desert Center 1 region was in an area that would potentially be subsumed in expansions of the Joshua Tree National Park and/or the McCoy Wilderness. In the fall of 2008, the BLM rejected the application for ROW grant for the use of the region.
Mule Mountain	Would not substantially reduce impacts of the Genesis Solar Energy Project; pending right-of-way grant application for the site, therefore not considered a viable alternative.
Black Hill	Would not substantially reduce impacts of the Genesis Solar Energy Project; pending right-of-way grant application for the site, therefore not considered a viable alternative.
Private Land Alternative	Portions of the private lands were analyzed as the Blythe Mesa Alternative in the Blythe Solar Power Project SA/EIS.
Western ROW Alternative	Would not substantially reduce impacts of the Genesis Solar Energy Project
Reclaimed Water Alternative	Sufficient reclaimed water is not available; would not substantially reduce impacts to the water accounting system for the groundwater basin
Stirling Dish Technology	Would not substantially reduce impacts of the Genesis Solar Energy Project.
Solar Power Tower Technology	Would not substantially reduce impacts of the Genesis Solar Energy Project.
Linear Fresnel Technology	Would reduce area required by about 40% but would not eliminate significant impacts of the Genesis Solar Energy Project.
Solar Photovoltaic Technology – Utility Scale	Would reduce water use but requires similar land area so would not substantially reduce impacts of the Genesis Solar Energy Project.
Distributed Solar Technology	While it will very likely be possible to achieve 250 MW of distributed solar energy over the coming years, the limited numbers of existing facilities make it difficult to conclude with confidence that this much distributed solar will be available within the timeframe required for the Genesis Solar Energy Project. Barriers exist related to interconnection with the electric distribution grid. Also, solar PV is one of the components of the renewable energy mix required to meet the California Renewable Portfolio Standard requirements, and additional technologies like solar thermal generation, would also be required.

Alternative	Rationale for Retention or Elimination
Wind Energy	While there are substantial wind resources in Riverside County, environmental impacts could also be significant so wind would not reduce impacts in comparison to the Genesis Solar Energy Project. Also, wind is one of the components of the renewable energy mix required to meet the California Renewable Portfolio Standard requirements, so additional technologies like solar thermal generation, would also be required.
Geothermal Energy	Despite the encouragement provided by Renewable Portfolio Standards and ARRA funding, few new geothermal projects have been proposed in the Imperial Valley and no geothermal projects are included on the Renewable Energy Action Team list of projects requesting ARRA funds. Therefore, the development of 250 MW of new geothermal generation capacity within the timeframe required for the Genesis Solar Energy Project appears to be unlikely.
Biomass Energy	Most biomass facilities produce only small amounts of electricity (in the range of 3 to 10 MW) and so could not meet the project objectives related to the California Renewable Portfolio Standard. In addition, between 25 and 80 facilities would be needed to achieve 250 MW of generation, creating substantial adverse impacts.
Tidal Energy	Tidal fence technology is commercially available in Europe. However, it has not been demonstrated and proven at the scale that would be required to replace the proposed project, particularly with Pacific tides. It may also result in substantial adverse environmental impacts
Wave Energy	Unproven technology at the scale that would be required to replace the proposed project; it may also result in substantial adverse environmental impacts
Natural Gas	Would not attain the objective of generating renewable power meeting California's renewable energy needs
Coal	Would not attain the objective of generating renewable power meeting California's renewable energy needs and is not a feasible alternative in California
Nuclear Energy	The permitting of new nuclear facilities in California is not currently allowable by law
Conservation and Demand-side Management	Conservation and demand-management alone are not sufficient to address all of California's energy needs, and would not provide the renewable energy required to meet the California Renewable Portfolio Standard requirements

B.2.2 INTRODUCTION

Genesis Solar, LLC (a subsidiary of NextEra) proposes to build the Genesis Solar Energy Project (GSEP) on BLM-administered land, which is federal land under the

administrative jurisdiction of the BLM. Since the BLM is a federal agency, the GSEP is subject to review under the National Environmental Policy Act (NEPA) in addition to the California Environmental Quality Act (CEQA). The purpose of this alternatives analysis is to comply with State and Federal environmental laws by providing a reasonable range of alternatives which, under CEQA, could substantially reduce or avoid any potentially significant adverse impacts of the proposed project, or under NEPA, would inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment. This section summarizes the potentially significant impacts of the proposed project and analyzes different technologies and alternative sites that may reduce or avoid significant impacts.

Of the 25 alternatives, two alternatives were determined to be both reasonable for the BLM and feasible for the Energy Commission: the Reduced Acreage Alternative and the Dry Cooling Alternative. These alternatives and the no project/no action alternative are analyzed in further detail within each of the technical sections of this document, and are considered for selection as the preferred alternative.

This section presents analysis of one site alternative that is evaluated under CEQA only and presents the plan amendment alternatives evaluated under NEPA only. The section also presents the discussion and analysis of all alternatives eliminated from detailed consideration by both the Energy Commission and the BLM.

B.2.3 ALTERNATIVES DEVELOPMENT AND SCREENING PROCESS

Laws, Ordinances, Regulations, and Standards

NextEra proposes to build the GSEP facility on federal land administered by the BLM. Since the BLM is a federal agency and the California Energy Commission has State authority to approve thermal power plants, the GSEP is subject to review under both NEPA and CEQA.

California Environmental Quality Act Criteria

The *Guidelines for Implementation of the California Environmental Quality Act*, Title 14, California Code of Regulation, section 15126.6(a), provides direction by requiring an evaluation of the comparative merits of “a range of reasonable alternatives to the project, or to the location of the project, which would feasibly attain most of the basic objectives of the project but would avoid or substantially lessen any of the significant effects of the project.” In addition, the analysis must address the “no project” alternative (Cal. Code Regs., tit. 14, § 15126.6(e)).

The range of alternatives is governed by the “rule of reason” which requires consideration only of those alternatives necessary to permit informed decision making and public participation. CEQA states that an environmental document does not have to consider an alternative of which the effect cannot be reasonably ascertained and of which the implementation is remote and speculative (Cal. Code Regs., tit. 14, § 15125(d)(5)).

National Environmental Policy Act Criteria

NEPA requires that the decision-makers and the public be fully informed of the impacts associated with the proposed project. NEPA declares that the Federal government's continuing policy is to create and maintain conditions under which people and nature can exist in productive harmony and fulfill the social, economic, and other requirements of present and future generations of Americans.

Regulations promulgated by the Council on Environmental Quality (CEQ) require that an EIS rigorously explore and objectively evaluate a reasonable range of alternatives to a proposed action. Reasonable alternatives are those for which effects can be reasonably ascertained, whose implementation is not remote or speculative, that are feasible, effective, are not remote from reality, and those that are consistent with the basic policy objectives for management of the area. (40 CFR 1502.14; CEQ Forty Questions, No. 1A; Headwaters , Inc. v. BLM, 914 F.2d. 1174 (9th Cir. 1990)). Reasonable alternatives are dictated by the nature and scope of the proposed action. To determine reasonable alternatives, an agency must define the purpose and need of the proposal. The purpose and need of the proposed action is to be evaluated under a reasonableness standard.

Further, "[i]n determining the scope of alternatives to be considered, the emphasis is on what is 'reasonable' rather than on whether the proponent or applicant likes or is itself capable of carrying out a particular alternative." (CEQ Forty Questions, No. 2a.)

Consideration of a No Action alternative is mandated by NEPA. As with the CEQA No Project alternative, this is the scenario that would exist if the proposed project were not constructed and no land use plan amendment was approved.

U.S. Army Corps of Engineers Regulations

The U.S. Army Corps of Engineers has not yet issued a determination regarding whether ephemeral drainages on the proposed GSEP site are jurisdictional waters of the U.S. Federal regulations require that if waters of the U.S. are affected by a proposed project, alternatives must be considered that reduce effects on the waters of the U.S. These regulations are presented in CFR 40 Part 230 Section 404(b)(1) Guidelines for Specification of Disposal Sites for Dredged or Fill Material, Subpart B--Compliance With the Guidelines, Sec. 230.10 Restrictions on discharge. Those regulations require that the Corps prepare a "404(b)1 Analysis" to evaluate alternatives.

Regarding the Corps' required alternatives analysis, the regulations state the following:

> (a) Except as provided under section 404(b)(2), no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse environmental consequences.
>
> (1) For the purpose of this requirement, practicable alternatives include, but are not limited to:
>
> (i) Activities which do not involve a discharge of dredged or fill material into the waters of the United States or ocean waters;

(ii) Discharges of dredged or fill material at other locations in waters of the United States or ocean waters;

(2) An alternative is practicable if it is available and capable of being done after taking into consideration cost, existing technology, and logistics in light of overall project purposes. If it is otherwise a practicable alternative, an area not presently owned by the applicant, which could reasonably be obtained, utilized, expanded or managed in order to fulfill the basic purpose of the proposed activity may be considered.

(3) Where the activity associated with a discharge which is proposed for a special aquatic site (as defined in subpart E) does not require access or proximity to or sighting within the special aquatic site in question to fulfill its basic purpose (i.e., is not "water dependent"), practicable alternatives that do not involve special aquatic sites are presumed to be available, unless clearly demonstrated otherwise.

To meet these requirements, this alternatives analysis fully considers two alternatives within the boundaries of the proposed project, as described in Section B.2.6. In addition, a range of other alternatives that comply with the Corps' guidelines are presented in Section B.2.8 (alternatives considered but eliminated from detailed analysis), and an offsite alternative is evaluated in Section B.2.7 (Site Alternatives Evaluated Under CEQA).

B.2.4 SCREENING METHODOLOGY

To prepare the alternatives analysis, the following methodology was used:

1. Develop an understanding of the project, identify the basic objectives of the project, and describe its potentially significant adverse impacts.

2. Under CEQA, identify and evaluate technology alternatives to the project such as increased energy efficiency (or demand-side management) and the use of alternative generation technologies (e.g., solar or other renewable or nonrenewable technologies).

3. Under CEQA, identify and evaluate alternative locations.

4. Under CEQA, evaluate potential alternatives to select those qualified for detailed evaluation.

5. Under NEPA, explore and evaluate a reasonable range of alternatives, and of those reasonable alternatives, identify those that would avoid or minimize adverse impacts or enhance the quality of the human environment.

6. Evaluate the impacts of not constructing the project, known as the No Project Alternative under CEQA and the No Action Alternative under NEPA.

Based on this methodology, each potential alternative was evaluated according the following criteria for its ability to:

- for CEQA purposes avoid or substantially lessen one or more of the potential significant effects of the project as described above;
- for CEQA purposes meet most project objectives;
- for NEPA purposes be consistent with the purpose and need to which BLM is responding.

B.2.4.1 Applicant's Project Objectives

The following objectives and purpose are set forth by NextEra (GSEP 2009a):

- To construct, operate, and maintain an efficient, economic, reliable, safe, and environmentally sound solar powered generating facility throughout its useful life to help: (i) achieve the State of California objectives mandated by SB 1078 (California Renewable Portfolio Standard Program); (ii) AB 32 (California Global Warming Solutions Act of 2006); and (iii) other local mandates adopted by the State's municipal electric utilities to meet the requirements for the long-term wholesale purchase of renewable electric energy for distribution to their customers.
- To develop a site with an excellent solar resource.
- To develop a site with close proximity to transmission infrastructure in order to minimize environmental impacts.
- To develop a new utility-scale solar energy project using proven concentrated solar trough technology.
- To develop a site with available water resources to allow wet cooling in order to optimize power generation efficiency and reduce project cost.

Additionally, NextEra states that the project would:

- Address local mandates that California's electric utilities have adopted for the provision of renewable energy.
- Assist the California Independent System Operator (CAISO) in meeting its strategic goals for the integration of renewable resources.
- Contribute to reductions in greenhouse gas emissions.

B.2.4.2 Project Objectives of the Energy Commission (CEQA)

After considering the objectives set out by the applicant, the Energy Commission has identified the following basic project objectives, which are used to evaluate the viability of alternatives in accordance with CEQA requirements:

- To construct a utility-scale solar energy project of up to 250 MW and interconnect directly to the CAISO Grid while minimizing additions to electrical infrastructure; and
- To locate the facility in areas of high solar insolation.

In addition, when considering retention or elimination of alternative renewable technologies, in addition to evaluating the likelihood of reducing or eliminating the potential impacts of Genesis Solar Energy Project at its proposed site, staff evaluated whether alternative technologies could meet the following key project objectives:

- to provide clean, renewable electricity to support California's Renewable Portfolio Standard Program (RPS);
- to assist in reducing greenhouse gas emissions as required by the California Global Warming Solutions Act; and
- to contribute to the achievement of the 33 percent renewables RPS target set by California's governor and legislature.

B.2.4.3 BLM Purpose and Need for Proposed Project and Plan Amendment

Bureau of Land Management. The Energy Policy Act of 2005 (EPAct) encourages the United States Department of the Interior (DOI), BLM's parent agency, to approve at least 10,000 MW of renewable energy on public lands by 2015. Executive Order 13212, dated May 18, 2001, mandates that agencies expedite their "review of permits or take other actions as necessary to accelerate the completion of such projects, while maintaining safety, public health, and environmental protections" in the "production and transmission of energy in a safe and environmentally sound manner."

Secretarial Order 3283, *Enhancing Renewable Energy Development on the Public Lands*, requires the BLM to ensure that processing and permitting of renewable energy projects comply with the requirements of the National Environmental Policy Act, Endangered Species Act, National Historic Preservation Act, and all other laws and regulations; improve efficiencies in the processing of renewable energy applications and the consistent application of renewable energy policies; and develop Best Management Practices for renewable energy projects on public lands to ensure the most environmentally responsible development of renewable energy, among other goals.

Secretarial Order 3285, *Renewable Energy Development by the Department of the Interior*, requires BLM to encourage the development of environmentally responsible renewable energy generation. Both of these Secretarial Orders will be considered in responding to the NextEra application for the proposed GSEP.

NextEra has filed an application with BLM for a right-of-way (ROW) grant pursuant to the Federal Land Policy and Management Act (FLPMA, 43 USC 1761). Under FLPMA Title V Section 501 (a)(4) (Rights-of-Way), the United States Secretary of the Interior, as delegated to the BLM, is authorized to grant ROW on lands administered by the BLM for the purpose of allowing systems for generation, transmission, and distribution of electric energy.

The **BLM's Purpose and Need** for the GSEP is to respond to the NextEra application under Title V of FLMPA for a ROW grant to construct, operate and decommission a solar thermal facility and associated infrastructure in compliance with FLPMA, BLM ROW regulations, and other applicable federal laws. The BLM will decide whether to approve, approve with modification, or deny issuance of a ROW grant to NextEra for the proposed GSEP. A land use plan amendment to the California Desert Conservation

Area (CDCA) Plan of 1980 would be required before BLM could issue the ROW grant. The decision the BLM will make is whether or not to grant a ROW and, if so, under what terms and conditions, and whether or not to amend the land use plan.

BLM Plan Amendment. As discussed in Section A, solar power facilities are an allowable use of lands designated as Multiple Use Class (MUC) L (limited use) areas (CDCA). Since the site for the proposed GSEP is currently classified within an MUC L area, solar power facilities are generally allowed. However, Chapter 3, the "Energy Production and Utility Corridors Element" of the CDCA Plan requires that newly proposed sites associated with power generation or transmission facilities not already identified in the Plan will be considered through the plan amendment process. The proposed GSEP site is not currently identified in the proposed power facility and transmission line element within the Plan. As such, a plan amendment is required in order to approve the site location consistent with the CDCA Plan. The plan would have to be amended prior to the approval of the proposed project. The result of the plan amendment may be that the Multiple Use Class would change from MUC L (limited use) to MUC I.

Department of Energy. NextEra has also applied to the United States (US) Department of Energy (DOE) for a loan guarantee pursuant to Title XVII of the EPAct. Title XVII of EPAct authorizes the United States Secretary of Energy to make loan guarantees for a variety of types of projects, including those that "avoid, reduce, or sequester air pollutants or anthropogenic emissions of greenhouse gases, and employ new or significantly improved technologies as compared to commercial technologies in service in the United States at the time the guarantee is issued." The two principal goals of the loan guarantee program are to encourage commercial use in the United States of new or significantly improved energy-related technologies and to achieve substantial environmental benefits. The purpose and need for action by DOE is to comply with their mandate under EPAct by selecting eligible projects that meet the goals of the Act.

American Recovery and Reinvestment Funds. NextEra has also applied for American Recovery and Reinvestment Funds (ARRA) Renewable Energy Grant Program. Two goals of the ARRA Renewable Energy Grant Program are to enhance America's energy independence and create near-term employment opportunities for Americans. To be eligible for the ARRA funds, NextEra must begin construction on the GSEP by the end of 2010.

B.2.4.4 Impacts of the Proposed Project

Based on the analysis presented in the technical sections of this Staff Assessment/Draft Environmental Impact Statement (SA/DEIS), the following impacts, discussed in full in Sections C and D, have been identified as issues of greatest concern for the GSEP:

- Cultural Resources: The proposed GSEP would have a significant direct impact on 14 historically significant archaeological resources and a potential significant indirect impact on 1 ethnographic resource. Mitigation for project impacts to cultural resources will be handled in a Programmatic Agreement (PA) negotiated among all stakeholders-federal, state, and private. Development of the PA by the BLM is underway, but will not be completed until mid-summer.

- Biological Resource: The GSEP would have significant impacts to biological resources, eliminating all of the Sonoran creosote bush scrub and other native plant and wildlife communities within the approximately 1,880-acre site. The GSEP would result in loss of an extensive network of desert washes comprising approximately 83 acres of state jurisdictional waters, and would significantly alter the hydrology of the area by re-routing ephemeral drainages through engineered channels. The GSEP would impact 1,786 acres of desert tortoise habitat, including 23 acres within the Chuckwalla Desert Critical Habitat Unit. The proposed groundwater pumping would have an impact on groundwater levels in the Chuckwalla Valley Groundwater Basin with potential adverse effects to groundwater dependent sensitive plant communities and to wildlife. Cumulative Impacts: the indirect effects of development of the Chuckwalla Valley will contribute cumulatively to the overall loss of dune habitat, desert washes, and the fragmentation and degradation of the remaining habitat for Mojave fringe-toed lizard and several dune-dependent rare plant species. Proposed renewable energy development in Chuckwalla Valley could threaten what remains of the habitat and places several populations at risk, most notably, the local Chuckwalla population of the Mojave fringe-toed lizard.
- Soil and Water Resources: The proposed project would pump groundwater from the Chuckwalla Valley Groundwater Basin (CVGB). The proposed Project would have an impact on levels of groundwater in the Chuckwalla Valley Groundwater Basin (CVGB). However, the magnitude of potential impacts cannot be determined precisely. Proposed water use suggests that groundwater withdrawn from production wells draw from the Palo Verde Mesa groundwater basin, a tributary to the Colorado River and as a result, the proposed GSEP pumping may induce flows from the Colorado River. The proposed Project would be located on an alluvial fan where flash flooding and mass erosion could impact the Project. Project-related changes to the alluvial fan hydrology could result in impacts to adjacent land users. Cumulative impacts: analysis indicates that groundwater extraction during construction and operation of this and other reasonably foreseeable projects would place the basin into an overdraft condition. This impact may be exacerbated by other renewable energy projects in the I-10 corridor, which has been targeted as a potential area for further renewable energy development. However, the amount of water that is storage in the basin greatly exceeds the amount of cumulative overdraft, rendering the project's contribution to this cumulative impacts less than cumulative considerable.
- Other Cumulative Impacts: For visual resources, the anticipated cumulative operational visual impacts of the GSEP in the Chuckwalla Valley are considered potentially significant from some sensitive viewpoints, particularly within the Chuckwalla Wilderness. Anticipated cumulative operational impacts of region-wide projects in the southern California desert are considered cumulatively considerable and potentially significant.
- Cumulative impacts to land use: approximately one million acres of land are proposed for solar and wind energy development in southern California desert lands. Cumulative impacts to approximately one million acres of land would all combine to result in adverse effects on agricultural lands and recreational resources. The cumulative conversion of these lands would preclude numerous existing land uses

including recreation, wilderness, rangeland, and open space, and therefore, result in a significant and unavoidable cumulative land use impact.

The alternatives analysis focuses on the consideration of these impacts and the extent to which they could be reduced or eliminated with use of alternative sites or technologies.

B.2.5 SUMMARY OF SCOPING AND SCREENING RESULTS

The public scoping comment period allowed the public and regulatory agencies an opportunity to comment on the scope of the environmental document, comment on the alternatives considered, and to identify issues that should be addressed in the environmental review. The discussion below presents the key issues identified from the written and oral comments received on the GSEP. The specific issues raised during the public scoping process that relate to Alternatives are summarized as follows:

- Suggestion to eliminate the western portion of the Genesis project near Palen Dry Lake ACEC (western portion of the Genesis project has not been included in the proposed GSEP design);
- Regarding groundwater impacts, the applicant's hydrologist makes the assertion that local wildlife waters are fed by a perched aquifer, and that since the project proposes
- Request that a dry cooling alternative be considered (See Section B.2.6.2);
- Project should be pulled back from dunes and other sensitive areas onsite, or preferably moved to an alternative site closer to existing disturbance and transmission (See Section B.2.7.2);
- Alternatives should include consideration of disturbed, private lands near the GSEP (Sufficient disturbed, private lands for a 250 MW solar power plant were not available near the GSEP, an alternative on disturbed, private lands elsewhere was considered. See Section B.2.7.2);
- Alternatives should not be tied to a specific Power Purchase Agreement that the applicant may have entered into (See Section B.2.6.1);
- Alternatives should consider using disturbed private lands, including land that is outside of BLM jurisdiction, and distributed generation (See Section B.2.7.2 and Section B.2.8.2);
- The AFC filed by NextEra fails to include a reasonable range of alternatives including the No Action Alternative and the reasonably foreseeable alternative of locating solar photovoltaic (PV) distributed generation (DG) near to load centers on brown-field sites (roof tops) where new transmission infrastructure may not be needed to connect these solar resources (See Section B.2.6.3 and Section B.2.8.2);
- Alternatives should be placed near existing transmission lines (The I-10 corridor is a designated utility corridor with existing and planned transmission lines);
- Private sites should not be rejected simply because they have numerous owners – there is no indication the level of effort the applicant put into acquiring private lands (See Section B.2.7.2);

- Agencies should compare the GSEP and its impacts with all other identified "fast-track" projects on BLM land in order to identify the least environmentally harmful projects among the applications that have been selected for expedited permitting;
- According the Energy Commission, only 128,000 acres maximum (both private and public) are needed to achieve the RPS goal so there is ample opportunity to consider species migration needs and patterns, established wildlife corridors and climate change implications on proposed project lands; and

Scoping comments are also listed in the **Summary of Comments** in the **Introduction** section of this SA/DEIS.

B.2.6 ALTERNATIVES EVALUATED UNDER NEPA AND CEQA

A number of scoping comments requested that the project be reconfigured or reduced in size to avoid sensitive resources and to consider technologies that would reduce impacts to water use. Scoping comments suggested including the disturbed lands in the vicinity of the project in the project footprint to make up for any loss in acreage. The scoping comments are addressed in the alternatives described herein and in the site alternative evaluated in Section B.2.7. This section describes three alternatives to the proposed project: the Reduced Acreage Alternative, the Dry Cooling Alternative, and the "No Project/No Action" Alternative. The alternatives are evaluated under both NEPA and CEQA in Section C (Environmental Analysis).

In addition, scoping comments identified the need for more comprehensive Land Use Plan Amendments that could further address minimizing the cumulative effects of large scale renewable projects along the I-10 Corridor. Proposed Land Use Plan Amendments are depicted in Appendix B and include consideration of those areas both inside and outside the project footprint that could be managed specifically for right away avoidance or exclusion areas, habitat conductivity and targeted acquisition areas that would function for compensatory mitigation for sensitive species.

B.2.6.1 Reduced Acreage Alternative

The Reduced Acreage Alternative would essentially be Unit 1 (or one-half) of the proposed project, including a 125 MW solar facility located within the boundaries of the proposed project as defined by NextEra. This alternative is analyzed for two major reasons: (1) it eliminates about 50 percent of the proposed project area so all impacts are reduced, and (2) by eliminating the eastern solar field, it would reduce the water required for wet cooling by 50 percent. The boundaries of the Reduced Acreage Alternative are shown in **Alternatives Figure 1**. As with the proposed GSEP, a land use plan amendment to the California Desert Conservation Area (CDCA) Plan of 1980 would be required before BLM could issue the ROW grant for the Reduced Acreage Alternative.

The Reduced Acreage Alternative would have a net generating capacity of approximately 125 MW and would occupy approximately 900 acres of land. This alternative would retain 50 percent of the proposed project's generating capacity, and would affect 50 percent of the land affected by the proposed project. Specifically, the alternative would retain the Unit 1 solar field, including the construction parking, construction trailers, and temporary construction laydown area; the administration

building and warehouse; the solar collector assembly area; the western evaporation pond area (approximately 24 acres); and the land farm area (approximately 10 acres). The alternative would require relocating the switchyard, from the Unit 2 power block to the Unit 1 power block. The eastern evaporation pond area (approximately 24 acres) that corresponds with Unit 2 would not be included in the Reduced Acreage Alternative. This area could be used for the relocated gas yard if needed.

Similar to the proposed project, the Reduced Acreage Alternative would transmit power to the grid through the Colorado River Substation. It would require infrastructure including groundwater wells, transmission line, road access, administration building, and evaporation ponds. The required infrastructure and transmission line for the Reduced Acreage Alternative would follow the routes defined for the proposed project, even though Unit 2 would not be constructed. The linear facilities would require approximately 90 acres. The gas pipeline would be approximately 1 mile longer than for the proposed project.

Dry cooling is being evaluated as an alternative to the proposed project, so could also be used with this configuration. However, if wet cooling were used, cooling would require approximately 822 acre-feet per year.

According to the applicant, independent studies have indicated a 250 MW size project hits an optimal size range where economies of scale and the potential for excess parasitic losses balance out and that there is no substantial environmental advantage to a smaller size project (GSEP 2009a). A detailed cost-benefit analysis for a reduced-size project would be required in order to determine the economic feasibility of this alternative. As a result, feasibility is uncertain at this time.

B.2.6.2 Dry Cooling Alternative

Description of the Process and Equipment Required

There are two types of dry cooling systems: direct dry cooling and the lesser used indirect dry cooling. In both systems, fans blow air over a radiator system to remove heat from the system via convective heat transfer (instead of once-through cooling or evaporative heat transfer). In the direct dry cooling system, also known as an air-cooled condenser (ACC), steam from the steam turbine exhausts directly to a manifold radiator system that rejects heat to the atmosphere, condensing the steam inside the radiator. Direct dry cooling is analyzed as the alternative to the wet cooling proposed by NextEra for the GSEP.

Dry cooling is the best choice of cooling technologies for a steam power plant to conserve water and minimize wastewater. However, this technology can create both environmental and economic concerns, depending on the location and specific situation. These concerns are evaluated for the GSEP site specifically in Sections C and D of this SA/DEIS. As with the proposed GSEP, a land use plan amendment to the California Desert Conservation Area (CDCA) Plan of 1980 would be required before BLM could issue the ROW grant for the Dry Cooling Alternative.

Advantages and Disadvantages of Dry Cooling

The following is a general list of the general advantages and disadvantages of dry cooling.

Advantages of Dry Cooling Systems

- Dry cooling allows a power plant location to be independent of a water source. It has essentially no water intake or water discharge requirements.
- Dry cooling minimizes the use of water treatment chemicals.
- Dry cooling minimizes the generation of liquid and solid wastes.
- Dry cooling does not generate visible plumes that are commonly associated with wet cooling towers.
- Dry cooling eliminates impacts to aquatic biological resources.
- Dry cooling eliminates the need for discharge permits.
- Dry cooling eliminates the need for disturbance of wetland/aquatic substrate habitat.

Disadvantages of Dry Cooling Systems

- Dry cooling requires air-cooled condensers that could have negative visual effects.
- Compared to once-through cooling, dry cooling requires the disturbance of a larger area for the air-cooled condensers than that required for cooling towers.
- Dry cooling can have noise impacts that are greater than once-through or wet cooling systems because of the number of fans and the considerably greater total airflow rate. New quieter fans and other mitigation measures are available to reduce these impacts.
- Using dry cooling, the power plant steam cycle efficiency and output can be slightly reduced, depending on site conditions and seasonal variations in ambient conditions. Also, extra power is needed to operate the cooling fans.
- Capital costs for building air-cooled condensers are generally higher than capital costs for once-through cooling.

Description of the Air Cooled Condensers

In order to compare the performance and impacts of a dry cooling system or ACC with that of the wet-cooled system, the operating conditions at a common design point must be established. The design and operation of an ACC are highly dependent upon the ambient conditions at a specific site.

Size, Configuration, and Layout

The size of an ACC is a function of the heat load from the steam turbine generator and the ambient conditions. The ACC is composed of tube bundles with fins attached to the tubes to enhance heat transfer to the air. These bundles are grouped together and mounted in an A-frame configuration on a steel support structure. These A-frame tube bundles are aligned in rows or bays. Steam is ducted directly from the steam turbine exhaust to the ACC where it enters in a parallel flow into the tubes across the top of the

bays. Air is blown from below across the finned tube bundles by a series of large fans, which are located beneath the A-frame tube bundles. Each fan is considered a module. To accommodate the large mass of air required for cooling the steam, the A-frame tube bundles are elevated on top of an open structure. As the steam passes down through the tube bundles, it is condensed and drains by gravity flow into a tank from which it is pumped back to the steam turbine. Since the steam is exhausted directly from the steam turbine generator after it has expanded through the turbine, it is at both a very low pressure and large volume. This condition limits the distance that the ACC can be located from the steam turbine generator, due to the drop in pressure that results during the transport of the steam; this limitation must be taken into consideration when configuring the plant layout.

Staff has not developed and analyzed detailed layouts for the ACC system. However, it is assumed that the ACC system would be located where the cooling towers are currently proposed. **Alternatives Figure 2** illustrates the approximate size and location of the ACC on the power block layout.

Approximately 18 ACC fans would be required for cooling each 125 MW power block when the ambient temperature is above 50 degrees Fahrenheit (GSEP 2009f). The 18 ACC fans described in the GSEP cooling study would have a length of approximately 279 feet, a width of approximately 127 feet, and a height of 98 feet (GSEP 2009f). However, based on the ACC preliminary designs for nearby solar thermal projects in similar ambient temperatures, an additional 11,690 square feet could be required for siting of the fans and the fans would be up to 120 feet in height. In addition to the ACC fans, NextEra would use a small Wet Surface Air Cooler when needed to provide auxiliary cooling during extremely hot days (GSEP 2009f). The proposed wet cooling towers and associated equipment occupy an area of about 420 feet long by 60 feet wide. While the ACCs would require about 40 to 50 percent more land area than the proposed wet cooling towers, from the site layout, it appears that such a system would fit in the approximate current location of the cooling tower as there is unused space between the power block and the solar collector assembly (GSEP 2009a). This unused space would have been previously graded as it is designed to be used for construction parking and construction trailers. An environmental assessment of the impacts of using dry-cooling instead of wet-cooling is presented in Sections C and D, for each resource element.

Economic Feasibility

As stated above, a NextEra project objective was to use a site that would allow wet cooling in order to optimize power generation efficiency and reduce project cost. Wet-cooling maximizes power plant fuel efficiency by providing a continuous source of effective cooling for the plant's steam condensers. Dry cooling will typically provide less effective cooling of the condensers, reducing the efficiency of the steam cycle portion of the power plant, and thus the overall fuel efficiency of the facility. The FSA for the Beacon Solar Energy Project (08-AFC-2; BSEP 2009) showed that annual average fuel efficiency would be reduced 5-7 percent compared to a wet cooling system. The applicant stated that use of dry cooling would result in a 7.4 percent decrease in total annual net MWh compared with a wet cooling system which NextEra considerers significant, since peak demand for the Project would be during the summer when ACC

performance is limited (GSEP 2009a). NextEra concludes that the use of dry cooling will decrease the project output, which will render the Project economically unsound or noncompetitive (GSEP 2009a).

The Genesis Solar Energy Project Cooling Study states that because of the brackish water being proposed for the site, the evaluated installed cost difference between wet and dry cooling was less than 1 percent (GSEP 2009f). As such, it is not the installation cost difference between wet and dry cooling that would render dry cooling economically unsound or noncompetitive but the decrease in total annual new MWh. Additionally, the cooling study estimates a decrease of annual net MWh when using dry cooling of 6.9 percent, as opposed to the 7.4 percent mentioned in the AFC by the applicant (GSEP 2009f).

When considering a dry cooling alternative in the Beacon Solar Energy Project FSA, the applicant proposed expanding the solar field by 12 percent to counter the reduction in generation that would result from dry cooling (BSEP 2009). The GSEP applicant also addresses an expanded solar field and states that the proposed project has been optimized for the land available, and a solar field expansion would be infeasible at this site (GSEP 2009a). However, the power block and solar arrays would occupy approximately 1,360 acres of the 1,800-acre site. Evaporation ponds, access roads, administration buildings, and other support facilities would require a portion of the 1,800-acre site, and there is also remaining open space (GSEP 2009a). A 12 percent increase in the GSEP solar field would require an additional 150 acres. While it is uncertain whether the entire 150 acres is available for use and would comply with the engineering requirements for GSEP, it is clear from the site plan that there is some available land immediately adjacent to existing solar trough rows and this land could be used to offset all or a portion of the efficiency loss due to the use of dry-cooling.

The FSA for the Beacon Solar Energy Project performed a detailed cost analysis for that project using dry cooling (BSEP 2009). In the FSA, it was found that the Beacon Solar Energy Project was economically feasible using dry cooling because it surpassed the benchmark internal rate of return established for economic feasibility. Furthermore, the Beacon Solar Energy Project was found to be economically feasible using dry cooling both with and without an expanded solar field (BSEP 2009). While not all circumstances of the Beacon Solar Energy Project and the GSEP are identical , the applicant has not shown sufficient evidence that the additional cost or lost profitability from incorporating dry cooling into the GSEP are sufficiently severe as to render dry cooling impracticable to proceed with the project.

This is further shown, as highlighted in the Beacon Solar Energy Project FSA, by the overall market (supply side) – the solar power plant development industry in California. The market was defined by the project using only solar thermal technologies with capacity of 50 megawatts or greater, constructed within the last 10 years in California or proposed to be built in California. Of the solar thermal projects being considered by the Energy Commission all but two were designed using dry cooling (air cooled condenser). This includes the three solar thermal projects in the same general area (climate) as the GSEP, which would have similar if not identical efficiency losses from using dry cooling. Because of this, dry cooling is considered potentially economically feasible and evaluated under both NEPA and CEQA in Section C (Environmental Analysis).

B.2.6.3 No Project/No Action Alternative

CEQA No Project Alternative

The No Project Alternative under CEQA defines the scenario that would exist if the proposed GSEP were not constructed. The CEQA Guidelines state that "the purpose of describing and analyzing a 'no project' alternative is to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project" (Cal. Code Regs., tit. 14 § 15126.6(i)). The No Project analysis in this SA/DEIS considers existing conditions and "what would be reasonably expected to occur in the foreseeable future if the project were not approved." (Cal. Code Regs, tit. 14 § 15126.6(e)(2)).

If the No Project Alternative were selected, the construction and operational impacts of the GSEP would not occur. There would be no grading of the site, no loss of resources or disturbance of desert habitat, and no installation of power generation and transmission equipment. The No Project Alternative would also eliminate contributions to cumulative impacts on a number of resources and environmental parameters in Riverside County and in the Mojave Desert as a whole.

In the absence of the GSEP, however, other power plants, both renewable and non-renewable, may have to be constructed to serve the demand for electricity and to meet the RPS. The impacts of these other facilities may be similar to those of the proposed project because these technologies require large amounts of land like that required for the GSEP. The No Project/No Action Alternative may also lead to siting of other non-solar renewable technologies to help achieve the California RPS.

Additionally, if the No Project/No Action Alternative were chosen, additional gas-fired power plants may be built, or that existing gas-fired plants may operate longer. If the proposed project were not built, California would not benefit from the reduction in greenhouse gases that this facility would provide, and California utilities would not receive the 250 MW contribution to its renewable state-mandated energy portfolio.

NEPA No Action Alternatives

Under NEPA, the No Action Alternative is used as a benchmark of existing conditions by which the public and decision makers can compare the environmental effects of the proposed action and the alternatives. Like the No Project Alternative described above, under the No Action Alternative, the impacts of the Genesis Solar Energy Project would not occur.

BLM is considering two separate actions (whether to approve a plan amendment and whether to approve the proposed project or an alternative). BLM's "action alternative" would be to amend the CDCA Plan to include GSEP (250 MW), and to approve the project as proposed. The GSEP and ancillary facilities are approved, a ROW grant is issued, and the CDCA Plan is amended to include the GSEP generation facilities and transmission line as an approved site under the Plan. Similarly, BLM could amend CDCA Plan to include one of the alternatives fully analyzed in this Draft EIS (the Dry Cooling Alternative or Reduced Acreage Alternative), and approve the construction and operation of those alternatives. The alternative and ancillary facilities would be

approved, a ROW grant for the appropriate acreage would be issued, and the CDCA Plan would be amended to include the alternative power generation facilities and transmission line as an approved site under the Plan.

BLM's alternatives related to the No Action Alternative and the Plan amendment are the following:

- **No Action on Genesis Solar Energy Project application and on CDCA land use plan amendment**. The Genesis Solar Energy Project is not approved (denied), no ROW grant is issued, and no CDCA Plan amendment is approved. There is no consideration of information that would allow approval of a CDCA Plan amendment that would make the land available for large scale energy development in the future.
- **No Action on Genesis Solar Energy Project application and amend the CDCA land use plan to make the area available for future solar development.** The Genesis Solar Energy Project is not approved (project denied), and no ROW grant is issued to SES, but the CDCA plan is amended to make the project area available for large scale renewable energy development under a future project .
- **No Action on Genesis Solar Energy Project and amend the CDCA land use plan to make the area unavailable for future solar development.** The Genesis Solar Energy Project is not approved (project denied), and no ROW grant is issued to Genesis, LLC and the CDCA plan is amended to make the project area unavailable for large scale renewable energy development.

Each of these No Action Alternatives is addressed under each resource element of Sections C and D of this SA/EIS.

B.2.7 CEQA-ONLY ALTERNATIVE RETAINED

One site alternative is evaluated by the Energy Commission under CEQA only. The alternative site evaluated in this section (the Gabrych Alternative) is located on private land. BLM has determined that it would be inconsistent with its purpose and need for the action under consideration or would otherwise be unreasonable. Under NEPA reasonable alternatives are dictated by the nature and scope of the proposed action and are defined by the purpose and need. Because the offsite alternative would not be within BLM jurisdiction, BLM would have no discretionary approval authority for this alternative.

The Energy Commission does not have the authority to approve an alternative or require NextEra to move the proposed project to another location, even if it identifies an alternative site that meets the project objectives and avoids or substantially lessens one or more of the significant effects of the project. Implementation of an alternative site would require that the applicant submit a new Application for Certification (AFC), including revised engineering and environmental analysis. This more rigorous AFC-level analysis of any of the alternative sites could reveal environmental impacts; nonconformity with laws, ordinances, regulations, and standards; or potential mitigation requirements that were not identified during the more general alternatives analysis presented herein. Preparation and review of a new AFC would require substantial additional time.

No specific alternative site for the GSEP was suggested in scoping comments; however, a number of commenters requested that alternatives on disturbed private lands be considered.

B.2.7.1 Site Selection Criteria for the Retained CEQA Alternative

The following site selection criteria identified in the GSEP AFC were used to choose the proposed site (GSEP 2009a):

- The site must receive insolation of no less than 7.0 kilowatt-hours per square meter per day (kWh/m^2/day).
- The site must be large enough (at least 1,800 contiguous acres) to support a 250-MW plant and arranged in a way that allows an efficient and cost-effective layout.
- The site needs to be relatively flat, with a slope of three percent or less.
- To be economically viable, the site should be located on property currently available at a reasonable cost, have reasonable proximity to infrastructure, and have good solar resources. Sites with excellent solar resources may be able to carry somewhat higher mitigation costs or infrastructure costs.
- The site needs to be located so it can be interconnected with an existing transmission system without the need for new, long dedicated transmission lines, while also providing good access to water for power plant cooling. The site also needs reasonable access to a natural gas pipeline.
- The land for the power plant site and linear facilities has to be available for purchase or lease.

A number of scoping comments included the criteria list for areas to avoid in siting renewable projects defined by Audubon California and other groups:

- Locations that support sensitive biological resources, including: federally designated and proposed critical habitat; significant populations of federal or state threatened and endangered species, significant populations of sensitive, rare and special status species, and rare or unique plant communities;
- Areas of Critical Environmental Concern, Wildlife Habitat Management Areas, proposed HCP and NCCP Conservation Reserves;
- Lands purchased for conservation including those conveyed to the BLM;
- Landscape-level biological linkage areas required for the continued functioning of biological and ecological processes;
- Proposed Wilderness Areas, proposed National Monuments, and Citizens' Wilderness Inventory Areas;
- Wetlands and riparian areas, including the upland habitat and groundwater resources required to protect the integrity of seeps, springs, streams or wetlands;
- National Historic Register eligible sites and other known cultural resources;
- Locations directly adjacent to National or State Park units.

It is noted also that during the FLPMA ROW grant pre-application period, BLM worked closely with the project applicant to identify a feasible site without known environmental concerns. This effort resulted in identification of the proposed site, and in fact reflected many of the suggested criteria for siting presented by Audubon California noted above. As a result of the pre-application activity and the scoping and public comment process, the alternative site considered in this SA/DEIS was selected based on an attempt to meet as many of these criteria as possible.

Other Sites on BLM Land

The BLM has received a large number of utility-scale solar energy project proposals for BLM-administered lands in California. The BLM processes solar energy right-of-way applications under its Solar Energy Development Policy (Instructional Memorandum No. 2007-097) and addresses environmental concerns for the utility-scale energy projects on a case-by-case basis in conformance with its existing policies, manuals, and statutory and regulatory authorities. Under its existing regulations, BLM determines if competing applications exist for the same facility or system. Applications that are first in time are given priority in consideration and are not considered competing applications with those filed later in time.

In addition, a site with an active pending application is not considered to be a reasonable alternative to a proposed project, such as GSEP. This is because selection and approval of a site with an active pending application in lieu of the proposed project cannot be assured, given the precedence of the first application. If BLM were to consider the site with an active pending application as an alternative to the proposed project, it would inherently be making a determination of reasonableness of the proposed alternative. However, an active pending application is given priority in consideration for that site location. Unless and until the active pending application is eliminated from consideration, BLM would not approve the site with the active pending application over the proposed project. Therefore, an alternative site on BLM land with an active pending application for another project is not considered a reasonable alternative to the proposed project for purposes of alternatives analysis.

The BLM and Department of Energy (DOE) are preparing a Programmatic Environmental Impact Statement (PEIS) on solar energy development in six states in the western U.S. (Arizona, California, Colorado, New Mexico, Nevada, and Utah) (USDOE 2008). As part of the PEIS, the BLM and DOE identified 24 tracts of BLM-administered land for in-depth study for solar development, some or all of which may be found appropriate for designation as solar energy zones in the future. The public scoping period on the solar energy zone maps ended in September 2009. The Draft PEIS should be published in 2010; the appropriateness of siting solar energy plants on various land use designations may be revisited in the PEIS.

California Governor Executive Order S-14-08 requires the Renewable Energy Action Team to establish a Desert Renewable Energy Conservation Plan (DRECP) for the Mojave and Colorado Desert regions. The Planning Agreement regarding the DRECP was entered into by the Energy Commission, California Department of Fish and Game, BLM, and U.S. Fish and Wildlife Service and is charged with identifying areas suitable for renewable energy project development and areas that will contribute to the

conservation of sensitive species and natural communities. A draft report is currently being drafted.

Design of the Proposed Project

The proposed project (Genesis Solar Energy Project) is a nominal 250 MW solar plant located on approximately 1,800 acres. The project is divided into two independent concentrated solar electric generating facilities, where the two power blocks and solar fields would each be located on approximately 680 acres and would create 125 MW of solar energy. Additional acreage would be required for evaporation ponds, access roads, administration buildings, other support facilities, and land treatment units (NextEra 2009a). This layout defines the area required for an alternative site.

B.2.7.2 Gabrych Alternative

The proposed GSEP is described above. Scoping comments requested that an alternative site on disturbed land be considered, thereby lessening the potential impacts to the desert environment. Commenters also noted that disturbed agriculture lands occur in the vicinity of the project and should be considered as possible alternatives.

The applicant stated that three private land sites were considered in the Blythe area (GSEP 2009f). The applicant did not pursue any of these alternatives because of concerns that any water use in the Blythe area would impact the Colorado River water basin (GSEP 2009f). Of the three alternatives considered by the applicant, the Gabrych site is considered here because (a) it seemed to have the best potential to reduce impacts to biological and cultural resources and (b) it was not already considered as an alternative to a different solar project.

The Gabrych Alternative site is located along Neighbors Boulevard just south of the Riverside/Imperial County line, and approximately 12 miles south of I-10. The Gabrych Alternative is located on ten parcels of private land making up 1,800 acres of land and would avoid the Harvey's Fishing Hole community, adjacent to the Colorado River. The Gabrych Alternative is shown in **Alternative Figure 3**.

The Gabrych Alternative would be within the Colorado Desert with appropriate slope and solarity requirements. The elevation of the site is between 200 and 250 feet above sea level. The site would be accessed via Neighbors Boulevard off the I-10. A small rural community, Harvey's Fishing Hole, would be located just south of the solar field but would be avoided by the project. A small sand/gravel mining operation occurs just west of the residential area and would also be avoided by the solar project. The Gabrych Alternative is defined as a project that would incorporate dry cooling, reducing the amount of water needed for the project to 66 AFY (GSEP 2009f).

The Gabrych Alternative sites would be made up of approximately 10 unique parcels with one land owner. The Final Phase 2a Report published by the Renewable Energy Transmission Initiative (RETI) and updated in September 2009 identified private land areas for solar development only if there were no more than 20 owners in a two square mile (1,280 acre) area. Additionally, the Gabrych Alternative site was identified by the Final Phase 2a Report as disturbed land that would support renewable energy development. However, the Gabrych parcels support agricultural operations.

Transmission Interconnection. The nearest designated transmission ROW is located approximately 5 miles west of the Gabrych Alternative site. The transmission interconnection would head west five miles, crossing agricultural lands, to reach a BLM CDD designated utility corridor. At this point, the transmission interconnection would turn north for approximately ten miles until reaching the proposed Colorado Substation. The transmission interconnection would be adjacent to a WAPA 161 kV line for most of the route.

Environmental and Engineering Assessment of the Gabrych Alternative

Air Quality

Environmental Setting. The Gabrych Alternative would be located in the Salton Sea Air Basin (SSAB) under the jurisdiction of the Imperial County Air Pollution Control District (ICAPCD). The Imperial County portion of the SSAB is designated as non-attainment for the federal and state ozone standards, the federal PM10 standard, and the state PM10 standard. This area is designated as attainment or unclassified for the state and federal CO, NOx, SOx, and PM2.5 standards. The entire SSAB is classified as attainment for the federal standard and unclassified for the state standards. This divergence in PM10 and PM2.5 attainment status indicates that a substantial fraction of the ambient particulate matter levels are most likely due to localized fugitive dust sources, such as vehicle travel on unpaved roads, agricultural operations, or wind-blown dust. The Gabrych Alternative is surrounded primarily by agricultural operations.

Environmental Impacts. Exhaust emissions from heavy-duty diesel and gasoline-powered construction equipment and fugitive particulate matter (dust) would be essentially the same at any site. Exhaust emissions would also be caused by workers commuting to and from the work sites, from trucks hauling equipment and supplies to the sites, and crew trucks (e.g., derrick trucks, bucket trucks, pickups). Workers and trucks hauling equipment and supplies would have to commute approximately 12 miles north (from Blythe) to reach the Gabrych Alternative. The proposed project is located approximately 20 miles west of Blythe. Appropriate mitigation at the Gabrych Alternative site would likely involve similar, locally oriented recommendations such as the conditions of certification presented in the **Air Quality** section of this SA/DEIS. However, as the Gabrych Alternative is located in Imperial County, it would be required to comply with the existing District rules and regulations and the applicable Imperial County air quality plans.

As with the proposed GSEP, the Gabrych Alternative would emit some GHG emissions. However, the contribution of the project if built at the Gabrych Alternative to the system build-out of renewable resources to meet the goals of the Renewable Portfolio Standard (RPS) in California would result in a net cumulative reduction of energy generation and GHG emissions from new and existing fossil-fired electricity resources. Electricity is produced by operation of inter-connected generation resources. Operation of one power plant, like GSEP, affects all other power plants in the interconnected system. The operation of the GSEP at the Gabrych Alternative site would affect the overall electricity system operation and GHG emissions in several ways:

- Gabrych Alternative would provide low-GHG, renewable generation.

- Gabrych Alternative would facilitate to some degree the replacement of high GHG emitting (e.g., out-of-state coal) electricity generation that must be phased out to meet the State's 2006 Emissions Performance Standard.
- Gabrych Alternative could facilitate to some extent the replacement of generation provided by aging fossil-fired power plants that use once-through cooling.

These system impacts would result in a net reduction in GHG emissions across the electricity system providing energy and capacity to California. Thus, as with the proposed GSEP, the Gabrych Alternative would result in a cumulative overall reduction in GHG emissions from power plants, does not worsen current conditions, and would not result in impacts that are cumulatively CEQA significant.

Comparison to Proposed Project. The construction and operational emissions at the Gabrych Alternative site would be similar to those of the GSEP at the proposed site.

Biological Resources

Environmental Setting. The Gabrych Alternative site is located in the Colorado Desert bioregion, encompassing all of Imperial County, the southeastern portion of Riverside County, the eastern end of San Bernardino County, and the eastern portion of San Diego County. This agriculturally rich bioregion is semi-arid and heavily irrigated (California Environmental Resources Evaluation System [CERES] 2010). The Gabrych Alternative is located in the Palo Verde Valley, east of the Palo Verde Mesa and the City of Palo Verde, immediately north and west of the Colorado River.

The Colorado Desert is the western extension of the Sonoran desert, which covers southern Arizona and northwestern Mexico. Much of the Colorado Desert lies below 1,000 feet in elevation. Mountain peaks rarely exceed 3,000 feet. Common habitats include sandy desert, scrub, palm oasis, and desert wash. Summers are hot and dry, and winters are cool and moist (CERES 2010).

The Colorado Desert supports a diverse array of plant and animal species including the Yuma antelope ground squirrel (*Ammospermophilus harrisii*), white-winged dove (*Zenaida asiatica*), muskrat (*Ondatra zibethicus*), southern mule deer (*Odocoileus hemionus fuliginata*), coyote (*Canis latrans*), bobcat (*Lynx rufus*), and raccoon (*Procyon lotor*). Rare animals include desert pupfish (*Cyprinodon macularius*), flat-tailed horned lizard (*Phrynosoma mcallii*), Andrew's dune scarab beetle (*Pseudocotalpa andrewsi*), Coachella Valley fringe-toed lizard (*Uma inornata*), Le Conte's thrasher (*Toxostoma lecontei*), and California leaf-nosed bat (*Macrotus californicus*). Rare plants include Orcutt's woody aster (*Xylorhiza orcuttii*), Orocopia sage (*Salvia greatae*), foxtail cactus (*Coryphantha alversonii*), Coachella Valley milk-vetch (*Astragalus lentiginosus* var. *coachellae*), and crown of thorns (*Euphorbia* sp.; CERES 2010).

A reconnaissance field survey of the Gabrych Alternative was conducted in January 2010. Because the Gabrych Alternative is located on private land, the survey was limited to public access points. While detailed vegetation mapping was not conducted for the Gabrych Alternative site, vegetation polygons were sketched based on what could be seen from public access points in the field as well as aerial photograph interpretation. These polygons were then digitized using a Geographic Information

System (GIS), thereby providing a rough estimate of the total acreage for each vegetation community on the Gabrych Alternative site. This mapping and the acreages derived from it are extremely preliminary (reconnaissance level) and should be used only to provide a generalized understanding of the amount and types of vegetation present. A full vegetation mapping effort would be required to provide more accurate maps and figures.

The Gabrych Alternative site consists mainly of active agricultural fields and active sheep grazing. Neighbors Boulevard traverses the central portion of the site from north to south, and several unnamed dirt roads cross the site between agricultural fields. Five named irrigation canals cross the site: C Canal, D-23-1 Canal, D-23-1-3 Canal, D-23-1-4 Canal, and D-23-1-5 Canal. Several residences occur in a concentrated area at the southern end of Neighbors Boulevard, adjacent to the river. These residences and the surrounding areas would be avoided by the alternative. A small sand/gravel mining operation occurs just west of the residential area.

Approximately 160 acres of the site support native vegetation communities; these parcels occur primarily in the southwest corner of the site. Surrounding lands include the Colorado River to the east and south, and active agriculture to the west and north. Cibola National Wildlife Refuge is located approximately three miles south of the site, in Arizona. Topography on site is relatively flat, with elevation ranging from approximately 235 to 245 feet above mean sea level (AMSL). There are nine soil series mapped for this alternative: Cibola, Gilman, Glenbar, Holtville, Imperial, Indio, Meloland, Ripley, and Rositas, much of which prime farmland (Soil Survey Staff 2009).

Approximately 7 acres of the Colorado River occur within the southern portion of the site, and is jurisdictional to the ACOE and CDFG. As with the residences in the southern portion of the site, the Colorado River would be avoided by the alternative layout. A small stand of riparian scrub occurring along the D-23-1-3 Canal in the northeast portion of the site, as well as more extensive riparian habitat occurring along the C Canal in the southwestern portion of the site and along the Colorado River in the southern portion of the site would be considered waters of the state under the jurisdiction of the CDFG and may be considered waters of the U.S. under the jurisdiction of the ACOE. Areas of arrowweed scrub occurring in the southwestern corner of the site also would be considered waters of the state under the jurisdiction of the CDFG and may be considered waters of the U.S. under the jurisdiction of the ACOE. The named on-site canals may be considered connected to the Colorado River and as such are potentially jurisdictional to the ACOE and CDFG. A jurisdictional delineation and coordination with the ACOE and CDFG would be necessary to formally determine the jurisdictional areas on site.

Wildlife Use. Undeveloped portions of the site (the southwest corner) are used by a variety of common animal species such as coyote (*Canis latrans*), black-tailed jackrabbit (*Lepus californicus*), desert cottontail (*Sylvilagus bachmani*), raccoon (*Procyon lotor*), and various resident and migratory bird species such as American kestrel (*Falco sparverius*), Gambel's quail (*Callipepla gambelii*), white-crowned sparrow (*Zonotrichia leucophrys*), sage sparrow (*Amphispiza belli*), Say's phoebe (*Sayornis saya*), and black phoebe (*Sayornis nigricans*), as well as the desert kangaroo rat (*Dipodomys deserti*). Agricultural areas on site support foraging habitat for red-tailed hawk (*Buteo*

jamaicensis), northern harrier (*Circus cyaneus*), turkey vulture (*Cathartes aura*), American kestrel, and phoebes. The canals carrying water support potential foraging habitat for species such as the belted kingfisher (*Ceryle alcyon*) and white-faced ibis (*Plegadis chihi*).

Although the site itself does not function as a movement corridor for wildlife, the adjacent Colorado River and contiguous undeveloped lands (where present) do provide corridor functions for several species.

Vegetation Communities. Active agriculture, riparian scrub, arrowweed scrub, desert saltbush scrub (including disturbed), disturbed habitat, and developed land are the six primary vegetation communities on the alternative site. The acreages presented below are rough estimates, as detailed vegetation mapping was not conducted.

Active and fallow agriculture (including crops and sheep grazing) occurs on approximately 1,817 acres (approximately 85 percent) of this alternative site. The edges of the fields consist of low dirt berms supporting sparse non-native plant cover, including crabgrass (*Digitaria* sp.), London rocket (*Sisymbrium irio*), and nettleleaf goosefoot (*Chenopodium murale*). The active and previously farmed areas would be included in the alternative solar fields.

Riparian scrub occurs on approximately 38 acres, almost all of which is adjacent to the river in the southern portion of the site and along the C Canal where it traverses disturbed saltbush scrub in the southwest corner of the site. This habitat is comprised of a mix of black willow (*Salix gooddingii*), arrowweed (*Pluchea sericea*), and tamarisk (*Tamarix* sp.), along with presence of cattails (*Typha* sp.) in the wetter areas, and occasional horsetail (*Equisetum* sp.). This area would be avoided by the solar field arrays.

Arrowweed scrub occurs on approximately 82 acres in the south and southwestern portions of the site. This habitat consists primarily of arrowweed, with some areas supporting a mix of arrowweed, tamarisk, four-wing saltbush (*Atriplex canescens*), and other saltbush species (*Atriplex* spp.). This area would be avoided by the solar field arrays.

Desert saltbush scrub occurs on approximately 35 acres, consisting of approximately nine acres of undisturbed desert saltbush scrub and 26 acres of disturbed desert saltbush scrub located in the southwestern corner of the site. Undisturbed desert saltbush scrub consists of habitat with moderate to dense coverage by saltbush (*Atriplex* spp.), while disturbed saltbush scrub consists primarily of old alluvial deposits that appear to have been cleared of vegetation in the past and are still recovering. Shrub cover in these disturbed areas is approximately five to ten percent, comprised of various species of saltbush, as well as occasional creosote bush (*Larrea tridentata*) and arrowweed, while herbaceous cover is approximately 35 to 45 percent, consisting primarily of Mediterranean grass (*Schismus barbatus*) with occasional plicate coldenia (*Tiquilia plicata*) and Russian thistle (*Salsola tragus*).

Disturbed habitat comprises approximately 126 acres of land in the southwestern corner of the site that has been cleared of vegetation and supports sparse coverage by non-

native species, as well as areas west of the residential area, including areas formerly used for camping and illegal dumping. This area would be avoided by the solar field arrays.

Developed land comprises approximately 34 acres at the southern terminus of Neighbors Boulevard, comprising approximately 26 acres of residential development and eight acres of ongoing sand/gravel mining along the north side of the river. This area would be avoided by the solar field arrays.

Special Status Species Special status species observations have been reported to the CNDDB within five miles of the alternative site (Table 2). These CNDDB records include two non-listed, special status plant species, bitter hymenoxys (*Hymenoxys odorata*) and Wiggins cholla (*Cylindropuntia wigginsii*), three listed animal species, federally and state listed endangered razorback sucker (*Xyrauchen texanus*), federally endangered and state threatened Yuma clapper rail (*Rallus longirostris yumanensis*), and federal candidate and state endangered western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), as well as eight non-listed special status animal species, Couch's spadefoot (*Scaphiopus couchii*), vermillion flycatcher (*Pyrocephalus rubinus*), Yuma myotis (*Myotis yumanensis*), Townsend's big-eared bat (*Corynorhinus townsendii*), pallid bat (*Antrozous pallidus*), American badger (*Taxidea taxus*), and Colorado River cotton rat (*Sigmodon arizonae plenus*).

Alternatives Table 2 California Natural Diversity Database Records for Special Status Species within Five Miles of the Gabrych Alternative Site

Common Name ***Scientific Name***	**Status State/Fed/CNPS/BLM**	**Occurrence Within 5 Miles of Gabrych Alternative Site**
PLANTS		
Bitter hymenoxys *(Hymenoxys odorata)*	--/--/List 2/--	Reported approximately 2.5 miles west of the site.
Wiggins cholla *(Cylindropuntia wigginsii)*	--/--/List 3.3/--	Reported approximately 2.5 miles west of the site.
Razorback sucker *(Xyrauchen texanus)*	SE/FE/--/--	Reported approximately 1 mile southwest of the site and 2.5 miles west of the site.
Couch's spadefoot *(Scaphiopus couchii)*	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
Yuma clapper rail *(Rallus longirostris yumanensis)*	ST/FE/--/--	Reported approximately 2 miles southwest of the site in a natural meander of the Colorado River, west of the channelized river.
Western yellow-billed cuckoo *(Coccyzus americanus occidentalis)*	SE/FC/--/--	Reported along the eastern edge of the site, in riparian habitat associated with the river.
Vermillion flycatcher (*Pyrocephalus rubinus*)	SSC/--/--/--	Reported approximately 2.5 miles west of the site.

Common Name *Scientific Name*	Status State/Fed/CNPS/BLM	Occurrence Within 5 Miles of Gabrych Alternative Site
Yuma myotis (*Myotis yumanensis*)	--/--/--/S	Reported along the southern boundary of the site, where Neighbors Boulevard crosses the river.
Townsend's big-eared bat (*Corynorhinus townsendii*)	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
Pallid bat (*Antrozous pallidus*)	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
American badger (*Taxidea taxus*)	SSC/--/--/--	Reported approximately 2.5 miles west of the site.
Colorado River cotton rat (*Sigmodon arizonae plenus*)	SSC/--/--/--	Reported approximately 2.5 miles west of the site.

Status Codes (Source: CDFG 2009**):**

Federal FE - Federally listed endangered: species in danger of extinction throughout a significant portion of its range
FT - Federally listed threatened: species likely to become endangered within the foreseeable future

State SE - State listed endangered
ST = State listed threatened
SSC = Species of special concern

California Native Plant Society (CNPS)
List 1B - Rare, threatened, or endangered in California and elsewhere
List 2 - Rare, threatened, or endangered in California but more common elsewhere
List 3 - Plants which need more information
List 4 - Limited distribution – a watch list
0.1 - Seriously threatened in California (high degree/immediacy of threat)
0.2 - Fairly threatened in California (moderate degree/immediacy of threat)
0.3 - Not very threatened in California (low degree/immediacy of threats or no current threats known)

U.S. Bureau of Land Management (BLM)
S **=** Sensitive
BLM Manual § 6840 defines sensitive species as "…those species that are (1) under status review by the FWS/NMFS; or (2) whose numbers are declining so rapidly that federal listing may become necessary, or (3) with typically small and widely dispersed populations; or (4) those inhabiting ecological refugia or other specialized or unique habitats." <www.blm.gov/ca/pdfs/pa_pdfs/biology_pdfs/SensitiveAnimals.pdf>

Northern harrier was the only special status species observed on the alternative site during the field reconnaissance. There are other special status plant and animal species with potential to occur on the alternative site (Appendix A), but the primary species of concern are the desert tortoise and burrowing owl. The desert tortoise is unlikely to occur on the alternative site as native habitat is limited and is isolated from other potential habitat areas. Special status species most likely to use the site are species associated with foraging in agricultural fields (e.g., burrowing owl), and bird species associated with riparian habitat along the river. There is moderate potential for burrowing owl to use the site for foraging; owls also may inhabit burrows in berms constructed along irrigation canals, though no burrows were observed during the field reconnaissance.

NECO Habitat Management Areas. The Gabrych Alternative occurs just outside of the NECO planning area and does not occur within or adjacent to any NECO Wildlife Habitat Management Area (WHMA; BLM and CDFG 2002).

Landforms. The Gabrych Alternative is located just southeast of the NECO planning area. The nearest NECO landforms are cultivated lands, as shown on Map 3-4 of the NECO (BLM and CDFG 2002).

Critical Habitat. No critical habitat for special status plant or animal species occurs on or adjacent to the Gabrych Alternative. The site is located just southeast of the NECO planning area; the NECO Desert Tortoise Habitat Model (BLM and CDFG 2002) shows low quality desert tortoise habitat (potential value of 0) adjacent to the site.

Environmental Impacts

Construction. It is expected that the facility could be sited on the least sensitive 1,800 acres of the 2,137-acre Gabrych Alternative site. All riparian areas and native vegetation communities in the southwestern corner of the site could be avoided. Potential impacts may still occur to canals, depending on the site design, which may result in impacts to waters of the State and/or waters of the U.S.

It is unlikely that any special status plant species occur on site, and if so, they could be avoided by constructing the facility outside of the native vegetation areas in the southwestern corner of the alternative. Few impacts to special status animal species would be expected because the alternative site is largely active agricultural land and native habitat along the river and in the southwestern corner could be avoided while still having the minimum 1,800 acres needed for facility construction. However, a northern harrier was observed foraging on site, and burrowing owl, which is known to use agricultural land for foraging, also may be affected if it is present.

Two special status species documented in CNDDB records could be affected if riparian habitat along the river and in the southwestern corner is impacted. These include western yellow-billed cuckoo and Colorado River cotton rat. Impacts to razorback sucker are not anticipated as this species inhabits the Colorado River and is not expected to occur on site. Several species of bats may forage along the river, but are not anticipated to be affected by facility construction. There is also some potential for special status plant species to occur in the native habitat areas in the southwestern corner. These include Harwood's milk-vetch, desert unicorn plant, Abrams spurge, and dwarf germander.

Wildlife movement across the site would be impeded by project development but would not affect overall wildlife movement in the area, as movement is likely to be concentrated along the river corridor.

Additional impacts to vegetation communities, and possibly special status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the alternative site. However, the transmission interconnection would traverse agriculture lands before reaching the CDD Designated Utility Corridor, so impacts caused by the transmission interconnection are expected to be reduced.

General Construction Impacts to Wildlife. Any wildlife residing on the Gabrych Alternative site would potentially be displaced, injured, or killed during project construction activities. Animal species in the project area could fall into construction trenches, be crushed by construction vehicles or equipment, or be harmed by project personnel. In addition, construction activities may attract predators or crush animal burrows or nests.

Migratory/Special Status Bird Species Impacts. The Gabrych Alternative site provides foraging, cover, and/or breeding habitat for migratory birds. Project construction could impact nesting birds in violation of the Migratory Bird Treaty Act.

Spread of Noxious Weeds. Construction of a solar project at the Gabrych Alternative site could result in the introduction and/or dispersal of invasive or exotic weeds. The permanent and temporary earth disturbance adjacent to native habitats increases the potential for exotic, invasive plant species to establish and disperse into native plant communities, which leads to community and habitat degradation.

Excessive Noise. Noise from construction activities on the Gabrych Alternative site could temporarily discourage wildlife from foraging and nesting immediately adjacent to the project area. Many bird species rely on vocalization during the breeding season to attract a mate within their territory. Noise levels from certain construction activities could reduce the reproductive success of nesting birds.

Operational Impacts. Operation of transmission lines associated with a solar project on the alternative site could result in increased avian mortality due to collision with the new transmission lines.

An increased incidence of accidental wildfire is also a possibility during operation (although the potential is low) from downed transmission lines. Additionally, there would be the potential for edge effects to special status animal species in surrounding habitat areas from operational night lighting or noise. Furthermore, the desert tortoise could be subjected to increased predation from common ravens (*Corvus corax*; observed during the reconnaissance on alternative site), which may increase in numbers along the transmission interconnection where desert tortoise habitat is present.

Comparison to Proposed Project. Definitive conclusions about the amount of potential adverse impacts to biological resources in the absence of site-specific survey and project design information for the Gabrych Alternative site cannot be made. However, provided that riparian and other native habitat areas on the Gabrych Alternative site could be avoided, development of a solar project at the Gabrych Alternative site would impact fewer biological resources compared to the GSEP footprint because development of the alternative site would occur primarily on agricultural land, whereas development of the Proposed Project site would occur primarily on land supporting native vegetation communities.

Furthermore, while a number of special status plant and animal species have been reported to the CNDDB within five miles of the Gabrych Alternative site, these are primarily associated with the Colorado River as well as riparian areas east of the City of Palo Verde. Burrowing owl, loggerhead shrike, and northern harrier are the special status species most likely to be affected if the agricultural lands were developed. The Proposed Project footprint also may support these same species, in addition to supporting special status plant species (Wiggins' cholla, Harwood's milk-vetch, and desert unicorn plant) and other special status animal species (desert tortoise and kit fox). Due to its location within a larger expanse of native habitat, which also connects to the Palen/McCoy Wilderness Area, the GSEP site has greater potential to support a variety of special status species, such as the American badger and wild burro, which

are not expected to occur on the Gabrych Alternative site. If riparian and native habitats were avoided, development of a solar project on the Gabrych Alternative site would have fewer impacts to biological resources than development of a solar project on the Proposed Project site.

Cultural Resources

Environmental Setting. The Gabrych Alternative is located on agricultural land in Imperial County, California. The alternative site is located in the southern end of the Palo Verde Valley, on Holocene floodplain sediments along the west side of the lower Colorado River. The Valley is bordered by the Palo Verde Mesa to the northwest and west, which are Pleistocene Colorado River terraces partially covered with alluvial cobble pavements used by prehistoric inhabitants for toolstone. The Cibola Valley is south and the Triago Mountains are to the east of the alternative. The proposed Project is located approximately 25 miles northwest of the Gabrych Alternative, north of Interstate 10 midway between Blythe and Desert Center near Ford Lake.

The Palo Verde Valley is part of the northern extent of the Colorado Desert, subdivision of the greater Sonoran Desert. Conditions within the Colorado Desert are among the hottest in the United States. Annual rainfall totals within the Colorado Desert are among the lowest in the greater Sonoran Desert, averaging less than 2 inches (5 cm) per year in the Salton Trough and between 2 to 4 inches (5-10 cm) along the Colorado River (Crosswhite and Crosswhite 1982).

The Colorado River is the only perennial source water near the Gabrych Alternative area, which is one of the major river systems of North America. Springs in the area are very rare and tend to flow seasonally. West of the project area, in the McCoy Mountains, is the McCoy Spring. McCarthy (1993) identified a “halo” type settlement pattern around these perennial waters sources, where site density and complexity are much higher near the permanent water sources. The alternative area, prior to the construction of Boulder Dam, was susceptible to seasonal flooding, which left temporary lakes and a marsh environment (McDonald and Schafer 1998).

The prehistoric use of the Colorado Desert was apparently episodic, with long periods of low-intensity use of the land during particularly arid times. The earliest inhabitants of the region were highly mobile hunter-gatherers exploiting a variety of plants and animals. The settlement patterns of these Late Pleistocene and Early Holocene inhabitants suggest that they preferred to live along the shores of prehistoric lakes and on mesas near perennial washes (Schaefer and Laylander 2007). Roughly 7,000 years ago, local pluvial lakes began to evaporate and settlement shifted to the Colorado River and to perennial springs in the mountains and valley floors.

A number of ethnographically documented culture groups are associated with the Palo Verde Valley through historic use and oral history. These include the Mohave, Halchidhoma, Quechan, and Chemehuevi, along the lower Colorado River, and the Cahuilla of the western deserts and mountains (Bean 1972; Bean and King 1974; Bean and Vane 1978; Fowler and Fowler 1971; Laird 1976; Rogers 1939, 1966; Schaefer 2003; Singer 1984), collectively referred to as Yuman. The stretch of the Colorado River immediately adjacent to the alternative area was notably contentious, changing hands more than once in the Protohistoric period. Hostilities ended with Gold Rush and

establishment of Fort Yuma and Mojave in the middle of the 19th century. The final conflict occurred in 1860, when the U.S. Army defeated the Mohave (Sherer 1994)

The west side of the Colorado River was also an important corridor for travel between southern and northern river groups, particularly the Quechan and Mohave. North-south running trails have been identified along the river as transportation routes as well as ceremonial ways linking key mountains, springs, and other landscape features (Stone 1981; Woods 1986). These prehistoric trails and important landscape features are frequently associated with rock and earth art, as well as small rock piles known as cairns. As well, trails headed west as part of a long-distance transportation corridor from the Colorado River to Lake Cahuilla and the Pacific Coast (Bean and Vane 1978, Davis 1961, King 1981, Sample 1950, Singer 1984).

Subsistence patterns of Yuman cultural groups were mixed, consisting of both small-scale agriculture supplemented by foraging, fishing and hunting. Agricultural strategies optimized the use of flood waters as means of providing moisture to the fields; seeds were dispersed after floodwaters receded. Cultivated crops included maize, beans, squash, melon and semi-wild grasses (McDonald and Schafer 1998).

The first documented exploration of the Colorado Desert by non-indigenous people occurred in the 16th century, but sustained Euro-American settlement of the region did not occur until the mid-19th century. The first recorded exploration of the interior Colorado Desert region was undertaken by Father Eusebio Francisco Kino, a Jesuit missionary, cartographer, and explorer. Starting in 1691, Kino established a string of missions in northern Mexico and southern Arizona, finally reaching the Colorado River in 1702.

The first Americans to arrive in the Colorado Desert in any numbers were prospectors hunting for the next big gold strike (Rice et al. 1996; Morton 1977). Sustained economic development in the Colorado Desert region only began in the 1870s, and came to fruition in the early part of the 20th century. Development was dependent largely on two things: transportation and water. The first of these came in 1872, with the construction of the Southern Pacific Railroad from the ocean to the eastern edge California. The railroad was the single most important boost to mining in the southeastern Colorado Desert, offering convenient transportation of heavy mining equipment, supplies, and personnel.

Agriculture became an important industry, second only to mining, by the late 1850s. To transform arid land into productive farming and grazing lands, water was the fundamental key. Agriculture became an important industry in the Palo Verde Valley near Blythe during the early 20th century, based largely on diverting water from the Colorado River. Agriculture continues to be a significant contributor to the Blythe economy.

A records search for the alternative area, at the Eastern Information Center and the South Coastal Information Center of the California Historical Information System reveals that the alternative, which is located in Palo Verde Valley, has a very low frequency of documented sites because less than two percent of the alternative has been systematically surveyed. The records and literature search identified five studies within

a one-mile radius of the project alternative, all of which are within or immediately adjacent to the alternative. These studies identified two built environment resources and one archaeological resource. The archaeological resource is a trail that was identified in historical documents, but has never been field checked. The built environment resources are canals, one of which transects the project area (P13-008401; Canal C).

Nearly 90 percent of the Gabrych Alternative has been disturbed by on-going agricultural activities since the 1930's, in addition to the construction of canals, roads, and OHV activity. While much of the surface prehistoric archaeology has been impacted, a review of the literature suggests that the potential for prehistoric sites within such close proximity to the Colorado River is moderately high. However, intact sites are likely buried and would not be identified through surface inventory.

Environmental Impacts. The construction and operation of a solar facility on the Gabrych Alternative may have impacts on buried sites or built environment resources eligible for the National Register of Historic Places (NRHP) or California Register of Historic Resources (CRHR). The majority of the 2,138 acre project APE is currently under cultivation or has been impacted by irrigation or other agricultural infrastructure. Analysis of aerial photographs (USDA 1939, 1953) shows that the area has been under cultivation since before 1953 and after 1939. Depth of agricultural disturbance likely varies between two and three feet. Approximately 233 acres of the project does remain relatively undisturbed, except for OHV, irrigation, and two-track impact. The likelihood of cultural resources present in this area, located within the western third of the project APE is moderate. Surface contours and aerial photos suggest that this area may have been a small back-water or cut-off channel, now in-filled, which contained flowing water in 1939 and may have contained a rich array of floral and faunal resources. The possibility of such an environment with greater resource density implies a higher potential for significant archaeological prehistoric sites.

In prehistoric times, the Colorado River Floodplain habitat would have been particularly attractive to Native American groups due to the proximity of water. The local flood plain would have provided access to fertile agricultural lands ideal for small-scale agriculture. The river itself contains fish and attracts wildlife that would have provided a consistent food source. Also, because of increased soil moisture, plant resources would have been more diverse and dense than the surrounding deserts. These factors would have provided an attractive area for human populations; therefore, it is likely that settlements in the alternative area were more permanent and larger than the deserts around the Blythe area.

Sediments within the alternative area are of recent alluvial origin deposited by over-bank events of the Lower Colorado River. Without in-field analysis, it is difficult to assume the age and structure of the surface sediments; however, comparison with sedimentation models (Waters 1992) for large river flood plains suggests that vertical accretion of sediments within the alternative area would be rather rapid suggesting high potential for buried prehistoric sites. Further, depositional energy in such settings is low, especially with increasing distance from the channel, and therefore the potential for intact subsurface sites would be high. The potential for buried archaeological prehistoric sites at the Gabrych Alternative, therefore, is high and any ground disturbing activities

below the depth of agricultural disturbance could disturb significant archaeological deposits.

Built environment resources in the alternative area consist of irrigation works, specifically a drainage canal (P13-008401), several residences or farms, and plowed fields. The drainage canal, also named Canal C, transects the western quarter of the alternative area. According to an aerial photograph (USDA 1939) portions of the canal were built prior to 1939. Later, as observed on a 1953 aerial photograph, the canal was extended to a small lake south of the alternative area. Between 1939 and 1953 a second canal, D-21-1, which appears to be a spur or feeder to Canal C, was constructed and supplies water to the southern and eastern portion of the alternative area. Other canals constructed prior to 1953may be present; however, it is difficult to discern from the aerial photographs. Two residences appear to have been built after 1939 (USDA 1939) showing up on the 1953 aerial photograph and the 1975 Palo Verde, CA 7.5' USGS quadrangle. In the late 1930's, the entire alternative area was in its natural state. By 1953, about one-third of the alternative area had been cleared for agriculture, mostly in the central and southeastern portions of the alternative area.

One prehistoric site was identified in the records search area. CA-IMP-877 is a historical period Indian trail. The site location was taken from a mid-1800's GLO map; however, the exact location is not known and its assumed location is near the western edge of the alternative area. Due to agricultural activity of the 20th century, it is likely that the site is no longer extant. No other prehistoric sites have been recorded in the area.

Comparison to Proposed Project. The development of a solar facility on the Gabrych Alternative would likely have fewer impacts than those of the Proposed Project near Ford Lake. The cultural resources survey of the Proposed Project found 21 archaeological sites (5 historic, 15 prehistoric, and 1 multicompenent) and two built environment sites within the project APE. Of the 21 sites, two (CA-RIV-9072 and CA-RIV-9224/H) are potentially eligible for inclusion on the National Register of Historic Places. Additional analysis of built resources of the canals and agricultural residences may find that these resources are eligible for inclusion on the CRHP and NRHP. Geoarchaeological studies of the Proposed Project indicate that the entire area is highly sensitive for buried cultural resources, particularly on the southern side closer to the Ford Lake. With the exception of 233 acres, the entire surface of the Gabrych Alternative has been plowed or impacted by other agricultural activities, thereby destroying the surface component of any late period cultural resources present in the APE throughout the remaining 1,905 acres of the alternative. Thus the potential for finding new significant sites during a Class III surface inventory is greatly reduced. Surface sediments within the alternative are of a recent Holocene age and likely low energy based on a cursory map-based geoarchaeological investigation of the area, suggesting that the potential for buried intact cultural resources is high. Impacts to potential, undiscovered subsurface archaeological sites at both the Gabrych Alternative and Proposed Project is comparable. While, analysis shows that the development of the Gabrych Alternative would likely impact fewer surface cultural resources, more site-specific details about cultural resources resulting from an intensive survey of the alternative would be needed to support this comparison.

Hazardous Materials Management

Environmental Setting. The topography of the Gabrych Alternative site is essentially flat, as are the immediately surrounding areas. Sensitive receptors are present within the Gabrych Alternative although the residential community located in the southern portion of the alternative site would be avoided by the solar filed layout. This notwithstanding, the residential community would be located within 1,000 feet of the portion of the Gabrych Alternative site that would be required for the solar facility.

Access to the Gabrych Alternative would likely be via Interstate 10 to Neighbors Boulevard. At Neighbors Boulevard, transport would turn south for approximately 12 miles through primarily agriculture lands.

Environmental Impacts. Hazardous materials use at the Gabrych Alternative, including the quantities handled during transportation and disposal, would be the same as those of the proposed project. As stated in the **Hazardous Materials** section for the proposed project, hazardous materials used during the construction phase of the project would include heat transfer fluid (HTF), diesel fuel, mineral insulating oil, lube oil, and small quantities of solvents and paints. No acutely toxic hazardous materials would be used on site during construction, and none of these materials pose a significant potential for off-site impacts as a result of the quantities on site, their relative toxicity, their physical states, and/or their environmental mobility.

Hazardous materials will be used and stored on site during the operation of the project, including 2 million gallons of HTF in the solar trough system. As stated in the **Hazardous Materials** section, Therminol VP1 is the HTF that will be used in the solar panels to collect solar heat and transfer it in order to generate steam to run the steam turbines. Therminol is a mixture of 73.5% diphenyl ether and 26.5% biphenyl, and is a solid at temperatures below ~54 °F. Therminol can therefore be expected to remain liquid if a spill occurs. While the risk of off-site migration is minimal, Therminol is highly flammable and fires have occurred at other solar generating stations that use it. Isolation valves would be placed throughout the HTF piping system. They will be designed to automatically block off sections of the piping in which a loss of pressure is detected (GSEP 2009). It appears that the placement of additional isolation valves in the HTF pipe loops throughout the solar array would add significantly to the safety and operational integrity of the entire system by allowing a loop to be closed if a leak develops in a ball joint, flex-hose, or pipe, instead of closing off the entire HTF system and shutting down the plant. In order to ensure that HTF leaks do not pose a significant risk, a condition of certification which would require the project owner to install a sufficient number of isolation valves that can be either manually or remotely activated would be required, as with the proposed BSPP.

A natural gas fueled auxiliary boiler would be used to support both freeze protection and rapid start-up of each of the two 125 MW plants each morning. As with the proposed GSEP site, the risk of a fire and/or explosion on site can be reduced to insignificant levels through adherence to applicable codes and the development and implementation of effective safety management practices. The National Fire Protection Association (NFPA) code 85A requires both the use of double-block and bleed valves for gas shut off and automated combustion controls. These measures will significantly reduce the likelihood of an explosion in gas-fired equipment. The safety management plan

proposed by the applicant would address the handling and use of natural gas, and would significantly reduce the potential for equipment failure because of either improper maintenance or human error.

Transportation of hazardous materials to the Gabrych Alternative site would require passing near residences located in the Palo Verde Valley. The transportation would be on Interstate 10 and Neighbors Boulevard. Neighbors Boulevard has few residences located in the vicinity as it primarily traverses agricultural lands.

Comparison to Proposed Project. The hazardous materials that would be used at the Gabrych Alternative site would be the same as those used at the proposed GSEP site; however, the Gabrych Alternative site has a greater number of sensitive subgroups or residences nearby. As such, the potential impacts at the Gabrych Alternative would likely be somewhat greater than at the proposed site. With adoption of the proposed conditions of certification, the Gabrych Alternative would comply with all applicable laws, ordinances, regulations, and standards (LORS) and result in no significant impacts to the public.

Public Health and Safety

Environmental Setting. The Gabrych Alternative site is located in an isolated area dedicated to farming and adjacent to the Colorado River and recreational areas. The nearest residences are located approximately 500 to 1,000 feet from the alternative site. There are no nearby schools or other sensitive receptors.

Environmental Impacts. While the meteorological conditions and topography at the site are not exactly the same as at the proposed GSEP site, they are similar enough that the results of air dispersion modeling and a human health risk assessment for the Gabrych Alternative site would be expected to be very similar to that for the proposed site. The cancer risk and hazard indices are much below the level of significance at the point of maximum impact, so the project would be unlikely to pose a significant risk to public health at this location.

Two wet cooling towers for each power block are proposed by the applicant to cool ancillary equipment. In addition to being a source of potential toxic air contaminants, the possibility exists for bacterial growth to occur in the cooling towers, including Legionella. Legionella is a bacterium that is ubiquitous in natural aquatic environments and is also widely distributed in manufactured water systems. It is the principal cause of legionellosis, otherwise known as Legionnaires' Disease, which is similar to pneumonia. Additional information regarding legionellosis can be found in the **Public Health** section of the SA/DEIS. With the incorporation of conditions of certification such as those recommended in the **Public Health** section this impact would be less than significant.

Comparison to Proposed Project. There is no substantial difference in public health between this location and the proposed site.

Soil and Water Resources

Soils in the Gabrych Alternative site include Cibola, Gilman, Glenbar, Holtville, Imperial, Indio, Meloland, Ripley, and Rositas, much of which prime farmland (Soil Survey Staff 2009). These soils are formed in mixed alluvium and in sandy deposits blown from

alluvium and in gravelly to silty clay loam (CPUC 2006). Soil types include gravelly to sandy loam, silty clay loam to clay loam, and fine sand, very fine sand, silt loam and loam. Soils containing high percentages of fine sands and silt and that are low in density are generally the most erodible. Approximately 1,800 acres of land on this alternative site would be disturbed by the construction.

Imperial-Glenbar-Gilman soils are the soils of the adjacent agricultural area of Imperial County. Wind erosion potential is moderate with high runoff erosion potential. Permeability is relatively low. These soils are highly productive for farmland. Glenbar and Gilman soils have been listed by the California Department of Conservation as meeting the criteria for prime farmland. Imperial soils are designated by the same agency as meeting the criteria for farmland of statewide importance.

The Gabrych Alternative site lies within the Palo Verde Valley Groundwater Basin part of the Colorado River Hydrologic Region. The site is located on agriculture land. Five named irrigation canals cross the site: C Canal, D-23-1 Canal, D-23-1-3 Canal, D-23-1-4 Canal, and D-23-1-5 Canal. Approximately 7 acres of the Colorado River occur within the southern portion of the site, and is jurisdictional to the ACOE and CDFG. These acres would be avoided by the alternative.

A small stand of riparian scrub occurring along the D-23-1-3 Canal in the northeast portion of the site, as well as more extensive riparian habitat occurring along the C Canal in the southwestern portion of the site and along the Colorado River in the southern portion of the site would be considered waters of the state under the jurisdiction of the CDFG and may be considered waters of the U.S. under the jurisdiction of the ACOE.

The Palo Verde Irrigation District (PVID) is the sole entity in Palo Verde with rights to divert and use Colorado River water. PVID annually provides irrigation water to approximately 93,000 acres of farmland, primarily in the valley, with water diverted from the Colorado River. A major portion of the water that PVID diverts is consumed by the crops it irrigates. The portion of the applied water that is not consumed by crops percolates past the root zone to recharge the underlying aquifer.

Topography on the Gabrych Alternative site is relatively flat, with elevation ranging from approximately 200 to 300 feet above mean sea level. The Gabrych Alternative would use irrigation district water as the water supply; however, dry cooling would be required to reduce any impacts to Colorado River water. Unless reclaimed water could be used for construction purposes, it is likely that the water used during construction of the project would be offset by fallowing surrounding agricultural lands (a Water Conservation Offset Program) or by converting the Gabrych Alternative to non-agricultural uses.

Environmental Impacts

Soil Erosion Potential by Wind and Water. As discussed in the **Soils and Water** section of this SA/DEIS, construction activities can lead to adverse impacts to soil resources including increased soil erosion, soil compaction, loss of soil productivity, and disturbance of soils crucial for supporting vegetation and water-dependent habitats. Activities that expose and disturb the soil leave soil particles vulnerable to detachment

by wind and water. Soil erosion results in the loss of topsoil and increased sediment loading to nearby receiving waters. Although access to the site would be from existing roads, construction of the solar fields would require substantial grading as in the proposed project. While the volume of earth movement required at the alternative site is unknown, the topography and slope of the Gabrych Alternative site are less severe than at the proposed GSEP site and have already been tilled for agriculture.

Being situated in an area near the banks of the Colorado River, portions of the Gabrych Alternative would be subject to sediment deposition and flooding from large floods on crossing the site. This impact would primarily affect the project itself, but the adverse effect could be significant. It may not be possible to practically mitigate this impact except by mapping and avoiding the severe hazard areas, which would result in a smaller alternative.

As at the GSEP site, grading plans, a Storm Water Pollution Prevention Plan (SWPPP), and a Drainage Erosion and Sediment Control Plan (DESCP) would be required. Due to the flat terrain and existing disturbed condition of this site, the SWPPP and DESCP would likely be sufficient to mitigate soil erosion impacts to a level less than significant.

Project Water Supply. The Gabrych Alternative site would require the use of water from the Palo Verde Irrigation District. Because of this, it is likely that use of water at the Gabrych Alternative site would require a Water Conservation Offset Program intended to offset the water required during project construction. As with the proposed GSEP site, the applicant would need to complete Conditions of Certification that would require acquisition of entitlements to Lower Colorado River water to mitigate the project's contribution to impacts to the Colorado River, as well as comply with the Palo Verde Irrigation District regulations. However, the Palo Verde Irrigation District has an existing program with the Metropolitan Water District transferring saved water to urban Southern California. Should the project incorporate dry cooling, the amount of water used at the Gabrych Alternative site would be reduced from the current agriculture use and would potentially be applicable for inclusion in the Metropolitan Water District project.

Wastewater/Storm Water Quality. Storm water runoff from the site during construction and operation could have similar impacts as proposed for the proposed project. However, the Gabrych Alternative would be located near the Colorado River and would potentially have greater contamination concerns than at the proposed GSEP site. The site construction will require a SWPPP which will specify Best Management Practices (BMPs) to minimize or eliminate water contamination.

As stated in the **Soil and Water** section of the SA/DEIS, the Land Treatment Unit (LTU) on the site would be used to treat soil that is impacted with Therminol® VP1 HTF, as a result of minor leaks or spills that occur during the course of daily operational or maintenance activities. At ambient temperatures, HTF is a highly viscous material that is virtually insoluble in water. Operation of an LTU is not expected to impact surface water or groundwater quality beneath the site. The LTU would be surrounded on all four sides by berms that would protect the LTU from surface water flow. Because of the viscous and insoluble nature of HTF, it is not likely to mobilize from the soil downwards to the water table. The LTU would be operated under the requirements of CCR Title 23, Division 3, Chapter 15, and Title 27, Section 2000 et seq. and Title 23, Section 2510 et

seq. Further discussion regarding the HTF and any HTF leaks can be found in the **Soil and Water** section.

Sanitary waste disposal would likely be through on-site facilities as for the proposed project. No significant adverse impact is anticipated.

Comparison to Proposed Project. The level terrain with minimal existing drainage on the Gabrych Alternative would result in impacts similar to the proposed project. With incorporation of approximate BMPs, impacts to water quality would likely be similar as with the proposed project. With the incorporation of dry cooling and water conservation offsets, impacts due to water use would be reduced when compared with the proposed project. Unlike building at the proposed GSEP site, the Gabrych Alternative would not create impacts to Chuckwalla Wind Transport Corridor, nor would it create impacts to the Palen-McCoy Wind Transport Corridor.

Land Use

Environmental Setting. The Gabrych Alternative is located west of the Colorado River, in eastern Imperial County, just south of the Riverside County border. The Gabrych Alternative is crossed by Neighbors Boulevard and would be less than 1,000 feet north of a residential community. The Cibola National Wildlife Refuge is located three miles south of the site in Arizona. Federal land under BLM jurisdiction is located approximately five miles west of the site and would be crossed by the transmission interconnection. The Palo Verde Landfill, closed in 2007, is located approximately 4.5 miles southwest of the Gabrych Alternative site, on Stallard Road. Portions of the Gabrych Alternative belonged to the BLM but were part of a land exchange with the SF Pacific Properties INC, a subsidiary of the Catellus Development Corporation as succeeded by Eugene Gabrych and Marian Gabrych (BLM 2006).

The site consists of primarily fallow and active agricultural land. The surrounding area consists of primarily agriculture and the rural community of Harvey's Fishing Hole and Palo Verde. The Gabrych Alternative was designated as Agriculture in the Land Use Plan, updated in March, 2007 (Imperial County 2007).

According to the Imperial County General Plan Land Use Element, industrial uses are not permitted on agricultural lands except for those directly associated with agricultural products and processes. Electrical and other energy generating facilities are considered heavy industrial uses except for geothermal, hydroelectric, wind and solar facilities which may be regulated differently than other types of power plants. Geothermal plants may be permitted in agricultural lands with a conditional use permit subject to zoning and environmental review.

In April 2009, Imperial County and the IID signed a Joint Resolution for the Creation of an Imperial Valley Renewable Energy Development Program to promote renewable energy resources in Imperial Valley (Imperial County 2009). This resolution encourages the growth of renewable energy in Imperial Valley and focuses on creating a data bank where developers, investors, and government regulators can access available data about permitting processes and encourages both the IID and Imperial County to maximize development of renewable resources in a manner consistent with sound environmental and land use planning principles (Imperial County 2009). However,

because the proposed project is a result of a Power Purchase Agreement between San Diego Gas & Electric and the Applicant, development of this project would not contribute to Imperial County's energy supplies. As such, development of the Agricultural Lands Alternative could be inconsistent with the IID and Imperial County Joint Resolution.

Agriculture. The Gabrych Alternative site is comprised of active and previously farmed agricultural lands. The Gabrych Alternative consists of approximately 960 acres of Prime Farmland, 680 acres of Farmland of Statewide Importance, and 160 acres of Unique Farmland. Prime Farmland includes lands with the best combination of physical and chemical features able to sustain long-term agricultural production that has been used for irrigated agriculture within the previous four years. Farmland of Statewide Importance is similar to Prime Farmland with some shortcomings such as a greater slope or lesser ability to store soil moisture. Unique Farmland consists of lesser quality soil for the production of agriculture crops and while usually irrigated may include non-irrigated orchards or vineyards. The Gabrych Alternative parcels are not under Williamson Act contracts.

Aerial spraying (i.e., crop dusting) is used to control insects, weeds, and diseases that may affect crops in the Imperial Valley. Aerial spraying occurs in those areas of the Imperial Valley actively cultivated with field crops. Aerial applicators fly at low elevations and sometimes at speeds in excess of 100 miles per hour. Fatalities associated with aerial applicators can partly be attributed to flying at low altitudes and high speeds, as well as the presence of obstacles such as power lines, trees, towers, or buildings within the flight area (CPUC, 2008). Where transmission lines exist in an agricultural area, pilots must fly over, beside, and (occasionally) under the lines to complete aerial spraying activities. Transmission lines and towers thus present a substantial obstacle to be avoided during aerial spraying operations, and require additional attention from the pilots. The transmission interconnection would require a new transmission line crossing approximately 4 miles of agriculture lands.

Sensitive Land Uses. As stated above, the Gabrych Alternative would be located north of a small rural community, Harvey’s Fishing Hole, located at the intersection of Neighbors Boulevard and the Colorado River.

Transmission Interconnection. The transmission interconnection would trend westward for five miles through primarily agriculture lands until reaching the CDD designated utility corridor at which point the transmission interconnection would turn north. The transmission interconnection would then trend northward for approximately 12 miles adjacent to the WAPA 161 kV transmission line until reaching the proposed SCE Colorado Substation. Where the transmission interconnection would cross federal land under the management of the BLM, it would remain within a CDD designated utility corridor and would not require a land use plan amendment.

Environmental Impacts. Because of the desire to consider use of disturbed lands for large solar projects, the Gabrych Alternative site is located primarily on active and non-active agricultural lands. The Imperial County General Plan states that, in general, industrial uses are not permitted on agricultural lands; however, some renewable energy is allowed on agricultural lands with a conditional use permit subject to zoning and environmental review.

The construction and operation of the GSEP project at the Gabrych Alternative site would result in the conversion of up to 1,800 acres of actively-used agricultural land to renewable energy production. The construction and operation of the solar power plant would eliminate the existing agricultural operations and foreseeable future agricultural use on this site. This loss of agricultural lands is a potentially significant impact, and would likely require mitigation to offset the loss. The California Agricultural Land Evaluation and Site Assessment (LESA) Model was used to assess impacts to the Gabrych Alternative site.

The California Agricultural LESA Model prepared by the California Department of Conservation is an optional model to use in assessing impacts on agriculture and farmland (CCR 2006).The formulation of a California Agricultural LESA Model is the result of Senate Bill 850 (Stats. 1993, ch. 812, section 3), which charged the Resources Agency, in consultation with the Governor's Office of Planning and Research, with developing an amendment to Appendix G of the California Environmental Quality Act (CEQA) Guidelines concerning agricultural lands. Such an amendment is intended "to provide lead agencies with an optional methodology to ensure that significant effects on the environment of agricultural land conversions are quantitatively and consistently considered in the environmental review process" (Public Resources Code Section 21095).

The California Agricultural LESA Model is composed of six different factors. Two "Land Evaluation" (LE) factors are based upon measures of soil resource quality. Four "Site Assessment" (SA) factors provide measures of a given project's size, water resource availability, surrounding agricultural lands, and surrounding protected resource lands. For a given project, each of these factors is separately rated on a 100-point scale. The factors are then weighted relative to one another and combined, resulting in a single numeric score for a given project, with a maximum attainable score of 100 points. It is this project score that becomes the basis for making a determination of a project's potential significance, based upon a range of established scoring thresholds (DOC 1997).

The LESA Model for the Gabrych Alternative site was conducted in accordance with the detailed instructions provided in the LESA Model Instruction Manual. The LESA score is based on a scale of 0 to 100. The Final LESA score for the Gabrych Alternative is 73. Based on the California Agricultural LESA Thresholds, a score of 73 would result in adverse effects due to the permanent conversion of 1,800 acres of Farmland. As stated above, agriculture is the most important industry in Pale Verde Valley. This amount of land conversion along with all other existing, planned, and proposed projects would result in adverse cumulative land conversion. The completed LESA Model worksheets for the Gabrych Alternative parcels are included within **APPENDIX Alts-1** at the end of this section.

Construction activities for the alternative would create temporary disturbance to residential areas (i.e., heavy construction equipment on temporary and permanent access roads and moving building materials to and from construction staging areas). Conditions of certification to reduce noise and air quality impacts are presented in the Noise and Air Quality sections of this SA/DEIS for the proposed GSEP site. Because

this disturbance would be temporary at any one location, the impacts would likely be less than significant.

Comparison to Proposed Project. Selecting the Gabrych Alternative site would not require the use of BLM land, and would not require a land use plan amendment. However, use of the Gabrych Alternative site would result in greater impacts to agricultural land than the project site, including the loss of Prime Farmland and Farmland of Statewide Importance and the loss of approximately 1,800 acres of active farmland resulting in a significant impact per the LESA model. Loss of agricultural lands would likely require conditions of certification to offset the loss of these lands.

Recreation and Wilderness

Environmental Setting. The Gabrych Alternative would not be located adjacent to or near any wilderness areas. As such impacts to wilderness will not be addressed.

The Gabrych Alternative would be located north of the Colorado River and approximately 3 miles north of the Cibola National Wildlife Refuge. The Colorado River is used for a variety of recreational opportunities including boating. Some of the Colorado River recreational opportunities near the Gabrych Alternative include Taylor Ferry, an old, disused cable ferry; Gould Wash, a day use area; Harvey's Fishing Hole Boat Ramp, that includes campsites, boat rentals and repairs, fishing, and other amenities; and Cibola Farmers Bridge (CDBW 2010).

The Cibola National Wildlife Refuge is located in the floodplain of the lower Colorado River and surrounded by a fringe of desert ridges and washes. The refuge encompasses both the historic Colorado River channel as well as a channelized portion constructed in the late 1960's. Along with these main water bodies, several important backwaters are home to many wildlife species that reside in this portion of the Sonoran Desert. Recreational activities include fishing, hunting, and wildlife observation and photography (USFWS 2010).

Environmental Impacts. Project construction activities would create a number of temporary conditions that may impact recreationists travelling down the Colorado River. Noise, dust and heavy equipment traffic generated during construction activities would negatively affect a visitor's enjoyment of the recreation area. Disturbances to recreational activities would potentially cause a temporary reduction of visitation to Harvey's Fishing Hole as it is located immediately south of the Gabrych Alternative; however, the impacts to any boaters on the river would be temporary until the boat had passed beyond the Gabrych Alternative.

As stated above, a solar project at the Gabrych Alternative site would have a direct impact on recreational users at Harvey's Fishing Hole due to the changes to the landscape in the immediate area, construction and operational noise, and overall change to the pastoral setting. Some proportion of recreational users may ultimately prefer to visit other areas due to the industrial views of the Gabrych Alternative site. To mitigate the potential negative effects of the changes to the viewshed, landscaping may be required, or recreational facilities that support these users may be improved or installed.

Comparison to Proposed Project. While the Gabrych Alternative site would be located near the Colorado River, frequently used for boating, the GSEP site would be near to BLM ACECs and wilderness areas, and the GSEP linears would cross one "open" route (as designated in the NECO Plan) . Additionally, impacts to recreation along the Colorado River would be temporary as recreationists would be traveling along the river and not remaining in one area. Because of this, impacts to recreation would be slightly less at the alternative site.

Noise

Environmental Setting. Generally low levels of ambient noise are expected along the Gabrych Alternative as this region is primarily for agriculture. However, ambient noise levels are expected to be elevated near Harvey's Fishing Hole.

Nearby sensitive receptors include the rural residences at Harvey's Fishing Hole, south of the Gabrych Alternative. The nearest residential area would be between approximately 500 to 1,000 feet south of the alternative site. There are no nearby sensitive receptors to the proposed site.

Environmental Impacts. As stated in the **Noise** section of this SA/DEIS, the construction of the GSEP would create noise, or unwanted sound. The character and loudness of this noise, the times of day or night at which it is produced, and the proximity of the facility to sensitive receptors combine to determine whether the facility would meet applicable noise control laws and ordinances and whether it would cause significant adverse environmental impacts.

The Gabrych Alternative site is located on land that is used for agriculture. Additionally, rural residences are located within 1,000 feet of the Gabrych Alternative within the town of Harvey's Fishing Hole. It is expected that operational noise would raise the ambient noise levels.

Comparison to Proposed Project. Building the GSEP at the Gabrych Alternative site would create a slightly greater impact than at the proposed site because of the closer proximity to a greater number of sensitive receptors (residences).

Socioeconomics and Environmental Justice

Environmental Setting. The Gabrych Alternative site is located in Imperial County, just south of the Riverside County border. The demographic characteristics of Riverside County are described in the **Socioeconomics and Environmental Justice** section of this SA/DEIS.

In 2000, as reported by the U.S. Census, the population of the Palo Verde/Harvey's Fishing Hole area was 287 people. Imperial County had a total population of 142,361 in 2000 and 161,867 in 2007 (California Department of Finance 2000 and Census Bureau). The unemployment rate for Imperial County was 24.5% in February 2009 (not seasonally adjusted). This is not full employment for Imperial County. Over the past few decades, full employment has been typically defined as approximately 4.0% to 5.5% unemployment. For California, the unemployment rate was 10.9% in February 2009 (not seasonally adjusted) (State of California Employment Development Department 2008a).

Environmental Impacts. Construction workers would most likely be from larger nearby cities such as Blythe. While there is limited housing available in the vicinity of the Gabrych Alternative site, workers could commute from Blythe, approximately 12 miles north of the Gabrych Alternative site. There are residential opportunities or amenities in Blythe in addition to campgrounds, RV parks, or motels (GSEP 2009a). Because it is unlikely that the construction workers would relocate to the immediate vicinity of the Gabrych Alternative site, this alternative would not cause a significant adverse socioeconomic impact on the area's housing, schools, police, emergency services, hospitals, and utilities.

There would be no adverse socioeconomic impacts since most of the construction and operation workforce is within the regional labor market area, and construction activities are short-term. Gross public benefits from the GSEP, including capital costs, construction and operation payroll, and sales taxes, should it be built at the Gabrych Alternative site, are likely to be similar to the benefits from GSEP at the proposed site, although some of the economic benefits would likely occur in Palo Verde, Imperial County as well as in Blythe, Riverside County. Section 73 of the California Revenue and Taxation Code allows a property tax exclusion for certain types of solar energy systems installed between January 1, 1999 and December 31, 2016. The components that would be excluded include the solar components such as mirrors, solar boiler, heat exchangers in addition to the storage devices, power conditioning equipment, transfer equipment, and parts. As such, property tax income would not be expected to increase significantly from its current state.

Comparison to Proposed Project. The socioeconomic impacts of the GSEP at the Gabrych Alternative site would be similar to building and operating the project at the proposed site.

Traffic and Transportation

The Gabrych Alternative site is located south of I-10; access to the Gabrych Alternative site would be via Neighbors Boulevard off of I-10. Workers employed to construct the project at this alternative site would most likely commute from Blythe (12 miles) or the Coachella and Indio (up to 90 miles). Given the limited use of I-10 east of Palm Springs, added construction traffic on the I-10 would be unlikely to impact the level of service.

The Gabrych Alternative would be located approximately 1,000 feet north of Harvey's Fishing Hole, a public boating launch.

Environmental Impacts. Before construction could occur at the Gabrych Alternative site, a construction traffic control and transportation demand implementation program would need to be developed in coordination with Caltrans. This analysis may result in the need to limit construction-period truck and commute traffic to off-peak periods to avoid or reduce traffic and transportation impacts. These impacts would likely similar to those of the proposed project as both projects would require the use of I-10 and other smaller roads for access and are located adjacent to each other.

Glare. Similar to the proposed project, there is the potential for highly distracting diffuse glare from the project to affect nearby motorists. Staff developed Condition of Certification VIS-4, which requires mitigation in the form of including opaque privacy

slats on the perimeter chain link fencing proposed by Applicant along the length of the project adjacent to Interstate 10. That measure would be adapted to this alternative along Neighbors Boulevard. Fewer motorists would be impacted by glare at the Gabrych Alternative site than at the proposed GSEP site; however, the rural community of Harvey's Fishing Hole would be potentially impacted by glare as it is located between 500-1,000 feet south of the project site.

Comparison to Proposed Project. Impacts to traffic and transportation at the Gabrych Alternative site would be similar to those at the proposed GSEP site.

Transmission Line Safety and Nuisance

Environmental Setting. The Gabrych Alternative site would connect with the SCE system at the proposed Colorado Substation through a new transmission line that would exit the alternative site and trend west for approximately 5 miles then turn north for approximately 12 miles The new transmission line would cross BLM land and active and fallow agricultural land and would be located adjacent to the existing WAPA 161 kV transmission line and would be located within an existing CDD designated utility corridor.

The transmission line would be within 500 feet of rural residences within the town of Palo Verde.

Environmental Impacts. Similar to the proposed project, this alternative site would not be likely to cause transmission line safety hazards or nuisances with implementation of conditions of certification such as those described in the **Transmission Line Safety and Nuisance** section of the SA/DEIS. The potential for nuisance shocks would be minimized through grounding and other field-reducing measures that would be implemented in keeping with current standard industry practices, and the potential for hazardous shocks would be minimized through compliance with the height and clearance requirements of CPUC's General Order 95. Compliance with Title 14, California Code of Regulations, section 1250, would minimize fire hazards, while the use of low-corona line design, together with appropriate corona-minimizing construction practices, would minimize the potential for corona noise and its related interference with radio-frequency communication in the area around the route.

As with the proposed GSEP transmission lines, the public health significance of any related field exposures cannot be characterized with certainty. The only conclusion to be reached with certainty is that the proposed lines' design and operational plan would be adequate to ensure that the generated electric and magnetic fields are managed to an extent the CPUC considers appropriate in light of the available health effects information.

Comparison to Proposed Project. The Gabrych Alternative site would require a shorter transmission line interconnection with the SCE transmission system; however, much of the GSEP transmission interconnection would be located on already existing poles as the conductor would be strung on poles erected for the Blythe Energy Transmission Line. While the electric and magnetic fields would be managed to an extent the CPUC considers appropriate, the transmission line would be located within 500 feet of approximately 15 residences. The transmission interconnection for the

proposed site would not be located within 500 feet of any residential properties; as such, this impact would be greater for the Gabrych Alternative site than for the proposed site.

Visual Resources

Environmental Setting. The Gabrych Alternative site is located on primarily private land surrounded by agricultural lands east of the town of Palo Verde in Imperial County. The rural community of Harvey's Fishing Hole is located south of the Gabrych Alternative site along the Colorado River. A small sand/gravel mining operation occurs just west of the residential area. The site is crossed by Neighbors Boulevard. This infrastructure introduces developed and industrial features to the otherwise visually open and rural setting.

Views from the Gabrych Alternative site to the north and west are pastoral, of agriculture lands. Views to the east and south are of the Colorado River and further views are also of agriculture lands and some open space in Arizona.

The linear facilities associated with the Gabrych Alternative site include a 230 kV transmission line approximately 17 miles long. The transmission lines would be primarily located in a CDD Designated Utility Corridor.

Environmental Impacts. As stated in the **Visual Resource** section, the Energy Commission staff, in coordination with BLM, used a standard visual assessment methodology developed by California Energy Commission staff and applied to numerous siting cases in the past in this study. A description of this methodology is provided in **Appendix VR-1** for the proposed GSEP project**.**

The existing visible physical environmental setting and the anticipated visual change introduced by the proposed project are considered from representative, fixed vantage points. The likelihood of a visual impact is determined in this study by two fundamental factors: the susceptibility of the setting to impact as a result of its existing characteristics (reflected in its current level of visual quality, the potential visibility of the project, and the sensitivity to scenic values of its viewers); and the degree of visual change anticipated as a result of the project. These two factors are summarized respectively as *visual sensitivity* (of the setting and viewers), and *visual change* (due to the project).

With the addition of the project, views of the alternative site would change from an open and pastoral landscape to a substantially more industrial, highly altered one. The industrial landscape would be dominated by the eighteen hundred acres of solar troughs, approximately 30-feet tall. There would be no natural features to block the view of the solar facilities on any side. However, the alternative site would be located adjacent to a gravel mine which would have already introduced some built environment into the area.

The Gabrych Alternative site views would be prominent from Neighbors Boulevard for both northbound and southbound traffic, which is relatively minimal. Travelers would be immediately adjacent to the project, and there is little elevation or natural contouring to block views of the solar field. The GSEP would be located over 3 miles from the I-10 and would not be highly visible from the I-10.

The landscape surrounding the alternative site is within the Palo Verde Irrigation District and is flat, exhibits a prominent horizontal line, and is relatively non-descript. The more distant, angular mountains provide a backdrop of visual interest. Landform colors are tan to dark green. The overall landscape character and visual quality is predominantly pastoral in appearance with a few structures at Palo Verde and Harvey's Fishing Hole slightly visible above the vegetative line.

The alternative's 230 kV transmission line interconnection would introduce additional industrial character to this agriculture area; however, it would be partially located within a CDD Designated Utility Corridor and would be adjacent to an existing 161 kV transmission line for 12 miles. The Gabrych Alternative transmission line would be required to cross SR 78.

Comparison to Proposed Project. The Gabrych Alternative site would be located in a more developed and disturbed area compared with the proposed GSEP site. However, the Gabrych Alternative would be expected to be visible to a greater number of viewers than the GSEP site and would create somewhat greater visual impacts.

The Gabrych Alternative transmission line would create a lesser visual impact than the GSEP proposed site transmission interconnection because it would not need to cross the I-10 to reach the substation, and would not be located adjacent to a heavily used freeway. The Gabrych Alternative transmission line would be required to cross SR 78; however, this has a fewer number of viewers than the I-10. Both transmission lines would be adjacent to existing transmission lines.

Waste Management

Environmental Setting. In 2002, a leaking diesel fuel tank caused a sheen on the Colorado River just south of the Gabrych Alternative (OES 2002). The report filed by the California Fish & Game stated that the leak was caused by one of three 4,000 gallons tanks of diesel on a farm in Arizona across from Harvey's Fishing Hole (OES 2002). Additionally, because the site and surrounding area is used for agriculture, it is possible that the site has been contaminated by agriculture residues.

Environmental Impacts. Both nonhazardous and hazardous wastes would be created by the construction of the project at the Gabrych Alternative site in similar quantities as at the proposed site and would be disposed of at the same facilities as for the proposed project. The applicant would be required to obtain a unique hazardous waste generator identification number for the site prior to starting construction and would be required to comply with conditions of certification similar to those identified for the proposed site. The project at either the GSEP site or the Gabrych Alternative site would produce minimal maintenance and plant wastes.

As discussed in the **Waste Management** section of this SA/DEIS, preparation and construction of the two phases of the proposed solar project and its associated facilities would last approximately 37 months and generate both non-hazardous and hazardous wastes in solid and liquid forms. Before construction can begin, the project owner will be required to develop and implement a Construction Waste Management Plan per mitigation similar to the Condition of Certification proposed for the GSEP, to ensure that the waste will be recycled when possible and properly disposed of in landfills when

necessary. As with the proposed GSEP project, construction activities would generate an estimated 40 cubic yards per week of non-hazardous solid wastes, consisting of scrap wood, steel, glass, plastic, and paper, and another 1 cubic yard per week of office-related waste. Of these items, recyclable materials would be separated and removed as needed to recycling facilities. Non-recyclable materials (insulation, other plastics, food waste, roofing materials, vinyl flooring and base, carpeting, paint containers, packing materials, etc.) would be disposed at a Class III landfill.

Non-hazardous liquid wastes would be generated during construction, and would include 200 gallons of sanitary waste per day. Sanitary wastes would be pumped to tanker trucks by licensed contractors for transport to a sanitary water treatment plant.

During construction, anticipated hazardous wastes include waste paint, spent construction solvents, waste cleaners, waste oil, oily rags, and waste batteries. Estimated amounts are 1 cubic yard of empty containers (per week), 175 gallons of oils, solvents, paint, and oily rags (every 90 days), and 10 batteries (per year). Empty hazardous material containers would be returned to the vendor or disposed at a hazardous waste facility; solvents, used oils, paint, oily rags, and adhesives would be recycled or disposed at a hazardous waste facility; and spent batteries would be disposed at a recycling facility. In addition, a one-time generation of 1,000 gallons of Heat Exchanger cleaning solvent (chelant type solution) would require disposal at a permitted hazardous waste facility (GSEP 2009a, pages 5.13-5).

The generation of hazardous waste requires a unique hazardous waste generator identification number. The hazardous waste generator number is determined based on site location and therefore, both the construction contractor and the project owner/operator could be considered the generator of hazardous wastes at the site. Therefore, the project owner would be required to obtain a unique hazardous waste generator identification number for the site prior to starting construction. This would ensure compliance with California Code of Regulation Title 22, Division 4.5.

Comparison to Proposed Project. The environmental impacts of waste disposal at the Gabrych Alternative site would be similar to those at the proposed GSEP site.

Worker Safety and Fire Protection

Environmental Setting. The Gabrych Alternative site would be located within an area that is primarily agricultural and adjacent to the Colorado River. Although the Gabrych Alternative is located in Imperial County, the nearest fire departments are located in Riverside County. The two nearest county fire stations are RCO Station #45, located at Blythe Air Base, 17280 W. Hobson Way, Blythe, and RCO Station #44, located at Ripley, 13987 Main Street, Ripley (RCFD 2010a). The Worker Safety and Fire Protection section in this SA/EIR provides more information regarding the Riverside County Fire Department. The fire risks of this alternative site would be similar to those of the proposed GSEP site as both have desert conditions.

Environmental Impacts. A solar plant at the Gabrych Alternative site would require a Project Demolition and Construction Injury and Illness Prevention Program and a Project Operations Safety and Health Program in order to ensure adequate levels of industrial safety. The applicant would also be required to provide safety and health

programs for project construction, operation, and maintenance, similar to the requirements for the proposed project site. The Riverside County Fire Department and the Imperial County Fire Department would be contacted to assure that the level of staffing, equipment, and response time for fire services and emergency medical services are adequate.

Comparison to Proposed Project. The environmental impact of worker safety and fire protection at the Gabrych Alternative site would be similar to the proposed site although the response time would be expected to be better at the alternative site due to its proximity to the RCO Station #44.

Engineering Assessment for Gabrych Alternative

Facility Design

The design of a 250 MW project at the Gabrych Alternative would be similar to that of GSEP at the proposed site. Staff-recommended measures may be appropriate to ensure compliance with engineering laws, ordinances, regulations, and standards applicable to the design and construction of the project.

Geology, Paleontology and Minerals

Environmental Setting. The Gabrych Alternative is located near the southeastern edge of the Palo Verde Valley, a river valley of the Colorado River, in the Colorado Desert Region. The Colorado Desert region lies mostly at a low elevation and consists of desert basins with interspersed northwest-trending mountain ranges. The Gabrych Alternative generally crosses alluvial plains and valleys. Geologic units underlain by the alternative site are primarily recent alluvium (Qal) or unconsolidated alluvial fan, river channel, and stream deposits consisting of silt, sand, clay, and gravel (CPUC 2007). Recent alluvium also includes recent floodplain deposits of the Colorado River (silt, sand, and clay).

The Gabrych Alternative is located in an area of low seismic activity. No active faults cross the alignment or are located in the vicinity. The estimated peak horizontal acceleration for this alternative route is less than 0.2 g; therefore, this area should not experience strong groundshaking. The lack of strong groundshaking and deep groundwater elevations preclude liquefaction-related phenomena. This alternative is located on flat to gently sloping alluvial fans and alluvial plains that are not susceptible to landslides (CPUC 2007).

Liquefaction is the phenomenon in which saturated granular sediments temporarily lose their shear strength during periods of earthquake-induced, strong groundshaking. The susceptibility of a site to liquefaction is a function of the depth, density, and water content of the granular sediments, and the magnitude and frequency of earthquakes in the surrounding region. Saturated, unconsolidated silts, sands, and silty sands within 50 feet of the ground surface are most susceptible to liquefaction. Liquefaction-related phenomena include lateral spreading, ground oscillation, flow failures, loss of bearing strength, subsidence, and buoyancy effects (CPUC 2007). In addition, densification of the soil resulting in vertical settlement of the ground can also occur. As the Gabrych Alternative site is located less than 1,000 feet north of the Colorado River, liquefaction is consid-

ered a potential hazard (CPUC 2007). However, due to the low potential for strong groundshaking, liquefaction would likely occur only during a “great” earthquake (CPUC 2007).

One mineral resource site is located within the alternative site; a gravel pit surface mining operation owned by Empire Communities, LLC (BLM 2010). This mining facility would be avoided by the solar field layout.

The Gabrych Alternative is expected to have a low potential for finding paleontological resources because it is primarily underlain by Holocene Alluvium and because it has been previously disturbed for agricultural practices.

Environmental Impacts. Minimal seismic ground shaking is expected at the Gabrych Alternative site because it is not located within a seismically active area and is not on a known fault line. The severity and frequency of ground shaking associated with earthquake activity at the Gabrych Alternative site is expected to be similar to that of the proposed site. However, the potential for liquefaction in this area is high due to anticipated depths of groundwater. As such, design criteria would be required for the Gabrych Alternative site in accordance with a design-level geotechnical report and California Building Code (2007) standards. Adequate design parameters for the facility would need to be determined through a site-specific evaluation by a Certified Engineering Geologist or Geotechnical Engineer. Impacts due to seismic hazards and soil conditions, such as subsidence, would be addressed by compliance with the requirements and design standards of the California Building Code.

The paleontological sensitivity and potential to encounter significant paleontological resources at this alternative site and the GSEP site is similar. As stated in the **Geology, Paleontology, and Minerals** section, construction of the proposed project will include mass grading, deep foundation excavation, and utility trenching. There exists the probability of encountering paleontological resources. As with the proposed project site, the proposed conditions of certification are designed to mitigate any paleontological resource impacts to a less-than-significant level.

Comparison to Proposed Project The Gabrych Alternative site is subject to a similar risk of geologic hazards as the proposed project site. Although not expected, strong ground shaking could be effectively mitigated through facility design. The potential to encounter geologic resources and significant paleontological resources at the alternative site is similar to the GSEP site. The conditions of certification provided in the **Geology, Paleontology and Minerals** section would be applicable to the Gabrych Alternative site.

Power Plant Efficiency

The plant configuration and solar trough technology that would be employed at the Gabrych Alternative site would be similar to the proposed project, which means it would result in similar consumption of fuel, and it would result in a similar level of efficiency.

Power Plant Reliability

The plant configuration at the Gabrych Alternative site would be similar to the proposed project, which means it would result in similar levels of equipment availability. Plant

maintainability, fuel and water availability, and reliability of the plant in relation to natural hazards would each be similar at this alternative site to the proposed project.

Transmission System Engineering

Locating a solar facility at the Gabrych Alternative site would require a shorter connector line than at the proposed site. Once collected, the power would interconnect with the proposed Colorado River Substation. As such, the transmission system evaluation for the Gabrych Alternative site would be similar to that of the proposed GSEP.

Summary of Impacts – Gabrych Alternative

The Gabrych Alternative site would have impacts similar to the proposed GSEP site for 10 of the 20 environmental and engineering resource elements discussed above: air quality, public health, socioeconomics, traffic and transportation, waste management, facility design, geology, paleontology and minerals, power plant efficiency, power plant reliability, and transmission system engineering.

The proposed GSEP site is preferred over the Gabrych Alternative site in five resource elements: hazardous materials, land use, noise, visual resources, and transmission line safety and nuisance.

The Gabrych Alternative site is preferred over the proposed GSEP site for six resource elements: recreation and wilderness, soils and water, worker safety and fire protection, biology, and cultural resources. Impacts to biological and cultural resources are anticipated to be reduced at the Gabrych Alternative site compared to at the GSEP site because the Gabrych Alternative site would be located on disturbed land. This would lessen the amount of sensitive species habitat that would be lost due to the construction of the project and would potentially lessen impacts to cultural resources. However, without having completed detailed site surveys of biological and cultural resources at the Gabrych Alternative site, a detailed comparison is not possible.

B.2.8 ALTERNATIVES CONSIDERED BUT NOT EVALUATED IN FURTHER DETAIL

B.2.8.1 Site Alternatives

This section considers potential alternatives to the proposed GSEP that were evaluated, and determined to not be feasible or result in lesser impacts than the proposed action. Because these alternatives would not avoid or substantially reduce the adverse impacts of the proposed GSEP or because they do not meet project objectives, the purpose and need for the project, or are otherwise not reasonable alternatives, they are not analyzed in further detail in this SA/DEIS. The following alternative sites were evaluated in this analysis:

- McCoy Alternative
- Desert Center 1 Alternative
- Mule Mountain Alternative
- Black Hill Alternative

- Private Land Alternative
- Western ROW Alternative
- Reclaimed Water Alternative

McCoy Alternative

The McCoy Alternative was identified by NextEra in the AFC as a potential alternative site for the proposed project. The McCoy Alternative is located on BLM-administered land at T5S R21E Section 28. It is located northwest of Blythe, Riverside County (see **Alternatives Figure 4)** and is west of a CDCA utility corridor. The elevation of McCoy Alternative is between approximately 500 and 600 feet above sea level. The alternative identifies approximately 7,750 acres; however, it is assumed that approximately 1,800 acres of land would be required for the alternative.

McCoy was not pursued by NextEra as a possible site for the proposed project because it is being considered for a future solar project by NextEra.

Environmental Assessment. As with the proposed GSEP solar site, the McCoy Alternative site would require use of approximately 1,800 acres of land and would result in the permanent loss of approximately 1,800 acres of desert habitat. The project would require grading of approximately 1,800 acres and it is expected that because of the extensive grading, the alternative site would result in impacts to biological and cultural resources. The project site is adjacent to Nelson Bighorn Sheep Wildlife Habitat Management Area.

Both the proposed GSEP site and McCoy site would have a large footprint and require extensive grading, potentially resulting in erosion and runoff. The McCoy site is crossed by three large desert washes, potentially increasing the sediment flow in and around the site. Given the size of the power plants and the approximately 30-ft tall solar trough structures, visual impacts would be considerable. However, few sensitive receptors would be located adjacent to the McCoy site. The McCoy site would cross a designated open route (NECO Plan) and would potentially create impact to recreational uses of the route.

Rationale for Elimination. The McCoy site is located on undisturbed public land. This alternative would not reduce impacts of the proposed GSEP without creating severe impacts of its own. Therefore, the McCoy Alternative was eliminated from further consideration in this SA/DEIS.

Additionally, under its existing regulations, BLM determines if competing applications exist for the same facility or system. Applications that are first in time are given priority in consideration and are not considered competing applications with those filed later in time. Therefore, an alternative site on BLM-administered land with a pending application for another project is not considered a reasonable alternative to the proposed project for purposes of alternatives analysis. Therefore, an alternative site on BLM-administered land with a pending application, such as the McCoy Alternative, would not be a reasonable alternative for the proposed GSEP project unless that other application is rejected or withdrawn.

Desert Center 1 Alternative

The Desert Center 1 Alternative was identified by NextEra in the AFC as a potential alternative site for the proposed project. The Desert Center 1 Alternative is located on BLM-administered land north of Desert Center, adjacent to Highway 177, in Riverside County (see **Alternatives Figure 4)**. The elevation of Desert Center 1 Alternative is between approximately 500 and 700 feet above sea level. The site is located east of Joshua Tree National Park. Joshua Tree National Park is nearly 800,000 acres large and is used for hiking, mountain biking, rock climbing, and includes nine campgrounds. In 2007, NextEra applied for a right-of-way grant for the Desert Center 1 Alternative but after additional examination including environmental concerns, road access, conflicting uses, and transmission option, the application was withdrawn (GSEP 2009a). Most recently, the Solel project (CACA 49494) was proposed at this location (BLM 2009).

Rationale for Elimination The Desert Center 1 Alternative was not found to be a reasonable alternative for the proposed project. In August of 2008, the BLM indicated that the Desert Center 1 region was in an area that would potentially be subsumed in expansions of the Joshua Tree National Park and/or the McCoy Wilderness (AECOM 2010a). The BLM rejected the Solel application for this location in October of 2009 due to lack of due diligence.

Mule Mountain Alternative

The Mule Mountain Alternative was identified by NextEra in the AFC as a potential alternative site for the proposed project. The Mule Mountain Alternative is located on federal land administered by the BLM, and is located west of the town of Blythe, south of the I-10 in eastern Riverside County; see **Alternatives Figure 4**. The elevation of Mule Mountain Alternative is approximately 500 feet above sea level. The site would be located on 6,950 acres, at T7S R20E, Section 12. In 2007, NextEra applied for a right-of-way grant for the Mule Mountain Alternative but after additional examination including environmental concerns, road access, conflicting uses, and transmission option, the application was withdrawn (GSEP 2009a). The Bullfrog Green Energy Mule Mountain solar project is proposed at this location (BLM 2009b).

Environmental Assessment. As with the proposed GSEP site, the Mule Mountain Alternative site would require use of approximately 1,800 acres of land and would result in the permanent loss of approximately 1,800 acres of desert habitat. The project would require grading of approximately 1,800 acres and it is expected that because of the extensive grading, the alternative site would result in impacts to biological and cultural resources. According to CNDDB records, the site would support Desert Tortoise, Harwood's Milk Vetch, Cave Myotis, and California leaf-nosed bat (GSEP, 2009f).

Both the proposed GSEP site and Mule Mountain site would have a large footprint and require extensive grading, potentially resulting in erosion and runoff. The Mule Moutnain site is crossed by two large desert washes, potentially increasing the sediment flow in and around the site. Given the size required for solar power plants and the approximately 30-ft tall solar trough structures, visual impacts would be considerable and similar to those at the proposed GSEP solar site. The Mule Mountain site would be visible from the Mule Mountains ACEC to the east.

Rationale for Elimination. The Mule Mountain site is located on undisturbed public land. This alternative would not reduce impacts of the proposed GSEP without creating severe impacts of its own. Therefore, the Mule Mountain Alternative was eliminated from further consideration in this SA/DEIS.

Additionally, under its existing regulations, BLM determines if competing applications exist for the same facility or system. Applications that are first in time are given priority in consideration and are not considered competing applications with those filed later in time. Therefore, an alternative site on BLM-administered land with a pending application for another project is not considered a reasonable alternative to the proposed project for purposes of alternatives analysis. Therefore, an alternative site on BLM-administered land with a pending application, such as the Mule Mountain Alternative, would not be a reasonable alternative for the proposed GSEP project unless that other application is rejected or withdrawn.

Black Hill Alternative

The Black Hill Alternative was identified by NextEra in the AFC as a potential alternative site for the proposed project. The Black Hill Alternative is located on BLM-administered land north of Blythe, in Riverside County; see **Alternatives Figure 4**. The elevation of the Black Hill Alternative is between approximately 600 to 700 feet above sea level. NextEra stated that the total acreage for the Black Hill Alternative is 8,720 acres (GSEP 2009f). In 2007, NextEra applied for a right-of-way grant for the Black Hill Alternative but after additional examination including environmental concerns, road access, conflicting uses, and transmission option, the application was withdrawn (GSEP 2009a). Most recently the OTB Power Holdings, Inc. project (CACA 049098) was proposed at this site and denied by the BLM (BLM 2009b).

Environmental Assessment. As with the proposed GSEP site, the Black Hill Alternative would require use of approximately 1,800 acres and would result in the permanent loss of desert habitat. The project would require grading of approximately 1,800 acres and it is expected that due to the extensive grading requirement, building the GSEP at the alternative site would likely result in impacts to biological and cultural resources.

Impacts to land use and recreation at the Black Hill Alternative would potentially be significant as it is located adjacent to the Big Maria Mountains Wilderness and is crossed by three designated open routes (NECO Plan). Because it is immediately north of several rural residences, impacts to public health, noise and visual resources would potentially be worse than at the proposed site.

Both the proposed GSEP site and Black Hill Alternative site would have a large footprint and require extensive grading, potentially resulting in erosion and runoff. The Black Hill Alternative site is crossed by ephemeral waters and washes that would likely be rerouted. As stated above, Black Hills Alternative site is north of several residences and would likely be visible from these residences. Given the size required for solar power plants and the approximately 30-ft tall solar trough structures, visual impacts would be considerable and similar to those at the proposed GSEP site.

Rationale for Elimination. The Black Hills Alternative would not reduce impacts of the proposed GSEP without creating significant impacts of its own. Therefore, the Black Hills Alternative was eliminated from further consideration in this SA/DEIS.

Additionally, in the fall of 2008, the BLM rejected the OTB Power Holdings, Inc. application for a right-of-way grant at the Black Hills Alternative site (BLM 2009b). This application was rejected for lack of due diligence.

Private Land Alternative

Two private landholdings were considered by NextEra in addition to the Gabrych private land addressed above. However, after additional research the applicant determined that any water use in the Blythe area might impact the Colorado River water basin (GSEP 2009f). As such, the private lands were eliminated from consideration by the applicant (GSEP 2009f). Because dry cooling is a feasible technology that could be used with any alternative site, private land alternatives near the Blythe area were not immediately eliminated for purposes of the SA/DEIS. As such, the Gabrych Alternative was retained for CEQA purposes and is discussed in **Section B.2.7.2.**

The additional private sites considered by the applicant, the Farmland Reserve site and the Sunworld site, would also be located on private, disturbed land, and would include portions of land that were previously used for agriculture but that are no longer actively farmed. However, the portions of the Farmland Reserve and Sunworld sites that are no longer actively farmed have been considered as a potential alternative to the Blythe Solar Power Project [09-AFC-6] (CEC 2010a). Additional inactive agriculture land is located near Desert Center and is analyzed as the North of Desert Center Alternative for the Palen Solar Power Project SA/DEIS [09-AFC-7] (CEC 2010b).

They not fully analyzed for the GSEP because the Gabrych Alternative is considered to be an adequate consideration of a private land alternative. However, it should be recognized that more than 1,800 acres of no longer active agriculture land are located northwest of Blythe and has been analyzed in the Blythe Solar Power Project SA/DEIS as the Blythe Mesa Alternative.

Western Right of Way Alternative

The Genesis ROW application is for a total of 4,640 acres. The GSEP, as proposed, would occupy 1,800 acres within the eastern portion of the ROW application. The remaining 2,840 acres are not occupied by the project. Because of concern regarding impacts to sand transport by wind from the two aeolian corridors (west along the Chuckwalla Valley parallel with I-10 and south down the Palen-McCoy valley), and water-based sand transport down the multiple alluvial fan channels that the site intersects, incorporating a portion of the western ROW was considered. The western portion of the ROW would not accommodate a 125 MW solar field as configured for the proposed GSEP. However, the western portion of the ROW occupies sufficient acreage for revised configuration a 125 MW solar field. Use of the western ROW would require longer linear infrastructure.

After further study of both the Palen-McCoy Valley aeolian sand corridor and the Chuckwalla Valley sand transport, it was concluded that the proposed GSEP footprint

was less of a concern from an aeolian perspective. The proposed footprint avoids most of the Chuckwalla sand corridor and most of the dominant aeolian sand migration in the Palen-McCoy corridor. A sand transport report is included as the **Soils and Water Section Appendix A.**

When considering use of the western ROW, additional concerns were raised. A reconfigured solar field in the western ROW would increase the linear footprint of the project and potentially cause greater impacts to the alluvial fan drainage plan. A more linear footprint would require collecting additional channels into an interceptor drain and concentrating the flow and releasing it downstream. Concerns regarding the western ROW's proximity to the Palen Dry Lake ACEC and the potential to impact significant sensitive cultural resources were also raised. Because use of the western ROW did not reduce impacts as originally believed and would have the potential to introduce additional impacts, it was not evaluated in further detail.

Reclaimed Water Alternative

The applicant considered a variety of reclaimed water sources as alternatives to the proposed on-site groundwater wells. These include (GSEP 2009f):

- City of Blythe Water Production and Treatment Facility, Reclaimed Water (approximately 400 acre feet);
- Chuckwalla State Prison, Wastewater (approximately 600 acre feet);
- Colorado River Sewage System Joint Venture, Westates, near Parker AZ (N/A); and
- Metropolitan Water District of Southern California, Desert Center Plant Wastewater (approximately 10-20 acre feet).

Additional water sources were identified in Section 3.0 Facility Description of the AFC, but these sources, such as Colorado River water, are not considered reclaimed water. None of the reclaimed water sources identified by the applicant would have sufficient reclaimed water supply as to make a viable alternative water supply.

Additionally, directly using reclaimed water would not change the overall water balance for the groundwater basin. Reclaimed water is already accounted for as recharge to the groundwater system. An upgraded treatment, including a pump station and pipeline may actually lessen the amount of water in the overall water balance due to increased losses in the treatment and transport. Evaporation losses would likely increase with additional treatment as well. As such, this alternative was not evaluated in further detail.

B.2.8.2 Alternative Solar Generation Technologies

In addition to the range of alternative sites discussed earlier, several alternative solar generation technologies were evaluated as potential alternatives to the proposed GSEP (which would use the solar trough technology). Although alternative solar generation technologies would achieve most of the project objectives, each would have different environmental or feasibility concerns. The following solar generation technologies are considered in this analysis:

- Stirling energy systems technology

- solar power tower technology
- linear Fresnel technology
- photovoltaic technology

Among the solar thermal technology alternatives, the linear Fresnel alternative has the potential for least impacts due to its more compact configuration (reducing ground disturbance); however, the technology is proprietary and is not available to other developers. The distributed solar alternative would have fewer impacts than the proposed project because it would be located on already existing buildings or on already disturbed land. However, achieving 250 MW of distributed solar PV or solar thermal would depend on additional policy support, manufacturing capacity, and lower cost than currently exists to provide the renewable energy required to meet the California Renewable Portfolio Standard requirements. Additional technologies, like utility-scale solar thermal generation, are also necessary.

The following analyses assumed that the alternative technologies would be implemented on the site for the proposed GSEP, in eastern Riverside County.

Alternatives Table 3. Summary Characteristics of Solar Technologies

Technology	Parabolic trough	Solar Power Tower	Stirling Engine	Linear Fresnel	Photovoltaic
Water Use/ 100 MW (Assumes dry cooling)	~65 AFY	~20 AFY	~5 AFY	~12 AFY	~2-10 AFY
Acres per MW	6-7	10	9	4	8-12
Low Impact Construction Possible	No	Yes	Yes	No	Yes
Tallest component (does not include cooling towers or Transmission Line)	25 feet – trough	300 - 650 feel	38 feet - engine	56 feet	10 -15 feet (+ inverter station)
Slope requirements	2% or less	5% or less, can use LID	6% or less, can use LID	1% or less	3% or less, can use LID
Siting restrictions	Troughs are 1300 feet long, requires contiguous land	Heliostats must be in concentric circles around power tower	Can be sited in irregular shapes	Requires rectangles, requires contiguous land	Can be sited in irregular shapes
Heat Transfer Fluid (do not include water)	Yes	No	No	No (water used)	No

Stirling Dish Technology

The Stirling dish technology converts thermal energy to electricity by using a mirror array to concentrate and focus sunlight on the receiver end of a Stirling engine. The curved dishes that focus the sun's energy are approximately 45 feet tall and occupy a maximum horizontal space of approximately 1,135 square feet (0.026 acres), with an

anchored footprint of 12.5 square feet (assumed 4-foot diameter caisson). See **Alternatives Figure 5** for an illustration. The internal side of the receiver heats hydrogen gas, which expands. The pressure created by the expanding gas drives a piston, crankshaft, and drive shaft. The drive shaft turns a small electricity generator. The entire energy conversion process takes place within a canister the size of an oil barrel. The generation process requires no water, and the engine does not produce emissions as no combustion takes place. Each concentrator consists of one Stirling engine mounted above one mirror array. Once installed, each concentrator requires very little maintenance aside from periodic washing of the mirrored surfaces of the dish.

In general, the Stirling system requires 7 to 9 acres of land per MW of power generated. Based on literature search, a 250 MW Stirling engine field would require from 1,750 acres to 2,250 acres of land. The two proposed solar thermal power plants using Stirling engine technology currently being considered by BLM and the Energy Commission, SES Solar 1 and 2, have a land use per MW of installed capacity of approximately 8.3 acres per MW, and would require a greater footprint than the GSEP.

Site preparation involves sinking a cement base with an embedded pedestal to support the dish (SES 2008). Each Stirling dish generates 25 kilowatts (KW) of power, so 10,000 dishes would be required to generate 250 MW. Each dish includes two major elements:

- **Solar Concentrator.** Large parabolic concentrators include 89 mirror facets attached to a frame by three point adjusting mounts (SES 2008). They are designed in five subassembly units for ease of transport and installation on site. Two small motors are attached to the pedestal and programmed to swivel the dish on two axes, following the sun's progress across the sky during the day.
- **Power Conversion Unit.** The Stirling engine's cylinder block incorporates four sealed cylinder assemblies along with coolers, regenerators, and heater heads (SES 2008). Concentrated solar energy heats up self-contained gas (hydrogen) in the power conversion unit, causing the gas to expand into the cylinders, moving the cylinders, and generating electricity. This cycle is repeated over and over as the engine runs at a steady rate of 1,800 rpm (SES 2008). Power is generated by heat transfer from the concentrated solar rays to the working gas in the engine's heater head, which converts the heat energy into mechanical motion.

The generator of each unit in a utility-scale project is connected by underground transmission line to a small substation where the power can be transformed into a higher voltage for more efficient transmission across the grid.

Environmental Assessment. The land area required for a 250 MW Stirling engine power plant is greater than that required for the proposed GSEP. However, it is not necessary to grade the entire parcel as only the 18-inch diameter pedestal of the Stirling engine requires level ground. It would still be necessary to grade permanent access roads between every two rows of Stirling engines due to the need for regular washing of the mirrors. This grading would cause removal of vegetation. Additionally, because the proposed GSEP site is crossed by several desert washes, the installation of 10,000 Stirling engines could require a larger total acreage of land, resulting in a greater loss of habitat.

Stirling engines systems require minimal water use during operations. The SES Solar Two, a 750 MW project using the SunCatcher technology, would require approximately 32.7 acre feet per year. This technology would require less water than the proposed solar trough technology.

Due to the size and height of the Stirling mirrors, impacts to visual resources would be similar or greater to those of the GSEP. The 10,000 Stirling engines would introduce an industrial character and transformation of the site with the 45 foot tall engines. There would be less grading for the Stirling engine structures, but the numerous access roads required for cleaning the energy systems would create a high contrast between the disturbed area and its surroundings. The project would still require use of I-10 for commuting workers during both construction and operation.

Summary of Impacts. The large area needed for a Stirling engine power plant would be greater than the land requirement for the GSEP. Although grading requirements for the Stirling engines and solar concentrators are relatively small, grading for access roads would be extensive because access roads are required for every other row of Stirling engines (SES 2008). For these reasons, recreation and land use, and biological resources impacts would be similar to those of the GSEP facility. In addition, due to the extent of the facility and the height of each concentrator, visual impacts would not be significantly reduced by this alternative and may be greater considering that the 45-foot high solar concentrators would be more pronounced than the approximately 30-foot high solar troughs. However, the Stirling technology does not require a turbine and would use less water than the GSEP.

Rationale for Elimination

Stirling engine systems are a viable renewable technology but would potentially increase the footprint of the project between 10 and 45 percent. Additionally, due to its greater height, it would potentially increase visual impacts. With a minimum size of nearly 1,750 acres, Stirling engine technology would not eliminate any of the significant impacts of the GSEP plant. Therefore, this alternative technology was eliminated from further consideration in this SA/DEIS.

Solar Power Tower Technology

The solar power tower technology converts thermal energy to electricity by using heliostat (mirror) fields to focus energy on a boiler located on power tower receivers near the center of each heliostat array. Each mirror tracks the sun during the day. The heliostats would be 7.2 feet high by 10.5 feet wide. See **Alternatives Figure 6** for an illustration. The solar power towers can be up to 600 feet tall with additional 10-foot tall lightning rods. The solar power tower would receive heat from the heliostats then convert the heat into steam by heating water in the solar boilers. A secondary phase would convert the steam into electricity using Rankine-cycle reheat steam turbine electric generator housed in a power block facility at each of the plants.

In general, a solar power tower power plant requires 5 to 10 acres of land per MW of power generated. A 250 MW solar power tower field would require from 1,250 acres to 2,500 acres of land. The proposed solar power tower plant currently being considered by BLM and the Energy Commission, Ivanpah Solar Electric Generating System, is

using approximately 10 acres per MW, and would require a greater footprint than the GSEP.

Site preparation involves grading at the base of the heliostat and grading the access roads required for maintenance. Each heliostat field has the following primary components.

- **Heliostats.** The heliostat mirrors are arranged around each solar receiver boiler. Each mirror tracks the sun throughout the day and reflects the solar energy to the receiver boiler. The heliostats are approximately 7.2 feet high by 10.5 feet wide. They are arranged in arcs around the solar boiler towers asymmetrically.
- **Power Tower.** Tower structure height is up to 600 feet. Primary thermal input is via solar receiver boilers, superheater and reheaters at the top of the distributed power towers.
- **Steam Turbine Generator**. The steam turbine system consists of a condensing steam turbine generator with reheat, gland steam system, lubricating oil system, hydraulic control system, and steam admission/induction valving.

Power will be generated by the STGs at 19 kV (hydrogen cooled) and then stepped up by transformers for more efficient transmission across the grid.

Environmental Assessment

The land area required for a 250 MW solar power tower plant is likely greater to that required for the proposed GSEP. Grading of permanent access roads would be required due to the need for regular washing of the mirrors. This grading would cause removal of vegetation. Additionally, because the proposed GSEP site is crossed by several desert washes, the installation of the heliostats and power towers could require a larger total acreage of land, resulting in a greater loss of habitat.

Due to the size and height of the solar power towers, up to 600 feet, and mirrors, impacts to visual resources would be greater than those of the GSEP and would introduce an industrial character to this site and the surrounding areas.

Because of the height of the solar power towers and the direction that the sun is reflected by the heliostats, there may be concerns regarding any nearby aviation operations or military operations. Power tower technology would need to be reviewed for consistency with the Compatibility Plan adopted by the Riverside County Airport Land Use Commission. Policy 4.3.7 of the Countywide Policies of the 2004 Riverside County Airport Land Use Compatibility Plan includes guidance on characteristics to be avoided including glare or distracting lights which could be mistaken for airport lights. The Compatibility Plan also prohibits any use which would cause sunlight to be reflected toward an aircraft engaged in an initial straight climb following takeoff or toward an aircraft engaged in a straight final approach toward a landing at the airport.

Rationale for Elimination

The large area needed for a solar power tower plant would be greater than the land requirement for the GSEP. Grading requirements for the solar power tower would be less than for the GSEP because the solar power tower technology does not require

grading of the entire solar field; however, grading would still be required for the access roads in between the rows of heliostats. For these reasons, recreation and land use, biological resources, and cultural resource impacts would be similar to those of the GSEP. In addition, due to the extent of the facility and the height of the power towers, impacts to the Desert Center Airport would potentially be greater for this alternative.

Because no substantial reduction in impacts would occur under this alternative technology, the solar power tower technology was eliminated from further consideration in this SA/DEIS as an alternative technology.

Linear Fresnel Technology

A solar linear Fresnel power plant converts solar radiation to electricity by using flat moving mirrors to follow the path of the sun and reflect its heat on the fixed pipe receivers located about the mirrors. During daylight hours, the solar concentrators focus heat on the receivers to produce steam, which is collected in a piping system and delivered to steam drums located in a solar field and then transferred to steam drums in a power block (Carrizo 2007). The steam drums transferred to the power block will be used to turn steam turbine generators and produce electricity. The steam is then cooled, condensed into water, and recirculated back into the process.

In general, the linear Fresnel technology requires 4 to 5 acres of land per MW of power generated. A 250 MW solar linear Fresnel field would require approximately 1,000 – 1,250 acres of land.

Each row-segment is supported by large hoops that rotate independently on metal castors. Rotation of the reflectors would be driven by a small electrical pulse motor. Reflectors are stowed with the mirror aimed down at the ground during the night. The major components are:

- **Compact Linear Fresnel Reflector (CLFR) Solar Concentrator.** A solar Fresnel power plant would use Ausra's CLFR technology which consists of slightly curved linear solar reflectors that concentrate solar energy on an elevated receiver structure. Reflectors measure 52.5 by 7.5 feet (Carrizo 2007). There are 24 reflectors in each row. A line is made up of 10 adjacent rows and operates as a unit, focusing on a single receiver (Carrizo 2007).
- **Receiver Structure.** The receiver structure is approximately 56 feet tall (Carrizo 2007). It would carry a row of specially coated steel pipes in an insulated cavity. The receiver would produce saturated steam at approximately 518°F from cool water pumped through the receiver pipes and heated (Carrizo 2007). The steam would drive turbines and produce electricity.

Rationale for Elimination

The Fresnel solar technology is a proprietary technology owned by Ausra, Inc. However, Ausra, Inc. has changed its focus to being a technology and equipment provider rather than an independent power developer and owner, Ausra will focus on medium-sized (50 MW) solar steam generating systems for customers including steam users, such as food processors, enhanced oil recovery firms, and utilities for power augmentation systems that deliver steam into existing fossil-fuel power plants. A project

of 250 MW is theoretically possible, and would require smaller acreage per megawatt. However, at nearly 1,250 acres for 250 MW, this technology would not eliminate the significant impacts of the proposed solar trough technology at this site.

Solar Photovoltaic Technology – Utility Scale

A utility scale solar photovoltaic (PV) power generation facility would consist of PV panels that would absorb solar radiation and convert it directly to electricity. The definition of a utility scale photovoltaic projects varies; for this analysis utility scale project would consist of any solar photovoltaic facilities that would require transmission to reach the load center, or center of use.

PV facilities have been suggested using two general technologies:

- Thin film installed on fixed metal racks, as proposed by First Solar (see **Alternatives Figure 7**)
- Concentrating photovoltaics installed in elevated groups of panels that track the sun. These technologies are available from companies such as SunPower and Amonix. SunPower's PowerTracker technology consists of a single-axis mechanism that rotates the PV panels to follow the sunlight. The Amonix technology allows tracking on two axes. See **Alternatives Figure 7**.

Examples of existing utility scale PV facilities are:

- El Dorado Energy (Boulder City, NV): First Solar built a 10 MW facility using thin film technology for Sempra Energy demonstrating the commercial viability of its technology. The facility consists of over 167,000 solar modules on 80 acres of land and was completed in December 2008. (Sempra 2008). Additionally, Sempra Generation will begin expanding the facility by 48 MW in January 2010. All 58 MWs would be purchased by PG&E (Sempra 2009).
- NRG Solar (Blythe, CA): NRG Solar acquired a 21 MW thin film PV project in Blythe, CA. Commercial operation of the facility began in December 2009 and the electricity generated by the project is being sold to SCE under a 20 year power purchase agreement (NRG 2009).

Because PV technologies vary, the acreage required per MW of electricity produced from a large solar PV power plant is wide ranging and likely to change as technology continues to develop. The land requirement varies from approximately 3 acres per MW of capacity for crystalline silicon to more than 10 acres per MW produced for thin film and tracking technologies (NRDC 2008c). Therefore, a nominal 250 MW solar PV power plant would require between 750 and 2,500 acres.

Utility-scale solar PV installations require land with less than 3 percent slope. Solar photovoltaics do not require water for electricity generation. Because some water will be required to wash the solar panels to maintain efficiency, approximately 2-10 AFY of water is estimated to be required for a 100 MW utility solar PV installation or 10 to 50 AFY for a 250 MW installation (NRDC 2008c). The SunPower-CA Valley Solar Ranch states that the facility would use approximately 11.6 AFY for a 250 MW PV facility (SLO 2009).

Solar PV arrays and inverters would be approximately 15 to 20 feet high; however, some components of the solar PV facility, such as collector power lines or a transmission interconnection may be substantially taller (SLO 2009).

As with any large solar facility, additional operational components may be required. The SunPower-California Valley Solar Ranch would require operational components such as electrical equipment, collector power lines, access roads, a substation, an operation and maintenance building, and water tanks (SLO 2009).

Environmental Assessment. A utility scale solar PV facility would create a number of substantial adverse effects similar to those created by the proposed GSEP facility. If utility scale solar PV technology were built at the GSEP site, approximately 750 to 2,500 acres may be required, depending on the technology. The types of impacts from developing a solar PV project at the GSEP site are discussed below.

Development and installation of solar PV at the proposed project site could have adverse impacts to vegetation and wildlife from construction of access roads, transmission lines and any needed ancillary facilities (e.g., substation, water tank and a maintenance building). PV technologies require level ground of less than 3 percent slope; however, as the criteria for the GSEP site was a slope of 3 percent or less, it is expected that less grading would be required to site the PV arrays. Construction of a PV project would cause both temporary (during construction from vegetation clearing) and permanent (displacement of vegetation with project features) impacts to vegetation and wildlife habitat. Construction activities may also result in the alteration of soil conditions, including the loss of native seed banks and changes in topography and drainage, such that the ability of a site to support native vegetation after construction is impaired. Desert ecosystems are especially sensitive to ground disturbance and can take decades to recover, if at all. PV facilities could require security fencing; however some projects have proposed fencing that leaves 12 inch spacing from the ground to allow wildlife to enter into the solar array areas to aid in wildlife movement (SLO 2009).

Solar PV facilities would potentially require more land to generate 250 MW than the proposed parabolic trough technology for the GSEP. The amount of ground disturbance for a solar PV facility varies and depends on the PV technology used; however, in order to avoid sensitive resources it is expected that greater amounts of land would be required than with the parabolic trough technology. For example, the California Valley 250 MW solar PV project is proposed on a 4,365 acre site, although only a portion of that would be covered with solar PV arrays (SLO 2009).

The construction activities associated with solar PV development at the GSEP site have the potential to adversely impact surface water quality. During grading and construction activities there is the potential for surface water runoff to carry pollutants and sediment offsite and degrade water quality in nearby waters. Common pollutants that could be introduced into storm water during construction include, but are not limited to, fertilizers from landscape management, petroleum hydrocarbons and heavy metals from construction vehicles. Accelerated wind and water-induced erosion may result from construction. Precipitation, or high intensity and short duration runoff events coupled with ground disturbing activities, can result in onsite erosion eventually increasing the

sediment load into nearby waters. Soils devoid of vegetation have a high potential for erosion, particularly when disturbed.

Because the solar PV technology does not require any water for cooling or steam generation, the technology uses less water during operations than solar concentrating technologies. For certain PV technologies, water is required only for washing the solar PV arrays. Solargen's 420 MW Panoche Valley Solar Farm (2009) would use 10.5 AFY during operation. First Solar's 550 MW Desert Sunlight Solar Farm (thin film) operation water estimates are for domestic purposes (drinking, washing, and toilets) and would be no more than a few hundred gallons per day. However, during construction an estimated 1,800 AFY would be required for soil compaction, dust control and sanitary needs (First Solar 2010).

Summary of Impacts. The large land area required for PV development would result in similar impacts to recreation, land use, biological and cultural resources, and soil and water resources as to those of the GSEP facility. However, a utility scale PV project would reduce impacts to glare and would require minimal water for washing of the PV panels and would require no water use for cooling.

Rationale for Elimination

Utility scale solar PV technology is a viable renewable technology, but it is not retained for analysis because, as stated above, in order for California to meet the renewable portfolio standards, it must have access to all types of renewable technologies. In addition, use of utility scale solar PV would not reduce major impacts of the GSEP facility because the extent of land and access roads required would be similar. Therefore, solar PV technology would not eliminate the impacts of the GSEP associated with ground disturbance. While a utility solar PV alternative would reduce impact from water used during cooling, the Dry Cooling Alternative, retained for consideration for this project would also eliminate this impact. Therefore, this alternative technology was eliminated from further consideration in this SA/DEIS.

Distributed Solar Technology

There is no single accepted definition of distributed solar technology. The *2009 Integrated Energy Policy Report* (IEPR) defines distributed generation resources as "grid-connected or stand-alone electrical generation or storage systems, connected to the distribution level of the transmission and distribution grid, and located at or very near the location where the energy is used."

Distributed solar facilities vary in size from kilowatts to tens of megawatts but do not require transmission to get to the areas in which the generation is used. Distributed solar generation is generally considered to use photovoltaic (PV) technology although at slightly larger scales it is also being implemented using solar thermal technologies. Both technologies are considered below.

Distributed Solar PV Systems

A distributed solar alternative would consist of PV panels that would absorb solar radiation and convert it directly to electricity. The PV panels could be installed on residential, commercial, or industrial building rooftops or in other disturbed areas such

as parking lots or disturbed areas adjacent to existing structures such as substations. To be a viable alternative to the proposed GSEP, there would have to be sufficient newly-installed panels to generate 250 MW of capacity.

California currently has over 500 MW of distributed solar PV systems which cover over 40 million square feet (CPUC 2009). During 2008, 158 MW of distributed solar PV was installed in California, doubling the amount installed in 2007 (78 MW), and with 78 MW installed through May 2009, installation data suggests that at least the same amount of MW could be installed in 2009 as in 2008 (CPUC 2009).

Rooftop PV systems and parking lot systems exist in small areas throughout California. Larger distributed solar PV installations are becoming more common. Examples of the different distributed PV systems are:

- Nellis Air Force Base (AFB, Nevada): Over 72,000 solar panels, generating 14 MW of energy, were constructed in 2007, by SunPower Corp. on 140 acres of Nellis AFB land (Whitney 2007). Energy generated is used at the Nellis AFB.
- Southern California Edison (Fontana, CA): SCE has installed over 3 MW of distributed solar energy in two phases on over 1 million square-foot commercial roof using thin film PV technology provided by First Solar. This is the beginning of a planned installation of 3.5 million PV panels that would generate 250 MW of capacity (SCE 2009).
- San Diego Gas & Electric (San Diego, CA): SDG&E's Solar Energy Project is designed to install up to 80 MW of solar PV, which would include PV installation on parking structures and tracking systems on open land (SDG&E 2008).
- Pacific Gas & Electric (San Francisco, CA): PG&E launched a five-year program to develop 250 MW of solar PV power. The program would consist of 250 MW of utility-owned PV generation and an additional 250 MW to be built and operated by independent developers under a streamlined regulatory process. PG&E's program targets mid-sized projects, between 1 to 20 MWs, mounted on the ground or rooftops within its service area (PG&E 2009).
- City of San Jose (San Jose, CA): The City of San Jose is considering the development and implementation of 50 MW of renewable solar energy on city facilities and/or land (San Jose 2009). San Jose's Green Vision lays out a goal of achieving 100 percent of the city's electricity from renewable energy by 2020 and plans to implement strategies, such as a 24-month period to increase solar installations in San Jose by 15 percent. The City anticipates that City facilities with appropriate solar access including parking lots, garages, lands and landfills would be eligible for solar installation. San Jose received ARRA funding for the project.

Like utility-scale PV systems, the acreage of rooftops or other infrastructure required per MW of electricity produced is wide ranging. As stated above, California has approximately 40 million square feet (approximately 920 acres) of distributed solar PV accounting for 441 MW installed (CPUC 2008b). However, based on SCE's use of 600,000-square-feet for 2 MW of energy, 75 million square feet (approximately 1,750 acres) would be required for 250 MW.

Riverside County is estimated to have the technical potential for over 3,000 MW of distributed solar PV (CEC, 2007b). However, distributed solar PV could be located throughout the State. The location of the distributed solar PV would impact the capacity factor of the distributed solar PV.[1] The capacity factor depends on a number of factors including the insolation[2] of the site. Because a distributed solar PV alternative would be located throughout the State, the insolation at some of these locations would be less than in the Mojave Desert. The Renewable Energy Transmission Initiative (RETI) assumed a capacity factor of approximately 30 percent for solar thermal technologies and tracking solar PV and approximately 20 percent capacity factor for rooftop solar PV which is assumed to be non-tracking, for viable solar generation project locations (B&V 2008; CEC 2009). Tracking distributed solar PV would have a higher capacity factor as well.

Distributed Solar Thermal Systems

Solar thermal technology, specifically Concentrated Solar Power (CSP) technology, has also been adapted for use at distributed locations. In August 2009, eSolar began operations of a new distributed solar power tower technology. This technology uses small, flat mirrors which track the sun and reflect the heat to tower-mounted receivers that boil water to create superheated steam (eSolar 2009). An example of the eSolar system is the Sierra SunTower, located in Lancaster, CA, which produces 5 MW of energy for SCE on 20 acres of land (eSolar 2009). Each eSolar module locates one tower, one thermal receiver, and 12,000 mirrors on ten acres of land and produces 2.5 MW of power. Additionally, eSolar has developed a larger module, a 46 MW CSP plant that would include sixteen towers, a turbine generator set, and a steam condenser which would be located on approximately 160 acres (eSolar 2009).

Another solar thermal technology, the solar trough technology, could also be used as distributed technology. The NextEra Andasol 1 power plant in Spain generates 50 MW of power on approximately 127 acres (not including ancillary facilities) and went online in November 2008 (Solar Millenium 2008). The Andasol plant includes thermal storage systems which absorb a portion of the heat produced in the solar field during the day and can run the turbines for approximately 7.5 hours at full load, regardless of the solar conditions at the time (Solar Millenium 2008).

Both the solar thermal technologies have been implemented recently and are described here as an example of the evolving distributed solar technologies.

Environmental Assessment

Installations of 250 MW distributed solar PV would require up to 75 million square feet. Distributed solar PV is assumed to be located on already existing structures or disturbed areas so little to no new ground disturbance would be required and there would be few associated biological impacts.

[1] The capacity factor of a power plant is a percentage that tells how much of a power plant's capacity is used over time (CEC 2008a)

[2] Insolation is the total amount of solar radiation striking a surface exposed to the sky (CEC 2008a).

Minimal grading or few new access roads would be required and relatively minimal maintenance and washing of the solar panels would be required. As such, it is unlikely that the rooftop solar PV alternative would create erosion impacts. Some water would be required to wash the solar panels, especially with larger commercial rooftop solar installations; however, the commercial facilities would likely already be equipped with drainage systems. Therefore, the wash water would not contribute to runoff or to erosion.

Because most PV panels are black to absorb sun, rather than mirrored to reflect it, glare would be lessened. Additionally, the distributed solar PV alternative would not require the additional operational components, such as dry-cooling towers, substations, transmission interconnection, maintenance and operation facilities with corresponding visual impacts. Solar PV panels would be visible to passing residents and may be viewed by a larger number of people.

Consideration of CEQA/NEPA Criteria

Reduction of Impacts. Distributed solar technology is assumed to be located on already existing structures or disturbed areas so little to no new ground disturbance would be required; there would be few associated impacts to biological and cultural resources. Additionally, impacts to soils and waters as well as visual resources would be reduced.

Meet Most Project Objectives. A distributed solar technology alternative, if constructed at 250 MW, would meet the CEC project objectives to operate 250 MW of renewable power in California capable of selling competitively priced renewable energy. The solar technology would not necessarily meet the objective to locate the facility in areas of high solarity, because the distributed technology could be located throughout the State.

Feasibility. The rate of PV manufacturing and installation is expected to continue to grow very quickly. However, given that there are currently only about 500 MW of distributed solar PV in California, the addition of an additional 250 MW to eliminate the need for the Genesis Solar Energy Project cannot be guaranteed. This would require an even more aggressive deployment of PV at more than double the historic rate of solar PV than the California Solar Initiative program currently employs. Challenges to an accelerated implementation of distributed solar PV are discussed below.

- **RETI Consideration of Subsidies, Tariffs, Cost, and Manufacturing.** The RETI Discussion Draft Paper *California's Renewable Energy Goals – Assessing the Need for Additional Transmission Facilities* published with the RETI Final Phase 2A Report (September 2009), addresses the likelihood of a scenario of sufficient distributed solar PV to remove the need for utility scale renewable development. This discussion paper identified the factors likely to influence the pace of large scale deployment of distributed solar PV: subsidies, feed-in tariffs, manufacturing and installation cost, and manufacturing scale-up.
- **Cost.** The 2009 IEPR states that solar PV technology has shown dramatic cost reductions since 2007, and is expected to show the most improvement of all the technologies evaluated in the 2009 IEPR model, bringing its capital cost within range of that of natural gas-fired combined cycle units. However, the CPUC *33% Renewables Portfolio Standard Implementation Analysis Preliminary Results*

considered a number of cases to achieve a 33 percent RPS standard. The results of this study state that the cost of a high distributed generation case is significantly higher than the other 33 percent RPS alternative cases. The study explains that this is due to the heavy reliance on solar PV resources which are more expensive than wind and central station solar.

- **Tariffs**. Additionally, the IEPR discusses the need to adjust feed-in tariffs to keep downward pressure on costs. Feed-in tariffs should be developed based on the size and type of renewable resources, given that the cost of generating energy from a 100-MW wind farm is less than the cost of generating to ensure a good mix of new renewable energy projects. According to the report, differentiating feed-in tariffs by type and size can ensure a good mix of new renewable energy projects and avoid paying too much for some technologies and too little for others.
- **Limited Installations**. Examples of large scale distributed solar projects are still limited. In the spring of 2008, SCE proposed 250 to 500 MW of rooftop solar PV to be installed in five years. As of January 2010, SCE had installed only 3 MW. As the 2009 IEPR points out, the potential for distributed resources remains largely untapped and integrating large amounts of distributed renewable generation on distribution systems throughout the State presents challenges.
- **Electric Distribution System**. The State's electric distribution systems are not designed to easily accommodate large quantities of randomly installed distributed generation resources at customer sites. Accomplishing this objective efficiently and cost-effectively will require the development of a new transparent distribution planning framework.

The 2009 IEPR makes a number of recommendations to support the integration of distributed generation into the California grid, expand feed-in tariffs, and support the efforts to achieve the RPS goals as a whole. It also recommends supporting new renewable facilities and the necessary transmission corridors and lines to access the facilities.

In testimony filed by the Center for Biological Diversity in the Ivanpah Solar Electric Generating System (ISEGS) proceeding [Docket No. 07-AFC-5], Bill Powers stated his disagreement with the conclusions of the ISEGS Alternatives FSA/DEIS section addressing distributed solar PV. Powers believed that the technology and manufacturing capacity would be adequate to develop 400 MW of distributed PV, and that the distribution system would be able to accommodate the additional distributed generation. He presented numerous examples of California utility programs that have committed to development of hundreds of megawatts of additional distributed solar PV.

The conclusion of this section is that, while it will very likely be possible to achieve 250 MW of distributed solar energy over the coming years, the very limited numbers of existing facilities make it difficult to conclude with confidence that it will happen within the timeframe required for the GSEP. As a result, this technology is eliminated from detailed analysis in this SA/DEIS.

B.2.8.3 Alternative Renewable Technologies

Non-solar renewable generation technologies were considered as potential alternatives to the proposed project. The following renewable generation technologies were considered in this analysis:

- wind energy
- geothermal energy
- biomass energy
- tidal energy
- wave energy

The non-solar renewable technologies alternatives (wind, geothermal, biomass, tidal, wave) would either be infeasible at the scale of the GSEP, or would not eliminate significant impacts caused by the project without creating significant impacts in other locations. Specifically, wind and geothermal energy that would be viable at some locations in Riverside County could create significant impacts to biological, visual, cultural, and water and soils resources.

None of these non-solar renewable technologies would meet the BLM's purpose and need, which is to approve, modify, or deny the applicant's request for a right-of-way and to help develop an reliable supply of renewable energy in California. These technologies would be too great a departure from the application to be considered a modification of the applicant's proposal.

Wind Energy

Wind carries kinetic energy that can be utilized to spin the blades of a wind turbine rotor and an electrical generator, which then feed alternating current (AC) into the utility grid. Most state-of-the-art wind turbines operating today convert 35 to 40 percent of the wind's kinetic energy into electricity. A single 1.5-MW turbine operating at a 40 percent capacity factor generates 2,100 MWh annually.

Wind turbines currently being manufactured have power ratings ranging from 250 watts to 5 MW, and units larger than 7 MW in capacity are now under development (AWEA 2008). The average capacity of wind turbines installed in the United States in 2007 was 1.65 MW (EERE 2008). The perception of wind as an emerging energy source reached a peak in the early 1980s, when wind turbine generators to convert wind power into electricity were being installed in California at a rate of nearly 2,000 per year. Progress slowed a few years later, however, as start-up tax subsidies disappeared and experience demonstrated some deficiencies in design. At the present time, technological progress again has caught up, contributing lower cost, greater reliability, and reason for genuine optimism for this renewable energy source in the future.

The technology is now well developed and can be used to generate significant amounts of power. There are now approximately 2,490 MW of wind being generated in California (AWEA 2008).

Wind Resources at the GSEP Site. Wind resources are not viable at the GSEP site (BLM 2005a). The nearest medium to high wind resources are located immediately north of the GSEP site in a BLM designated wilderness area (BLM 2005a). Development of a wind project in wilderness is not a viable alternative.

San Gorgonio Pass. The nearest viable wind resource area to the GSEP site is the San Gorgonio Pass, northwest of Palm Springs. This is considered one of the best regions in California for producing wind energy. However, there is little undeveloped land remaining for expansion beyond the already existing wind farms (WAPA 2003). Because there is minimal expansion room, the wind industry is instead replacing the older turbines in the region with newer ones, called "repowering" (WAPA 2003). At one time, there were more than 4,000 turbines in the Pass but wind farm operators have been replacing smaller, less efficient machines with larger, more modern turbines that need less maintenance and that can harness (WAPA 2003).

Environmental Assessment. Wind turbines can create environmental impacts, as summarized below (AWEA 2008):

- Wind energy requires between 5 and 17 acres per MW of energy created. As such a nominal 250 MW power plant would require between 1,250 and 4,250 acres. However, wind turbine "footprints" typically occupy only 5 percent of the total area.
- Erosion can be a concern in certain habitats such as the desert or mountain ridgelines. Standard engineering practices can be used to reduce erosion potential.
- Birds collide with wind turbines. Avian deaths, particularly raptors, are a significant concern depending on raptor use of the area.
- Wind energy can negatively impact birds and other wildlife by fragmenting habitat, both through installation and operation of wind turbines themselves and through the roads and power lines that are required.
- Bats collide with wind turbines. The extent of bat mortality depends on turbine placement and bat flight patterns.
- Visual impacts of wind turbines can be significant, and installation in scenic and high traffic areas can result in strong local opposition. Other impressions of wind turbines are that they are attractive and represent clean energy.

Summary of Impacts. Approximately 1,250 to 4,250 acres of land would be required for a 250 MW wind electricity power plant. While wind plants would not necessarily impact the same types of wildlife and vegetation as the GSEP plant, the significant acreage necessary for a 250 MW wind plant would still cause significant habitat loss in addition to potentially significant impacts from habitat fragmentation and bird and bat mortality. Wind turbines are often over 400 feet high for 2-MW turbines. As such, any wind energy project would be highly visible.

Rationale for Elimination

While wind electricity generation is a viable and important renewable technology in California, it would not reduce the large-scale ground disturbance and visual impacts associated with the GSEP. Therefore wind generation was eliminated from further consideration.

Geothermal Energy

Geothermal technologies use steam or high-temperature water obtained from naturally occurring geothermal reservoirs to drive steam turbine/generators. There are vapor dominated resources (dry, super-heated steam) and liquid-dominated resources where various techniques are used to extract energy from the high-temperature water.

Geothermal plants account for approximately 5 percent of California's power and range in size from under 1 MW to 200 MW. California is the largest geothermal power producer in the United States, with about 1,800 MW installed capacity; in 2007, 13,000 gigawatt hours of electricity were produced in California (CEC 2008). Geothermal plants provide highly reliable baseload power, with capacity factors from 90 to 98 percent.

Geothermal plants must be built near geothermal reservoir sites because steam and hot water cannot be transported long distances without substantial thermal energy loss. Geothermal power plants are currently operating in the following California counties: Lake, Sonoma, Imperial, Inyo, Mono, and Lassen. The RETI Phase 1A Report (2008) estimated an incremental capacity of approximately 2,400 MW for the entire State by 2018.

Geothermal Resources at the GSEP Site. There are no viable geothermal resources at the GSEP site. The nearest medium or high geothermal resources are located in the Salton Sea region.

Geothermal Alternative Scenario. There is no single 250 MW geothermal project that would be viable as an alternative to the GSEP. Approximately 2-7 smaller projects would be required to achieve 250 MW of geothermal energy. The amount of land required for a geothermal facility varies greatly. Two hundred and fifty MW of geothermal energy could require the use of many thousands of acres of land. However, the amount of ground disturbance on that area would be less than 10 percent. Additionally, while components of the power plant, cooling towers and brine ponds would likely be fenced, there would not likely be fencing required for the wells and well pads. In that 2-7 geothermal facilities would be required for provision of 250 MW, depending on the locations of the new facilities, more transmission lines and switchyards with corresponding potential impacts (i.e., biological, cultural, soil & water, land use, visual) may be required for grid interconnection, when compared to the proposed GSEP.

Environmental Assessment. Concerns regarding geothermal power plants include air quality, hazardous materials, and geology. Benefits from geothermal power plants include an increased reliability and less ground disturbance than some renewable resources, including solar.

Air Quality. Toxic air contaminants and odors would be emitted as a result of fuel combustion in construction-related equipment and vehicles and as a result of geothermal steam released during well testing. Hydrogen sulfide (H_2S) in geothermal steam is a toxic air contaminant and a colorless, flammable, poisonous compound with a characteristic rotten-egg odor. Ammonia also occurs in geothermal steam and is a toxic air contaminant with a pungent, penetrating odor. Ammonia is also a precursor pollutant to particulate matter in the ambient air. Releasing geothermal steam during well testing

and development would cause substantial emissions of these toxic air contaminants and odors over the construction phase. Aside from closely managing the well testing schedule, few mitigation options are available, and the impact of toxic air contaminants and odors during construction would be significant and unavoidable.

Extracting power from geothermal steam equipment can cause emissions of ammonia and H_2S, which are odors and toxic air contaminants present in the geothermal brine. Ammonia emissions also react with ambient air to form inhalable PM10, and H_2S in the atmosphere will oxidize to SO_2 and sulfuric acid. Without proper control, emissions of these contaminants would cause increased health risks, create objectionable odors, and cause or substantially contribute to violations of H_2S and/or PM10 ambient air quality standards. These contaminants would be emitted during any short-term commissioning activities or uncontrolled releases of geothermal steam, but these impacts would be less than significant because they would be short-term and managed in accordance with permitting requirements.

Ammonia and H_2S emissions could be avoided with sulfur control systems and use of an air-cooling system to reduce cooling tower drift. Commonly, water cooling causes the geothermal fluid entering the cooling tower to be emitted to the atmosphere as water vapor, which results in high levels of ammonia and H_2S in the vapor from the cooling tower. However, a binary cycle plant emits only fresh water vapor from the cooling tower. Cool geothermal brine is injected into the ground after the energy is extracted.

Hazardous Materials. Geothermal plants can also produce waste and byproducts that can have significant impacts. The most potentially harmful gas generally encountered in geothermal systems is H_2S, which at concentrations higher than 30 parts per million (ppm) is toxic (CEC 2003). It can cause a variety of problems including dizziness, vomiting, and eventually death if one is exposed for long periods of time. In concentrations above 100 ppm, H_2S can be fatal. H_2S is heavier than air and can accumulate in low-lying areas (equipment pits, ravines, and other depressions) and become concentrated over time.

H_2S releases could potentially be of concern during drilling, well testing, and plant start-up and shut-down operations, although recent technology improvements in atmospheric separators can significantly decrease emissions and noise during these operations. H_2S is now often abated at geothermal power plants, resulting in a conversion of close to 100 percent of the H_2S into elemental sulfur (GEA 2007). Since 1976, H_2S emissions have decreased from 1,900 pounds per hour to 200 pounds per hour despite an increase in geothermal power production from 500 MW to 2,000 MW (GEA 2007).

One additional concern regarding hazardous materials present in geothermal facilities includes the possibility for bacterial growth to occur in the cooling tower, including Legionella. Legionella is a type of bacteria that grows in water and causes Legionellosis, otherwise known as Legionnaires' disease. Untreated or inadequately treated cooling systems in the United States have been correlated with outbreaks of Legionellosis. These outbreaks are usually associated with building heating, ventilating, and air conditioning (HVAC) systems but it is possible for growth to occur in industrial cooling towers. In order to ensure that Legionella growth is kept to a minimum, mitigation would require the project owner to prepare and implement a biocide and anti-

biofilm agent monitoring program to ensure that proper levels of biocide and other agents are maintained within the cooling tower water at all times, that periodic measurements of Legionella levels are conducted, and that periodic cleaning is conducted to remove bio-film buildup. With the use of an aggressive antibacterial program coupled with routine monitoring and biofilm removal, the chances of Legionella growing and dispersing would be reduced to insignificance.

Geology, Paleontology, and Minerals. Active seismicity and subsidence generally occur in areas with high levels of tectonic activity (e.g., volcanic regions, fault zones), which are the same areas in which geothermal resources occur; therefore, it is difficult to discern between power plant-induced and naturally occurring seismicity and subsidence. Drilling deep into the earth's crust to access high-temperature geothermal resources and subsequent re-injection of fluid into the geothermal reservoir may result in microearthquakes, which are generally below magnitude 2-3 on the Richter scale. These microearthquakes are typically centered on the injection site and are too low to be noticed by humans (Kagel 2007).

Land Use. Geothermal power projects require less ground disturbance than almost any other energy source, typically from about 0.2 to 0.5 acres per MW; however, geothermal plants must be built where the resource is since the steam cannot be piped long distances without significant heat loss. This results in a highly secure and predictable fuel supply and some inflexibility in siting. It may also result in a long interconnection requirement to reach a transmission system.

Because of the minimal ground disturbance required, impacts to biological resources and cultural resources would likely be minimized compared to the GSEP.

Reliability. Geothermal facilities may achieve a 95 percent or higher availability (CEC 2003). Because the geothermal steam is available throughout the day, geothermal facilities provide an adequate level of reliability throughout the entire day.

Rationale for Elimination

Geothermal generation is a commercially available technology and is important for California's renewable energy future because it provides baseload power that is available 24 hours a day. It also can be developed with substantially less ground disturbance than that needed for the GSEP, so impacts related to biological and cultural resources, water and soils resources, and traffic/transportation would reduced. However, despite the encouragement provided by Renewable Portfolio Standard targets and ARRA funding, few new projects have been proposed and no geothermal projects are included on the Renewable Energy Action Team list of projects requesting ARRA funds. Therefore, while the technology is clearly feasible and additional development is expected, the technology is not retained for detailed analysis in this SA/DEIS

Biomass Energy

Electricity can be generated by burning organic fuels in a boiler to produce steam, which then turns a turbine; this is biomass generation. Biomass can also be converted into a fuel gas such as methane and burned to generate power. Wood is the most commonly used biomass for power generation. Major biomass fuels include forestry and mill

wastes, agricultural field crop and food processing wastes, and construction and urban wood wastes. Several techniques are used to convert these fuels to electricity, including direct combustion, gasification, and anaerobic fermentation. Biomass facilities do not require the extensive amount of land required by the other renewable energy sources discussed, but they generate much smaller amounts of electricity.

Currently, nearly 19 percent of the state's renewable electricity derives from biomass and waste-to-energy sources (CEC 2007). Most biomass plant capacities are in the 3- to 10-MW range and typically operate as baseload capacity. The average size of a sales generation biomass plant is 21 MW (CBEA 2008). Unlike other renewables, the locational flexibility of biomass facilities would reduce the need for significant transmission investments. Solid fuel biomass (555 MW) makes up about 1.75 percent of the state's electricity, and landfill gas generation (260 MW) makes up about 0.75 percent. Existing landfills not now producing electricity from gas could add a maximum of about 170 MW of new generation capacity (CBEA 2008).

Biomass Resources at the GSEP Site. Biomass resources are not viable at the GSEP site (NREL 2009) due to its remote location and distance from the agricultural production areas surrounding Blythe. Transportation of agricultural waste to this site would result in generation of additional vehicle emissions that would offset the potential benefits of using a renewable fuel.

Environmental Assessment. Generally, small amounts of land are required for biomass power facilities; however, a biomass facility should be sited near a relatively large source of biomass in order to minimize the cost and impacts of bringing the biomass waste to the facility.

Operational noise impacts may be a concern, originating from truck engines as a result hauling operations coming from and going to the facility repeatedly on a daily basis. Other operations of the biomass facilities, while internal to the main structure, can result in increased noise due to the material grinding equipment.

The emissions due to biomass fuel-fired power plant operation are generally unavoidable. Direct impacts of criteria pollutants could cause or contribute to a violation of the ambient air quality standards. Significant impacts can potentially occur for PM10 and ozone because emissions of particulate matter and precursors and ozone precursors would contribute to existing violations of the PM10 and ozone standards. Biomass/biogas facility emissions could also adversely affect visibility and vegetation in federal Class I areas or state wilderness areas, which would significantly deteriorate air quality related values in the wilderness areas. Toxic air contaminants from routine operation would also cause health risks that could locally adversely affect sensitive receptors.

Rationale for Elimination

Most biomass facilities produce only small amounts of electricity (in the range of 3 to 10 MW) and so could not meet project objectives. Biomass facilities also generate significant air emissions and require numerous truck deliveries to supply the plant with the waste. Also, in waste-to-energy facilities, there is some concern regarding the emission of toxic chemicals, such as dioxin, and the disposal of the toxic ash that

results from biomass burning. Therefore, this technology is not analyzed in detail as an alternative to the GSEP project.

Tidal Energy

The oldest technology to harness tidal power for the generation of electricity involves building a dam, known as a *barrage*, across a bay or estuary that has large differences in elevation between high and low tides. Water retained behind a dam at high tide generates a power head sufficient to generate electricity as the tide ebbs and water released from within the dam turns conventional turbines.

Certain coastal regions experience higher tides than others. This is a result of the amplification of tides caused by local geographical features such as bays and inlets. In order to produce practical amounts of power for tidal barrages, a difference between high and low tides of at least 5 meters is required. There are about 40 sites around the world with this magnitude of tidal range. The higher the tides, the more electricity can be generated from a given site and the lower the cost of electricity produced. Worldwide, existing power plants include a 240-MW plant in France, a 20-MW plant in Nova Scotia, and a 0.5-MW plant in Russia (EPRI 2006).

Tidal Fences

Tidal fences are effectively barrages that completely block a channel. If deployed across the mouth of an estuary, they can be very environmentally destructive. However, in the 1990s, their deployment in channels between small islands or in straits between the mainland and islands was increasingly considered a viable option for generation of large amounts of electricity.

The advantage of a tidal fence is that all the electrical equipment (generators and transformers) can be kept high above the water. Also, by decreasing the cross-section of the channel, current velocity through the turbines is significantly increased.

The United Kingdom is currently considering the feasibility of tidal energy across the Bristol Channel. The feasibility study began with the consideration of the Severn tidal barrage. The barrage would work similarly to a dam which generates hydroelectric power by holding water back before it is allowed to flow at speed through a pipe at the base of the dam to drive the turbines (BBC 2007). Since then, alternative tidal projects have been proposed, including a tidal fence that would allow shipping to move freely and keep ports at Cardiff and Bristol open (BBC 2008). The results of the feasibility study are expected to be published in 2010; however, preliminary results from the Sustainable Development Commission confirmed the potential of the huge Severn tidal range to generate approximately 5 percent of United Kingdom’s electricity (BIS 2009).

Tidal Turbines

Tidal turbines are the chief competition to the tidal fence. Looking like an underwater wind turbine, they offer a number of advantages over the tidal fence. They are less disruptive to wildlife, allow small boats to continue to use the area, and have much lower material requirements than the fence.

Tidal turbines function well where coastal currents run at 2 to 2.5 meters per second (slower currents tend to be uneconomic while larger ones stress the equipment). Such currents provide an energy density four times greater than air, meaning that a 15-meter-diameter turbine will generate as much energy as a 60-meter-diameter windmill. In addition, tidal currents are both predictable and reliable, a feature which gives them an advantage over both wind and solar systems. The tidal turbine also offers significant environmental advantages over wind and solar systems; the majority of the assembly is hidden below the waterline, and all cabling is along the sea bed.

There are many sites around the world where tidal turbines could be effectively installed. The ideal site is close to shore (within 1 kilometer) in water depths of about 20 to 30 meters. In April 2007, the first major tidal-power project was installed in the United States off New York City's Roosevelt Island (Fairley 2007). The Roosevelt Island Tidal Energy (RITE) project completed the Phase 2 Demonstration at the end of 2008. This phase included operating six full-scale turbines and resulted in 70 MW hours of energy delivered to two end users (Verdant 2009). Phase 3 of the RITE project is currently underway, and Verdant Power applied to the Federal Energy Regulatory Commission for a pilot license in November 2008. If granted, this license would allow Verdant Power to build out the RITE Project in the east channel of the East River to a 30-turbine 1 MW pilot project and to commercially deliver the energy generated by the field (Verdant 2009).

Turbines such as those used in New York City use in-flow turbines, thereby lessening the environmental impacts. A study conducted in 2006, *System Level Design, Performance, Cost and Economic Assessment – San Francisco Tidal In-Stream Power Plant*, concluded that a tidal plant located under the Golden Gate Bridge could create approximately 35 MW of power with no significant impacts to the environment and recommended further research and development into both ocean energy technology and a pilot project in San Francisco (EPRI 2006a).

Environmental Assessment. Tidal technologies, especially tidal fences, have the potential to cause significant biological impacts, especially to marine species and habitats. Fish could be caught in the unit's fins by the sudden drop in pressure near the unit. The passageways, more than 15 feet high and probably sitting on the bay floor, could squeeze out marine life that lives there or alter the tidal flow, sediment build-up, and the ecosystem in general. Even the in-flow turbines can have environmental impacts on marine systems. The in-flow turbines off New York City underwent environmental monitoring for 18 months to ensure the turbines would not create environmental impacts to the river's marine wildlife. The results thus far show no observed evidence of increased fish mortality or injury; however, Verdant will continue to monitor activities during the Phase 3 build-out of the project to analyze impact from larger arrays (Verdant 2009). Also, depending on the location of the tidal technology, commercial shipping could be disrupted during construction.

The reduced tidal range (difference between high and low water levels) resulting from tidal energy generation can destroy inter-tidal habitat used by wading birds. Sediment trapped behind the barrage could also reduce the volume of the estuary over time.

Rationale for Elimination

Tidal fence technology is a commercially available technology in Europe, although limited to areas that are adjacent to a body of water with a large difference between high and low tides, and it creates significant environmental impacts to ocean ecosystems. In-flow tidal turbines are a relatively new technology and are not considered an alternative to the GSEP project because they are an unproven technology at the scale that would be required to replace the proposed project. Additionally, the environmental impacts of tidal turbines are still under review, as demonstrated by the pilot project under continued environmental monitoring in New York. Therefore, this technology is not analyzed in detail in this SA/DEIS as an alternative to the GSEP.

Wave Energy

Wave power technologies have been around for nearly 30 years. Setbacks and a general lack of confidence have contributed to slow progress towards proven devices that would have a good probability of becoming commercial sources of electrical power.

The highest energy waves are concentrated off the western coasts in the 40^{o} to 60^{o} latitude range north and south. The power in the wave fronts varies in these areas between 30 and 70 kilowatts per meter (kW/m) with peaks up to 100 kW/m in the Atlantic southwest of Ireland, the Southern Ocean and off Cape Horn. Many wave energy devices are still in the research and development stage and would require large amounts of capital to get started. Additional costs from permitting and environmental assessments also make wave energy problematic (WEC 2007). Nonetheless, wave energy is likely to increase in use within the next 5 to 10 years.

The total power of waves breaking on the world's coastlines is estimated at 2 to 3 million megawatts. In favorable locations, wave energy density can average 65 MW per mile of coastline. Three approaches to capturing wave energy are:

- **Floats or Pitching Devices.** These devices generate electricity from the bobbing or pitching action of a floating object. The object can be mounted to a floating raft or to a device fixed on the ocean floor.
- **Oscillating Water Columns.** These devices generate electricity from the wave-driven rise and fall of water in a cylindrical shaft. The rising and falling water column drives air into and out of the top of the shaft, powering an air-driven turbine.
- **Wave Surge or Focusing Devices.** These shoreline devices, also called "tapered channel" or "tapchan" systems, rely on a shore-mounted structure to channel and concentrate the waves, driving them into an elevated reservoir. Water flow out of this reservoir is used to generate electricity, using standard hydropower technologies.

In December 2007, PG&E signed a power purchase agreement with Finavera Renewables, which had planned to operate a wave farm approximately 2.5 miles off the coast of Eureka, California. The agreement was for 2 MW of power beginning in 2012. On October 16, 2008, the California Public Utilities Commission rejected PG&E's request for approval of a renewable resource procurement contract with Finavery Renewables because, among other reasons, the CPUC concluded the project had not been shown to be viable. As stated in the decision, there is significant uncertainty

surrounding wave technology and the wave energy industry is at a beginning stage (CPUC 2008). The CPUC did authorize up to $4.8 million for PG&E to undertake its WaveConnect project in D.09-01-036. WaveConnect is designed to document the feasibility of a facility that converts wave energy into electricity by using wave energy conversion (WEC) devices in the open ocean adjacent to PG&E's service territory.

In January 2010, the California State Lands Commission and the Federal Energy Regulatory Commission issued a Request for Statements of Interest to prepare an environmental document for the PG&E WaveConnect project discussed above. PG&E has selected a wave energy project siting area that is between 2.5 and 3.0 nautical miles (nm) from the shore in Humboldt County. WaveConnect consists of: (1) wave energy converters (WECs) including multi-point catenary moorings and anchors; (2) marker buoys, navigation lights, and environmental monitoring instruments; (3) subsea electrical cables extending on-shore to (4) land-based power conditioning equipment; (5) an above-ground transmission line and interconnection to the electrical grid; (6) data acquisition and telemetry equipment; and (7) security and safety equipment.

Environmental Assessment. The environmental impacts of wave power have yet to be fully analyzed. A recent study published by the U.S. Department of Commerce and National Oceanic and Atmospheric Administration listed a number of potentially significant environmental impacts created by wave power (Boehlert 2008). These include (Boehlert 2008):

- Significant reduction to waves with possible effects to beaches (e.g. changes to sediment transport processes).
- The use of buoys may have positive effects on forage fish species, which in turn could attract larger predators. Structures need to reduce potential entanglement of larger predators, especially marine turtle species.
- Modifications to water circulation and currents may result in changes to larval distribution and sediment transport.
- Wave energy development may affect community structures for fish and fisheries.
- Lighting and above-water structures may result in marine bird attraction and collisions and may alter food webs and beach processes.
- A diversity of concerns would arise regarding marine mammals including entanglement issues.
- Energy-absorbing structures may affect numerous receptors and should avoid sensitive habitats.
- Chemicals used in the process must be addressed both for spills and for a continuous release such as in fouling paints.
- New hard structures and lighting may break loose and increase debris accumulation.
- Impacts on fish and marine mammals caused by noise coming from the buoys should be understood and mitigated.
- Electromagnetic effects may affect feeding or orientation and should be better understood.

- Impact thresholds need to be established. As projects scale up in location or implementation, new risks may become evident.

Rationale for Elimination

Wave energy is new and may not be technologically feasible; as stated above, PG&E is proposing to sponsor a project to test the feasibility of harnessing wave energy. Additionally, wave power must be located where waves are consistently strong; even then, the production of power depends on the size of waves, which result in large differences in the amount of energy produced. Wave technology is not considered an alternative to the GSEP because is an unproven technology at the scale that would be required to replace the proposed project and because it may also result in substantial adverse environmental impacts. Therefore, this technology is not analyzed in detail in this SA/DEIS as an alternative to the GSEP.

B.2.8.4 Alternative Methods of Generating or Conserving Electricity

Nonrenewable generation technologies that require use of natural gas, coal, or nuclear energy would not achieve the key project objective for GSEP: to construct and operate an approximately 250 MW project that would contribute clean, renewable solar energy to the State of California's renewable energy goals.

These generation technologies would not be practical at the GSEP site due to the lack of available fuels at the site and the distance of the site from major access roads. While these generation technologies would not achieve this key objective, nor would they be practical at the GSEP site, they are presented here in brief for the benefit of the public and decision makers. Conservation and demand-side management is also briefly addressed in this section.

The following topics are considered in this analysis:

- natural gas
- coal
- nuclear energy
- conservation and demand-side management

Of the nonrenewable generation alternatives (natural gas, coal, and nuclear), only the natural gas-fired power plants would be viable alternatives within California. However, gas-fired plants would fail to meet a major project objective: to construct and operate a renewable power generating facility in California capable of selling competitively priced renewable energy consistent with the needs of California utilities, and would therefore not achieve the purpose and need of the project. Because these alternatives would not support renewable power generation within California, and could have significant environmental impacts of their own, they were eliminated from further consideration.

None of these non-renewable energy technologies would meet the BLM's purpose and need, which is to approve, modify, or deny the applicant's request for a right-of-way and to help develop reliable sources of renewable energy in California. These technologies

would be too great a departure from the application to be considered a modification of the applicant's proposal

Natural Gas Generation

Natural gas power generation accounts for approximately 22 percent of all the energy used in the United States and comprises 40 percent of the power generated in California (CEC 2007). Natural gas power plants typically consist of combustion turbine generators, heat recovery steam generators, a steam turbine generator, wet or dry cooling towers, and associated support equipment. An interconnection with a natural gas pipeline, a water supply, and electric transmission are also required.

A gas-fired power plant generating 250 MW would generally require less than 50 acres of land.

Environmental Assessment. Natural gas power plants may result in numerous environmental impacts such as the following.

- Overall air quality impacts would increase because natural gas-fired power plants contribute to local violations of PM10 and ozone ambient air quality standards, and operational emissions could result in toxic air contaminants that could adversely affect sensitive receptors. Net increases in greenhouse gas emissions due to natural gas-firing in the conventional power plants would also be significant.
- Environmental justice may be a concern. Gas-fired power plants tend to be located in developed urban areas that are zoned for heavy industry. In some instances, low-income and minority populations are also located in such areas.
- In order to avoid land use impacts, natural gas-fired power plants must be consistent with local jurisdiction zoning.
- Several hazardous materials, including regulated substances (aqueous ammonia, hydrogen, and sulfuric acid), would be stored at a natural gas power plant during operation. Aqueous ammonia would be stored in amounts above the threshold quantity during the final stages of construction, initial start-up, and operations phase. Transport of hazardous materials during power plant operation includes delivery of aqueous ammonia and removal of wastes. During operation, the aqueous ammonia transporter would be required to obtain a Hazardous Material Transportation License in accordance with California Vehicle Code section 32105 and would be required to follow appropriate safety procedures and routes.
- Cultural impacts can be severe depending on the power plant siting; however, because natural gas power plants require significantly fewer acres per megawatt of power generated, impacts to cultural resources would be expected to be fewer than with solar facilities.
- Power plant siting may result in the withdrawal of agricultural lands. However, because natural gas power plants require significantly fewer acres per megawatt of power generated, impacts to agriculture would be expected to be less than with solar facilities should they be sited on agricultural lands.
- Visual impacts may occur with natural gas power plants because they introduce large structures with industrial character. The most prominent structures are

frequently the cooling towers, which may reach 100 feet tall, and the power plant stacks, which may reach over 100 feet tall. Visible plumes from the cooling tower would also potentially occur.

Rationale for Elimination

Although natural gas generation is clearly a viable technology, it is not a renewable technology, so it would not attain the objective of generating renewable power meeting California's renewable energy needs. The air quality impacts of gas-fired plants include emission of greenhouse gases and are one major reason that California's Renewable Portfolio Standard was developed. Therefore, this alternative is not considered in detail as an alternative to the GSEP.

Coal Generation

Coal-fired electric generating plants are the cornerstone of America's central power system. Traditional coal-fired plants generate large amounts of greenhouse gases. New "clean coal technology" includes a variety of energy processes that reduce air emission and other pollutants from coal-burning power plants. The Clean Coal Power Initiative is providing government co-financing for new coal technologies that help utilities meet the Clear Skies Initiative to cut sulfur, nitrogen, and mercury pollutants by nearly 70 percent by 2018. The Clean Coal Power Initiative is now focusing on developing projects that utilize carbon sequestration technologies and/or beneficial reuse of carbon dioxide (DOE 2008). However, these technologies are not yet in use.

In 2006, approximately 15.7 percent of the energy used in California came from coal fired sources; 38 percent of this was generated in state, and 62 percent was imported (CEC 2007). The in-state coal-fired generation includes electricity generated from out-of-state, coal-fired power plants owned by and reported by California utilities (CEC 2007). In 2006, California enacted SB 1368 (Perata, Chapter 598, Statutes of 2006), which prohibits utilities from making long-term commitments for electricity generated from plants that create more carbon dioxide (CO_2) than clean-burning natural gas plants (CEC 2007).

Environmental Assessment. Coal-fired power plants may also result in numerous environmental impacts such as the following.

- Overall, air quality impacts would increase because coal-fired power plants contribute carbon dioxide, sulfur dioxide, nitrogen oxides, mercury, and fly ash (USEPA 2008a). Mining, cleaning, and transporting coal to the power plants generates additional emissions. Average emissions of a coal-fired power plant are 2,249 pounds per megawatt hour of carbon dioxide, 13 pounds per megawatt hour of sulfur dioxide and 6 pounds per megawatt hour of nitrogen oxides (EPA 2008a). Net increases in greenhouse gas emissions due to coal-firing in the conventional power plants would be significant.
- Health risks associated with power plants have also been documented, including problems associated with exposure to fine particle pollution or soot, an increase in asthma, and an increase in non-fatal heart attacks.

- Large quantities of water are generally required to produce steam and for cooling. When coal-fired power plants use water from a lake or river, fish or other aquatic life can be impacted (EPA 2008).

Rationale for Elimination

Although coal generation is a viable technology, it is not a renewable technology, so it would not attain the objective of generating renewable power meeting California's renewable energy needs. Existing technology for coal-fired plants results in high greenhouse gas emissions. Therefore, coal generation was eliminated from detailed analysis.

Nuclear Energy

Due to environmental and safety concerns, California law currently prohibits the construction of any new nuclear power plants in California until the California Energy Commission finds that the federal government has approved and there exists a demonstrated technology for the permanent disposal of spent fuel from these facilities (CEC 2006). In June 1976, California enacted legislation directing the Energy Commission to perform an independent investigation of the nuclear fuel cycle. This investigation was to assess whether the technology to reprocess nuclear fuel rods or to dispose of permanently high-level nuclear waste had been demonstrated and approved and was operational (Public Resources Code §§ 25524.1 (a)(1), 25524.1 (b), and 25524.2 (a)). After extensive public hearings, the Energy Commission determined that it could not make the requisite affirmative findings concerning either reprocessing of nuclear fuel or disposal of high-level waste. This information was published in a report: *Status of Nuclear Fuel Reprocessing, Spent Fuel Storage and High-level Waste Disposal*, Energy Commission publication P102-78-001, January 1978.) As a result, the development of new nuclear energy facilities in California was prohibited by law.

It has been more than 25 years since the last comprehensive Energy Commission assessment of nuclear power issues. The *Nuclear Power in California: 2007 Status Report*, published in October of 2007, gives a detailed description of the current nuclear waste issues and their implications for California. This was prepared as part of the development of the Energy Commission's *2007 Integrated Energy Policy Report* (CEC 2007a).

Rationale for Elimination

The permitting of new nuclear facilities in California is currently illegal, so this technology is infeasible.

Conservation and Demand-Side Management

Conservation and demand-side management consist of a variety of approaches to reduction of electricity use, including energy efficiency and conservation, building and appliance standards, and load management and fuel substitution. In 2005 the Energy Commission and CPUC's Energy Action Plan II declared cost-effective energy efficiency as the resource of first choice for meeting California's energy needs. The Energy Commission noted that energy efficiency helped flatten the state's per capita electricity use and saved consumers more than $56 billion since 1978 (CPUC 2008). The

investor-owned utilities' 2006-2008 efficiency portfolio marks the single-largest energy efficiency campaign in U.S. history, with a $2 billion investment by California's energy ratepayers (CPUC 2008). However, with population growth, increasing demand for energy, and the need to reduce greenhouse gases, there is a greater need for energy efficiency.

The CPUC, with support from the Governor's Office, the Energy Commission, and the California Air Resources Board, among others, adopted the California Long-Term Energy Efficiency Strategy Plan for 2009 to 2020 in September 2008 (CPUC 2008). The plan is a framework for all sectors in California including industry, agriculture, large and small businesses, and households. Major goals of the plan include:

- All new residential construction will be zero net energy by 2020;
- All new commercial construction will be zero net energy by 2030;
- Heating, ventilation, and air conditioning industries will be re-shaped to deliver maximum performance systems;
- Eligible low-income customers will be able to participate in the Low Income Energy Efficiency program and will be provided with cost-effective energy efficiency measures in their residences by 2020.

Rationale for Elimination

Conservation and demand-side management is important for California's energy future and cost effective energy efficiency is considered as the resource of first choice for meeting California's energy needs. However, with population growth and increasing demand for energy, conservation and demand-management alone is not sufficient to address all of California's energy needs. Additionally, it will not provide the renewable energy required to meet the California Renewable Portfolio Standard requirements, so technologies, like solar thermal generation, would be required.

B.2.9 CONCLUSIONS OF ALTERNATIVES ANALYSIS

In this analysis of the GSEP, 25 alternatives to the proposed GSEP were developed and evaluated. These include six alternative sites, solar and renewable technologies, generation technologies using different fuels, and conservation/demand-side management. Of the 25 alternatives, two alternatives were determined to be feasible by the Bureau of Land Management (BLM) and the Energy Commission and have the potential to result in reduced impacts in comparison with the proposed project: the Reduced Acreage Alternative and the Dry Cooling Alternative. Additionally the BLM and Energy Commission considered the No Project/No Action Alternative.

The Reduced Acreage Alternative would be half as large as the proposed project and was found to reduce the impacts of the proposed GSEP by approximately 50 percent. It would affect substantially less Mojave fringe-toed lizard habitat, would substantially reduce the geomorphic impacts, and would create no impacts to the Chuckwalla and Palen-McCoy sand corridors. However, as highlighted in the Section C.1 (Air Quality), the Reduced Acreage Alternative would reduce the benefits of the proposed GSEP by approximately 50 percent. While the Reduced Acreage Alternative would meet most project objectives, it is uncertain whether the Reduced Acreage Alternative is

economically feasible at this time. As with the proposed GSEP, a land use plan amendment to the California Desert Conservation Area (CDCA) Plan of 1980 would be required before BLM could issue the ROW grant for the Reduced Acreage Alternative.

The Dry Cooling Alternative was found to have similar impacts for most resource elements. However, it would reduce impacts to groundwater-dependent ecosystems, use substantially less water than the proposed project, and reduce impacts of the visible vapor plumes that the proposed project would create with use of cooling towers. The Dry Cooling Alternative was found to reduce the efficiency of the steam power cycles, which would slightly reduce the total amount of power generated. As a result, the benefits of the GSEP in replacing gas-fired power plants and associated greenhouse gases would be reduced. The Dry Cooling Alternative meets most project objectives. At this time, it appears to be economically feasible as alternative to GESP's use of wet cooling. As with the proposed GSEP, a land use plan amendment to the California Desert Conservation Area (CDCA) Plan of 1980 would be required before BLM could issue the ROW grant for the Dry Cooling Alternative.

One site alternative is evaluated in detail by the Energy Commission in this SA/DEIS under the California Environmental Quality Act (CEQA) only: the Gabrych Alternative site. While the impacts of this site would be similar to those of the proposed site in many resource elements, the alternative site is likely to have less severe cultural impacts and would also have reduced impacts to biological resources.

All six site alternatives are considered unreasonable by the BLM because they would not meet BLM's Purpose and Need, which is to respond to the applicant's request for a right-of-way by granting, granting a modified, or not granting the right of way, or are otherwise unreasonable alternatives under NEPA, as discussed above.

Alternative solar thermal technologies (Stirling engine systems, solar power tower, utility scale solar photovoltaics, and linear Fresnel) were also evaluated. As compared with the proposed GSEP, these technologies would not substantially change the severity of visual, biological resources and cultural resources impacts, although the land requirements vary among the technologies. Rooftop solar PV facilities would require extensive acreage although it would minimize the need for undisturbed or vacant land. However, increased deployment of rooftop solar PV faces challenges in manufacturing capacity, cost, and policy implementation. These alternatives also do not meet the BLM's purpose and need because they would be too great a departure from the application to be considered a modification of the application.

Other generation technologies (wind, geothermal, biomass, tidal, wave, natural gas, and nuclear) were also examined as possible alternatives to the proposed GSEP. These technologies would either be infeasible at the scale of the GSEP, or would not eliminate substantial adverse impacts caused by the GSEP without creating their own substantial adverse impacts in other locations. These alternatives also do not meet the BLM's purpose and need because they would be too great a departure from the application to be considered a modification of the application. A natural gas plant would contribute to greenhouse gas emissions and would not meet the project's renewable generation objective. Construction of new nuclear power plants is currently prohibited under California law.

Conservation and demand side management programs would likely not meet the state's growing electricity needs that could be served by the GSEP. In addition, these programs would not provide the renewable energy required to meet the California Renewable Portfolio Standard requirements.

CEC Staff also concludes that the No Project/No Action Alternative is not superior to the proposed project. This alternative would likely delay development of renewable resources or shift renewable development to other similar areas, and would lead to increased operation of existing power plants that use non-renewable technologies.

APPENDICES TO ALTERNATIVES SECTION

1. List of bio species on Gabrych Alternative
2. LESA model results for Gabrych Alternative

APPENDIX A
Sensitive Species Potentially Occurring in the Vicinity of the Genesis Solar Project and Potential Alternatives

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
PLANTS					
Angel trumpets *(Acleisanthes longiflora)*	Federal – None State – None CNPS List 2.2	Sonoran Desert Scrub generally on limestone, mountains or base of mountains at elevations of 0-2500 m. Blooms April through May.	None – no limestone or rocky habitat; not observed. Two occurrences in CA from 1906 and 1970 at same location at base of Big Maria Mts, north of Blythe; to TX and northern MX.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
Chaparral sand verbena (*Abronia villosa* var. *aurita*)	Federal – None State – None CNPS – 1B.1	Found in chaparral, coastal sage scrub, and desert dunes, loose to aeolian sands at elevations of 80-1600m. Blooms January through September.	Highly unlikely/Not observed	Low. Very little suitable habitat exists on site.	Low. Very little suitable habitat exists on site.
Desert sand-parsley (*Ammoselinum giganteum*)	Federal – None State – None CNPS List 2.3	Sonoran Desert, in creosote bush scrub, desert mesa and valley bottoms in open to heavy soils under shrubs 396 m. Herbaceous annual that blooms March through April.	Highly unlikely, but possible. Not observed. Known from one site, near Hayfield Dry Lake at 366 m.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Small-flowered androstephium (*Androstephium breviflorum*)	Federal – None State – None CNPS List 2.2	Perennial herb, primarily found in open sandy flats and bajadas, often stabilized blowsand, at low to moderate elevations (between 270 and 640m). Blooms in March possibly through May. Relatively short period of active growth, distribution in California poorly documented.	Would not be expected – all known locations well to north and generally higher; not observed.	Low. Suitable habitat on site, however site elevation likely to low.	Low. Suitable habitat on site, however site elevation likely to low.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Harwood's milkvetch (*Astragalus insularis* var. *harwoodii*)	Federal – None State – None CNPS List 2.2	Sonoran Desert, sandy to gravelly areas 0 to 366 m. Annual that blooms January through May	Observed during surveys	Moderate to high. Suitable habitat exists on site but species was not observed during rare plant surveys.	Low. Little suitable habitat occurs on site.
Coachella Valley milkvetch (*Astragalus lentiginosus* var. *coachellae*)	Federal – Endangered State – None CNPS List 1B.2	Sonoran Desert, in sandy areas growing at elevations of 0 to 350m. Annual or perennial herb that flowers February through May.	Highly unlikely; no known nearby populations (population in Chuckwalla Valley misidentified)/Not observed	Low. No known nearby populations.	Very low. Suitable habitat does not exist on site.
Ayenia (*Ayenia compacta*)	Federal – None State – None CNPS List 2.3	Sandy and gravelly washes and canyons in desert scrubs, 150 – 1095m. Blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site, but site is just below the low end of the species' elevation range.	Very low. Suitable habitat does not exist on site.
Pink fairyduster (*Calliandra eriophylla*)	Federal – None State – None CNPS List 2.3	Sonoran Desert, sandy washes, slopes, and mesas typically found at ± 1500m. Shrub <1 foot in height; blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Sand evening primrose (*Camissonia arenaria*)	Federal – None State – None CNPS List 2.2	Sandy washes and rocky slopes below 900 m. Blooms November through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Crucifixion thorn (*Castela emoryi*)	Federal – None State – None CNPS List 2.3	Mojavean and Sonoran desert scrub on dry, gravelly washes, slopes, plains ±650m Shrub <10 feet in height; blooms April through May.	Unlikely/Not observed	Low. Habitat is suitable but site elevation is too low.	Very low. Suitable habitat does not exist on site.
Abram's spurge (*Chamaesyce abramsiana*)	Federal – None State – None CNPS List 2.2	Sandy sites in Mojavean and Sonoran Desert Scrubs in eastern California; 0 – 915m. Blooms September through November.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Arizona spurge (*Chamaesyce arizonica*)	Federal – None State – None CNPS List 2.3	Sandy flats in Sonoran Desert Scrub below ~ 300m. Blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Flat-seeded spurge (*Chamaesyce platysperma*)	Federal – None State – None CNPS List 2	Sandy flats in Sonoran Desert Scrub below ~ 100m. Blooms February through September.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Las Animas colubrine (*Colubrina californica*)	Federal – None State – None CNPS List 2.3	Sonoran Desert creosote bush scrub <1100m in deeper, well incised washes. Plants are generally <1 m in height; blooms June through July.	Observed north of project area in Zone of Influence surveys	Moderate. Some suitable habitat occurs on site.	Very low. Suitable habitat does not exist on site.
Spiny abrojo (*Condalia globosa* var. *pubescens*)	Federal – None State – None CNPS List 4.2	Sonoran Creosote Bush Scrub, 150 to 1000m. Blooms March through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Foxtail cactus (*Coryphantha alversonii*)	Federal – None State – None CNPS List 4.3	Primarily rocky substrates between 75 and 1200m in Creosote Bush Scrub.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Winged cryptantha *(Cryptantha holoptera)*	Federal – None State – None CNPS List 4.3	CNPS: 100-1690 m, Moj. And Son. D. scrubs; Jepson: 100-1200 m in eastern Moj. And Son. D.; sandy to rocky soils; creosote bush scrub San Diego to Inyo Cos., including Los Angeles, San Bernardino, Riverside, and Imperial Cos., to AZ, NV, and Sonora, MX.	Possible, but not observed. CalFlora has 11 Riverside Co. records, 9 Imperial Co. records, and 7 San Bernardino Co. records, none within miles of the Genesis Project. (Note: The NECO Plan stated that there were no records in the NECO Planning Area and there are no nearby records in the CNDDB data base. However, there is a 1992 location near McCoy Spring.)	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Wiggins' cholla (*Cylindropuntia wigginsii*)	Federal – None State – None CNPS List 3.3	Sonoran Creosote Bush Scrub; 30 – 900m. Blooms in March.	Possibly observed during surveys.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Glandular ditaxis (*Ditaxis claryana*)	Federal – None State – None CNPS List 2.2	Sonoran Desert at elevations <465m in sandy soils in creosote bush scrub Annual or perennial herb; blooms from December through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
California ditaxis (*Ditaxis serrata* var. *californica*)	Federal – None State – None CNPS List 3.2	Sonoran creosote bush scrub from 30 – 1000 m. Blooms March through December.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Harwood's phlox (*Eriastrum harwoodii*)	Federal – None State – None CNPS List 1B.2	Desert slopes below 2200m, eastern Riverside and San Bernardino Counties.	Possibly observed during Zone of Influence surveys; however, now flower to positively ID	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Bitter hymenoxys *(Hymenoxys odorata)*	Federal – None State – None CNPS List 2	Sandy flats near the Colorado River. An annual herb producing a branching stem to a maximum height near 60 centimeters. Blooms February to November.	Highly unlikely – known only from the Colorado River alluvial plain; not observed	Very low. Known only from the Colorado River alluvial plain.	Moderate. Site is adjacent to the Colorado River and supports some potentially suitable habitat. CNDDB records for this species occur 2.5 miles west, near Palo Verde.
Pink velvet-mallow (*Horsfordia alata*)	Federal – None State – None CNPS List 4.3	Perennial subshrub, Sonoran Desert at elevations of 100–500 m. in rocky canyons, creosote-bush scrub, washes. Blooms from Mar–Apr, Nov–Dec	None – no rocky habitat on project; not observed	Low to moderate. Suitable habitat (creosote bush scrub) occurs on site, though species was not observed during surveys.	Very low. Suitable habitat does not exist on site.
Spearleaf (*Matelea parvifolia*)	Federal – None State – None CNPS List 2.3	Rocky ledges and slopes, 440 to 1095m, in Mojave and Sonoran Desert Scrubs. Blooms March through May.	Unlikely; no habitat/Not observed	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Argus blazing star (*Mentzelia puberla*)	Federal – None State – None CNPS List 2	Perennial herb found on rocky or gravelly sites in creosote bush scrub below 760m. Ord/Chocolate Mountains to AZ and northern Mexico. Blooms from March – May.	Highly unlikely based on habitat and range; not observed.	Low. Outside of known range.	Very low. Suitable habitat does not exist on site.
Slender woolly-heads (*Nemacaulis denudate* var. *gracilis*)	Federal – None State – None CNPS List 2.2	Dunes in coastal and Sonoran Desert scrubs, primarily in the Coachella Valley; below 400m. Blooms April-May.	Possible/Not observed	Low to moderate. A small amount of suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Lobed ground-cherry (*Physalis lobata*)	Federal – None State – None CNPS List 2.3	Mojave desert scrub (decomposed granite) and playas at elevations of 500-800 m. Blooms September-January.	None – all known locations well to north and at higher elevations than project.	Low. Outside of known elevation and geographic range.	Very low. Suitable habitat does not exist on site and site is outside of known range.
Desert portulaca (*Portulaca halimoides*)	Federal – None State – None CNPS List 4.2	Sandy washes and flats in desert mountains at 1000-1200 m. Blooms in September.	None – No habitat and project elevations too low.	Low. Suitable habitat on site, however elevations likely too low.	Very low. Suitable habitat does not exist on site and site is outside of known elevation range.
Desert unicorn plant (*Proboscidea althaeifolia*)	Federal – None State – None CNPS – None	Sandy areas in Sonoran Desert Scrub throughout southeastern California, below 1000m. Blooms May-August.	Observed during surveys.	Present on site.	Low. Some suitable habitat on site.
Orocopia sage (*Salvia greatae*)	Federal – None State – None CNPS List 1B.3 BLM	Mojavean and Sonoran Desert Scrub; gravelly/rocky bajadas, mostly near washes; below 825m. Blooms March-April.	Unlikely/Not observed	Low to moderate. Some suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Coves' cassia (*Senna covesii*)	Federal – None State – None CNPS List 2.2	Dry, sandy desert washes, slopes of the Sonoran Desert between 305 to 1070m. Small perennial shrub to 2 feet tall; blooms March-June.	Possible, but elevations may be too low/Not observed	Low. Suitable habitat on site, however elevations likely too low.	Very low. Suitable habitat does not exist on site.
Mesquite neststraw (*Stylocline sonorensis*)	Federal – None State – None CNPS List 1A	Open sandy drainages; known from one site near Hayfield Spring at 425m. Blooms in April.	Highly unlikely; not observed	Low to moderate. Some suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Dwarf germander (*Teucrium cubense* ssp. *depressum*)	Federal – None State – None CNPS List 2.2	Sandy soils, washes, and fields in the Sonoran Desert below 366m. Annual plants up to 6 inches tall; blooms from March through May	Possible/Not observed	Moderate. Suitable habitat exists on site and CNDDB records for this species occur approximately 4 miles to the southeast.	Low. Little suitable habitat occurs on site.
Jackass-clover (*Wislizenia refracta* ssp. *Refracta*)	Federal – None State – None CNPS List 2.2	Sandy washes, roadsides, and alkaline flats in the Mojave Desert and northern Sonoran Desert between 790 to 820 m. Annual; blooms April through November	Unlikely – elevations too low on the site/Not observed	Low. Suitable habitat on site, however elevations likely too low.	Low. Suitable habitat on site, however elevations likely too low.
AMPHIBIANS					
Couch's spadefoot (*Scaphiopus couchii*)	Federal – None State – SSC BLM sensitive	Various arid communities in extreme southeastern California; breeds in temporary rain-filled pools	Possible, but not observed.	Low to moderate. Some potentially suitable habitat exists on site.	Low to moderate. Some potentially suitable habitat exists on site. CNDDB records for this species occur approximately 3 mile west of the site.
REPTILES					
Desert tortoise (*Gopherus agassizii*)	Federal – Threatened State – Threatened BLM – None	Found in various desert scrubs and desert washes up to 5,000 feet	Carcass, carcass fragments, burrows, and tracks only observed during surveys.	Moderate. Suitable habitat occurs on site but no recent activity was observed during surveys, only old bone fragments.	Very low. Suitable habitat does not exist on site.
Desert rosy boa (*Charina trivirgata gracia*)	Federal – None State – None BLM Sensitive	Rocky uplands and canyons; often near stream courses	Unlikely due to lack of habitat	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
Colorado Desert fringe-toed lizard (*Uma notata*)	Federal – None State – SSC BLM Sensitive	Restricted to aeolian sandy habitats in the Sonoran Desert	Possible hybrids with *U. scoparia*/Possibly observed	Low. Little suitable habitat occurs on site.	Low. Little suitable habitat occurs on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Mojave fringe-toed lizard (*Uma scoparia*)	Federal – None State – SSC BLM Sensitive	Restricted to aeolian sandy habitats in the Mojave and northern Sonoran Desert	Observed during surveys	Low. Little suitable habitat occurs on site.	Low. Little suitable habitat occurs on site.
BIRDS					
Golden eagle[2] (*Aquila chrysaetos*)	Federal – None State – Fully Protected BLM – None	Nesting occurs on cliff ledges or in trees on steep slopes, with foraging occurring primarily in grassland and sage scrub.	Possible forager on site, may nest in adjacent mountains/Not observed	High. Suitable foraging habitat/prey exists on site, and suitable nesting habitat is plentiful in nearby mountains.	Very low. Suitable habitat does not exist on site, proximity to development would be a deterrent for foraging.
Short-eared owl (*Asio flammeus*)	Federal –none State – SSC BLM – None	Open habitats; nests marshes, fields; nests on ground and roosts on ground and low poles	Observed during surveys	High. Species observed approximately 4 miles to the west.	Low to moderate. May use site for foraging.
Western burrowing owl (*Athene canicularia hypugaea*)	Federal – None State – SSC BLM sensitive	Found mainly in grassland and open scrub from the seashore to foothills. Also found in deserts and scrublands. Strongly associated with the burrows of ground squirrels or other fossorial mammals.	Observed during surveys	High. Suitable habitat exists on site. Inactive burrows observed.	Moderate. Suitable foraging habitat and potential for burrows occurs on site.
Ferruginous hawk *(Buteo regalis)*	Federal – None State – CDFG Watch List (wintering) BLM – None	Open country, primarily plains, prairies, badlands, sagebrush, shrubland, desert.	Observed incidentally.	High. Suitable foraging habitat exists on site.	High. Suitable foraging habitat exists on site. Species observed foraging over agricultural fields approximately 3 miles north of the alternative site.
Mountain plover (*Charadrius montanus*)	Federal –BCC State – SSC BLM – Sensitive	Occurs in dry upland habitats, short-grass prairies and is a winter migrant in agricultural areas.	Highly unlikely, but possible winter visitor on Ford Dry Lake and adjacent shore	Low to moderate. Suitable habitat occurs on site.	Moderate potential for occurring in agricultural areas during winter.
Northern harrier (*Circus cyaneus*)	Federal – None State – SSC BLM – None	Open habitats; nests in shrubby open land and marshes	Observed during surveys	High. Suitable foraging habitat/prey exists on site	Present. Observed during surveys.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
American peregrine falcon (*Falco peregrinus anatum*)	Federal – Delisted BCC State – Fully Protected BLM – sensitive	Dry, open country, including arid woodlands; nests in cliffs	Possible forager on site, may nest in adjacent mountains/Not observed	High. Suitable foraging habitat/prey exists on site, and suitable nesting habitat is plentiful in nearby mountains	Low to moderate potential for foraging on site.
Greater sandhill crane[2] (*Grus canadensis*)	Federal – None State – Threatened BLM – None	Sandhill cranes are primarily birds of open fresh water wetlands; they occur at their highest breeding density in habitats that contain open sedge meadows in wetlands that are adjacent to short vegetation in uplands. Rural farm fields may attract foraging cranes.	Very low. No suitable habitat on site.	Very low. No suitable habitat on site.	Moderate. Two cranes were observed flying overhead approximately 0.25 miles west of the site during the field reconnaissance and this species is known to overwinter in the Cibola National Wildlife Refuge approximately 3 miles south of the site.
Yellow-breasted chat (*Icteria virens*)	Federal – None State – SSC BLM – None	Dense streamside thickets, willows; brushy hillsides and canyons	Highly unlikely due to lack of habitat, but possible transient/Not observed	Very low. No suitable habitat exists on site.	Moderate in dense riparian areas along the river. Not expected on agricultural lands.
Loggerhead shrike (*Lanius ludovicianus*)	Federal –BCC State – SSC BLM – None	Occurs in semi-open country with utility posts, wires, and trees to perch on. Although declining over most of the range in California and elsewhere, and now absent over large areas, this species is still common in the California deserts.	Observed during surveys	High. Suitable foraging habitat/prey exists on site	High. Suitable foraging habitat/prey exists on site. Observed perching approximately 2 miles west of the site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Gila woodpecker[2] (*Melanerpes uropygialis*)	Federal – None State – SE BLM – None	Formerly numerous along the Colorado River and less abundant in the Imperial Valley. Non-migratory species that nests in cavities in riparian groves that provide ample shade trees such as cottonwoods, date palms, palo verde, honey mesquite, and desert ironwood (Edwards and Schnell 2000). Requires live tree-size cactus or dead trees (Winkler et al. 1995). In California, the primary factor in determining the presence of this woodpecker is the availability of excavatable tree trunks for nesting (Grinnell and Miller 1944).	Very low. No suitable habitat exists on site.	Very low. No suitable habitat exists on site.	Moderate in riparian areas along the Colorado River. Not expected on agricultural lands.
Vermillion flycatcher[2] (*Pyrocephalus rubinus)*	Federal – None State – SSC BLM – None	Found in the arid Southwest, occurring almost exclusively near water. Favors wooded groves of cottonwood, willow, oak, mesquite, and sycamore bordering rivers, especially near open, brushy, grassy, or agricultural fields.	Very low. No suitable habitat exists on site.	Very low. No suitable habitat exists on site.	Moderate in willow riparian areas along the river; may forage over adjacent fields. Reported to CNDDB approximately 2.5 miles west of the site.
Bendire's thrasher (*Toxostoma bendirei*)	Federal –BCC State – SSC BLM – sensitive	Arid to semi-arid brushy habitats, usually with yuccas, cholla, and trees	Unlikely/Not observed	Low. Habitat on site is not very suitable.	Low. Habitat on site is not very suitable.
Crissal thrasher (*Toxostoma crissale*)	Federal – None State – SSC BLM – None	Mesquite brushland and densely vegetated washes.	Highly unlikely due to lack of habitat/Not observed	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
Le Conte's thrasher (*Toxostoma lecontei*)	Federal – None State – SSC BLM – None	Desert flats with sparse bushes; preferred nest sites are in large shrubs along washes.	Moderate. Some suitable habitat occurs on site.	Moderate. Some suitable habitat occurs on site.	Low. Little suitable habitat occurs on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
MAMMALS					
Pallid bat (Antrozous pallidus)	Federal – None State – SSC BLM – Sensitive	This gregarious species usually roosts in small colonies in rock crevices and buildings, but may nest in caves, mines, rock piles, and tree cavities. It prefers narrow crevices in caves as hibernation sites. Prey includes flightless arthropods and may include lizards and rodents (Claire et al. 1989).	Possible/Not observed	Moderate for foraging. No roosting potential.	Moderate for foraging. No roosting potential.
Townsend's big-eared bat (*Corynorhinus townsendii*)	Federal – None State – SSC BLM – Sensitive	Broad habitat associations. Roosts in caves and manmade structures; feeds in trees	Possible/Not observed	Moderate for foraging. No roosting potential.	Moderate for foraging. No roosting potential.
Wild burro (*Equus asinus*)	Federal – protected State – None BLM – None	Found in alkali desert scrub, desert scrub, desert succulent shrub, desert riparian, desert wash, Joshua tree, pinyon-juniper, montane chaparral, and pasture. Feed on grasses and forbs. During summer, spend much time in riparian habitats and desert washes. In fall and winter, disperse to open shrub habitats on sloping and rolling terrain. They avoid rocky habitats and steep slopes.	Unlikely/Not observed	High. Scat observed on lands to west.	Very low. Suitable habitat does not occur on site.
Spotted bat (*Euderma maculatum*)	Federal – None State – SSC BLM – Sensitive	Arid scrub and grasslands, to coniferous forests, roosts in cliffs. Forages along waterways.	Unlikely/Not observed	Very low potential for foraging and no potential for roosting.	Moderate potential for foraging along the river.
Western mastiff bat (*Eumops perotis californicus*)	Federal – None State – SSC BLM – Sensitive	Cliffs, trees, tunnels, buildings in desert scrub	Possible/Not observed	Moderate potential for foraging; very low potential for roosting.	Moderate potential for foraging; low potential for roosting.
Yuma puma (*Felis concolor) brownii*)	Federal – None State – None BLM – Sensitive	Yuma pumas live in the southern Colorado Desert from Joshua Tree National Park south and west to the lower Colorado River	Possible/Not observed	Moderate. Suitable foraging habitat exists on site.	Very low. No suitable habitat on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
California leaf-nosed bat *(Macrotus californicus)*	Federal – None State – SSC BLM – Sensitive	Caves, mines, and rock shelters, mostly in Sonoran desert scrub. Roost sites are usually located near foraging areas. These bats do not migrate or hibernate. They feed upon a wide variety of insects, including caterpillars, and supplement their diets with cactus fruit.	Unlikely/Not observed	Low to moderate potential for foraging; very low potential for roosting.	Very low. No suitable habitat on site.
Arizona myotis (*Myotis occultus*)	Federal – None State – SSC BLM – None	Lowlands of the Colorado River and adjacent mountain ranges, up to ponderosa pine habitat; mines, buildings, bridges, riparian woodlands, often near water	Unlikely/Not observed	Low potential for foraging; very low potential for roosting.	Moderate potential for foraging along the river.
Southwestern cave myotis (*Myotis velifer brevis)*	Federal – None State – SSC BLM – Sensitive	Prefers a cave habitat, but will choose other roosting areas if a suitable cave is not available. These alternate areas can include mines, rock crevices, abandoned buildings, barns and under bridges. They feed upon a wide variety of insects are sensitive to human activity and will abandon a roosting area if disturbed.	Unlikely/Not observed	Very low potential for foraging or roosting. Habitat on site is not suitable.	Moderate potential for foraging; low potential for roosting.
Yuma myotis (*Myotis yumanensis ymanensis*)	Federal – None State – None BLM – Sensitive	Several habitat associations, but typically near open water; often roosts in manmade structures	Unlikely/Not observed	Very low potential for foraging or roosting. Habitat on site is not suitable.	Moderate potential for foraging; Low to moderate potential for roosting.
Colorado Valley woodrat (*Neotoma albigula venusta*)	Federal – None State – None BLM – None	Under mesquite in creosote bush scrub; southeastern California	Unlikely due to lack of habitat/Not observed	Low. Suitable habitat does not exist on site.	Low. Suitable habitat does not exist on site.
Big free-tailed bat (*Nyctinomops femorosaccus*)	Federal – None State – SSC BLM – None	Variety of arid areas in pinyon-juniper woodland, desert scrubs, palm oases, drainages, rocky areas	Unlikely/Not observed	Low potential for foraging.	Very low. Suitable habitat does not occur on site.
Pocketed free-tailed bat (*Nyctinomops macrotis*)	Federal – None State – SSC BLM – None	Habitats used include pinyon-juniper woodlands, desert scrub, desert succulent shrub, desert riparian, desert wash, alkali desert scrub, Joshua tree, and palm oasis. Prefers rock crevices in cliffs as roosting sites.	Low to moderate potential for foraging; no suitable roosting areas on site.	Low to moderate potential for foraging; no suitable roosting areas on site.	Low to moderate potential for foraging; no suitable roosting areas on site.

Species	Sensitivity Status	Habitat	Potential to Occur / Status on Site		
			Proposed Project Site[1]	Reduced Acreage Alternative	Gabrych Alternative
Burro deer (*Odocoileus hemionus eremicus*)	Federal – None State – Game species BLM – None	Browse various riparian and microphyllous woodland trees and shrubs.	Possible	Low to moderate. Tracks observed approximately 6 miles southeast of the site.	Low to moderate potential to occur along the river.
Desert bighorn sheep (*Ovis canadensis nelsoni*)	Federal – Endangered State – Threatened BLM – Sensitive	Mountain slopes with sparse growth of trees above the desert floor in California. The species prefers open areas that are steep and rocky to avoid predators (Bleich et al. 1990). Threats to this species include the loss of adequate amounts of desert floor habitat to allow sheep to move between mountains and contact with domestic sheep. Lambs are especially susceptible to pneumonia and other diseases of domestic sheep (DeForge and Scott 1982). Competition with cattle and feral burrows for water resources is another threat to bighorn sheep (Dunn and Douglas 1982).	Possible in Palen and McCoy Mountains/Not observed	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
American badger (*Taxidea taxus)*	Federal – None State – SSC BLM – None	Inhabits coastal sage scrub, mixed chaparral, grassland, oak woodland, chamise chaparral, mixed conifer, pinyon-juniper, desert scrub, desert wash, montane meadow, open areas, and sandy soils.	Observed (burrow only)	High. Suitable foraging habitat/prey exists on site	Low. Limited suitable habitat occurs on site and is isolated from other native habitat areas.
Desert kit fox[2] *(Vulpes macrotis arsipus)*	Federal – None State – Calif. Code of Regulation: PFM BLM – None	Suitable habitat for this fossorial mammal consists of arid open areas, shrub grassland, and desert ecosystems.	Numerous burrow complexes observed.	Present. Numerous burrow complexes observed.	Low to moderate potential to occur in the southwestern corner.

Notes:
1 - Except where noted, data taken from Tetra Tech Biological Resources Technical (BTR) Report for the Project Site (2009a) or associated Data Requests Responses.
2 - Species not covered in Tetra Tech BTR report/Data Requests Responses
m = meters
BLM = Bureau of Land Management
CNPS = California Native Plant Society
SSC = California Species of Special Concern
BCC = USFWS Bird of Conservation Concern

B.3 - Cumulative Scenario

Testimony of Susan V. Lee

B.3.1 INTRODUCTION

Preparation of a cumulative impact analysis is required under both CEQA and NEPA. "Cumulative impact" is the impact on the environment which results from the incremental impact of the Proposed Project when considered with other past, present, and reasonably foreseeable future actions regardless of which agency (federal or non-federal) or person undertakes such other actions (40 CFR §1508.7).

Under CEQA Guidelines, "a cumulative impact consists of an impact which is created as a result of the combination of the project evaluated in the EIR together with other projects causing related impacts" (14 Cal Code Regs §15130(a)(1)). Cumulative impacts must be addressed if the incremental effect of a project, combined with the effects of other projects is "cumulatively considerable" (14 Cal Code Regs §15130(a)). Such incremental effects are to be "viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects" (14 Cal Code Regs §15164(b)(1)). Together, these projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis.

CEQA also states that both the severity of impacts and the likelihood of their occurrence are to be reflected in the discussion, "but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion of cumulative impacts shall be guided by standards of practicality and reasonableness, and shall focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact" (14 Cal Code Regs §15130(b)).

NEPA states that cumulative effects can result from individually minor but collectively significant actions taking place over a period of time" (40 CFR §1508.7). Under NEPA, both context and intensity are considered. When considering intensity of an effect, we consider "[w]hether the action is related to other actions with individually minor but cumulatively significant impacts. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts." 40 CFR §1508.27(b)(7).

B.3.2 RENEWABLE RESOURCES IN CALIFORNIA

A large number of renewable projects have been proposed on BLM managed land, State land, and private land in California. As of January 2010, there were 244 renewable projects proposed in California in various stages of the environmental review process or under construction. As of December 2009, *49* of these projects, representing approximately 10,500 MW, were planning on requesting American Recovery and Reinvestment Act funds from the Federal government. Solar, wind, and geothermal development applications have requested use of BLM land, including approximately one million acres of the California desert. State and private lands have also been targeted for renewable solar and wind projects.

Cumulative Figures 1 and **Cumulative Tables 1A and 1B** illustrate the numerous proposed renewable projects on BLM, State and private land in California. In addition, nearly 80 applications for solar and wind projects are being considered on BLM land in Nevada and Arizona.

Likelihood of Development. The large renewable projects now described in applications to the BLM and on private land are competing for utility Power Purchase Agreements, which will allow utilities to meet state-required Renewable Portfolio Standards. Not all of the projects listed in **Tables 1A** and **1B** will complete the environmental review, and not all projects will be funded and constructed. It is unlikely that all of these projects will be constructed for the following reasons:

- Not all developers will develop the detailed information necessary to meet BLM and Energy Commission standards. Most of the solar projects with pending applications are proposing generation technologies that have not been implemented at large scales. As a result, preparing complete and detailed plans of development (PODs) is difficult, and completing the required NEPA and CEQA documents is especially time-consuming and costly.
- As part of approval by the appropriate Lead Agency under CEQA and/or NEPA (generally the Energy Commission and/or BLM), all regulatory permits must be obtained by the applicant or the prescriptions required by the regulatory authorities incorporated into the Lead Agency's license, permit or right-of-way grant. The large size of these projects may result in permitting challenges related to endangered species, mitigation measures or requirements, and other issues.
- Also after project approval, construction financing must be obtained (if it has not been obtained earlier in the process). The availability of financing will be dependent on the status of competing projects, the laws and regulations related to renewable project investment, and the time required for obtaining permits.

Incentives for Renewable Development. A number of existing policies and incentives encourage renewable energy development. These incentives lead to a greater number of renewable energy proposals. Example of incentives for developers to propose renewable energy projects on private and public lands in California, Nevada and Arizona, include the following:

- **U.S. Treasury Department's Payments for Specified Energy Property in Lieu of Tax Credits** under §1603 of the American Recovery and Reinvestment Act of 2009 (Public Law 111-5) - Offers a grant (in lieu of investment tax credit) to receive funding for 30% of their total capital cost at such time as a project achieves commercial operation (currently applies to projects that begin construction by December 31, 2010 and begin commercial operation before January 1, 2017).
- **U.S. Department of Energy (DOE) Loan Guarantee Program** pursuant to §1703 of Title XVII of the Energy Policy Act of 2005 - Offers a loan guarantee that is also a low interest loan to finance up to 80% of the capital cost at an interest rate much lower than conventional financing. The lower interest rate can reduce the cost of financing and the gross project cost on the order of several hundred million dollars over the life of the project, depending on the capital cost of the project.

B.3.3 DEFINITION OF THE CUMULATIVE PROJECT SCENARIO

Cumulative impacts analysis is intended to highlight past actions that are closely related either in time or location to the project being considered, catalogue past projects and discuss how they have harmed the environment, and discuss past actions even if they

were undertaken by another agency or another person. Most of the projects listed in the cumulative projects tables (**Cumulative Tables 1A and 1B, 2, and 3** at the end of this section) have, are, or will be required to undergo their own independent environmental review under either CEQA.

Under CEQA, there are two acceptable and commonly used methodologies for establishing the cumulative impact setting or scenario: the "list approach" and the "projections approach". The first approach would use a "list of past, present, and probable future projects producing related or cumulative impacts." 14 Cal Code Regs §15130(b)(1)(A). The second approach is to use a "summary of projections contained in an adopted general plan or related planning document, or in a prior environmental document which has been adopted or certified, which described or evaluated regional or area wide conditions contributing to the cumulative impact" (14 Cal Code Regs §15130(b)(1)(B)). This Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) uses the "list approach" for purposes of state law to provide a tangible understanding and context for analyzing the potential cumulative effects of a Project.

Under NEPA, an EIS must provide a sufficiently detailed catalogue of past, present, and reasonably foreseeable future projects, and provide an adequate analysis of how these projects, in conjunction with the proposed action, are thought to have impacted or are expected to impact the environment. While NEPA requires an adequate cataloging of past projects, it also requires a discussion of consequences of those past projects. NEPA is designed to inform decision making and through disclosure of relevant environmental considerations, permit informed public comment.

In order to provide a basis for cumulative analysis for each discipline, this section provides information on other projects in both maps and tables. The Energy Commission and the BLM have identified the California desert as the largest area within which cumulative effects should be assessed for all disciplines, as shown in two maps and accompanying tables. However, within the desert region, the specific area of cumulative effect varies by resource. For this reason, each discipline has identified the geographic scope for the discipline's analysis of cumulative impacts. **Cumulative Figures 1 and 2** are on the following pages, and **Cumulative Tables 1, 2, and 3** are presented at the end of this section.

Cumulative Impacts Figure 2 (I-10 Corridor Existing and Future/Foreseeable Projects) and **Tables 2 and 3** define the projects in the immediate vicinity of the I-10 corridor. The area included on these tables consists of an approximate 15 to 20-mile radius around the project site. Table 2 presents existing projects and Table 3 presents future foreseeable projects. Both tables indicate project name, type, location, and status. This data is presented for consideration within each discipline.

B.3.4 APPROACH TO CUMULATIVE IMPACT ANALYSIS

This Staff Assessment/Draft EIS evaluates cumulative impacts within the analysis of each resource area, following these steps:

1. Define the geographic scope of cumulative impact analysis for each discipline, based on the potential area within which impacts of the Genesis Solar Energy Project could combine with those of other projects.

2. Evaluate the effects of the Genesis Solar Energy Project in combination with past and present (existing) projects within the area of geographic effect defined for each discipline.

3. Evaluate the effects of the Genesis Solar Energy Project with foreseeable future projects that occur within the area of geographic effect defined for each discipline.

Each of these steps is described below.

GEOGRAPHIC SCOPE OF CUMULATIVE ANALYSIS

The area of cumulative effect varies by resource. For example, air quality impacts tend to disperse over a large area, while traffic impacts are typically more localized. For this reason, the geographic scope for the analysis of cumulative impacts must be identified for each resource area.

The analysis of cumulative effects considers a number of variables including geographic (spatial) limits, time (temporal) limits, and the characteristics of the resource being evaluated. The geographic scope of each analysis is based on the topography surrounding the Genesis Solar Energy Project and the natural boundaries of the resource affected, rather than jurisdictional boundaries. The geographic scope of cumulative effects will often extend beyond the scope of the direct effects, but not beyond the scope of the direct and indirect effects of the proposed action and alternatives.

In addition, each project in a region will have its own implementation schedule, which may or may not coincide or overlap with the Genesis Solar Energy Project's schedule. This is a consideration for short-term impacts from the Genesis Solar Energy Project. However, to be conservative, the cumulative analysis assumes that all projects in the cumulative scenario are built and operating during the operating lifetime of the Genesis Solar Energy Project.

PROJECT EFFECTS IN COMBINATION WITH FORESEEABLE FUTURE PROJECTS

The intensity, or severity, of the cumulative effects should consider the magnitude, geographic extent, duration and frequency of the effects (CEQ, 1997). The magnitude of the effect reflects the relative size or amount of the effect; the geographic extent considers how widespread the effect may be; and the duration and frequency refer to whether the effect is a one-time event, intermittent, or chronic (CEQ, 1997).

Each discipline evaluates the impacts of the proposed project on top of the current baseline; the past, present (existing) and reasonably foreseeable or probable future

projects in each I-10 corridor project vicinity as illustrated in **Cumulative Impacts – Figure 2 (I-10 Corridor Existing and Future/Foreseeable Projects)** and **Cumulative Impacts Tables 2 (existing projects) and 3 (future/foreseeable projects)**.

Reasonably foreseeable projects that could contribute to the cumulative effects scenario depend on the extent of resource effects, but could include projects in the immediate I-10 corridor area as well as other large renewable projects in the California, Nevada, and Arizona desert regions. These projects are illustrated in **Cumulative Impacts Figures 1 and 2**. As shown in the map and table, there are a number of projects in the immediate area around the I-10 corridor whose impacts could combine with those of the proposed project. As shown on **Cumulative Impacts Figure 1** and in **Table 1**, solar and wind development applications for use of BLM land have been submitted for approximately one million acres of the California Desert Conservation Area. Additional BLM land in Nevada and Arizona also has applications for solar and wind projects.

Table 1A. Renewable Energy Projects in the California Desert District

BLM Field Office	Number of Projects & Acres	Total MW
Solar Energy		
Barstow Field Office	• 18 projects • 132,560 acres	• 12,875 MW
El Centro Field Office	• 7 projects • 50,707 acres	• 3,950 MW
Needles Field Office	• 17 projects • 230,480 acres	• 15,700 MW
Palm Springs Field Office	• 17 projects • 123,592 acres	• 11,873 MW
Ridgecrest Field Office	• 4 projects • 30,543 acres	• 2,835 MW
TOTAL – CA Desert District	• **63 projects** • **567,882 acres**	• **47,233 MW**
Wind Energy		
Barstow Field Office	• 25 projects • 171,560 acres	• n/a
El Centro Field Office	• 9 projects (acreage not given for 3 of the projects) • 48,001 acres	• n/a
Needles Field Office	• 8 projects • 115,233 acres	• n/a
Palm Springs Field Office	• 4 projects • 5,851 acres	• n/a
Ridgecrest Field Office	• 16 projects • 123,379 acres	• n/a
TOTAL – CA Desert District	• **62 projects** • **433,721 acres**	• n/a

Table 1B. Renewable Energy Projects on State and Private Lands*

Project Name	Location	Status
Solar Projects		
Solargen Panoche Valley Solar Farm (400 MW Solar PV)	San Benito County	EIR in progress
Maricopa Sun Solar Complex (350 MW Solar PV)	Kern County	Information not available
Panoche Ranch Solar Farm (250 MW Solar PV)	Kern County	Information not available
Gray Butte Solar PV (150 MW Solar PV)	Los Angeles County	Information not available
Monte Vista (126 MW Solar PV)	Kern County	Information not available
San Joaquin Solar 1 and 2 (107 MW Solar hybrid)	Fresno	Under environmental review
NRG Alpine Suntower (40 MW solar PV and 46 MW solar thermal)	Los Angeles	Information not available
Palmdale Hybrid Power Project Unit 1 (50 MW solar thermal, part of a hybrid project)	City of Palmdale	Under environmental review
Lucerne Valley Solar (50 MW solar PV)	San Bernardino	Under environmental review
Lost Hills (32.5 solar PV)	Kern County	Information not available
Tehachapi Photovoltaic Project (20 MW solar PV)	Kern County	Information not available
Sun City Project Phase 1 (20 MW solar PV)	Kings County	Information not available
Boulevard Associates (20 MW solar PV)	San Bernardino County	Information not available
Stanislaus Solar Project I (20 MW solar PV)	Stanislaus County	Information not available
Stanislaus Solar Project II (20 MW solar PV)	Stanislaus County	Information not available
Synapse Solar 2 (20 MW solar PV/solar thermal)	Kings	Information not available
T, squared, Inc. (19 MW solar PV)	Kern County	Information not available
Rancho Seco Solar Thermal (15-17 MW solar trough)	Sacramento County	Information not available
Global Real Estate Investment Partners, LLC (solar PV)	Kern County	Information not available
Recurrent Energy (solar PV)	Kern County	Information not available
Man-Wei Solar (solar PV)	Kern County	Information not available
Regenesis Power for Kern County Airports Dept.	Kern County	Information not available
Abengoa Mojave Solar Project (250 MW solar thermal)	San Bernardino County, Harper Lake	Under environmental review
Rice Solar Energy Project (150 MW solar thermal)	Riverside County, north of Blythe	Under environmental review
3 MW solar PV energy generating facility	San Bernardino County, Newberry Springs	MND published for public review
Blythe Airport Solar 1 Project (100 MW solar PV)	Blythe, California	MND published for public review
First Solar's Blythe (21 MW solar PV)	Blythe, California	Under construction
California Valley Solar Ranch (SunPower) (250 MW solar PV)	Carrizo Valley, San Luis Obispo County	Under environmental review

Project Name	Location	Status
LADWP and OptiSolar Power Plant (68 MW solar PV)	Imperial County, SR 111	Under environmental review
Topaz Solar Farm (First Solar) (550 MW solar PV)	Carrizo Valley, San Luis Obispo County	Under environmental review
AV Solar Ranch One (230 MW solar PV)	Antelope Valley, Los Angeles County	Under environmental review
Bethel Solar Hybrid Power Plant (49.4 MW hybrid solar thermal and biomass)	Seeley, Imperial County	Under environmental review
Mt. Signal Solar Power Station (49.4 MW hybrid solar thermal and biomass)	8 miles southwest of El Centro, Imperial County	Under environmental review
Wind Projects		
Alta-Oak Creek Mojave Project (up to 800 MW)	Kern County, west of Mojave	Under environmental review
PdV Wind Energy Project (up to 300 MW)	Kern County, Tehachapi Mountains	Approved
City of Vernon Wind Energy Project (300 MW)	City of Vernon	Information not available
Manzana Wind Project (246 MW)	Kern County	Information not available
Iberdrola Tule Wind (200 MW)	San Diego County, McCain Valley	EIR/EIS in progress
Padoma Wind Energy (175 MW)	Shasta County	Information not available
Pine Canyon (150 MW)	Kern County	Information not available
Shiloh III (200 MW)	Montezuma Hills, Solano County	Information not available
AES Daggett Ridge (84 MW)	San Bernardino	EIS in progress
Granite Wind, LLC (81 MW)	San Bernardino	EIR/EIS in progress
Bear River Ridge (70 MW)	Humboldt County	Information not available
Aero Tehachapi (65 MW)	Kern County	Information not available
Montezuma Wind II (52-60)	Montezuma Hills, Solano County	Information not available
Tres Vaqueros (42 MW wind repower)	Contra Costa County	Information not available
Montezuma Hills Wind Project (34-37 MW)	Solano County	Information not available
Solano Wind Project Phase 3 (up to 128 MW)	Montezuma Hills, Solano County	Under environmental review
Hatchet Ridge Wind Project	Shasta County, Burney	Under construction
Lompoc Wind Energy Project	Lompoc, Santa Barbara County	Approved
Pacific Wind (Iberdrola)	McCain Valley, San Diego County	Under environmental review
TelStar Energies, LLC (300 MW)	Ocotillo Wells, Imperial County	Under environmental review
Geothermal Projects		
Buckeye Development Project	Geyserville, Sonoma	Under environmental review
Orni 18, LLC Geothermal Power Plant (49.9 MW)	Brawley, Imperial County	Information not available

Project Name	Location	Status
Black Rock Geothermal 1,2,and 3	Imperial County	Information not available

* This list is compiled from the projects on CEQAnet as of November 2009 and the projects located on private or State lands that are listed on the Energy Commission Renewable Action Team website as requesting ARRA funding. Additional renewable projects proposed on private and State lands but not requesting ARRA funds are listed on the website.

Table 2. Existing Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
1	Interstate 10	Linear project running from Santa Monica to Blythe (in California)	Caltrans	Existing	N/A	Interstate 10 (I-10) is a major east-west route for trucks delivering goods to and from California. It is a four lane divided highway in the Blythe region.
2	Chuckwalla Valley State Prison	19025 Wiley's Well Rd. Blythe, CA	CA Dept. of Corrections & Rehabilitation	Existing	1,080	State prison providing long-term housing and services for male felons classified as medium and low-medium custody inmates jointly located on 1,720 acres of State-owned property. APN 879040006,008, 012, 027, 028, 029, 030,
3	Ironwood State Prison	19005 Wiley's Well Rd. Blythe, CA	CA Dept. of Corrections & Rehabilitation	Existing	640	ISP jointly occupies with Chuckwalla Valley State Prison 1,720 acres of State-owned property, of which ISP encompasses 640 acres. The prison complex occupies approximately 350 acres with the remaining acreage used for erosion control, drainage ditches, and catch basins. 879040001, 004, 009, 010, 011, 015, 016, 017, 018, 019, 020
4	Devers-Palo Verde Transmission Line	From the Midpoint Substation to Devers Substation	SCE	Existing	N/A	Existing 500 kV transmission line parallel to I-10 from Midpoint Substation, approximately 10 miles southwest of Blythe, to the SCE Devers Substation, near Palm Springs.
5	Blythe Energy Project	City of Blythe, north of I-10, 7 miles west of the CA/AZ border	Blythe Energy, LLC	Existing	76	520 MW combined-cycle natural gas-fired electric-generating facility. Project is connected to the Buck Substation owned by WAPA.
6	West-wide Section 368 Energy Corridors	Riverside County, parallel to DPV corridor	BLM, DOE, U.S. Forest Service	Approved by BLM and U.S. Forest Service	N/A	Designation of corridors on federal land in the 11 western states, including California, for oil, gas, and hydrogen pipelines and electricity transmission and distribution facilities (energy corridors). One of the corridors runs along the southern portion of Riverside County.
7	Eagle Mountain Pumping Plant	Eagle Mountain Road, west of Desert Center	Metropolitan Water District of Southern California	Existing		144 ft. pumping plant that is part of the Metropolitan Water District of Southern California's facilities. APNs 807150007, 807150009, 807150010
8	Recreational Opportunities	Eastern Riverside County	BLM	Existing	N/A	BLM has numerous recreational opportunities on lands in eastern Riverside County along the I-10 corridor including the Wiley's Well Campground, Coon Hollow Campground, and Midland Long-Term Visitor Area.
9	Kaiser Mine	Eagle Mountain, north of Desert Center	Kaiser Ventures, Inc.	Mining activities stopped in 1983.		Kaiser Steel mined iron ore at Kaiser Mine in Eagle Mountain and provided much of the Pacific Coast steel in the 1950s. Mining project also included the Eagle Mountain Railroad, 51 miles long. Imported steel captured market share in the 1960s and 1970s and primary steelmaking closed in the 1980s. 701380031

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
A	Four Commercial Projects	Blythe, CA	Various	Approved	N/A	Four commercial projects have been approved by the Blythe Planning Department including the Agate Road Boat & RV Storage, Riverway Ranch Specific Plan, Subway Restaurant and Motel, and Agate Senior Housing Development.
B	Intake Shell	Blythe, CA		Under Construction	N/A	Reconstruction of a Shell facility located at Intake & Hobsonway. Demolition occurred in 2008, reconstruction planned for 2009-2010.
C	Fifteen Residential Developments	Blythe, CA	Various	Approved/Under Construction	N/A	Twelve residential development projects have been approved by the Blythe Planning Department including: Vista Palo Verde (83 Single Family Residential [SFR]), Van Weelden (184 SFR), Sonora South (43 SFR), Ranchette Estates (20 SFR), Irvine Assets (107 SFR), Chanslor Village (79 SFR), St. Joseph's Investments (69 SFR), Edgewater Lane (SFR), The Chanslor Place Phase IV (57 SFR), Cottonwood Meadows (103 Attached SFR), Palo Verde Oasis Phase IV (29 SFR). Three residential development projects have been approved and are under construction including: The Chanslor Phase II & III (78 SFR), River Estate at Hidden Beaches, Mesa Bluffs Villas (26 Attached SFR).
D	Devers-Palo Verde 2 Transmission Line Project	From the Midpoint Substation to Devers Substation	SCE	Project was approved by CPUC 11/2009.	N/A	New 500 kV transmission line parallel to the existing Devers-Palo Verde Transmission Line from Midpoint Substation, approximately 10 miles southwest of Blythe, to the SCE Devers Substation, near Palm Springs. The ROW for the 500 kV transmission line would be adjacent to the existing DPV ROW and would require an additional 130 feet of ROW on federal and State land and at least 130 feet of ROW on private land and Indian Reservation land.
E	Colorado Substation	10 miles southwest of Barstow	SCE	Project was approved by CPUC 11/2009.	44	The new 500/230 kV substation would be constructed within a rectangular area approximately 1,000 feet by 1,900 feet, resulting in approximately 44 acres permanently disturbed. The 500 kV switching station would include buses, circuit breakers, and disconnect switches. The switchyard would be equipped with 108-foot-high dead-end structures. Outdoor night lighting would be designed to illuminate the switchrack when manually switched on.
F	Blythe Energy Project Transmission Line	From the Blythe Energy Project (Blythe, CA) to Devers Substation	Blythe Energy, LLC	Under construction	N/A	Transmission Line Modifications including upgrades to Buck Substation, approximately 67.4 miles of new 230 kV transmission line between Buck Substation and Julian Hinds Substation, upgrades to the Julian Hinds Substation, installation of 6.7 miles of new 230 kV transmission line between Buck Substation and SCE's DPV 500 kV transmission line.

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
G	Desert Southwest Transmission Line	118 miles primarily parallel to DPV	Imperial Irrigation District	Final EIR prepared 2005. Approved by the BLM in 2006.	N/A	New, approximately 118-mile 500 kV transmission line from a new substation/switching station near the Blythe Energy Project to the existing Devers Substation located approximately 10 miles north of Palm Springs, California.
H	Green Energy Express Transmission Line Project	70-mile transmission line from the Eagle Mountain Substation to southern California	Green Energy Express LLC	September 9, 2009, Green Energy Express LLC filed a Petition for Declaratory Order requesting that FERC approve certain rate incentives for the project	N/A	70-mile double-circuit 500 kV transmission line and new 500/230 kV substation from near the Eagle Mountain Substation (eastern Riverside County) to Southern California
I	Blythe Energy Project II	Blythe, CA. Near the Blythe Airport and I-10	Blythe Energy, LLC	Approved December 2005	30 acres (located on Blythe Energy Project land)	520 MW combined-cycle power plant located entirely within the Blythe Energy Project site boundary. Blythe Energy Project II will interconnect with the Buck Substation constructed by WAPA as part of the Blythe Energy Project. Project is designed on 30 acres of a 76-acre site.
J	Eagle Mountain Pumped Storage Project	Eagle Mountain iron ore mine, north of Desert Center	Eagle Crest Energy Company	License application filed with FERC in June 2009	1,524	1,300 MW pumped storage project designed to store off-peak energy to utilize during on-peak hours. The captured off-peak energy will be used to pump water to an upper reservoir where the energy will be stored. The water will then be released to a lower reservoir through an underground electrical generating facility where the stored energy will be released back into the Southwestern grid during "high demand peak" times, primarily weekdays. Estimated water use is 8,100 AFY for the first four-year start-up period and replacement water is 1,763 AFY thereafter. 1

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
K	Genesis Solar Energy Project	North of I-10, 10 miles east of Desert Center	Solar Millennium LLC/Chevron Energy	Undergoing environmental review, construction to begin end of 2010 with one unit online in 2012 and one unit online in 2013.	5,200	500 MW solar trough project on 5,200 acres. Facility would consist of two 250 MW plants. Approximately 3,870 acres would be disturbed. Project would include interconnection to the SCE Red Bluff Substation. Project would use 300 AFY.
L	Blythe Solar Power Project	North of I-10, immediately north of the Blythe Airport	Solar Millennium LLC/Chevron Energy	Undergoing environmental review	9,400	1,000 MW solar trough facility on 9,400 acres
M	NextEra (FPL) McCoy	Northwest of Blythe, CA, immediately north of Blythe Solar Power Project	NextEra (FPL)	Plan of Development in to Palm Springs BLM	20,608	250 MW solar trough project. ROW in process for monitoring water well drilling.
N	McCoy Soleil Project	10 miles northwest of Blythe	enXco	Plan of Development in to Palm Springs BLM	1,959	300 MW solar power tower project located on 1,959 acres. Project would require a 14 mile transmission line to proposed SCE Colorado Substation south of I-10. Would use 575-600 AFY.
O	Genesis Solar Energy Project	North of I-10, 25 miles west of Blythe and 27 miles east of Desert Center	NextEra (FPL)	Undergoing environmental review. Construction to begin at the end of 2010.		250 MW solar trough project located on 4,640 acres north of the Ford Dry Lake. Project includes six mile natural gas pipeline and a 5.5 mile gen-tie line to the Blythe Energy Center to Julian Hinds Transmission Line, then travel east on shared transmission poles to the Colorado River Substation.
P	Big Maria Vista Solar Project	North of I-10, approximately 12 miles northwest of Blythe	Bullfrog Green Energy	Plan of Development submitted to BLM	2,684	500 MW solar photovoltaic project on 2,684 acres of land. Project would be built in three phases and would require 6,000 gallons of water monthly.
Q	Chuckwalla Solar I	1 mile north of Desert Center	Chuckwalla Solar I, LLC	Plan of Development submitted to BLM	4,083	200 MW solar photovoltaic project on 4,083 acres of land. Project would be developed in several phases and would tap into an existing SCE 161-kV transmission line crossing the site.
R	Rice Solar Energy Project	Rice Valley, Eastern Riverside County	Rice Solar Energy, LLC (SolarReserve, LLC)	Undergoing environmental review. Construction to begin in 2011	1,410	150 MW solar power tower project with liquid salt storage. Project is located on approximately 1,410 acres and includes a power tower approximately 650 feet tall and a 10-mile long interconnection with the WAPA Parker-Blythe transmission line.

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
S	Blythe Airport Solar I Project	Blythe Airport	U.S. Solar	Application has been submitted to City of Blythe, City of Blythe approved the project in November, 2009	640	100 MW solar photovoltaic project located on 640 acres of Blythe airport land.
T	Blythe PV Project	Blythe	First Solar	CPUC approved project terms of a 20 year power purchase agreement for sale of 7.5 MW, Under construction in forth quarter, 2009	200	7.5 MW solar photovoltaic project located on 200 acres. Project was constructed by First Solar and sold to NRG Energy.
U	Desert Quartzite	South of I-10, 8 miles southwest of Blythe	First Solar (previously OptiSolar)	POD in to BLM	7,724	600 MW solar photovoltaic project located on 7,724 acres. Adjacent to DPV transmission line and SCE Colorado Substation. Approximately 27 AF would be used during construction and 3.8 AFY during operation.
V	Desert Sunlight	North of Desert Center	First Solar (previously OptiSolar)	POD in to BLM	5,000-6,000	250 MW solar photovoltaic project located on 5,000-6,000 acres. Project would tie into the SCE Red Bluff Substation. Approximately 27 AF would be used during construction and 3.8 AFY during operation.
W	EnXco	North of Wileys Well Road, east of Genesis Solar Energy Project	enXco	POD in to BLM		300 MW solar photovoltaic project location on X acres.
X	Desert Lily Soleil Project	6 miles north of Desert Center	enXco		1,216	100 MW photovoltaic plant on 1,216 acres of BLM land. Would require a 5-8 mile transmission line to planned SCE Red Bluff Substation.
Y	Red Bluff Substation	Unknown at this time – near Desert Center	SCE		N/A	Proposed 230/500 kV Substation near Desert Center. Planned to interconnect renewable projects near Desert Center with the DPV transmission line.
Z	Chuckwalla Valley Raceway	Desert Center Airport (no longer a functioning airport)	Developer Matt Johnson	Under construction, track expected to be open in mid 2010	400	Proposed 500-mile race track located on 400 acres of land that used to belong to Riverside County and was used as the Desert Center airport. APN 811142016, 811142006

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
AA	Eagle Mountain Landfill Project	Eagle Mountain, North of Desert Center	Mine Reclamation Corporation and Kaiser Eagle Mountain, Inc.	U.S. Court of Appeals for the Ninth Circuit issued its regarding the EIS for the project in 11/09 and ruled that the land exchange for the project was not properly approved by the administrative agency. Kaiser's Mine and Reclamation is considering all available options.	~ 3,500	The project proposed to develop the project on a portion of the Kaiser Eagle Mountain Mine in Riverside County, California. The proposed project comprises a Class III nonhazardous municipal solid waste landfill and the renovation and repopulation of Eagle Mountain Townsite. The proposal by the proponent includes a land exchange and application for rights-of-way with the Bureau of Land Management and a Specific Plan, General Plan Amendment, Change of Zone, Development Agreement, Revised Permit to Reclamation Plan, and Tentative Tract Map with the County.The Eagle Mountain landfill project is proposed to accept up to 20,000 tons of non-hazardous solid waste per day for 50 years.
AB	Wileys Well Communication Tower (part of the Public Safety Enterprise Communication System)	East of Wileys Well Road, just south of I-10	Riverside County	Final EIR for the Public Safety Enterprise Communication System published in August 2008.	N/A	The Public Safety Enterprise Communication project is the expansion of the County of Riverside's fire and law enforcement agencies approximately 20 communication sites to provide voice and data transmission capabilities to assigned personnel in the field.
AC	Mule Mountain Solar Project	South of I-10, approximately 4 miles west of Blythe	Bullfrog Green Energy	Plan of Development in to Palm Springs BLM	2,684	500 MW solar concentrating photovoltaic project located on 2,684 acres. Considering interconnection with proposed SCE Colorado Substation. Approximately 6,000 gallons of water would be required monthly.
Additional Projects Outside Cumulative Figure Boundaries						

Table 3. Future Foreseeable Projects along the I-10 Corridor (Eastern Riverside County)						
ID #	Project Name; Agency ID	Location	Ownership	Status	Acres	Project Description
	Paradise Valley "New Town" Development	Approximately 30 miles west of Desert Center (7 miles east of the city of Coachella)	Glorious Land Company	Notice of Preparation of an EIR published in December of 2005. Still under environmental review.	6,397	Company proposed to develop a planned community as an international resort destination with residential, recreational, commercial, and institutional uses and facilities. The project is planned as a self-contained community with all public and quasi-public services provided. The project is located outside the Coachella Valley Water District (CVWD) boundaries and the applicant has entered into an agreement with the CVWD to manage artificial recharge of the Shaver's Valley groundwater. The proponent has purchased a firm water supply from Rosedale-Rio Bravo Water District in Kern County. In-kind water will be transferred to the MWD which will release water from the Colorado River Aqueduct to a 38 acre percolation pond on the project site. The MWD will deliver approximately 10,000 AFY to the percolation pond and over the long term, no net loss of groundwater in storage is anticipated.
	Proposed National Monument (former Catellus Lands)	Between Joshua Tree National Park and Mojave National Preserve		In December 2009, Senator Feinstein introduced bill S.2921 that would designate two new national monuments including the Mojave Trails National Monument.	941,000 acres	The proposed Mojave Trails National Monument would protect approximately 941,000 acres of federal land, including approximately 266,000 acres of the former railroad lands along historic Route 66. The BLM would be given the authority to conserve the monument lands and also to maintain existing recreational uses, including hunting, vehicular travel on open roads and trails, camping, horseback riding and rockhounding.
	BLM Renewable Energy Study Areas	Along the I-10 corridor between Desert Center and Blythe	BLM	Proposed		The DOE and BLM identified 24 tracts of land as Solar Energy Study Areas in the BLM and DOE Solar PEIS. These areas have been identified for in-depth study of solar development and may be found appropriate for designation as solar energy zones in the future.
	Solar Energy projects along Arizona Border	Approximately 15 miles east of the CA/ AZ border along I-10 corridor	Various	Applications filed in to Arizona BLM field offices, application status listed as pending.		Five solar trough and solar power tower projects have been proposed along the I-10 corridor approximately 15 miles east of the CA/AZ border. The projects have been proposed on BLM administered-land in the Yuma and Kingman Field Offices and have requested use of approximately 75,000 acres.

1. Water usage for the Eagle Mountain Pumped Storage Project was based on the information provided to FERC by the Eagle Crest Energy Company in the Responses to Deficiency of License Application and Additional Information Request dated October 26, 2009.

C. ENVIRONMENTAL ANALYSIS

C.1 - AIR QUALITY

Testimony of Joseph Hughes and William Walters, P.E.

C.1.1 SUMMARY OF CONCLUSIONS

U.S. Bureau of Land Management and California Energy Commission staff (hereinafter jointly referred to as "staff") find that with the adoption of the attached conditions of certification the proposed Genesis Solar Energy Project would comply with all applicable laws, ordinances, regulations, and standards and would not result in any significant California Environmental Quality Act air quality impacts. These Conditions of Certification meet the Energy Commission's responsibility to comply with the California Environmental Quality Act and Bureau of Land Management's responsibility to comply with the National Environmental Policy Act.

Staff have concluded that the proposed project would not have the potential to exceed Prevention of Significant Deterioration emission threshold levels during direct source operation and the facility is not considered a major stationary source with potential to cause adverse National Environmental Policy Act air quality impacts. However, without adequate control, the fugitive dust emissions from construction would have the potential to exceed Prevention of Significant Deterioration particulate emission threshold levels. This potential exceedance of a federal air quality emission threshold would be considered a direct, adverse impact under National Environmental Policy Act. This impact would be less than adverse with the proposed mitigation measures controlling fugitive dust emissions during construction.

The Genesis Solar Energy Project would emit substantially lower greenhouse gas[1] emissions per megawatt-hour than fossil fueled generation resources in California. The Genesis Solar Energy Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

C.1.2 INTRODUCTION

Genesis Solar, LLC (hereinafter referred to as the applicant) submitted an Application for Certification (AFC) to construct and operate a solar power plant in Riverside County, California. The proposed project's power block and solar arrays would occupy approximately 1,360 acres of the 1,800-acre project site that would be within a 4,640 right of way grant applied for with the BLM. Additionally, evaporation ponds, an access road, administration buildings and other support facilities, land treatment unit (LTU), and some open areas would be fenced for a total of 1,800 acres. The project site is located in an undeveloped area of Riverside County, approximately 25 miles west of Blythe, California and 27 miles east of Desert Center, California. Surrounding features include

[1] Greenhouse gas (GHG) emissions are not criteria pollutants, but they affect global climate change. In that context, staff evaluates the GHG emissions from the proposed project (Appendix Air-1), presents information on GHG emissions related to electricity generation, and describes the applicable GHG standards and requirements.

the McCoy Mountains to the east, the Palen Mountains (including the Palen/McCoy Wilderness Area) to the north, and Ford Dry Lake, a dry lakebed, to the south. Interstate 10 (I-10) is located approximately two miles south of the southernmost border of the Project site.

This analysis evaluates the expected air quality impacts from the emissions of criteria air pollutants from both the construction and operation of the Genesis Solar Energy Power Project (GSEP or proposed project). Criteria air pollutants are defined as air contaminants for which the state and/or federal governments have established ambient air quality standards to protect public health.

The criteria pollutants analyzed within this section are nitrogen dioxide (NO_2), sulfur dioxide (SO_2), carbon monoxide (CO), ozone (O_3), and particulate matter (PM). Lead is not analyzed as a criteria pollutant, but lead and other toxic air pollutant emissions impacts are analyzed in the Public Health Section of this Staff Assessment (SA). Two subsets of particulate matter are inhalable particulate matter (less than 10 microns in diameter, or PM10) and fine particulate matter (less than 2.5 microns in diameter, or PM2.5). Nitrogen oxides (NOx, consisting primarily of nitric oxide [NO] and NO_2) and volatile organic compounds (VOC) emissions readily react in the atmosphere as precursors to ozone and, to a lesser extent, particulate matter. Sulfur oxides (SOx) readily react in the atmosphere to form particulate matter and are major contributors to acid rain. Global climate change and greenhouse gas (GHG) emissions from the proposed project are discussed in an **Appendix Air-1** and analyzed in the context of cumulative impacts.

In carrying out this analysis, the California Energy Commission (Energy Commission) staff evaluated the following four major issues:

- whether GSEP is likely to conform with applicable federal, state, and Mojave Desert Air Quality Management District (MDAQMD or District) air quality laws, ordinances, regulations and standards (Title 20, California Code of Regulations, section 1744 (b));
- whether GSEP is likely to cause new violations of ambient air quality standards or contribute substantially to existing violations of those standards (Title 20, California Code of Regulations, section 1743);
- whether mitigation measures proposed for GSEP are adequate to lessen potential impacts under the California Environmental Quality Act (CEQA) to a level of insignificance (Title 20, California Code of Regulations, section 1742 (b)); and
- whether GSEP would exceed regulatory benchmarks used to analyze National Environmental Policy Act (NEPA) air quality impacts, before or after implementation of recommended mitigation measures.

C.1.3 METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The analysis of proposed project effects must comply with both CEQA and NEPA requirements given the respective power plant licensing and land use jurisdictions of the

California Energy Commission and U.S. Bureau of Land Management (BLM). Because this document is intended to meet the requirements of both NEPA and CEQA, the methodology used for determining environmental impacts of the proposed project includes a consideration of guidance provided by both laws. A significant impact is defined under CEQA as "a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (Cal.Code Regs., tit.14 [hereinafter CEQA Guidelines] Section 15382). Questions used in evaluating significance of air quality impacts are based on Appendix G of the CEQA Guidelines (CCR 2006). The specific approach used by Commission staff in determining CEQA significance is discussed in more detail below.

Similarly, NEPA states that "'Significantly' as used in NEPA requires considerations of both context and intensity…" (40 CFR 1508.27). Under NEPA, the agency considers three regulatory benchmarks in determining whether a project action would result in an adverse environmental impact when evaluated against the baseline. NEPA requires that an Environmental Impact Statement (EIS) be prepared when the proposed federal action (project) as a whole has the potential to "significantly affect the quality of the human environment." The three regulatory benchmarks that are used to assess impacts under NEPA are discussed in more detail below.

C.1.3.1 LAWS, ORDINANCES, REGULATIONS AND STANDARDS (LORS)

The federal, state, and local laws and policies applicable to the control of criteria pollutant emissions and mitigation of air quality impacts for the GSEP are summarized in **Air Quality Table 1**. Staff's analysis examines the project's compliance with these requirements.

Air Quality Table 1
Laws, Ordinances, Regulations, and Standards

Applicable LORS	Description
Federal	
40 Code of Federal Regulations (CFR) Part 52	Nonattainment New Source Review (NSR) requires a permit and requires Best Available Control Technology (BACT) and Offsets. Permitting and enforcement delegated to MDAQMD. Prevention of Significant Deterioration (PSD) requires major sources or major modifications to major sources to obtain permits for attainment pollutants. GSEP is a new source that does not have a rule listed emission source thus the PSD trigger levels are 250 tons per year for NOx, VOC, SO_2, PM2.5 and CO.
40 CFR Part 60	New Source Performance Standards (NSPS), Subpart Dc Standards of Performance for Small Industrial-Commercial-Institutional Steam Generation Units. Establishes recordkeeping and reporting requirements for natural gas fired steam generating units. Subpart IIII Standards of Performance for Stationary Compression Ignition Internal Combustion Engines. Establishes emission standards for compressions ignition internal combustion engines, including emergency generator and fire water pump engines.
40 CFR Part 93 General Conformity	Requires determination of conformity with State Implementation Plan for Projects requiring federal approvals if project annual emissions are above specified levels.

Applicable LORS	Description
State	
Health and Safety Code (HSC) Section 40910-40930	Permitting of source needs to be consistent with Air Resource Board (ARB) approved Clean Air Plans.
HSC Section 41700	Restricts emissions that would cause nuisance or injury.
California Code of Regulations (CCR) Section 93115	Airborne Toxics Control Measure for Stationary Compression Ignition Engines. Limits the types of fuels allowed, established maximum emission rates, establishes recordkeeping requirements on stationary compression ignition engines, including emergency generator and fire water pump engines.
Local (Mojave Desert Air Quality Management District)	
Rule 201 and 203 Permits Required	Requires a Permit to Construct before construction of an emission source occurs. Prohibits operation of any equipment that emits or controls air pollutant without first obtaining a permit to operate.
Rules 401, 402, and 403 Nuisance, Visible Emissions, Fugitive Dust	Limits the visible, nuisance, and fugitive dust emissions and would be applicable to the construction period of the project.
Rule 404 Particulate Matter - Concentration	Limits the particulate matter concentration from stationary source exhausts.
Rule 406 Specific Contaminants	The rule prohibits sulfur compound emissions in excess of 500 ppmv.
Rule 407 Liquid and Gaseous Air Contaminants	The rule prohibits carbon monoxide emissions in excess of 2,000 ppmv.
Rule 409 Combustion Contaminants	Limits the emissions from fossil fuel combustion.
Rule 431 Sulfur Content of Fuels	Limits the sulfur content of liquid fuels to no more than 0.5 percent by weight.
Rule 900 Standard of Performance for New Stationary Source	Incorporates the Federal NSPS (40 CFR 60) rules by reference.
Rule 1303 New Source Review	Specifies BACT/Offsets technology and requirements for a new emissions unit that has potential to emit any regulated pollutants.
Rule 1306 Electric Energy Generating Facilities	Describes actions to be taken for permitting of power plants that are within the jurisdiction of the Energy Commission.

C.1.3.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Energy Commission staff assesses four kinds of primary and secondary[2] impacts: construction, operation, closure and decommissioning, and cumulative. Construction impacts result from the onsite and offsite emissions occurring during site preparation and construction of the proposed project. Operational impacts result from the emissions of the proposed project during operation, which includes all of the onsite auxiliary equipment emissions (boilers, cooling towers, emergency engines, etc.), the onsite maintenance vehicle emissions, and the offsite employee and material delivery trip emissions. Closure and decommissioning impacts occur from the onsite and offsite emissions that would result from dismantling the facility and restoring the site. Cumulative impacts analysis assesses the impacts that result from the proposed project's incremental effect viewed over time, together with other closely related past, present, and reasonably foreseeable future projects whose impacts may compound or

[2] Primary impacts potentially result from facility emissions of NOx, SOx, CO and PM10/2.5. Secondary impacts result from air contaminants that are not directly emitted by the facility but formed through reactions in the atmosphere that result in ozone, and sulfate and nitrate PM10/PM2.5.

increase the incremental effect of the proposed project. (Pub. Resources Code § 21083; Cal. Code Regs., tit. 14, §§ 15064(h), 15065(c), 15130, and 15355.)

C.1.3.3 METHOD AND THRESHOLD FOR DETERMINING CEQA SIGNIFICANCE

CEC staff evaluates potential impacts per Appendix G of the CEQA Guidelines (CCR 2006) as appropriate for the project. A CEQA significant adverse impact is determined to occur if potentially significant CEQA impacts cannot be mitigated appropriately through the adoption of Conditions of Certification. Specifically, Energy Commission staff uses health-based ambient air quality standards (AAQS) established by the ARB and the U.S.EPA as a basis for determining whether a project's emissions will cause a significant adverse impact under CEQA. The standards are set at levels that include a margin of safety and are designed to adequately protect the health of all members of the public, including those most sensitive to adverse air quality impacts such as the aged, people with existing illnesses, children, and infants. Staff evaluates the potential for significant adverse air quality impacts by assessing whether the project's emissions of criteria pollutants and their precursors (NOx, VOC, PM10 and SO_2) could create a new AAQS exceedance (emission concentrations above the standard), or substantially contributes to an existing AAQS exceedance.

Staff evaluates both direct and cumulative impacts. Staff will find that a project or activity will create a direct adverse impact when it causes an exceedance of an AAQS. Staff will find that a project's effects are cumulatively considerable when the project emissions in conjunction with ambient background, or in conjunction with reasonably foreseeable future projects, substantially contribute to ongoing exceedances of an AAQS. Factors considered in determining whether contributions to ongoing exceedences are substantial include:

1. the duration of the activity causing adverse air quality impacts;

2. the magnitude of the project emissions, and their contribution to the air basin's emission inventory and future emission budgets established to maintain or attain compliance with AAQS;

3. the location of the project site, i.e., whether it is located in an area with generally good air quality where non-attainment of any ambient air quality standard is primarily or solely due to pollutant transport from other air basins;

4. the meteorological conditions and timing of the project impacts, i.e., do the project's maximum modeled pollutant impacts occur when ambient concentrations are high (such as during high wind periods, or seasonally);

5. the modeling methods, and how refined or conservative the impact analysis modeling methods and assumptions were and how that may affect the determined adverse impacts;

6. the project site location and nearest receptor locations; and whether the identified adverse impacts would also occur at the maximum impacted receptor location; and,

7. potential for future cumulative impacts; and whether appropriate mitigation is being recommended to address the potential for impacts associated with likely future projects.

C.1.3.4 NEPA AIR QUALITY ANALYSIS METHODOLOGY

The NEPA air quality analysis considers the following three regulatory benchmarks:

- The project would exceed General Conformity applicability thresholds for federal nonattainment pollutants. This regulatory threshold applies to both project construction and operation emissions.
- The project would exceed PSD permit applicability thresholds for federal attainment pollutants. This regulatory threshold only applies to project operation.
- The project would cause, for federal attainment pollutants, air quality impacts in exceedance of the NAAQS.

If the proposed project were to exceed either of the first two of these regulatory benchmarks then the impacts would be considered potentially adverse and would require a further refined impact and mitigation analysis in order to demonstrate that the proposed project would not result in an adverse impact based on the potential to cause exceedances of the NAAQS. However, regardless of the NEPA requirements for the proposed project, a refined impact and mitigation analysis has been conducted per CEQA requirements, and that analysis and the resulting NEPA findings are described in detail in this document.

C.1.3.5 IMPACTS FROM CLOSURE AND DECOMMISSIONING

Impacts from closure and decommissioning, as a one-time limited duration event, are evaluated with the same methods as construction emissions as discussed above.

C.1.4 PROPOSED PROJECT

C.1.4.1 SETTING AND EXISTING CONDITIONS

Climate and Meteorology

The project site is located 25 miles to the west of Blythe, California within the eastern portion of Riverside County in the Mojave Desert Air Basin (MDAB). This area surrounding the project site has a typical desert climate characterized by low precipitation, hot summers, mild winters, low humidity, and strong temperature inversions. Total rainfall in Blythe averages just less than four inches per year with about 50 percent of the total rainfall occurring during the December through March winter rainy season, and about 30 percent occurring during the August/September summer monsoon season (WC 2009).

The highest monthly average high temperature in Blythe is 109°F in July and the lowest average monthly low temperature is 39°F in December (WC 2009). The applicant provided wind roses from the Blythe Airport Automated Surface Observing System (ASOS) for the years 2002 to 2006. This wind data indicates the highest annual wind

direction frequencies are from the south through the southwest. Quarterly tables show prevailing winds from the south for spring and summer and from the northwest for fall and winter. Calm conditions occur approximately 16 percent of the time, and the annual average wind speed is approximately 7.6 miles per hour (mph). Due to the topography of the particular site, staff would expect a more westerly wind direction.

Sensitive Receptors

The general population includes many sensitive subgroups that may be at greater risk from exposure to emitted pollutants. These sensitive subgroups include the very young, the elderly, and those with existing illnesses. In addition, the location of the population in the area surrounding a project site may have a large bearing on health risk. There are no sensitive receptors within a two mile radius of the site center. The Ironwood and Chuckwalla State Prisons (adjacent to each other) are located approximately nine miles to the south of the Project site.

Existing Ambient Air Quality

The Federal Clean Air Act and the California Clean Air Act both require the establishment of standards for ambient concentrations of air pollutants, called ambient air quality standards (AAQS). The state AAQS, established by the California Air Resources Board, are typically lower (more protective) than the federal AAQS, which are established by the United States Environmental Protection Agency (U.S.EPA). The state and federal air quality standards are listed in **Air Quality Table 2**. The averaging times for the various air quality standards, the times over which they are measured, range from one-hour to an annual average. The standards are read as a concentration, in parts per million (ppm), or as a weighted mass of material per a volume of air, in milligrams or micrograms of pollutant in a cubic meter of air (mg/m^3 or $\mu g/m^3$, respectively).

Air Quality Table 2
Federal and State Ambient Air Quality Standards

Pollutant	Averaging Time	Federal Standard	California Standard
Ozone (O_3)	8 Hour	0.075 ppm[a] (147 µg/m^3)	0.070 ppm (137 µg/m^3)
	1 Hour	—	0.09 ppm (180 µg/m^3)
Carbon Monoxide (CO)	8 Hour	9 ppm (10 mg/m^3)	9.0 ppm (10 mg/m^3)
	1 Hour	35 ppm (40 mg/m^3)	20 ppm (23 mg/m^3)
Nitrogen Dioxide (NO_2)	Annual	0.053 ppm (100 µg/m^3)	0.03 ppm (57 µg/m^3)
	1 Hour	0.100 ppm[b]	0.18 ppm (339 µg/m^3)
Sulfur Dioxide (SO_2)	Annual	0.030 ppm (80 µg/m^3)	—
	24 Hour	0.14 ppm (365 µg/m^3)	0.04 ppm (105 µg/m^3)
	3 Hour	0.5 ppm (1300 µg/m^3)	—
	1 Hour	—	0.25 ppm (655 µg/m^3)
Particulate Matter (PM10)	Annual	—	20 µg/m^3
	24 Hour	150 µg/m^3	50 µg/m^3
Fine Particulate Matter (PM2.5)	Annual	15 µg/m^3	12 µg/m^3
	24 Hour	35 µg/m^3	—
Sulfates (SO_4)	24 Hour	—	25 µg/m^3
Lead	30 Day Average	—	1.5 µg/m^3
	Calendar Quarter	1.5 µg/m^3	—
Hydrogen Sulfide (H_2S)	1 Hour	—	0.03 ppm (42 µg/m^3)
Vinyl Chloride (chloroethene)	24 Hour	—	0.01 ppm (26 µg/m^3)
Visibility Reducing Particulates	8 Hour	—	In sufficient amount to produce an extinction coefficient of 0.23 per kilometer due to particles when the relative humidity is less than 70 percent.

Source: ARB 2009a.
Notes:
[a] The 2008 standard is shown above, but as of September 16, 2009 this standard is being reconsidered. The 1997 8-hour standard is 0.08 ppm.
[b] – The U.S. EPA is in the process of implementing this new standard, which is expected to become effective April 12, 2010. This standard is based on the 3-year average of the 98th percentile of the yearly distribution of 1-hour daily maximum concentrations. Due to this regulation not yet being effective, with a corresponding lack of guidance on impact analysis and existing background concentrations, staff has not completed an impact assessment for compliance with this standard.

In general, an area is designated as attainment if the concentration of a particular air contaminant does not exceed the standard. Likewise, an area is designated as non-attainment for an air contaminant if that contaminant standard is violated. In circumstances where there is not enough ambient data available to support designation as either attainment or non-attainment, the area can be designated as unclassified. The unclassified area is normally treated the same as an attainment area for regulatory purposes. An area could be attainment for one air contaminant while non-attainment for another, or attainment for the federal standard and non-attainment for the state standard for the same air contaminant.

The project site is located in the Mojave Desert Air Basin (MDAB) and is under the jurisdiction of the Mojave Desert Air Quality Management District (MDAQMD). The Riverside County portion of the MDAB is designated as non-attainment for the state ozone and PM10 standards. This area is designated as attainment or unclassified for all federal criteria pollutant ambient air quality standards and the state CO, NO_2, SO_2, and PM2.5 standards. **Air Quality Table 3** summarizes the project site area's attainment status for various applicable state and federal standards.

Air Quality Table 3
Federal and State Attainment Status
Project Site Area within Riverside County

Pollutant	Attainment Status [a]	
	Federal	**State**
Ozone	Attainment [b]	Moderate Nonattainment
CO	Attainment	Attainment
NO_2	Attainment [c]	Attainment
SO_2	Attainment	Attainment
PM10	Attainment [b]	Nonattainment
PM2.5	Attainment	Attainment

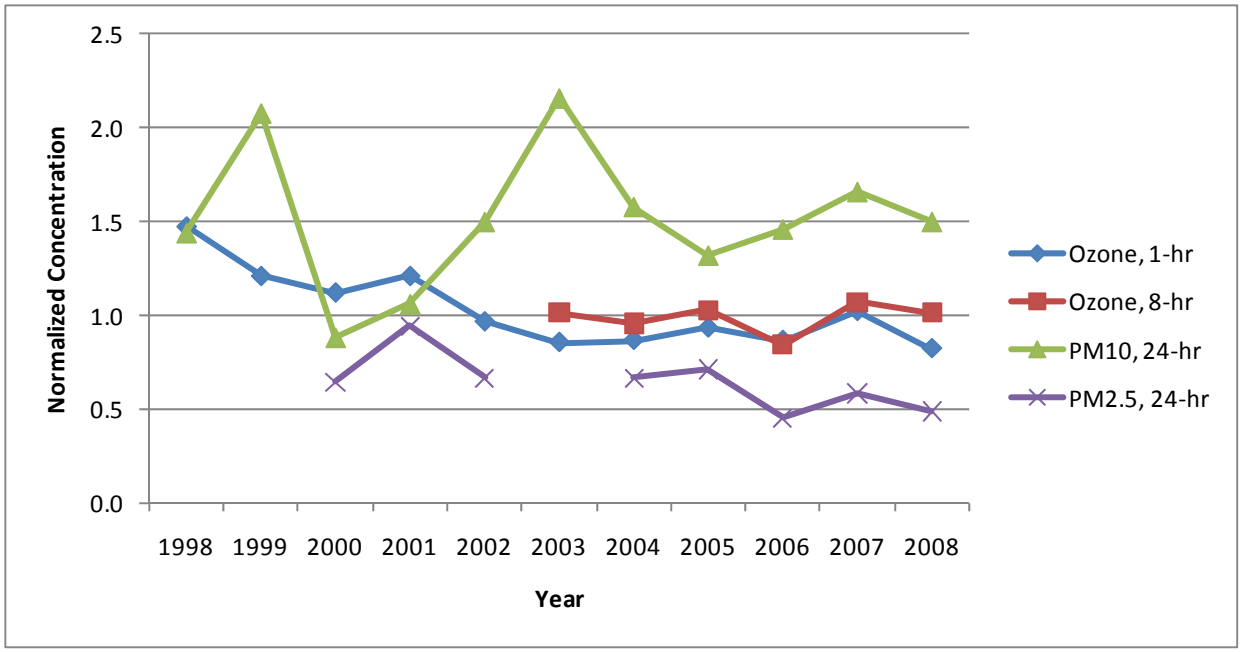
Source: ARB 2009b, U.S.EPA 2009a.
[a] Attainment = Attainment or Unclassified, where Unclassified is treated the same as Attainment for regulatory purposes.
[b] Attainment status for the site area only, not the entire MDAB.
[c] Nitrogen dioxide attainment status for the new federal 1-hour NO_2 standard is scheduled to be determined by January 2012.

Ambient air quality monitoring data for ozone, PM10, PM2.5, CO, NO_2, and SO_2, compared to most restrictive applicable standards for the years between 2004 through 2008 at the most representative monitoring stations for each pollutant are shown in **Air Quality Table 4,** and the 1-hour and 8-hour ozone, and 24-hour PM10 and PM2.5 data for the years 1999 through 2008 are shown in **Air Quality Figure 1**. Ozone data are from the Blythe-445 West Murphy Street monitoring station, PM10, PM2.5, NO_2, and CO data are from the Palm Springs-Fire Station monitoring station and SO_2 data are from the Victorville-14306 Park Avenue monitoring station.

Air Quality Table 4
Criteria Pollutant Summary
Maximum Ambient Concentrations (ppm or µg/m^3)

Pollutant	Averaging Period	Units	2004	2005	2006	2007	2008	Limiting AAQS[c]
Ozone	1 hour	ppm	0.078	0.084	0.078	0.092	0.074	0.09
Ozone	8 hours	ppm	0.067	0.072	0.059	0.075	0.071	0.07
PM10 [a,b]	24 hours	µg/m^3	79	66	73	83	75	50
PM10 [a,b]	Annual	µg/m^3	26.4	25.9	24.5	30.5	23.2	20
PM2.5 [a]	24 hours	µg/m^3	23.3	25	15.9	20.5	17.1	35
PM2.5 [a]	Annual	µg/m^3	9.0	8.4	7.7	8.7	7.2	12
CO	1 hour	ppm	2.1	2.1	2.3	1.5	1.3	20
CO	8 hours	ppm	0.8	0.8	0.85	0.79	0.54	9.0
NO_2	1 hour	ppm	0.066	0.059	0.093	0.063	0.049	0.18
NO_2	Annual	ppm	0.013	0.012	0.01	0.01	0.009	0.03
SO_2	1 hour	ppm	0.011	0.012	0.018	0.009	0.006	0.25
SO_2	3 hour	ppm	0.007	0.008	0.012	0.005	0.006	0.5
SO_2	24 hours	ppm	0.003	0.003	0.005	0.005	0.002	0.04
SO_2	Annual	ppm	0.0013	0.0013	0.0015	0.0013	0.0011	0.03

Source: ARB 2009c, U.S.EPA 2009b



Notes:

[a] Exceptional PM concentration events, such as those caused by wind storms are not shown where excluded by U.S.EPA; however, some exceptions events may still be included in the data presented.

[b] The PM10 data source is in the Coachella Valley that is classified as a serious PM10 nonattainment area.

[c] The limiting AAQS is the most stringent of the CAAQS or NAAQS for that pollutant and averaging period.

Air Quality Figure 1
1998-2008 Historical Ozone and PM Air Quality Data
Blythe and Palm Springs Monitoring Stations, Riverside County[a-c]

Source: ARB 2009c, U.S.EPA 2009b, SCAQMD 2009.
Notes:
[a] The highest measured ambient concentrations of various criteria air contaminants were divided by their applicable standard and provided as a graphical point. Any point on the chart that is greater than one means that the measured concentrations of such air contaminant exceed the standard, and any point that is less than one means that the respective standard is not exceeded for that year. For example the 24-hour PM10 concentration in 2008 is 75 µg/m^3/50 µg/m^3 standard = 1.5.
[b] All ozone data are from Blythe-445 West Murphy Street monitoring station. 8-hr ozone data was not available for this station before 2003.
[c] All PM data are from Palm Springs monitoring station. 24-hr PM2.5 data was not available for this station before 2000.

Ozone

Ozone is not directly emitted from stationary or mobile sources, but is formed as the result of chemical reactions in the atmosphere between directly emitted nitrogen oxides (NOx) and hydrocarbons (Volatile Organic Compounds [VOCs]) in the presence of sunlight to form ozone. Pollutant transport from the South Coast Air Basin (Los Angeles Area) is one source of the of the pollution experienced in the eastern Riverside County portion of the MDAB (SCAQMD 2007, p. 1-2).

As **Air Quality Table 4** and **Air Quality Figure 1** indicate, the 1-hour and 8-hour ozone concentrations measured at the eastern border of Riverside County have been very slowly decreasing and remaining nearly constant over time, respectively. The collected air quality data (not shown) indicate that the ozone violations occurred primarily during the sunny and hot periods typical during May through September.

Nitrogen Dioxide

The entire air basin is classified as attainment for the state 1-hour and annual and federal annual NO_2 standards. The nitrogen dioxide attainment standard could change due to the new federal 1-hour standard, although a review of the air basin wide monitoring data suggest this would not occur for the MDAB.

Approximately 90% of the NOx emitted from combustion sources is nitric oxide (NO), while the balance is NO_2. NO is oxidized in the atmosphere to NO_2, but some level of photochemical activity is needed for this conversion. The highest concentrations of NO_2 typically occur during the fall. The winter atmospheric conditions can trap emissions near the ground level, but lacking substantial photochemical activity (sun light), NO_2 levels are relatively low. In the summer the conversion rates of NO to NO_2 are high, but the relatively high temperatures and windy conditions disperse pollutants, preventing the accumulation of NO_2. The NO_2 concentrations in the project area are well below the state and federal ambient air quality standards.

Carbon Monoxide

The area is classified as attainment for the state and federal 1-hour and 8-hour CO standards. The highest concentrations of CO occur when low wind speeds and a stable atmosphere trap the pollution emitted at or near ground level. These conditions occur frequently in the wintertime late in the afternoon, persist during the night and may extend one or two hours after sunrise. The project area has a lack of significant mobile source emissions and has CO concentrations that are well below the state and federal ambient air quality standards.

Particulate Matter (PM10) and Fine Particulate Matter (PM2.5)

PM10 can be emitted directly or it can be formed many miles downwind from emission sources when various precursor pollutants interact in the atmosphere.

The area is non-attainment for state PM10 standards and unclassified for the federal PM10 standard. **Air Quality Table 4** and **Air Quality Figure 1** shows recent PM10/PM2.5 concentrations. The figure shows fluctuating concentrations patterns, and shows clear exceedances of the state 24-hour PM10 standard. It should be noted that exceedance does not necessarily mean violation or nonattainment, as exceptional events do occur and some of those events, which do not count as violations, may be included in the data. The MDAB is designated as nonattainment for the state PM10 standard.

Fine particulate matter, or PM2.5, is derived mainly from either the combustion of materials, or from precursor gases (SOx, NOx, and VOC) through complex reactions in the atmosphere. PM2.5 consists mostly of sulfates, nitrates, ammonium, elemental carbon, and a small portion of organic and inorganic compounds.

The entire MDAB is classified as attainment for the federal standard and, in the project area, is designated unclassified for the state PM2.5 standards. This divergence in the PM10 and PM2.5 concentration levels and attainment status indicates that a substantial fraction of the ambient particulate matter levels are most likely due to localized fugitive dust sources, such as vehicles travel on unpaved roads, agricultural operations, or wind-blown dust.

Sulfur Dioxide

The entire air basin is classified as attainment for the state and federal SO_2 standards. Sulfur dioxide is typically emitted as a result of the combustion of a fuel containing sulfur. Sources of SO_2 emissions within the MDAB come from a wide variety of fuels:

gaseous, liquid and solid; however, the total SO_2 emissions within the eastern MDAB are limited due to the limited number of major stationary sources and California's and U.S. EPA's substantial reduction in motor vehicle fuel sulfur content. The project area's SO_2 concentrations are well below the state and federal ambient air quality standards.

Summary

In summary, staff recommends the background ambient air concentrations in **Air Quality Table 5** for use in the modeling and impacts analysis. The recommended background concentrations are based on the maximum criteria pollutant concentrations from the past three years of available data collected at the most representative monitoring stations surrounding the project site.

Air Quality Table 5
Staff Recommended Background Concentrations (µg/m^3)

Pollutant	Averaging Time	Recommended Background	Limiting AAQS [b]	Percent of Standard
NO_2	1 hour	175	339	52%
	Annual	19	57	33%
CO	1 hour	2645	23,000	12%
	8 hour	944	10,000	9%
PM10	24 hour	83	50	166%
	Annual	30.5	20	153%
PM2.5	24 hour [a]	20.5	35	59%
	Annual	8.7	12	73%
SO_2	1 hour	47	655	7%
	3 hour	31	1,300	2%
	24 hour	13	105	12%
	Annual	4	80	5%

Source: ARB 2009c, U.S.EPA 2009b and Energy Commission Staff Analysis
Note:
[a] PM2.5 24-hour data shown in **Air Quality Table 4** are 98th percentile values which is the basis of the ambient air quality standard and the basis for determination of the recommended background concentration.
[b] The limiting AAQS is the most stringent of the CAAQS or NAAQS for that pollutant and averaging period.

Where possible, staff prefers that the recommended background concentration measurements come from nearby monitoring stations with similar characteristics. For this proposed project the Blythe monitoring station (ozone), at approximately 35 miles east of the project site, is the closest monitoring station. The Palm Springs monitoring station (PM10, PM2,5, NO_2,and CO) is located approximately 90 miles west of the project site. The Victorville monitoring station (SO_2) is located approximately 145 miles west northwest of the project site. In general, the Palm Springs and Victorville monitoring stations are considered to provide conservative estimates of the worst case background concentrations due to their proximity to the South Coast Air Basin (Metropolitan Los Angeles). Monitoring stations located in Imperial County were not selected or considered as representative due to the predominant air flow patterns and due to air pollution from Mexico that creates a significant local influence for the worst-case pollutant concentration readings within Imperial County.

The background concentrations for PM10 are well above the most restrictive existing ambient air quality standards, while the background concentrations for the other pollutants are all below the most restrictive existing ambient air quality standards.

The pollutant modeling analysis was limited to the pollutants listed above in **Air Quality Table 5**; therefore, recommended background concentrations were not determined for the other criteria pollutants (ozone, lead, visibility, etc.).

C.1.4.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Staff provided a number of data requests regarding the construction and operations emission estimates and air dispersion modeling analysis (CEC 2009d), which the applicant responded to by providing revised emissions estimates and substantially revised and more robust dispersion modeling analysis (GSEP 2009f, TTEC 2010h). Staff has reviewed the revised emission estimates and air dispersion modeling analysis[3] and finds them to be generally reasonable considering the level of emissions mitigation now stipulated to by the applicant.

Project Description

The Genesis Solar Energy Project (GSEP or proposed project) would consist of two independent concentrated solar electric generating facilities (aka power plants or units) with a nominal net electrical output of 125 megawatts (MW) each, for a total net electrical output of 250 MW. The proposed project would use well-established parabolic trough solar thermal technology to produce electrical power using steam turbine generators (STG) fed from solar steam generators (SSG) which transfers energy from the solar heated HTF to the steam that drives the STG.

Each plant would use one natural gas-fueled auxiliary boiler to reduce start-up time and provide HTF freeze protection. Freeze protection would maintain the HTF at a minimum temperature of 100 degrees Fahrenheit (°F).

The Project proposes to use a wet cooling tower for power plant cooling. Water for cooling tower make-up, process water make-up, and other industrial uses such as mirror washing would be supplied from on-site groundwater wells, which would also be

[3] This includes a review of the emission source inputs, including the type of source (point, volume, area) and the variables used to describe each source (emissions, height, location, temperature, etc. as appropriate). Staff does not agree with certain assumptions regarding the onsite fugitive dust calculations or the one way delivery trip assumptions.

The applicant's oversimplified fugitive dust emission calculations do not appear to provide a conservative estimate of the fugitive dust emission potential for the project's construction requirements. Staff may provide a revised fugitive dust emission estimate and modeling impact analysis in the SA addendum/FEIS document. However, this step may not be needed due to the lack of sensitive receptors near site and the fact that this underestimation would not otherwise impact staff's findings or recommended mitigation measures.

Additionally, staff does not believe that there are backhauling opportunities at this remote site for the regional trucking necessary to deliver materials from Phoenix, where the applicant assumed they are only responsible for one way delivery trips, which would underestimate the project's offsite emissions. However, this underestimate does not impact the onsite impact modeling analysis or other impact finding for this project, so staff has not made any corrections to the delivery vehicle offsite emission estimates.

used to supply water for employee use (*e.g.,* drinking, showers, sinks, and toilets). A package water treatment system would be used to treat the water to meet potable standards. A sanitary septic system and on-site leach field would be used to dispose sanitary wastewater.

Project cooling water blowdown would be piped to lined, on-site evaporation ponds. The ponds would be sized to retain approximately seven years' worth of solids and would be cleaned out periodically during the life of the plant to ensure the solids do not reach a depth greater than approximately three feet. Dewatered residues from the ponds would be sent to an appropriate off-site landfill as non-hazardous waste.

Other construction elements of the project include the access road, the natural gas pipeline connection, and the transmission line tie-in connection. The proposed project's access road from the I-10 would be approximately 6.5 miles long. Natural gas would be supplied via an 8-inch, 6 mile long pipeline that would be connected with the Southern California Gas Company pipeline located just north of the I-10. The transmission line connection would include the construction of an approximately 7 mile long (including the construction of 60 transmission line poles) 230 kV transmission line that would meet the Blythe Energy Project Transmission Line (currently in construction) which it would share, requiring new line cables be strung to the Colorado River Substation. The new transmission line, access road, and natural gas pipeline would be co-located in one linear corridor to serve the main project facility.

Project Emissions

Project Construction

The total duration of project construction for GSEP is estimated to be approximately 37 months. Different areas within the project site and the construction laydown areas would be disturbed at different times over the construction period. Total construction disturbance area would be approximately 1,800 acres, and the permanent disturbance area of the project operations would be approximately 1,360 acres. The maximum acreage disturbed on any one day during construction is estimated by the applicant to be 160 acres. Combustion emissions would result from the off-road construction equipment, including diesel construction equipment used for site grading, excavation, and construction of onsite structures, and water and soil binder spray trucks used to control construction dust emissions. Fuel combustion emissions also would result from exhaust from on-road construction vehicles, including heavy duty diesel trucks used to deliver materials, other diesel trucks used during construction, and worker personal vehicles and pickup trucks used to transport workers to and from and around the construction site. Fugitive dust emissions would result from site grading/excavation activities, installation of new transmission lines, water and gas pipelines, construction of power plant facilities, roads, and substations, and vehicle travel on paved/unpaved roads.

The shorter duration offsite construction activities are based on the following construction durations and construction period timeframes:

- Access Road Construction – 3 months (Months 1-3)

- Gas Pipeline Construction – 5 months (Months 15-19)
- Transmission Line Construction – 6 months (Months 4-9)

The applicant's maximum daily and total construction period emission estimates, that include the applicant's fugitive dust mitigation assumptions but fleet average off-road equipment emission factors, are provided below in **Air Quality Tables 6** and **7**.

Source: TTEC 2010h, Table 2.

The applicant used an oversimplified fugitive dust emission calculation method that staff does not consider appropriate for a project with the construction complexity and requirements of GSEP. Staff believes this oversimplified calculation method underestimates the fugitive dust emissions during construction. Additionally, the applicant did not provide a maximum annual emission estimate, and the air dispersion modeling analysis used a 12-month average value which understates the maximum annual emissions and impacts. Staff may create a separate emission estimate, and if necessary modeling analysis, to cover these deficiencies and if performed the results of this separate analysis will be provided in the SA Addendum/FEIS document.

Project Operation

The GSEP facility would be a nominal 250 Megawatt (MW) solar electrical generating facility. The direct air pollutant emissions from power generation are negligible; however, there are auxiliary equipment and maintenance activities necessary to operate and maintain the facility.

The following are the stationary and mobile emission source operating assumptions that were used to develop the operation emissions estimates for the GSEP:

Stationary emission sources[4]:

GSEP would consist of two 125 MW power plant units at the facility, each of which consists of the following equipment and emission estimate bases:

- Auxiliary Boiler: 30.0 MMbtu/hr, fired on natural gas. Emissions estimate is based on 14 hr/day, and 1,000 hr/year of full load operation each.
- Cooling tower: seven cell wet cooling tower unit that provides steam cycle and auxiliary plant cooling. Water recirculation rate of 94,623 gallons/minute, maximum recirculating water total dissolved solids content of 5,000 ppm, and mist eliminator efficiency of 0.0005 percent. Emissions are based on 15 hr/day and 3,200 hr/year of operation each.
- HTF Vent Control System: Venting emission rate based on project specific HTF decomposition rate and decomposition product assumptions. Venting carbon adsorption control system would reduce emissions by 99 percent.
- HTF Piping System: 2,500 valves in service 16 hr/day, 10 pump seals in service 16 hr/day, 3,000 connectors in service 16 hr/day and 10 pressure relief valves in service 8 hr/day. SOCMI light liquid and gas (PRVs) emission factors are used[5].

[4] In addition to the list of equipment below the applicant included emission estimates for a diesel tank and HTF waste load out. Staff has not included these emission sources due to: 1) their negligible emissions potential; 2) their exempt permitting status; and 3) to be consistent with other recent thermal solar project assessments.

[5] Staff is currently in the process of determining a consistent approach for HTF piping component emission factors with other local agencies that are currently permitting thermal solar facilities, where light liquid Synthetic Organic Chemical Manufacturing Industry (SOCMI) factors are being used to estimate VOC emissions for other projects that also use Therminol® VP-1 HTF. Staff will provide a revised emission estimate for this and other emission consistency issues related to the FDOC in the Air Quality Staff Assessment Addendum, if necessary.

- Fire pump engine: 315 horsepower (hp) diesel-fired engine. One hour per day and 52 hours per year maximum operation.
- Emergency generator engine: 1341 hp (1000 kW) diesel-fired engine. One hour per day and 52 hours per year maximum operation.
- Gasoline tank: 2,000 gallon tank: Phase 1 vapor recovery, no Phase 2 vapor recovery. Tank annual 10,768 gallons. Daily emissions based on annual emissions divided by 365 days/year.

Mobile emissions source:

- Mobile emissions sources required for operation and maintenance and employee trips are estimated based on vehicle miles traveled (VMT) and operating hours. Each mobile source has different basis for emissions estimates as provided in the applicant's revised emission estimate spreadsheets (TTEC 2010h).

The GSEP onsite stationary and onsite and offsite mobile source emissions, totaled or both power units, are estimated and summarized in **Air Quality Tables 8** and **9**.

Project Construction and Operation Overlapping

Units #1 and #2 would be developed in phases with construction for Unit #2 scheduled to begin twelve months after construction of Unit #1. Each unit would take approximately twenty five months to construct before beginning commercial operation. Unit #1 would be expected to begin commercial operation in the twenty fifth month of construction and Unit #2 would be expected to begin commercial operation after the thirty seventh month of construction. Although there would be an overlap of construction and commercial operation of twelve months, staff does not anticipate this overlap to be the maximum worst case scenario. Construction emissions are considerably higher than operating emissions and the maximum construction emissions occur early in the overall construction process (months 2 through 13), so any overlap after the maximum construction period is assumed not to create a new maximum emissions scenario. Therefore, staff concludes that the overlapping emissions and impacts during this overlapping period would be no worse than the worst-case construction impacts and has not performed any additional impact assessment of the construction/operation overlapping period.

Initial Commissioning

Initial commissioning refers to a period prior to beginning commercial operation when the equipment undergoes initial tests. Because of this proposed project's use of a non-fuel fired generating technology, staff does not expect major changes in emissions from the facility commissioning activities compared to that of normal operation.

Dispersion Modeling Assessment

While the emissions are the actual mass of pollutants emitted from the proposed project, the impacts are the concentration of pollutants from the proposed project that reach the ground level. When emissions are expelled at a high temperature and velocity through a relatively tall stack, the pollutants would be greatly diluted by the time they

reach ground level. For this proposed project there are no very tall emission stacks, but the construction and maintenance vehicles and emergency engine do have high temperature and velocity exhausts; and the boilers also have relatively high exhaust temperatures and velocities. The emissions from the proposed project, both stationary source and onsite mobile source emissions, are analyzed through the use of air dispersion models to determine the probable impacts at ground level.

Air dispersion models provide a means of predicting the location and ground level magnitude of the impacts of a new emissions source. These models consist of several complex series of mathematical equations, which are repeatedly calculated by a computer for many ambient conditions to provide theoretical maximum offsite pollutant concentrations short-term (1-hour, 3-hour, 8-hour, and 24-hour) and annual periods. The model results are generally described as maximum concentrations, often described as a unit of mass per volume of air, such as micrograms per cubic meter ($\mu g/m^3$).

The applicant used the U.S.EPA guideline ARMS/EPA Regulatory Model (AERMOD) model to estimate ambient impacts from project construction and operation. The construction emission sources for the site were grouped into two categories: equipment (off-road equipment); and vehicles (on-road equipment), where the exhaust and fugitive dust emissions for each type were calculated for particulate matter modeling. Emissions from onsite equipment engines during construction were modeled as point sources and fugitive emission sources were modeled as area sources. For operation the stationary sources were modeled as point sources and the maintenance vehicle emissions, tailpipe and fugitive dust emissions, were modeled as area sources.

The inputs for the air dispersion models include stack information (exhaust flow rate, temperature, and stack dimensions), specific fire pump engine, emergency generator, auxiliary boiler, cooling tower, and vehicle emission data; and meteorological data, such as wind speed, atmospheric conditions, and site elevation. For this project, the meteorological data used as inputs to the model included hourly wind speeds and directions measured at the Blythe Airport Automated Surface Observing Systems (ASOS) monitoring station during 2002 through 2006.

NOx emissions from internal combustion sources, such as diesel engines, are primarily in the form of nitric oxide (NO) rather than NO_2. The NO converts into NO_2 in the atmosphere, primarily through the reaction with ambient ozone. The applicant used the U.S.EPA ambient ratio method (ARM) default multiplier of 0.75 as the worst-case downwind annual NO_2/NOx ratio for the determination of the annual NO_2 concentration for construction. However, the applicant did not use any modeling procedures to consider the short-term NO_2/NOx ratio for construction or operation, which would be lower than the annual ARM value, or apply the ARM multiplier to determine the annual NO2 impacts determined for operation. Therefore, the modeling method is very conservative and will over predict actual worst-case 1-hour NO_2 concentrations.

Staff revised the background concentrations provided by the applicant, replacing them with the available highest ambient background concentrations from the last three years at the most representative monitoring stations as show in **Air Quality Table 5**. Staff added the modeled impacts to these background concentrations, and then compared the results with the ambient air quality standards for each respective air contaminant to

determine whether the proposed project's emission impacts would cause a new exceedance of an ambient air quality standard or would contribute to an existing exceedance.

The following sections discuss the proposed project's short-term direct construction and operation ambient air quality impacts, as estimated by the applicant, and describes appropriate mitigation measures.

Construction Impacts and Mitigation

Using estimated peak onsite hourly, daily and annual construction equipment exhaust emissions, the applicant modeled the proposed project's construction emissions to determine impacts (GSEP 2009f). To determine the construction impacts on ambient standards (i.e. 1-hour through annual) it was assumed that the emissions would occur during a daily construction schedule of 10 hour days (8 am to 6 pm). The predicted proposed project concentration levels were added to a conservatively estimated background of existing emission concentration levels (**Air Quality Table 5**) to determine the cumulative effect. The results of the applicant's modeling analysis are presented in **Air Quality Table 10**. The construction modeling analysis includes both the onsite fugitive dust and vehicle tailpipe emission sources estimated by the applicant (with applicant-proposed control measures) and summarized in **Air Quality Tables 6** and **7**.

Air Quality Table 10
Maximum Project Construction Impacts

Pollutants	Avg. Period	Project Impact [a] ($\mu g/m^3$)	Background ($\mu g/m^3$)	Total Impact ($\mu g/m^3$)	Standard ($\mu g/m^3$)	Percent of Standard
NO_2	1-hr.	84.1	175.2	259.3	339	76%
	Annual	0.34	19.0	19.3	57	34%
CO	1-hr	41.6	2,300	2,342	23,000	10%
	8-hr	10.8	944	955	10,000	10%
PM10	24-hr	45.0	83	128	50	256%

	3-hr	0.06	31.2	31.3	1,300	2%
	24-hr	0.02	13.1	13.1	105	12%
	Annual	<0.001	4	4	80	5%

Source: GSEP 2009f, DR 19.
Note:
[a] – These results do not include the fugitive dust emission revision performed by the applicant in the revised data responses (TTEC 2010h).

This modeling analysis indicates, with the exception of PM10 that the proposed project would not create new exceedances or contribute to existing exceedances for any of the modeled air pollutants. The conditions that would create worst-case project modeled impacts (low wind speeds) are not the same conditions when worst-case background is expected. Additionally, the worst-case PM10 impacts occur at the fence line and drop off quickly with distance from the fence line. In light of the existing PM10 non-attainment status for the project site area, staff considers the construction PM10 emissions to be potentially CEQA significant and recommends that the off-road equipment and fugitive dust PM10 emissions be mitigated pursuant to CEQA.

In light of the existing ozone non-attainment status for the project site area, staff considers the construction NOx and VOC emissions to be potentially CEQA significant and recommends that the off-road equipment NOx and VOC emissions be mitigated pursuant to CEQA.

Staff concludes that with implementation of staff-proposed mitigation measures the construction impacts would not contribute substantially to exceedances of PM10 or ozone standards.

The modeling analysis shows that, after implementation of the recommended emission mitigation measures, the proposed project's construction is not predicted to cause new exceedances of the NAAQS. Therefore, staff determined that no adverse NEPA impacts would occur after implementation of the recommended mitigation measures.

Construction Mitigation

Applicant's Proposed Mitigation

To mitigate the impacts due to construction of the facility, the applicant has stipulated to construction mitigation measures that are similar to older versions of staff's recommended conditions **AQ-SC3** and **AQ-SC5** used for gas turbine siting cases in the past (GSEP 2009a, Section 5.2.2.6). The measures specifically stipulated to by the applicant are listed below:

Proposed Exhaust Emissions Control:

- The Applicant will work with the construction contractor to use, to the extent feasible, EPA/Air Resources Board (ARB) Tier II/Tier III engine compliant equipment for equipment over 100 hp.
- Ensure periodic maintenance and inspections per the manufacturer's specifications.
- Reduce idling time through equipment and construction scheduling.
- Use California low sulfur diesel fuels (<=15 ppmw S).

Proposed Fugitive Dust Emissions Control:

- The Applicant will have an on-site construction mitigation manager who will be responsible for the implementation and compliance of the construction mitigation program. The documentation of the ongoing implementation and compliance with the proposed construction mitigations will be provided on a periodic basis.
- All unpaved roads and disturbed areas in the Project and laydown construction sites will be watered as frequently as necessary to control fugitive dust. The frequency of watering will be on an average schedule of every three hours during the daily construction activity period. Watering may be reduced or eliminated during periods of precipitation.
- On-site vehicle speeds will be limited to 15 miles per hour (mph) on unpaved areas within the Project construction site.
- The construction site entrance(s) will be posted with visible speed limit signs.

- All construction equipment vehicle tires will be inspected and cleaned as necessary to be free of dirt prior to leaving the construction site via paved roadways.
- Gravel ramps will be provided at the tire cleaning area.
- All unpaved exits from the construction site will be graveled or treated to reduce track-out to public roadways.
- All construction vehicles will enter the construction site through the treated entrance roadways, unless an alternative route has been provided.
- Construction areas adjacent to any paved roadway will be provided with sandbags or other similar measures as specified in the construction SWPPP to prevent runoff to roadways.
- All paved roads within the construction site will be cleaned on a periodic basis (or less during periods of precipitation), to prevent the accumulation of dirt and debris.
- The first 500 feet of any public roadway exiting the construction site will be cleaned on a periodic basis (or less during periods of precipitation), using wet sweepers or air-filtered dry vacuum sweepers, when construction activity occurs or on any day when dirt or runoff from the construction site is visible on the public roadways.
- Any soil storage piles and/or disturbed areas that remain inactive for longer than 10 days will be covered, or treated with appropriate dust suppressant compounds.
- All vehicles used to transport solid bulk material on public roadways and have the potential to cause visible emissions will be covered, or the materials will be sufficiently wetted and loaded onto the trucks in a manner to minimize fugitive dust emissions. A minimum freeboard height of two feet will be required on all bulk materials transport.
- Wind erosion control techniques (such as windbreaks, water, chemical dust suppressants, and/or vegetation) will be used on all construction areas that may be disturbed. Any windbreaks installed to comply with this condition will remain in place until the soil is stabilized or permanently covered with vegetation.
- Disturbed areas will be re-vegetated or covered with gravel or other dust suppressant material as soon as practical and restored in accordance with BLM requirements.

Adequacy of Proposed Mitigation

Staff generally concurs with the applicant's proposed mitigation measures, which mirror many of the staff mitigation recommendations from previous siting cases. But staff has been proposing additional fugitive dust mitigation, such as requiring the use of soil binders or paving to reduce emissions on unpaved roads, that is considered necessary to reduce the very high fugitive dust emission potential for large solar projects, such as GSEP. Staff also believes that the off-road equipment mitigation measures need to be updated to meet current staff recommendations.

Staff Proposed Mitigation

Staff recommends the applicant's proposed construction mitigation be formalized, with modifications that update the measures to meet current staff recommendations, in staff

Conditions of Certification **AQ-SC1** through **AQ-SC5**. Staff has determined that the proposed conditions of certification would mitigate all construction air quality impacts of the proposed project to less than significant levels pursuant to CEQA.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

Operational Impacts and Mitigation

The following section discusses the proposed project's direct operating ambient air quality impacts, as estimated by the applicant and evaluated by staff. Additionally, this section discusses the recommended mitigation measures.

Operational Modeling Analysis

Using estimated peak onsite hourly, daily and annual operating emissions, the applicant modeled the proposed project's operation emissions to determine impacts (GSEP 2009f). The predicted proposed project concentration levels were added to a conservatively estimated background of existing emission concentration levels (**Air Quality Table 5**) to determine the cumulative effect. **Air Quality Table 11** presents the results of the applicant's modeling analysis. Staff notes that the applicant's determined maximum 1-hour NO_2 concentration was not based on the ozone limiting method (OLM) calculation, or any other method to determine the NO_2/NOx ratio, and so assumes that all NOx emission are NO_2 which overstates the maximum NO_2 impacts. The operation modeling analysis includes emissions from the stationary sources and the onsite fugitive dust and vehicle tailpipe emission sources estimated by the applicant, which all include the applicant's proposed control measures, and that are summarized in **Air Quality Tables 8** and **9**.

Air Quality Table 11
Project Operation Emission Impacts

Pollutants	Avg. Period	Project Impact [a] ($\mu g/m^3$)	Background ($\mu g/m^3$)	Total Impact ($\mu g/m^3$)	Standard ($\mu g/m^3$)	Percent of Standard
NO_2	1-hr.	189.9	175.2	365.1	339	107%
	Annual	0.06	19.0	19.1	57	33%
CO	1-hr	12.3	2,300	2,312	23,000	10%
	8-hr	2.5	944	947	10,000	10%
PM10	24	15.9	83	98.8	50	198%
	Annual	4.3	30.5	34.8	20	174%
PM2.5	24	3.4	20.5	23.9	35	68%
	Annual	0.9	8.7	9.6	12	80%
SO_2	1-hr	0.184	47.2	47.4	665	7%
	3-hr	0.102	31.2	38.3	1,300	3%
	24-hr	0.008	13.1	13.1	105	12%
	Annual	0.0003	4	4	80	5%

Source: GSEP 2009f, DR 27, Table 6.
Note:
[a] – These results do not include the fugitive dust emission revision performed by the applicant after the data responses (TTEC 2010h).

This modeling analysis indicates, with the exception of 1-hour NO_2 and 24-hour and annual PM10 impacts that the proposed project would not create new exceedances or contribute to existing exceedances for any of the modeled air pollutants. The conditions that would create worst-case project modeled impacts (low wind speeds) are not the same conditions when worst-case background is expected for PM10/PM2.5. Additionally, the worst-case PM2.5 and PM10 impacts occur at the fence line and drop off quickly with distance from the fence line. Therefore, staff concludes that the operation impacts, when considering staff's mitigation measures, would not contribute substantially to exceedances of the PM10 CAAQS.

Staff also notes that the maximum background 1-hour NO_2 concentration, determined from a Palm Springs monitoring station, is very conservative both due to its proximity to the South Coast Air Basin (Los Angeles Metropolitan Area), and due to it being a single maximum value that would almost certainly not correspond to the same time period as the maximum modeled concentration. Staff's review of the modeling analysis indeed shows that the maximum hourly modeled concentration does not occur during this maximum background hour or the second highest background concentration. The next highest background concentration from the Palm Springs monitoring station from 2006 through 2008 is 118.7 $\mu g/m^3$, and pairing this background concentration with the very conservative 1-hour modeled concentration would give a total cumulative impact of 308.6 µg/m3 which does not create a new exceedance, and is 91 percent of the State 1-hour standard. Staff believes that the maximum worst-case impact, if a more refined NOx OLM modeling analysis were performed would be substantially lower than 91 percent of the State 1-hour standard. Therefore, staff concludes that the operation impacts, when considering appropriate background concentrations and the very conservative modeling methods, would not create new exceedances of the 1-hour NO_2 CAAQS.

However, in light of the existing PM10 and ozone non-attainment status for the project site area, staff considers the operation NOx, VOC, and PM emissions to be potentially CEQA significant and recommends that the off-road equipment and fugitive dust emissions be mitigated pursuant to CEQA.

The modeling analysis shows that, after implementation of the recommended emission mitigation measures, the proposed project's operation is not predicted to cause new exceedances of the NAAQS. Therefore, it has been determined that no adverse NEPA impacts would occur after implementation of the recommended mitigation measures.

Operations Mitigation

Applicant's Proposed Mitigation

Emission Controls

As discussed in the air quality section of the AFC and Data Reponses (GSEP 2009f, TTEC 2010h), the applicant proposes the following Best Available Control Technology (BACT) emission controls on the stationary equipment and other emission mitigation measures for the mobile equipment associated with the operation of the GSEP:

HTF Auxiliary Boilers

The applicant has proposed two 30.0 MMbtu/hr auxiliary boilers, which would be fired on pipeline quality natural gas, and would be equipped with low NOx burner technology. The operation of each boiler is limited to 14 hours a day and 1,000 hours per year. The proposed boilers would each have the following emission limits:

- NOx: 0.33 lbs/hr (9 ppmv @ 3% O2)
- CO: 0.563 lbs/hr (50 ppmv @ 3% O2)
- VOC: 0.088 lbs/hr
- PM10/PM2.5: 0.15 lbs/hr
- SO_2: 0.008 lbs/hr

Emergency Electrical Generators

The applicant has proposed two 1341 hp (1000 kW) emergency generator engines. The engines would meet BACT requirements through the engine design (U.S.EPA/ARB Tier 2 compliant engines), and ARB diesel fuel. Testing would be for less than 60 minutes per day per engine and the engines would not run for more than 50 hours per year each. The emergency generator engines would have the following emission guarantees:

- NOx: 4.93 gram/bhp-hour
- CO: 0.13 gram/bhp-hour
- VOC: 0.1 gram/bhp-hour
- PM10/PM2.5: 0.018 gram/bhp-h
- SO_2: ARB diesel fuel (15 ppm sulfur)

Fire Water Pump Engines

The applicant has proposed two 315 hp fire water pump engines. The engines would meet BACT requirements through the engine design (U.S.EPA/ARB Tier 3 compliant engines), and ARB diesel fuel. Testing would be for less than 60 minutes per day per engine and the engines would not run for more than 50 hours per year each. The fire water pump engines would have the following emission guarantees:

- NOx: 2.69 gram/bhp-hour
- CO: 0.45 gram/bhp-hour
- VOC: 0.06 gram/bhp-hour
- PM10/PM2.5: 0.055 gram/bhp-hour
- SO_2: ARB diesel fuel (15 ppm sulfur)

Cooling Towers

The applicant has proposed two seven-cell cooling towers, which are used for main steam power cycle and auxiliary cooling. The cooling towers would each have a high efficiency drift eliminator guaranteed to control drift to 0.0005 percent of the water recirculation rate. The cooling towers would have a maximum TDS of 5,000 ppm and

would operate 15 hours per day and 3,200 hours per year. Each cooling tower would have the following emission limits:

- PM10/PM2.5: 1.18 lbs/hr

HTF Vent Exhausts

The applicant has proposed one HTF ullage tank system for the project. The HTF breaks down over time and these breakdown products need to be released to maintain the working composition of the HTF. The breakdown products are a mixture of higher and lower boiling organic compounds (VOC) that are vented in order to remove them from the HTF mixture. The VOC emissions would be controlled with a carbon adsorption system with a control efficiency of 99%. VOC emissions would be limited to a maximum of 0.337 lb/hr after control, combined for both systems, and the HTF ullage tank would be vented a maximum of 8.8 hours per day and 3,200 hours/year:

HTF Piping Systems

The two HTF piping systems are composed of a number of piping components (pump seals, valves, pressure relief vents, flanges, etc.). These components would leak hot HTF that would evaporate and cause VOC emissions. The applicant is proposing to use double mechanical seals on pumps and maintenance inspections and repair of the piping system to reduce HTF leaks.

Gasoline Tank

The applicant has proposed a 2,000 gallon gasoline tank with Phase I vapor recovery for tank filling, but no Phase II vapor recovery for vehicle refueling. The annual tank throughput is estimated to be 10,768 gallons and would have the following emission factor and annual emissions:

- VOC: 13 lbs/1,000 gallons throughput and 0.07 tons/year

Operational and Maintenance Vehicles

To minimize operating emissions, the applicant has proposed mitigation measures to minimize the operating and maintenance vehicles emissions. Following are the proposed mitigation measures (GSEP 2009c, p.4; GSEP 2009f, DR 24).

- Vehicles (mobile sources) used for maintenance activities will meet all required exhaust standards as implemented and enforced by the CARB and the United States Environmental Protection Agency.
- Vehicles will use only CARB certified motor vehicle fuels.
- Vehicles will be maintained per the manufacturers' operations and maintenance schedules.
- Vehicles will be "smog" tested (as applicable) on the schedule as determined by the California DMV
- Onsite vehicle speeds will be limited to the following: (1) <=15 mph on onsite paved roads, and (2) <=5 mph on onsite unpaved (gravel) roads.

- Road maintenance will be performed as needed. Paved roads will be swept, sealed, and/or overlaid as needed. Gravel surfaces will inspected and maintained as necessary to insure the integrity of the gravel surface.

Additionally, the applicant would be willing to stipulate to a condition of certification that would require a review of available alternative low-emission vehicle technologies, including electric and hydrogen fueled vehicles, and use of those technologies to replace the proposed diesel and gasoline fueled vehicles used for operations maintenance if lower emission alternative technology vehicles are both available and not cost prohibitive (GSEP 2009f, DR 24).

Adequacy of Proposed Mitigation

Staff generally concurs with the District's preliminary determination that the proposed project's stationary source proposed emission controls/emission levels for criteria pollutants meet regulatory requirements and that the proposed stationary source emission levels are reduced adequately. However, staff will include a comment in the Energy Commission's PDOC Comment Letter regarding whether Phase II vapor controls are required by District rule for the proposed onsite gasoline tank.

Staff believes that additional or different mitigation measures are needed for adequate control of both vehicle tailpipe and fugitive dust emissions from maintenance operations. Specifically, additional fugitive emissions control is necessary by ensuring that vehicle travel is only conducted on paved and stabilized surfaces. Additionally, a few of the applicant's proposed vehicle mitigation measures are required by law, and therefore are not mitigation measures.

Staff Proposed Mitigation

As mentioned earlier in the discussions of the ozone and PM10 impacts, staff concludes that the proposed project's direct stationary source ozone precursor and PM10 emissions are minimal, but when combined with the maintenance vehicles emissions could be significant. Additionally, staff believes that a solar renewable project, which would have a 30-year life in a setting likely to continue to be impacted by both local and upwind emission sources, should address its contribution to the potentially ongoing nonattainment of the PM10 and ozone standards. Staff concludes that the applicant's proposed mitigation measures, that mirror staff's current mitigation requirements for other large solar projects, would adequately mitigate the proposed project's stationary source, mobile equipment, and fugitive dust emissions. Therefore, staff recommends the project owner be required to purchase new on-road and off-road vehicles that meet California emissions standards (**AQ-SC6**) and that the project owner be required to apply fugitive dust controls that are equivalent to those recommended for construction (**AQ-SC7**) to adequately mitigate the proposed project's operation emissions.

Staff is also proposing Condition of Certification **AQ-SC8** to ensure that the Energy Commission license is amended as necessary to incorporate changes to the air quality permits.

Staff has determined that the proposed emission controls and emission levels, along with the applicant proposed and staff recommended emission mitigation measures,

would mitigate all proposed project air quality impacts to less than significant pursuant to CEQA.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's direct air quality impacts have been reduced to less than significant, there is no environmental justice issue for air quality.

Indirect Pollutant and Secondary Pollutant Impacts

The proposed project would have direct emissions of chemically reactive pollutants (NOx, SOx, and VOC), but would also have indirect emission reductions associated with the reduction of fossil-fuel fired power plant emissions due to the proposed project displacing the need for their operation, since renewable energy operates on a must take basis. The exact nature and location of such reductions is not known, so the discussion below focuses on the direct emissions from the proposed project within the Riverside County portion of the Mojave Desert Air Basin.

Ozone Impacts

There are air dispersion models that can be used to quantify ozone impacts, but they are used for regional planning efforts where hundreds or even thousands of sources are input into the model to determine ozone impacts. There are no regulatory agency models approved for assessing single source ozone impacts. However, because of the known relationship of NOx and VOC emissions to ozone formation, it can be said that the emissions of NOx and VOC from the GSEP do have the potential (if left unmitigated) to contribute to higher ozone levels in the region. These impacts would be cumulatively significant under CEQA because they would contribute to ongoing violations of the state ozone ambient air quality standards.

PM2.5 Impacts

Secondary particulate formation, which is assumed to be 100 percent PM2.5, is the process of conversion from gaseous reactants to particulate products. The process of gas-to-particulate conversion, which occurs downwind from the point of emission, is complex and depends on many factors, including local humidity and the presence of air pollutants. The basic process assumes that the SOx and NOx emissions are converted into sulfuric acid and nitric acid first and then react with ambient ammonia to form sulfate and nitrate. The sulfuric acid reacts with ammonia much faster than nitric acid and converts completely and irreversibly to particulate form. Nitric acid reacts with ammonia to form both a particulate and a gas phase of ammonium nitrate. The particulate phase would tend to fall out; however, the gas phase can revert back to ammonia and nitric acid. Thus, under the right conditions, ammonium nitrate and nitric acid establish a balance of concentrations in the ambient air. There are two conditions that are of interest, described as *ammonia rich* and *ammonia poor*. The term ammonia rich indicates that there is more than enough ammonia to react with all the sulfuric acid and to establish a balance of nitric acid-ammonium nitrate. Further ammonia emissions in this case would not necessarily lead to increases in ambient PM2.5 concentrations. In the case of an ammonia poor environment, there is insufficient ammonia to establish a balance and thus additional ammonia would tend to increase PM2.5 concentrations.

The Riverside County portion of the Mojave Desert Air Basin has not undergone the rigorous secondary particulate studies that have been performed in other areas of California, such as the San Joaquin Valley, that have more serious fine particulate pollution problems. However, because of the known relationship of NOx and SOx emissions to PM2.5 formation it can be said that the emissions of NOx and SOx from GSEP do have the potential (if left unmitigated) to contribute to higher PM2.5 levels in the region; however, the region is in attainment with PM2.5 standards and the low level of NOx and SOx emissions from the proposed project would not significantly impact that status.

Impact Summary

The applicant is proposing to mitigate the proposed project's stationary source NOx, VOC, SO_2, and PM10/PM2.5 emissions through the use of Best Available Control Technology (BACT) and reduce the proposed project's mobile source emissions by using vehicles that meet ARB emission standards. With the applicant's stipulated vehicle emission mitigation, which is formalized and augmented in Staff Condition of Certification **AQ-SC6,** staff concludes that the proposed project would not cause significant secondary pollutant impacts.

C.1.4.3 CEQA LEVEL OF SIGNIFICANCE

Project Construction

Staff considers the unmitigated construction NOx, VOC, and PM emissions to be potentially CEQA significant and, therefore, staff is recommending that the NOx, VOC, and PM emission be mitigated pursuant to CEQA. Staff is recommending several mitigation measures (**AQ-SC1** through **AQ-SC5**), that also include the applicant's stipulated construction mitigation measures, to limit exhaust emissions and fugitive dust emissions during project construction to the extent feasible.

Therefore, while there would be adverse CEQA air quality impacts during construction, they are expected to be less than significant after implementation of the applicant's stipulated and staff's recommended mitigation measures.

Project Operation

Staff considers the unmitigated operation and maintenance NOx, VOC, and PM emissions to be potentially CEQA significant and, therefore, staff is recommending that the NOx, VOC, and PM emissions be mitigated pursuant to CEQA. Staff is recommending two mitigation measures (**AQ-SC6** and **AQ-SC7**), that also include the applicant's stipulated operations emission mitigation, to limit exhaust emissions and fugitive dust emissions during project operation to the extent feasible.

Therefore, while there would be adverse CEQA air quality impacts during operation, they are expected to be less than significant after implementation of the applicant's stipulated and staff's recommended mitigation measures.

Closure and Decommissioning

Eventually the facility would close, either at the end of its useful life or due to some unexpected situation such as a natural disaster or catastrophic facility breakdown. When the facility closes, all sources of air emissions would cease to operate and thus impacts associated with those emissions would no longer occur. The only other expected emissions would be equipment exhaust and fugitive particulate emissions from the dismantling activities. These activities would be of a much shorter duration than construction of the proposed project, equipment are assumed to have much lower comparative emissions due to technology advancement, and fugitive dust emissions would be required to be controlled in a manner at least equivalent to that required during construction. Therefore, while there would be adverse CEQA air quality impacts during decommissioning, they are expected to be less than significant.

C.1.5 REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would essentially be Unit 1 of the proposed project, and would be a 125 MW solar facility located within the boundaries of the proposed project as defined by NextEra. This alternative is analyzed for two major reasons: (1) it eliminates about 50 percent of the proposed project area so all impacts are reduced, and (2) by removing the eastern solar field, it would reduce the water required for cooling by 50 percent. The boundaries of the Reduced Acreage Alternative are shown in **Alternatives Figure 1**.

C.1.5.1 SETTING AND EXISTING CONDITIONS

This alternative is located entirely within the boundaries of the proposed project. It simply eliminates effects to the eastern 125 MW solar field and relocates the gas yard approximately 1.75 miles northwest of its present location. As a result, the environmental setting consists of the western portion of the proposed project, as well as the area affected by the linear project components.

The setting and existing conditions for this alternative are the same as the proposed project. The existing ambient air quality does not change and the facility would still be within the same air basin and subject to the same air quality LORS.

C.1.5.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The Reduced Acreage Alternative would reduce the total construction emissions of the proposed project by somewhat less than 50 percent, and operation emissions of the proposed project (see **Air Quality Tables 8** and **9**) by somewhat less than 50 percent, due to reduced efficiencies of the smaller project. However, the maximum daily and annual construction emissions are assumed to be similar to the proposed project assuming the same level of maximum activity with a reduction in the overall construction schedule. Therefore, the maximum construction emissions would be approximately the same as the emissions shown in **Air Quality Tables 6** and **7**.

The maximum short-term and maximum annual construction pollutant concentration impacts for the Reduced Acreage Alternative are assumed to be essentially the same

as that estimated for the proposed project, assuming the same maximum daily and annual construction activities. Therefore, the worst-case short-term and annual construction pollutant concentration impacts for this alternative are assumed to be essentially the same as those shown for the proposed project in **Air Quality Table 10**.

The maximum short-term and maximum annual operation pollutant concentration impacts for the Reduced Acreage Alternative are likely to be somewhat less than that for the proposed project as shown in **Air Quality Table 11**. However, the amount of reduction in impacts is uncertain as the worst case impacts are based on factors such as proximity to receptors and terrain as well as total emissions.

The results of the Reduced Acreage Alternative would be the following:

- The worst-case short-term construction emissions and ground level pollutant concentration impacts would be similar to the proposed project and would require the same level of mitigation. The total construction period and total construction emissions would be reduced from those required to construct the proposed project.
- The operation emissions and ground level pollutant concentration impacts would be somewhat lower than the proposed project, but the same level of mitigation would be required.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated, but mainly out of air basin, criteria pollutant emissions would be reduced.

If the Reduced Acreage Alternative were approved, other renewable projects may be developed on other sites in the Riverside County, the Colorado Desert, MDAB, or in adjacent states to fill the 125 MW gap not supplied by the proposed project as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates.

C.1.5.3 CEQA LEVEL OF SIGNIFICANCE

The level of significance under CEQA for the Reduced Acreage Alternative would be the same as for the proposed project, with the same significance rationale, where if left unmitigated there is the potential for significant PM10 and ozone precursor (NOx and VOC) emission impacts during the Alternative project's construction and operation. The mitigation that would be proposed for the Reduced Acreage Alternative would be the same as that proposed for the proposed project (staff and MDAQMD recommended conditions of certification).

C.1.6 DRY COOLING ALTERNATIVE

This section identifies the potential impacts of using air-cooled condenser (ACC) systems rather than the wet cooling towers proposed by NextEra for the Genesis project. It is assumed that the ACC systems would be located where the cooling towers are currently proposed for each of the two 125 MW power blocks, as illustrated in **Alternatives Figure 2** (see Section B.3).

Approximately 18 ACC fans would be required for each of the two solar fields. The 18 fans, or ACC's, would operate when the ambient temperature is above 50 degrees Fahrenheit. When the temperature is below 50 degrees Fahrenheit, only 10 of the fans would be used (GSEP 2009f). The 18 ACC fans would have a length of approximately 279 feet, a width of approximately 127 feet, and a height of 98 feet (GSEP 2009f). This alternative is analyzed because it would reduce the amount of water required for steam turbine cooling from 822 acre-feet per year (AFY) to 66 AFY. This reduction in water use would reduce impacts to water and biological resources.

C.1.6.1 SETTING AND EXISTING CONDITIONS

This alternative is located entirely within the boundaries of the proposed project. It simply eliminates the use of wet-cooling towers and incorporated the use of air-cooled condensers (ACC) in the same location. As a result, the setting and existing conditions for this alternative are the same as the proposed project. The existing ambient air quality does not change and the facility would still be within the same air basin and subject to the same air quality LORS.

C.1.6.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The magnitude of emissions from the construction of the air-cooled condenser (ACC) would be different than those from the construction of the proposed wet-cooled system. Approximately 40% more land would be disturbed for the ACCs as compared with the cooling towers, and the laydown area(s) may have to be increased to store and/or prepare the air-cooled radiator components prior to installation. Grading and construction equipment would be required to prepare the site and install the ACC system. The additional soil disturbance and equipment activity would result in increased fugitive dust and vehicle exhaust emissions (as compared to the emissions shown in **Air Quality Tables 6** and **7**), which could occur during the worst case construction periods. This additional construction in the context of the total construction requirements for the project are relatively minor, but would to some small extent increase the project's construction emissions.

There would be a minor reduction in particulate (PM10 and PM2.5) emissions from the removal of the two cooling towers, which as shown in **Air Quality Table 9** would be estimated to be a reduction of approximately 3.8 tons per year combined. However, the use of the ACCs would be expected to increase the auxiliary boilers startup requirements and increase the criteria pollutant emissions from the auxiliary boilers as shown in **Air Quality Tables 8** and **9**. Additionally, the ACCs would to a small extent reduce the steam power cycle's efficiency, which would to a small extent reduce the total amount of facility generation and reduce the displacement of fossil fuel fired power plant emissions from the GSEP.

The maximum short-term and maximum annual construction pollutant concentration impacts for the Dry Cooling Alternative would be slightly higher than that estimated for the proposed project, assuming that the increased ACC construction requirements occur during the maximum daily and annual construction periods. Therefore, the worst-case short-term and annual construction pollutant concentration impacts for this alternative would likely be slightly higher than those shown for the proposed project in

Air Quality Table 10. With the implementation of the staff proposed construction mitigation, staff believes that impacts from this construction emission increase would be less than significant.

The maximum short-term and maximum annual operation pollutant concentration impacts for the Dry Cooling Alternatives would be expected to be reduced for particulate (PM10/PM2.5) emissions and very slightly increased for the other criteria pollutants from those for the proposed project as shown in **Air Quality Table 11**. With the implementation of the District and staff proposed operation mitigation, staff believes that impacts from the operation emissions for this alternative would be less than significant.

The results of the Cooling Tower Alternative would be the following:

- The worst-case short-term construction emissions and ground level pollutant concentration impacts would very slightly higher than those of the proposed project and would require the same level of mitigation.
- The operation emissions and ground level pollutant concentration impacts of particulate emissions would be somewhat lower than the proposed project, and the operation emissions and ground level pollutant concentration impacts of the other criteria pollutants would be somewhat higher than the proposed project. However, the same level of mitigation, with the exception for the cooling tower emission controls, would be required.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated, but mainly out of air basin, criteria pollutant emissions would be very slightly reduced due to a small reduction in overall facility efficiency.

C.1.6.3 CEQA LEVEL OF SIGNIFICANCE

The level of significance under CEQA for the Dry Cooling Alternative would be the same as for the proposed project, with the same significance rationale, where if left unmitigated there is the potential for significant PM10 and ozone precursor (NOx and VOC) emission impacts during the Alternative project's construction and operation. The mitigation that would be proposed for the Dry Cooling Alternative would be the same as that proposed for the proposed project (staff and MDAQMD recommended conditions of certification), with the exception of the deletion of the District's cooling tower conditions **AQ-15** to **AQ-22**.

C.1.7 NO ACTION ALTERNATIVES

C.1.7.1 NO ACTION ON PROPOSED PROJECT APPLICATION AND ON CDCA LAND USE PLAN AMENDMENT

Under this alternative, the proposed GSEP would not be approved by the CEC and BLM and BLM would not amend the CDCA Plan. As a result, no solar energy project would be constructed on the project site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended.

The results of the No Project / No Action Alternative would be the following:

- The impacts of the proposed project would not occur. However, the land on which the project is proposed would become available to other uses that are consistent with BLM's land use plan, including another renewable energy project.
- The benefits of the proposed project in reducing fossil fuel use and greenhouse gas emissions from gas-fired generation would not occur. Both State and Federal law support the increased use of renewable power generation (see **Appendix Air-1 - Greenhouse Gas Emissions** for details).

If the proposed project is not approved, renewable projects would likely be developed on other sites in Riverside County, the Colorado Desert, or in adjacent states as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates. For example, as shown on **Cumulative Impacts Figure 1** and in **Table 1**, several dozen solar and wind development applications for use of BLM land have been submitted for approximately one million acres of the California Desert Conservation Area. Additional BLM land in Nevada and Arizona also has applications for solar and wind projects.

C.1.7.2 NO ACTION ON PROPOSED PROJECT AND AMEND THE CDCA LAND USE PLAN TO MAKE THE AREA AVAILABLE FOR FUTURE SOLAR DEVELOPMENT

Under this alternative, the proposed GSEP would not be approved by the CEC and BLM and BLM would amend the CDCA Land Use Plan of 1980, as amended, to allow for other solar projects on the site. As a result, it is possible that another solar energy project could be constructed on the project site.

Because the CDCA Plan would be amended, it is possible that the site would be developed with the same or a different solar technology. As a result, air pollutant emissions and impacts would result from the construction and operation of the solar technology and would likely be similar to the air quality impacts from the proposed project. Different solar technologies require different amounts of construction and operations maintenance; however, the benefits of the proposed project in displacing fossil fuel fired generation and reducing associated pollutant emissions could occur with a different solar technology at this site and therefore with this alternative. As such, this No Project/No Action Alternative could result in air quality impacts and benefits similar to the impacts under the proposed project.

C.1.7.3 NO ACTION ON PROPOSED PROJECT APPLICATION AND AMEND THE CDCA LAND USE PLAN TO MAKE THE AREA UNAVAILABLE FOR FUTURE SOLAR DEVELOPMENT

Under this alternative, the proposed GSEP would not be approved by the CEC and BLM and the BLM would amend the CDCA Plan to make the proposed site unavailable for future solar development. As a result, no solar energy project would be constructed on the project site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended.

Because the CDCA Plan would be amended to make the area unavailable for future solar development, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, the air quality of the site is not expected to change noticeably from existing conditions and, as such, this No Project/No Action Alternative would not result in air quality impacts under the proposed project nor would it result in the air quality benefits from the proposed project. However, in the absence of this project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects would have similar impacts in other locations.

C.1.8 CUMULATIVE IMPACTS

Cumulative impacts are defined by CEQA as "two or more individual effects which, when considered together, are considerable or . . . compound or increase other environmental impacts." (CEQA Guidelines, § 15355.) A cumulative impact consists of an impact that is created as a result of a combination of the project evaluated in the EIR together with other projects causing related impacts." (CEQA Guidelines, § 15130(a)(1).) Such impacts may be relatively minor and incremental, yet still be significant because of the existing environmental background, particularly when one considers other closely related past, present, and reasonably foreseeable future projects.

Cumulative effects are defined by the Council on Environmental Quality NEPA regulations as "…the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such actions" (40 CFR 1508.7).

This analysis is concerned with criteria air pollutants. Such pollutants have impacts that are usually (though not always) cumulative by nature. Rarely would a project by itself cause a violation of a federal or state criteria pollutant standard. However, a new source of pollution may contribute to violations of criteria pollutant standards because of the existing background sources or foreseeable future projects. Air districts attempt to attain the criteria pollutant standards by adopting attainment plans, which comprise a multi-faceted programmatic approach to such attainment. Depending on the air district, these plans typically include requirements for air offsets and the use of Best Available Control Technology (BACT) for new sources of emissions, and restrictions of emissions from existing sources of air pollution.

Thus, much of the preceding discussion is concerned with cumulative impacts. The "Existing Ambient Air Quality" subsection describes the air quality background in the Riverside County portion of the Mojave Desert Air Basin, including a discussion of historical ambient levels for each of the significant criteria pollutants. The "Construction Impacts and Mitigation" subsection discusses the proposed project's contribution to the local existing background caused by project construction. The "Operation Impacts and

Mitigation" subsection discusses the proposed project's contribution to the local existing background caused by project operation. The following subsection includes two additional analyses:

- a summary of projections for criteria pollutants by the air district and the air district's programmatic efforts to abate such pollution; and
- an analysis of the proposed project's *localized cumulative impacts*, the proposed project's direct operating emissions combined with other local major emission sources.

C.1.8.1 SUMMARY OF PROJECTIONS

The Riverside County portion of the MDAB is designated as attainment for all federal ambient air quality standards and the state CO, NO_2, SO_2 and PM10 standards, but is designated as non-attainment for State ozone and PM10 standards.

Ozone

Since a portion of San Bernardino County in the Mojave Desert Air Basin is currently classified as non-attainment for the federal 8-hour ozone standard north and west of the project site, the District is required to prepare and adopt an ozone attainment plan for submittal to the U.S. EPA describing how it will attain the federal 8- hour standard. The District completed this plan in 2008. The project is not specifically subject to the provisions in the federal attainment plan and the site is outside of the non-attainment area.

The District is required to prepare and adopt a state ozone attainment plan for submittal to ARB. The latest state ozone attainment plan was adopted by MDAQMD in 2004. The MDAQMD 2004 Ozone Attainment Plan contains attainment plans for both federal (for areas within San Bernardino County) and state ozone standards. The MDAQMD did not propose to adopt any additional control measures as part of the 2004 Plan. Additionally, while there are no additional control measures for direct ozone precursor reduction as part of the federal 2008 attainment plan, MDAQMD is committed to adopt all applicable Federal Reasonably Available Control Technology (RACT) rules it proposed in 8-hour Reasonably Available Control Technology – State Implementation Plan Analysis (RACT SIP Analysis) in 2006. In addition, the MDAQMD updated and indentified new measures in 2007, which will be adopted through 2014, as the State of California mandates all feasible measures. The RACT rules and other new measures do not impact the GSEP emission sources as proposed.

Particulate Matter

Since a portion of San Bernardino County in the Mojave Desert Air Basin is currently classified as non-attainment for the federal PM10 standards north and west of the project site, the District is required to prepare and adopt an attainment plan for submittal to the U.S. EPA describing how it will achieve attainment with the federal PM10 standards. However, the proposed project site that is in Riverside County is outside of the non-attainment area and is not subject to the provisions in the federal attainment plan. There is no legal requirement for air districts to provide plans to attain the state PM10 standard, so air districts have not developed such plans. Therefore, there are no

air quality management plan particulate emission control measures that are applicable to the proposed project.

As a solar power generation facility, the direct air pollutant emissions from power generation are negligible and the emission source would be limited to auxiliary equipment and maintenance activities. The emissions from the proposed project would be minimal compared to the other power generation facilities, and with staff's recommended construction and operation mitigation measures it is unlikely that the proposed project would have significant impact on particulate matter emissions.

Summary of Conformance with Applicable Air Quality Plans

The applicable air quality plan does not outline any new control measures applicable to the proposed project's operating emission sources. Therefore, compliance with existing District rules and regulations would ensure compliance with those air quality plans.

C.1.8.2 LOCALIZED CUMULATIVE IMPACTS

Since the power plant air quality impacts can be reasonably estimated through air dispersion modeling (see the "Operational Modeling Analysis" subsection) the proposed project's contributions to localized cumulative impacts can be estimated. To represent *past* and, to an extent, *present projects* that contribute to ambient air quality conditions, the Energy Commission staff recommends the use of ambient air quality monitoring data (see the "Existing Ambient Air Quality" subsection), referred to as the *background*. The staff takes the following steps to estimate what are additional appropriate "present projects" that are not represented in the background and "reasonably foreseeable projects":

- First, the Energy Commission staff (or the applicant) works with the air district to identify all projects that have submitted, within the last year of monitoring data, new applications for an authority to construct (ATC) or permit to operate (PTO) and applications to modify an existing PTO within six miles of the project site. Based on staff's modeling experience, beyond six miles there is no statistically significant concentration overlap for non-reactive pollutant concentrations between two stationary emission sources.
- Second, the Energy Commission staff (or the applicant) works with the air district and local counties to identify any new area sources within six miles of the project site. As opposed to point sources, area sources include sources like agricultural fields, residential developments or other such sources that do not have a distinct point of emission. New area sources are typically identified through draft or final Environmental Impact Reports (EIRs) that are prepared for those sources. The initiation of the EIR process is a reasonable basis on which to determine what is "reasonably foreseeable" for new area sources.
- The data submitted, or generated from the applications with the air district for point sources or initiating the EIR process for area sources, provides enough information to include these new emission sources in air dispersion modeling. Thus, the next step is to review the available EIR(s) and permit application(s), determine what sources must be modeled and how they must be modeled.

- Sources that are not new, but may not be represented in ambient air quality monitoring are also identified and included in the analysis. These sources include existing sources that are co-located with or adjacent to the proposed source (such as an existing power plant). In most cases, the ambient air quality measurements are not recorded close to the proposed project, thus a local major source might not be well represented by the background air monitoring. When these sources are included, it is typically a result of there being an existing source on the project site and the ambient air quality monitoring station being more than two miles away.
- The modeling results must be carefully interpreted so that they are not skewed towards a single source, in high impact areas near that source's fence line. It is not truly a cumulative impact of GSEP if the high impact area is the result of high fence line concentrations from another stationary source and GSEP is not providing a substantial contribution to the determined high impact area.

Once the modeling results are interpreted, they are added to the background ambient air quality monitoring data and thus the modeling portion of the cumulative assessment is complete. Due to the use of air dispersion modeling programs in staff's cumulative impacts analysis, the applicant must submit a modeling protocol, based on information requirements for an application, prior to beginning the investigation of the sources to be modeled in the cumulative analysis. The modeling protocol is typically reviewed, commented on, and eventually approved in the Data Adequacy phase of the licensing procedure. Staff typically assists the applicant in finding sources (as described above), characterizing those sources, and interpreting the results of the modeling. However, the actual modeling runs are usually left to the applicant to complete. There are several reasons for this: modeling analyses take time to perform and require significant expertise, the applicant has already performed a modeling analysis of the proposed project alone (see the "Operational Modeling Analysis" subsection), and the applicant can act on its own to reduce stipulated emission rates and/or increase emission control requirements as the results warrant. Once the cumulative project emission impacts are determined, the necessity to mitigate the proposed project emissions can be evaluated, and the mitigation itself can be proposed by staff and/or the applicant (see the "Operation Mitigation" subsection).

The applicant, in consultation with MDAQMD and SCAQMD, confirmed that there are no projects within a six miles radius from the Genesis Solar project site that are under construction or have received permits to be built or operate in the foreseeable future. Therefore, it has been determined that no stationary sources requiring a cumulative modeling analysis exist within a six mile radius of the proposed project site. However, there are several pending solar and wind projects in the I-10 corridor area between Desert Center and Blythe including two thermal solar projects, the Blythe Solar Power Project and Palen Solar Power Project siting cases, which are currently being evaluated by the Energy Commission and BLM. This potential for significant additional development within the air basin and corresponding increase in air basin emissions is a major part of staff's rationale for recommending Conditions of Certification **AQ-SC6** and **AQ-SC7** that are designed to mitigate the proposed project's cumulative impacts by reducing the dedicated on-site vehicle emissions and fugitive dust emissions during site operation. With these recommended CEQA-only mitigation measures, staff has concluded that the CEQA cumulative air quality impacts are less than significant.

Staff has considered the minority population surrounding the site (see **Socioeconomics Figure 1**). Since the proposed project's cumulative air quality impacts have been mitigated to less than significant, there is no environmental justice issue for air quality.

C.1.9 COMPLIANCE WITH LORS

The Mojave Desert Air Quality Control District issued a Preliminary Determination of Compliance (PDOC) for the GSEP on February 18, 2010 (MDAQMD 2010a), and will issue a Final Determination of Compliance after a 30 day public notice period. Compliance with all District rules and regulations was demonstrated to the District's satisfaction in the PDOC. The District's PDOC conditions are presented in the Conditions of Certification (**AQ-1** to **AQ-40**).

Staff expects to submit an official PDOC comment letter and expects that the FDOC may contain revisions to conditions due to Energy Commission, applicant, or third party comments, and staff will provide a Staff Assessment addendum with any revised FDOC findings or conditions of certification.

C.1.9.1 FEDERAL

The District is responsible for issuing the federal New Source Review (NSR) permit and has been delegated enforcement of the applicable New Source Performance Standard (Subparts Dc and IIII). However, this proposed project does not require a federal NSR or Title V permit and this proposed project would not require a PSD permit from U.S.EPA prior to initiating construction.

The proposed project requires the approval of a federal agency (BLM), but is located in an area that is in attainment or unclassified with all federal ambient air quality standards. Therefore, the proposed project is not subject to the general conformity regulations (40 CFR Part 93).

C.1.9.2 STATE

The project owner will demonstrate that the proposed project will comply with Section 41700 of the California State Health and Safety Code, which restricts emissions that would cause nuisance or injury, with the issuance of the District's Final Determination of Compliance and the Energy Commission's affirmative finding for the project.

The emergency generator and fire water pump engines are also subject to the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines. This measure limits the types of fuels allowed, established maximum emission rates, and establishes recordkeeping requirements. The proposed Tier 2 emergency engine and Tier 3 fire water pump engine meet the current emission limit requirements of this measure. This measure would also limit the engines' testing and maintenance operation to no more than 50 hours per year.

C.1.9.3 LOCAL

The District rules and regulations specify the emissions control and offset requirements for new sources such as the GSEP. Best Available Control Technology would be

implemented, and emission reduction credits (ERCs) are not required to offset the proposed project's emissions by District rules and regulations based on the permitted stationary source emission levels for the proposed project. Compliance with the District's new source requirements would ensure that the proposed project would be consistent with the strategies and future emissions anticipated under the District's air quality attainment and maintenance plans.

The applicant provided an air quality permit application to the MDAQMD and the District issued a PDOC on February 18, 2010 (MDAQMD 2010a). The PDOC states that the proposed project is expected to comply with all applicable District rules and regulations. The DOC evaluates whether and under what conditions the proposed project would comply with the District's applicable rules and regulations, as described below.

Regulation II – Permits

Rule 201 and 203 – Permit to Construct and Permit to Operate

Rule 201 establishes the emission source requirements that must be met to obtain a Permit to Construct. Rule 203 prohibits use of any equipment or the use of which may emit air contaminants without obtaining Permit to Operate. The applicant has complied with this rule by submitting the AFC and District permit applications materials.

Regulation IV – Prohibitions

Rule 401 - Visible Emissions

This rule limits visible emissions from emissions sources, including stationary source exhausts and fugitive dust emission sources. Compliance with this rule is expected. In the PDOC, the District has determined that the facility is expected to comply with this rule.

Rule 402 - Nuisance

This rule restricts discharge of emissions that would cause injury, detriment, annoyance, or public nuisance. The facility is expected to comply with this rule (identical to California Health and Safety Code 41700).

Rule 403 - Fugitive Dust

This rule limits fugitive emissions from certain bulk storage, earthmoving, construction and demolition, and manmade conditions resulting in wind erosion. With the implementation of recommended staff conditions **AQ-SC3**, **AQ-SC4**, and **AQ-SC7** the facility is expected to comply with this rule.

Rule 404 - Particulate Matter Concentration

The rule limits particulate matter (PM) emissions based on the volume discharge rate. The GSEP stationary sources subject to this rule (HTF heaters and emergency engines) would comply with the PM concentration limits of this regulation.

Rule 406 - Specific Contaminants

The rule prohibits sulfur emissions, calculated as SO_2, in excess of 500 ppmv. Compliance with this rule is assured with the required use of pipeline quality natural has for the boilers and heaters and California low sulfur diesel fuel for the emergency generator and fire pump engines.

Rule 407 - Liquid and Gaseous Air Contaminants

The rule prohibits carbon monoxide emissions in excess of 2,000 ppmv. The heaters and emergency generator and fire pump engines would have CO emissions well below this concentration limit. Compliance with this rule is expected.

Rule 409 - Fuel Burning Equipment - Combustion Contaminants

This rule limits discharge into the atmosphere from fuel burning equipment combustion contaminants exceeding in concentration at the point of discharge, 0.1 grain per cubic foot of gas calculated to 12 percent of carbon dioxide (CO_2) at standard conditions. The GSEP stationary sources would have particulate concentrations below limit of this rule.

Rule 431 - Sulfur Content of Fuels

The rule prohibits the burning of gaseous fuel with a sulfur content of more than 800 ppm and liquid fuel with a sulfur content of more than 0.5 percent sulfur by weight. The facility is expected to comply with this rule. Compliance with this rule is assured with the required use of pipeline quality natural gas and California low sulfur diesel fuel for the emergency engines.

Regulation IX – Standards of Performance for New Stationary Sources

Rule 900 – Standard of Performance For New Stationary Source (NSPS)

This rule incorporates the Federal NSPS (40 CFR 60) rules by reference. The proposed boilers are subject to subpart Dc. The District conditions would ensure compliance with the requirements of this rule.

The proposed Tier 2 and Tier 3 engines meet the current emission limit requirements of NSPS Subpart IIII. The exact model and size of the engines are only estimated at this time and it is uncertain exactly when the emergency engines would be purchased and whether Tier 4 engine emission limits may apply at that time. So, staff has added a requirement to the verification of District Condition of Certification (**AQ-31** and **AQ-40**) to require the applicant to provide documentation that demonstrates that the engines purchased meet the appropriate NSPS standards for new engines at the time of purchase.

Regulation XIII – New Source Review

Rule 1303 – New Source Review

This rule requires implementation of BACT for any emission source unit which emits or has the potential to emit 25 lbs/day or more and requires offsets if specific annual emission limits are exceeded. The PDOC concluded that the emergency engines trigger

BACT and the engines complied. The other stationary sources did not trigger BACT but would meet BACT requirements based on the applicant's proposed controls. The PDOC concluded that offsets were not required for the proposed project.

Rule 1306 – Electric Energy Generating Facilities

Describes actions to be taken for permitting of power plants. Compliance with this rule would be achieved with the completion of the FDOC.

C.1.10. NOTEWORTHY PUBLIC BENEFITS

Renewable energy facilities, such as GSEP, are needed to meet California's mandated renewable energy goals. While there are no local area air quality public benefits[6] resulting from the proposed project, it would indirectly reduce criteria pollutant emissions within the Southwestern U.S. by reducing fossil fuel fired generation.

C.1.11 MITIGATION MEASURES/ PROPOSED CONDITIONS OF CERTIFICATION

C.1.11.1 STAFF CONDITIONS OF CERTIFICATION

Staff conditions **AQ-SC1** through **AQ-SC4** are both CEQA and NEPA mitigation conditions. Staff conditions **AQ-SC5** through **AQ-SC8** are CEQA-only conditions.

AQ-SC1 Air Quality Construction Mitigation Manager (AQCMM): The project owner shall designate and retain an on-site AQCMM who shall be responsible for directing and documenting compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4** and **AQ-SC5** for the entire project site and linear facility construction. The on-site AQCMM may delegate responsibilities to one or more AQCMM Delegates. The AQCMM and AQCMM Delegates shall have full access to all areas of construction on the project site and linear facilities, and shall have the authority to stop any or all construction activities as warranted by applicable construction mitigation conditions. The AQCMM and AQCMM Delegates may have other responsibilities in addition to those described in this condition. The AQCMM shall not be terminated without written consent of the Compliance Project Manager (CPM).

Verification: At least 60 days prior to the start of ground disturbance, the project owner shall submit to the BLM's Authorized Officer and CPM for approval, the name, resume, qualifications, and contact information for the on-site AQCMM and all AQCMM Delegates.

AQ-SC2 Air Quality Construction Mitigation Plan (AQCMP): The project owner shall provide an AQCMP, for approval, which details the steps that will be taken

[6] Air quality benefits should not be confused with greenhouse gas/climate change benefits, which are discussed in Appendix AIR-1.

and the reporting requirements necessary to ensure compliance with Conditions of Certification **AQ-SC3**, **AQ-SC4,** and **AQ-SC5**.

Verification: At least 60 days prior to the start of any ground disturbance, the project owner shall submit the AQCMP to the BLM's Authorized Officer and CPM for approval. The AQCMP shall include effectiveness and environmental data for the proposed soil stabilizer. The BLM's Authorized Officer or CPM will notify the project owner of any necessary modifications to the plan within 30 days from the date of receipt.

AQ-SC3 Construction Fugitive Dust Control: The AQCMM shall submit documentation to the BLM's Authorized Officer and CPM in each Monthly Compliance Report that demonstrates compliance with the Air Quality Construction Mitigation Plan (AQCMP) mitigation measures for the purposes of preventing all fugitive dust plumes from leaving the project. Any deviation from the AQCMP mitigation measures shall require prior BLM Authorized Officer and CPM notification and approval.

Verification: The AQCMM shall provide the BLM's Authorized Officer and the CPM a Monthly Compliance Report (**COMPLIANCE-6**) to include the following to demonstrate control of fugitive dust emissions:

A. a summary of all actions taken to maintain compliance with this condition;

B. copies of any complaints filed with the District in relation to project construction; and

C. any other documentation deemed necessary by the BLM Authorized Officer, CPM, and AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

The following fugitive dust mitigation measures shall be included in the Air Quality Construction Mitigation Plan (AQCMP) required by **AQ-SC2**.

a. The main access roads through the facility to the power block areas will be either paved or stabilized using soil binders, or equivalent methods, to provide a stabilized surface that is similar for the purposes of dust control to paving, that may or may not include a crushed rock (gravel or similar material with fines removed) top layer, prior to initiating construction in the main power block area, and delivery areas for operations materials (chemicals, replacement parts, etc.) will be paved prior to taking initial deliveries.

b. All unpaved construction roads and unpaved operational site roads, as they are being constructed, shall be stabilized with a non-toxic soil stabilizer or soil weighting agent that can be determined to be as efficient as or more efficient for fugitive dust control than ARB approved soil stabilizers, and that shall not increase any other environmental impacts including loss of vegetation. All other disturbed areas in the project and linear construction sites shall be watered as frequently as necessary during grading; and after active construction activities shall be stabilized with a non-toxic soil stabilizer or soil weighting agent, or alternative approved soil stabilizing methods, in order to comply with the dust mitigation objectives of Condition of Certification **AQ-SC4**. The frequency of watering can be reduced or eliminated during periods of precipitation.

c. No vehicle shall exceed 10 miles per hour on unpaved areas within the construction site, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.

d. Visible speed limit signs shall be posted at the construction site entrances.

e. All construction equipment vehicle tires shall be inspected and washed as necessary to be cleaned free of dirt prior to entering paved roadways.

f. Gravel ramps of at least 20 feet in length must be provided at the tire washing/cleaning station.

g. All unpaved exits from the construction site shall be graveled or treated to prevent track-out to public roadways.

h. All construction vehicles shall enter the construction site through the treated entrance roadways, unless an alternative route has been submitted to and approved by the CPM and BLM Authorized Officer.

i. Construction areas adjacent to any paved roadway below the grade of the surrounding construction area or otherwise directly impacted by sediment from site drainage shall be provided with sandbags or other equivalently effective measures to prevent run-off to roadways, or other similar run-off control measures as specified in the Storm Water Pollution Prevention Plan (SWPPP), only when such SWPPP measures are necessary so that this condition does not conflict with the requirements of the SWPPP.

j. All paved roads within the construction site shall be swept daily or as needed (less during periods of precipitation) on days when construction activity occurs to prevent the accumulation of dirt and debris.

k. At least the first 500 feet of any paved public roadway exiting the construction site or exiting other unpaved roads en route from the construction site or construction staging areas shall be swept as needed (less during periods of precipitation) on days when construction activity occurs or on any other day when dirt or runoff resulting from the construction site activities is visible on the public paved roadways.

l. All soil storage piles and disturbed areas that remain inactive for longer than 10 days shall be covered, or shall be treated with appropriate dust suppressant compounds.

m. All vehicles that are used to transport solid bulk material on public roadways and that have potential to cause visible emissions shall be provided with a cover, or the materials shall be sufficiently wetted and loaded onto the trucks in a manner to provide at least one foot of freeboard.

n. Wind erosion control techniques (such as windbreaks, water, chemical dust suppressants, and/or vegetation) shall be used on all construction areas that may be disturbed. Any windbreaks installed to comply with this condition shall remain in place until the soil is stabilized or permanently covered with vegetation.

AQ-SC4 Dust Plume Response Requirement: The AQCMM or an AQCMM Delegate shall monitor all construction activities for visible dust plumes. Observations of visible dust plumes that have the potential to be transported (A) off the project site and within 400 feet upwind of any regularly occupied structures not owned by the project owner or (B) 200 feet beyond the centerline of the construction of linear facilities indicate that existing mitigation measures are not resulting in effective mitigation. The AQCMP shall include a section detailing how the additional mitigation measures will be accomplished within the time limits specified. The AQCMM or Delegate shall implement the following procedures for additional mitigation measures in the event that such visible dust plumes are observed:

Step 1: The AQCMM or Delegate shall direct more intensive application of the existing mitigation methods within 15 minutes of making such a determination.

Step 2: The AQCMM or Delegate shall direct implementation of additional methods of dust suppression if Step 1, specified above, fails to result in adequate mitigation within 30 minutes of the original determination.

Step 3: The AQCMM or Delegate shall direct a temporary shutdown of the activity causing the emissions if Step 2, specified above, fails to result in effective mitigation within one hour of the original determination. The activity shall not restart until the AQCMM or Delegate is satisfied that appropriate additional mitigation or other site conditions have changed so that visual dust plumes will not result upon restarting the shutdown source. The project owner may appeal to the CPM or BLM Authorized Officer any directive from the AQCMM or Delegate to shut down an activity, if the shutdown shall go into effect within one hour of the original determination, unless overruled by the CPM or BLM Authorized Officer before that time.

Verification: The AQCMM shall provide the BLM's Authorized Officer and the CPM a Monthly Compliance Report (**COMPLIANCE-6**) to include:

A. a summary of all actions taken to maintain compliance with this condition;

B. copies of any complaints filed with the District in relation to project construction; and

C. any other documentation deemed necessary by the CPM and AQCMM to verify compliance with this condition. Such information may be provided via electronic format or disk at the project owner's discretion.

AQ-SC5 Diesel-Fueled Engine Control: The AQCMM shall submit to the CPM, in the Monthly Compliance Report, a construction mitigation report that demonstrates compliance with the AQCMP mitigation measures for purposes of controlling diesel construction-related emissions. Any deviation from the AQCMP mitigation measures shall require prior and CPM notification and approval.

Verification: The AQCMM shall include in the Monthly Compliance Report (**COMPLIANCE-6**) the following to demonstrate control of diesel construction-related emissions:

A. A summary of all actions taken to maintain compliance with this condition;

B. A list of all heavy equipment used on site during that month, including the owner of that equipment and a letter from each owner indicating that equipment has been properly maintained; and

C. Any other documentation deemed necessary by the CPM, and the AQCMM to verify compliance with this condition, including any District permits necessary for temporary stationary diesel engines, or ARB certification for state registered portable equipment. Such information may be provided via electronic format or disk at the project owner's discretion.

The following off-road diesel construction equipment mitigation measures shall be included in the Air Quality Construction Mitigation Plan (AQCMP) required by **AQ-SC2**.

a. All diesel-fueled engines used in the construction of the facility shall have clearly visible tags issued by the on-site AQCMM showing that the engine meets the conditions set forth herein.

b. All construction diesel engines with a rating of 50 hp or higher and lower than 750 hp shall meet, at a minimum, the Tier 3 California Emission Standards for Off-Road Compression-Ignition Engines, as specified in California Code of Regulations, Title 13, section 2423(b)(1), unless a good faith effort to the satisfaction of the CPM that is certified by the on-site AQCMM demonstrates that such engine is not available for a particular item of equipment. Engines larger than 750 hp shall meet Tier 2 engine standards. In the event that a Tier 3 engine is not available for any off-road equipment larger than 100 hp and smaller than 750 hp, that equipment shall be equipped with a Tier 2 engine, or an engine that is equipped with retrofit controls to reduce exhaust emissions of nitrogen oxides (NOx) and diesel particulate matter (DPM) to no more than Tier 2 levels unless certified by engine manufacturers or the on-site AQCMM that the use of such devices is not practical for specific engine types. For purposes of this condition, the use of such devices is "not practical" for the following, as well as other, reasons.

    1. There is no available retrofit control device that has been verified by either the California Air Resources Board or U.S. Environmental Protection Agency to control the engine in question to Tier 2 equivalent emission levels and the highest level of available control using retrofit or Tier 1 engines is being used for the engine in question; or

    2. The construction equipment is intended to be on site for 5 days or less.

3. The CPM may grant relief from this requirement if the AQCMM can demonstrate a good faith effort to comply with this requirement and that compliance is not practical.

c. The use of a retrofit control device may be terminated immediately, provided that the CPM is informed within 10 working days of the termination and that a replacement for the equipment item in question meeting the controls required in item "b" occurs within 10 days of termination of the use, if the equipment would be needed to continue working at this site for more than 15 days after the use of the retrofit control device is terminated, if one of the following conditions exists :

   1. The use of the retrofit control device is excessively reducing the normal availability of the construction equipment due to increased down time for maintenance, and/or reduced power output due to an excessive increase in back pressure.

   2. The retrofit control device is causing or is reasonably expected to cause engine damage.

   3. The retrofit control device is causing or is reasonably expected to cause a substantial risk to workers or the public.

   4. Any other seriously detrimental cause which has the approval of the CPM prior to implementation of the termination.

d. All heavy earth-moving equipment and heavy duty construction-related trucks with engines meeting the requirements of (b) above shall be properly maintained and the engines tuned to the engine manufacturer's specifications.

e. All diesel heavy construction equipment shall not idle for more than five minutes. Vehicles that need to idle as part of their normal operation (such as concrete trucks) are exempted from this requirement.

f. Construction equipment will employ electric motors when feasible.

AQ-SC6 The project owner, when obtaining dedicated on-road or off-road vehicles for mirror washing activities and other facility maintenance activities, shall only obtain new model year vehicles that meet California on-road vehicle emission standards or appropriate U.S.EPA/California off-road engine emission standards for the model year when obtained.

Verification: At least 60 days prior to the start commercial operation, the project owner shall submit to the CPM a copy of the plan that identifies the size and type of the on-site vehicle and equipment fleet and the vehicle and equipment purchase orders and contracts and/or purchase schedule. The plan shall be updated every other year and submitted in the Annual Compliance Report (**COMPLIANCE-7**).

AQ-SC7 The project owner shall provide a site Operations Dust Control Plan, including all applicable fugitive dust control measures identified in the

verification of **AQ-SC3** that would be applicable to reducing fugitive dust from ongoing operations; that:

A. describes the active operations and wind erosion control techniques such as windbreaks and chemical dust suppressants, including their ongoing maintenance procedures, that shall be used on areas that could be disturbed by vehicles or wind anywhere within the project boundaries; and

B. identifies the location of signs throughout the facility that will limit traveling on unpaved portion of roadways to solar equipment maintenance vehicles only. In addition, vehicle speed shall be limited to no more than 10 miles per hour on these unpaved roadways, with the exception that vehicles may travel up to 25 miles per hour on stabilized unpaved roads as long as such speeds do not create visible dust emissions.

The site operations fugitive dust control plan shall include the use of durable non-toxic soil stabilizers on all regularly used unpaved roads and disturbed off-road areas, or alternative methods for stabilizing disturbed off-road areas, within the project boundaries, and shall include the inspection and maintenance procedures that will be undertaken to ensure that the unpaved roads remain stabilized. The soil stabilizer used shall be a non-toxic soil stabilizer or soil weighting agent that can be determined to be as efficient as or more efficient for fugitive dust control than ARB approved soil stabilizers, and that shall not increase any other environmental impacts including loss of vegetation.

The performance and application of the fugitive dust controls shall also be measured against and meet the performance requirements of condition **AQ-SC4**. The performance requirements of **AQ-SC4** shall also be included in the operations dust control plan.

Verification: At least 60 days prior to start of commercial operation, the project owner shall submit to the BLM's Authorized Officer and the CPM for review and approval a copy of the site Operations Dust Control Plan that identifies the dust and erosion control procedures, including effectiveness and environmental data for the proposed soil stabilizer, that will be used during operation of the project and that identifies all locations of the speed limit signs. At least 60 days after commercial operation, the project owner shall provide to the BLM's Authorized Officer and the CPM a report identifying the locations of all speed limit signs, and a copy of the project employee and contractor training manual that clearly identifies that project employees and contractors are required to comply with the dust and erosion control procedures and on-site speed limits.

AQ-SC8 The project owner shall provide the CPM copies of all District issued Authority-to-Construct (ATC) and Permit-to-Operate (PTO) documents for the facility.

The project owner shall submit to the CPM for review and approval any modification proposed by the project owner to any project air permit. The project owner shall submit to the CPM any modification to any permit proposed by the District or U.S. Environmental Protection Agency (U.S. EPA), and any revised permit issued by the District or U.S. EPA, for the project.

Verification: The project owner shall submit any ATC, PTO, and proposed air permit modifications to the CPM within 5 working days of its submittal either by 1) the project owner to an agency, or 2) receipt of proposed modifications from an agency. The project owner shall submit all modified air permits to the CPM within 15 days of receipt.

C.1.11.2 DISTRICT CONDITIONS

DISTRICT PRELIMINARY DETERMINATION OF COMPLIANCE CONDITIONS (MDAQMD 2010a)

District conditions **AQ-1** through **AQ-40** are CEQA-only required conditions.

Application No. 00010788 and 00010789 (Two - 30 MMBtu/hr Natural Gas Fired Auxiliary Boiler)

EQUIPMENT DESCRIPTION:

Two 30 MMBtu/hr natural gas boilers with low-NOx burner systems.

AQ-1 Operation of this equipment shall be conducted in compliance with all data and specifications submitted with the application under which this permit is issued unless otherwise noted below.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-2 This equipment shall be exclusively fueled with natural gas and shall be operated and maintained in strict accord with the recommendations of its manufacturer or supplier and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-3 Emissions from this equipment shall not exceed the following hourly emission limits at any firing rate, verified by fuel use and annual compliance tests:

a. NOx as NO_2:

1. 0.082 lb/hr operating at 25% load (based on 9.0 ppmvd corrected to 3% O_2 and averaged over one hour)

2. 0.330 lb/hr operating at 100% load (based on 9.0 ppmvd corrected to 3% O_2 and averaged over one hour)

b. CO:

1. 0.141 lb/hr operating at 25% load (based on 50 ppmvd corrected to 3% O_2 and averaged over one hour)

2. 0.563 lb/hr operating at 100% load (based on 50 ppmvd corrected to 3% O_2 and averaged over one hour)

c. VOC as CH_4:

1. 0.022 lb/hr operating at 25% load

2. 0.088 lb/hr operating at 100% load

d. SOx as SO_2:

1. 0.002 lb/hr operating at 25% load

2. 0.008 lb/hr operating at 100% load

e. PM10:

1. 0.038 lb/hr operating at 25% load

2. 0.150 lb/hr operating at 100% load

Verification: As part of the Annual Compliance Report (**COMPLIANCE-7**), the project owner shall include information demonstrating compliance with boiler operating emission rates.

AQ-4 The daily emission of the following pollutants CO, NOx (as NO2) and SOx (as SO2) as well as O2 (a diluent gas) shall be monitored using a Continuous Emissions Monitoring System (CEMS). This system shall be operating at all times in accordance with the District approved monitoring plan.

The following are the acceptability testing requirements for the CEMS:

a. For SO2 and NOx CEMS - Performance Specification 2 of 40 CFR 60 Appendix B.

b. For O2 CEMS - Performance Specification 3 of 40 CFR 60 Appendix B.

c. For CO CEMS - Performance Specification 4 of 40 CFR 60 Appendix B.

d. For quality assurance - Performance Specification 40 CFR 60 Appendix F.

Verification: As part of the Annual Compliance Report (**COMPLIANCE-7**), the project owner shall include CEMS information demonstrating compliance with boiler operating emission rates.

AQ-5 This equipment shall not be operated for more than 1,000 hours per rolling twelve month period and more than 14 hours per calendar day.

Verification: The project owner shall submit to the CPM the boiler hours of use records demonstrating compliance with this condition as part of the Annual Operation Report (**COMPLIANCE-7**).

AQ-6 The project owner shall maintain an operations log for this equipment on-site and current for a minimum of five (5) years, and said log shall be provided to District personnel on request. The operations log shall include the following information at a minimum:

a. Total operation time (hours per day, hours per month, and hours per rolling twelve month period);

b. Maximum hourly, maximum daily, and total calendar year emissions of NOx, CO, PM10, VOC and SOx (including calculation protocol); and,

c. Any permanent changes made to the equipment that would affect air pollutant emissions, and indicate when changes were made.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-7 The project owner shall perform initial compliance tests on this equipment in accordance with the MDAQMD Compliance Test Procedural Manual. The test report shall be submitted to the District within 180 days of initial start up:

a. NOx as NO_2 in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Methods 19 and 20).

b. VOC as CH_4 in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Methods 25A and 18).

c. SOx as SO_2 in ppmvd at 3% oxygen and lb/hr.

d. CO in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Method 10).

e. PM10 in mg/m^3 at 3% oxygen and lb/hr (measured per USEPA Reference Methods 5 and 202 or CARB Method 5).

f. Flue gas flow rate in dscf per minute.

g. Opacity (measured per USEPA reference Method 9).

Verification: The project owner shall notify the District and the CPM within fifteen (15) working days before the execution of the compliance test required in this condition. The test results shall be submitted to the District and to the CPM within 180 days of initial start up.

AQ-8 The project owner shall perform annual compliance tests on this equipment in accordance with the MDAQMD Compliance Test Procedural Manual. The test report shall be submitted to the District no later than six weeks prior to the expiration date of this permit. The following compliance tests are required:

a. NOx as NO_2 in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Methods 19 and 20).

b. VOC as CH_4 in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Methods 25A and 18).

c. SOx as SO_2 in ppmvd at 3% oxygen and lb/hr.

d. CO in ppmvd at 3% oxygen and lb/hr (measured per USEPA Reference Method 10).

e. PM10 in mg/m^3 at 3% oxygen and lb/hr (measured per USEPA Reference Methods 5 and 202 or CARB Method 5).

f. Flue gas flow rate in dscf per minute.

g. Opacity (measured per USEPA reference Method 9).

Verification: The project owner shall notify the District and the CPM within fifteen (15) working days before the execution of the compliance test required in this condition. The test results shall be submitted to the District and to the CPM within the timeframe required by this condition.

Application No. 00010842 and 00010843 (Two – HTF Ullage Expansion Tank)

EQUIPMENT DESCRIPTION:

Two HTF ullage/expansion tanks.

AQ-9 This tank stores HTF, specifically the condensable fraction of the vapors vented from the ullage system.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-10 This tank must be properly maintained at all times.

Verification: The project owner shall make the site available for inspection of HTF piping Inspection and Maintenance Program records (**AQ-13**) and HTF system equipment by representatives of the District, ARB, and the Energy Commission.

AQ-11 This tank shall be operated at all times under a nitrogen blanket.

Verification: The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-12 The ullage vent system shall be vented to control system with at least 99% control efficiency for VOC and toxic substances.

Verification: The project owner shall provide the District and CPM ullage vent control system manufacturer guarantee data showing compliance with this condition at least 30 days prior to the installation of the ullage vent system control system.

AQ-13 Inspect the tanks and distribution system (valves, flanges, pump seals, etc.) for the presence of leaks daily and repair or shutdown as soon as possible.

Verification: The project owner shall establish an inspection and maintenance program that that at a minimum includes the following:

A. All pumps, compressors and pressure relief devices (pressure relief valves or rupture disks) shall be electronically, audio, or visually inspected once every operating period.

B. All accessible valves, fittings, pressure relief devices (PRDs), hatches, pumps, compressors, etc. shall be inspected quarterly using a leak detection device such as a Foxboro OVA 108 calibrated for methane.

C. VOC leaks greater than 100-ppmv shall be tagged (with date and concentration) and repaired within seven calendar days of detection.

D. VOC leaks greater than 10,000-ppmv shall be tagged and repaired within 24-hours of detection.

E. The project owner shall maintain a log of all VOC leaks exceeding 10,000-ppmv, including location, component type, and repair made.

F. The project owner shall maintain record of the amount of HTF replaced on a monthly basis for a period of five years.

G. Any detected leak exceeding 100-ppmv and not repaired in 7-days and 10,000-ppmv not repaired within 24-hours shall constitute a violation of the District's Authority to Construct (ATC)/Permit to Operate (PTO).

H. Pressure sensing equipment shall be installed that will be capable of sensing a major rupture or spill within the HTF network.

The inspection and maintenance plan shall be submitted to the CPM for review and approval at least 30 days before taking delivery of the HTF. The project owner shall make the site available for inspection of HTF piping Inspection and Maintenance Program records and HTF system equipment by representatives of the District, ARB, and the Energy Commission.

AQ-14 If current non-criteria substances become regulated as toxic or hazardous substances and are used in this equipment, the project owner shall submit to the District a plan demonstrating how compliance will be achieved and maintained with such regulations.

Verification: The project owner shall submit a compliance plan of the toxic or hazardous substances for District approval and CPM review if current non-criteria substances in the HTF become regulated as toxic or hazardous substances.

Application No. 00010787 and 00010841 (Two Cooling Towers)

EQUIPMENT DESCRIPTION:

Two 7-cell cooling towers with drift eliminator rate of 0.0005% and water circulation rate of 94,623 gpm.

AQ-15 Operation of this equipment shall be conducted in compliance with all data and specifications submitted with the application under which this permit is issued unless otherwise noted below.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-16 This equipment shall be operated and maintained in strict accord with the recommendations of its manufacturer or supplier and/or sound engineering principles.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-17 The drift rate shall not exceed 0.0005 percent with a maximum circulation rate of 94,623 gallons per minute. The maximum hourly PM10 emission rate shall not exceed 2.36 pounds per hour, as calculated per the written District-approved protocol.

Verification: The manufacturer guarantee data for the drift eliminator, showing compliance with this condition, shall be provided to the CPM and the District 30 days prior to cooling tower operation. As part of the Annual Compliance Report (**COMPLIANCE-7**) the project owner shall include information on operating emission rates to demonstrate compliance with this condition.

AQ-18 The project owner shall perform weekly tests of the blow-down water total dissolved solids (TDS). The TDS shall not exceed 5,000 ppmv on a calendar monthly basis. The project owner shall maintain a log which contains the date and result of each blow-down water test in TDS ppm, and the resulting mass emission rate. This log shall be maintained on site for a minimum of five (5) years and shall be provided to District personnel on request.

Verification: The cooling tower recirculation water TDS content test results shall be provided to representatives of the District, ARB, and the Energy Commission upon request.

AQ-19 The project owner shall conduct all required cooling tower water tests in accordance with a District-approved test and emissions calculation protocol. Thirty (30) days prior to the first such test the project owner shall

provide a written test and emissions calculation protocol for District review and approval.

Verification: The project owner shall provide an emissions calculation and water sample testing protocol to the District for approval and CPM for review at least 30 days prior to the first cooling tower water test.

AQ-20 This equipment shall not be operated for more than 3,200 hours per rolling twelve month period and more than 15 hours per calendar day.

Verification: The project owner shall submit to the CPM the cooling tower operating data demonstrating compliance with this condition as part of the Annual Operation Report (**COMPLIANCE-7**).

AQ-21 The project owner shall maintain an operations log for this equipment on-site and current for a minimum of five (5) years, and said log shall be provided to District personnel on request. The operations log shall include the following information at a minimum:

a. Total operation time (hours per day, hours per month, and hours per rolling twelve month period); and

b. The date and result of each blow-down water test in TDS ppm, and the resulting mass emission rate.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-22 A maintenance procedure shall be established that states how often and what procedures will be used to ensure the integrity of the drift eliminators. This procedure is to be kept onsite and available to District personnel on request.

Verification: The project owner shall make available at request the written drift eliminator maintenance procedures for inspection by representatives of the District, ARB, and the Energy Commission.

Application No. 00010790 and 00010791 (Two - 1,341 HP Emergency IC Engine)

EQUIPMENT DESCRIPTION:

Two - Tier II 1,341 HP diesel fueled emergency generator engines, each driving a generator.

AQ-23 This equipment shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of contaminants. Unless otherwise noted, this equipment shall also be operated in accordance with all data and specifications submitted with the application for this permit.

Verification: The project owner shall make the site available for inspection of equipment and records by representatives of the District, ARB, and the Energy Commission

AQ-24 This unit shall only be fired on ultra-low sulfur diesel fuel, whose sulfur concentration is less than or equal to 0.0015% (15 ppm) on a weight per weight basis per CARB Diesel or equivalent requirements.

Verification: The project owner shall make the site available for inspection of equipment and fuel purchase records by representatives of the District, ARB, and the Energy Commission.

AQ-25 A non-resettable hour meter with a minimum display capability of 9,999 hours shall be installed and maintained on this unit to indicate elapsed engine operating time. (Title 17 CCR §93115.10(e)(1)).

Verification: At least thirty (30) days prior to the installation of the engine, the project owner shall provide the District and the CPM the specification of the hour meter.

AQ-26 This unit shall be limited to use for emergency power, defined as in response to a fire or when commercially available power has been interrupted. In addition, this unit shall be operated no more than 50 hours per year for testing and maintenance, excluding compliance source testing. Time required for source testing will not be counted toward the 50 hour per year limit.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-27 The project owner shall maintain a operations log for this unit current and on-site, either at the engine location or at a on-site location, for a minimum of two (2) years, and for another year where it can be made available to the District staff within 5 working days from the District's request, and this log shall be provided to District, State and Federal personnel upon request. The log shall include, at a minimum, the information specified below:

a. Date of each use and duration of each use (in hours);

b. Reason for use (testing & maintenance, emergency, required emission testing);

c. Calendar year operation in terms of fuel consumption (in gallons) and total hours; and,

d. Fuel sulfur concentration (the project owner may use the supplier's certification of sulfur content if it is maintained as part of this log).

Verification: The project owner shall submit records required by this condition that demonstrating compliance with the sulfur content and engine use limitations of conditions **AQ-24** and **AQ-26** in the Annual Compliance Report (**COMPLIANCE-7**),

including a photograph showing the annual reading of engine hours. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-28 This unit shall not be used to provide power during a voluntary agreed to power outage and/or power reduction initiated under an Interruptible Service Contract (ISC); Demand Response Program (DRP); Load Reduction Program (LRP) and/or similar arrangement(s) with the electrical power supplier.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-29 This engine may operate in response to notification of impending rotating outage if the area utility has ordered rotating outages in the area where the engine is located or expects to order such outages at a particular time, the engine is located in the area subject to the rotating outage, the engine is operated no more than 30 minutes prior to the forecasted outage, and the engine is shut down immediately after the utility advises that the outage is no longer imminent or in effect.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-30 This unit is subject to the requirements of the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines (Title 17 CCR 93115). In the event of conflict between these conditions and the ATCM, the more stringent shall govern.

Verification: Not necessary.

AQ-31 This unit is subject to the requirements of the Federal National Source Performance Standards (NSPS) for Stationary Compression Ignition Internal Combustion Engines (40 CFR Part 60 Subpart IIII).

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet NSPS emission limit requirements at the time of engine purchase.

Application No. 00010792 and 00010793 (Two - 315 HP Emergency IC Engine)

EQUIPMENT DESCRIPTION:

Two - Tier III 315 HP diesel fueled emergency generator engines, each driving a fire suppression water pump.

AQ-32 This equipment shall be installed, operated and maintained in strict accord with those recommendations of the manufacturer/supplier and/or sound engineering principles which produce the minimum emissions of contaminants. Unless otherwise noted, this equipment shall also be

operated in accordance with all data and specifications submitted with the application for this permit.

Verification: The project owner shall make the site available for inspection of equipment and records by representatives of the District, ARB, and the Energy Commission

AQ-33 This unit shall only be fired on ultra-low sulfur diesel fuel, whose sulfur concentration is less than or equal to 0.0015% (15 ppm) on a weight per weight basis per CARB Diesel or equivalent requirements.

Verification: The project owner shall make the site available for inspection of equipment and fuel purchase records by representatives of the District, ARB, and the Energy Commission.

AQ-34 A non-resettable hour meter with a minimum display capability of 9,999 hours shall be installed and maintained on this unit to indicate elapsed engine operating time. (Title 17 CCR §93115.10(e)(1)).

Verification: At least thirty (30) days prior to the installation of the engine, the project owner shall provide the District and the CPM the specification of the hour timer.

AQ-35 This unit shall be limited to use for emergency power, defined as in response to a fire or due to low fire water pressure. In addition, this unit shall be operated no more than 50 hours per year for testing and maintenance, excluding compliance source testing. Time required for source testing will not be counted toward the 50 hour per year limit. The 50 hour limit can be exceeded when the emergency fire pump assembly is driven directly by a stationary diesel fueled CI engine operated per and in accord with the National Fire Protection Association (NFPA) 25 - "Standard for the Inspection, Testing, and Maintenance of Water-Based Fire Protection Systems," 1998 edition. This requirement includes usage during emergencies. {Title 17 CCR 93115.3(n)}

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-36 The project owner shall maintain an operations log for this unit current and on-site, either at the engine location or at a on-site location, for a minimum of two (2) years, and for another year where it can be made available to the District staff within 5 working days from the District's request, and this log shall be provided to District, State and Federal personnel upon request. The log shall include, at a minimum, the information specified below:

a. Date of each use and duration of each use (in hours);

b. Reason for use (testing & maintenance, emergency, required emission testing);

c. Calendar year operation in terms of fuel consumption (in gallons) and total hours; and,

d. Fuel sulfur concentration (the project owner may use the supplier's certification of sulfur content if it is maintained as part of this log).

Verification: The project owner shall submit records required by this condition that demonstrating compliance with the sulfur content and engine use limitations of conditions **AQ-33** and **AQ-35** in the Annual Compliance Report (**COMPLIANCE-7**), including a photograph showing the annual reading of engine hours. The project owner shall make the site available for inspection of records by representatives of the District, ARB, and the Energy Commission.

AQ-37 This unit shall not be used to provide power during a voluntary agreed to power outage and/or power reduction initiated under an Interruptible Service Contract (ISC); Demand Response Program (DRP); Load Reduction Program (LRP) and/or similar arrangement(s) with the electrical power supplier.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-38 This engine may operate in response to notification of impending rotating outage if the area utility has ordered rotating outages in the area where the engine is located or expects to order such outages at a particular time, the engine is located in the area subject to the rotating outage, the engine is operated no more than 30 minutes prior to the forecasted outage, and the engine is shut down immediately after the utility advises that the outage is no longer imminent or in effect.

Verification: The project owner shall make the site available for inspection of records and equipment by representatives of the District, ARB, and the Energy Commission.

AQ-39 This unit is subject to the requirements of the Airborne Toxic Control Measure (ATCM) for Stationary Compression Ignition Engines (Title 17 CCR 93115). In the event of conflict between these conditions and the ATCM, the requirements of the ATCM shall govern.

Verification: Not necessary.

AQ-40 This unit is subject to the requirements of the Federal National Source Performance Standards (NSPS) for Stationary Compression Ignition Internal Combustion Engines (40 CFR Part 60 Subpart IIII).

Verification: The project owner shall submit the engine specifications at least 30 days prior to purchasing the engines for review and approval demonstrating that the engines meet NSPS emission limit requirements at the time of engine purchase.

C.1.12 CONCLUSIONS

Staff has made the following conclusions about the Genesis Solar Energy Project:

- The proposed project would not have the potential to exceed PSD emission levels during direct source operation and the facility is not considered a major stationary source with potential to cause adverse NEPA air quality impacts. However, without adequate fugitive dust mitigation, the proposed project would have the potential to exceed the PSD emission levels for PM10 during construction, and could cause potential localized exceedances of the PM10 NAAQS during construction. Recommended Conditions of Certification **AQ-SC1** through **AQ-SC4** would adequately mitigate these potentially adverse NEPA impacts.
- The proposed project would comply with applicable District Rules and Regulations and staff recommends the inclusion of the District's PDOC conditions as Conditions of Certification **AQ-1** through **AQ-40**
- If left unmitigated, the proposed project's construction activities would likely contribute to significant CEQA adverse PM10 and ozone impacts. Staff recommends **AQ-SC1** to **AQ-SC5** to mitigate the potential impacts.
- The proposed project's operation would not cause new violations of any NO_2, SO_2, PM2.5 or CO ambient air quality standards. Therefore, the project-direct operational NOx, SOx, PM2.5 and CO emission impacts are not CEQA significant.
- The proposed project's direct and indirect, or secondary emissions contribution to existing violations of the ozone and PM10 ambient air quality standards are likely CEQA significant if unmitigated. Therefore, staff recommends **AQ-SC6** to mitigate the onsite maintenance vehicle emissions and **AQ-SC7** to mitigate the operating fugitive dust emissions to ensure that the potential ozone and PM10 CEQA impacts are mitigated to less than significant over the life of the project.
- The proposed project would be consistent with the requirements of SB 1368 and the Emission Performance Standard for greenhouse gases (see **Appendix Air-1**).

APPENDIX AIR-1 - GREENHOUSE GAS EMISSIONS

Testimony of William Walters, P.E.

SUMMARY OF CONCLUSIONS

The Genesis Solar Energy Project (GSEP) is a proposed addition to the state's electricity system. GSEP is a solar concentrating thermal power plant, which would utilize parabolic trough solar thermal technology to solar heat a heat transfer fluid (HTF). This hot HTF would be used to generate steam in a solar steam generator. The proposed project is comprised of two solar plants, each of which would have 125-MW capacity, totaling 250 MW. As a solar project, GSEP would emit considerably less greenhouse gas (GHG) than the existing statewide average GHG emissions per unit of generation and would emit considerably less GHG emissions per unit of generation than existing fossil fuel fired power plants providing generation to California, and thus would contribute to continued reduction of GHG emissions in the interconnected California and the western United States electricity systems.

While GSEP would emit some GHG emissions, the contribution of GSEP to the system build-out of renewable resources to meet the goals of the Renewable Portfolio Standard (RPS) in California would result in a net cumulative reduction of energy generation and GHG emissions from new and existing fossil-fired electricity resources. Electricity is produced by operation of inter-connected generation resources. Operation of one power plant, like GSEP, affects all other power plants in the interconnected system. GSEP would be a must take facility and its operation would affect the overall electricity system operation and GHG emissions in several ways:

- GSEP would provide low-GHG, renewable generation.
- GSEP would facilitate to some degree the replacement high GHG emitting (e.g., out-of-state coal) electricity generation that must be phased out to meet the State's 2006 Emissions Performance Standard.
- GSEP could facilitate to some extent the replacement of generation provided by aging fossil-fired power plants that use once-through cooling.

These system impacts would result in a net reduction in GHG emissions across the electricity system providing energy and capacity to California. Thus, staff concludes that the proposed project would result in a cumulative overall reduction in GHG emissions from power plants, does not worsen current conditions, and would not result in impacts that are cumulatively CEQA significant.

Staff concludes that the short-term minor emission of greenhouse gases during construction that are necessary to create this new, low GHG-emitting power generating facility would be sufficiently reduced by "best practices" and would be more than offset by GHG emission reductions during operation. Thus, construction GHG emissions would not be CEQA significant.

The Genesis Solar Energy Project, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance

Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

The California Air Resources Board (ARB) has promulgated regulations for mandatory GHG emission reporting to comply with the California Global Warming Solutions Act of 2006 (AB 32 Núñez, Statutes of 2006, Chapter 488, Health and Safety Code sections 38500 et seq.) (ARB 2008a). The Genesis Solar Energy Project, which solely generates electricity from solar power, is exempt from the mandatory GHG emission reporting requirements for electricity generating facilities [CCR Title 17 §95101(c)(1)]. However, the proposed project may be subject to future reporting requirements and GHG reductions or trading requirements as additional state or federal GHG regulations are developed and implemented.

INTRODUCTION

Greenhouse gas (GHG) emissions are not criteria pollutants, but they are discussed in the context of cumulative impacts. However, on April 2, 2007, the U.S. Supreme Court found that GHGs are pollutants that must be covered by the federal Clean Air Act. In response, on September 30, 2009, the U.S. Environmental Protection Agency proposed to apply Prevention of Significant Deterioration (PSD) requirements to facilities whose carbon dioxide-equivalent emissions exceed 25,000 tons per year (U.S.EPA 2009c). The rule making is not finalized, but the GHG emissions for GSEP are not expected to exceed this amount.

The state has demonstrated a clear willingness to address global climate change through research, adaptation and inventory reductions. In that context, staff evaluates the GHG emissions from the proposed project, presents information on GHG emissions related to electricity generation, and describes the applicable GHG standards and requirements.

Generation of electricity can produce greenhouse gases with the criteria air pollutants that have been traditionally regulated under the federal and state Clean Air Acts. For fossil fuel-fired power plants, the GHG emissions include primarily carbon dioxide, with much smaller amounts of nitrous oxide (N_2O, not NO or NO_2, which are commonly known as NOx or oxides of nitrogen), and methane (CH_4 – often from unburned natural gas). For solar energy generation projects the stationary source GHG emissions are much smaller than fossil fuel-fired power plants, but the associated maintenance vehicle emissions are higher. Other sources of GHG emissions include sulfur hexafluoride (SF_6) from high voltage equipment and hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs) from refrigeration/chiller equipment. GHG emissions from the electricity sector are dominated by CO_2 emissions from carbon-based fuels; other sources of GHG emissions are small and also are more likely to be easily controlled or reused or recycled, but are nevertheless documented here as some of the compounds have very high global warming potentials.

Global warming potential is a relative measure, compared to carbon dioxide, of a compound's residence time in the atmosphere and ability to warm the planet. Mass emissions of GHGs are converted into carbon dioxide equivalent (CO2E) metric tonnes (MT) for ease of comparison.

LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The following federal, state, and local laws and policies in **Greenhouse Gas Table** 1 pertain to the control and mitigation of greenhouse gas emissions. Staff's analysis examines the proposed project's compliance with these requirements.

Greenhouse Gas Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable Law	Description
Federal	
40 Code of Federal Regulations Part 98	This rule requires mandatory reporting of GHG emissions for facilities that emit more than 25,000 metric tons of CO_2 equivalent emissions per year.
State	
California Global Warming Solutions Act of 2006, AB 32 (Stats. 2006; Chapter 488; Health and Safety Code sections 38500 et seq.)	This act requires the California Air Resource Board (ARB) to enact standards that will reduce GHG emission to 1990 levels by 2020. Electricity production facilities will be regulated by the ARB.
California Code of Regulations, tit. 17, Subchapter 10, Article 2, sections 95100 et. seq.	These ARB regulations implement mandatory GHG emissions reporting as part of the California Global Warming Solutions Act of 2006 (Stats. 2006; Chapter 488; Health and Safety Code sections 38500 et seq.)
Title 20, California Code of Regulations, section 2900 et seq.; CPUC Decision D0701039 in proceeding R0604009	The regulations prohibit utilities from entering into long-term contracts with any base load facility that does not meet a greenhouse gas emission standard of 0.5 metric tonnes carbon dioxide per megawatt-hour (0.5 $MTCO_2$/MWh) or 1,100 pounds carbon dioxide per megawatt-hour (1,100 lbs CO_2/MWh).

GLOBAL CLIMATE CHANGE AND ELECTRICITY PRODUCTION

There is general scientific consensus that climate change is occurring and that human activity contributes in some measure (perhaps substantially) to that change. Man-made emissions of greenhouse gases, if not sufficiently curtailed, are likely to contribute further to continued increases in global temperatures. Indeed, the California Legislature finds that "[g]lobal warming poses a serious threat to the economic well-being, public health, natural resources, and the environment of California" (Cal. Health & Safety Code, sec. 38500, division 25.5, part 1).

In 1998, the Energy Commission identified a range of strategies to prepare for an uncertain climate future, including a need to account for the environmental impacts associated with energy production, planning, and procurement (CEC 1998, p.5). In 2003, the Energy Commission recommended that the state require reporting of greenhouse gases (GHG) or global climate change[7] emissions as a condition of state licensing of new electric generating facilities (CEC 2003, IEPR p. 42). In 2006, California enacted the California Global Warming Solutions Act of 2006 (AB 32). It requires the California Air Resources Board (ARB) to adopt standards that will reduce statewide GHG emissions to statewide GHG emissions levels in 1990, with such

[7] Global climate change is the result of greenhouse gases, or air emissions with global warming potentials, affecting the global energy balance, and thereby, climate of the planet. The term greenhouse gases (GHG) and global climate change (GCC) gases are used interchangeably.

reductions to be achieved by 2020.[8] To achieve this, ARB has a mandate to define the 1990 emissions level and achieve the maximum technologically feasible and cost-effective GHG emission reductions.

The ARB adopted early action GHG reduction measures in October 2007, adopted mandatory reporting requirements and the 2020 statewide target in December 2007, and adopted a statewide scoping plan in December 2008 to identify how emission reductions will be achieved from major sources of GHG via regulations, market mechanisms, and other actions. ARB staff is developing regulatory language to implement its plan and holds ongoing public workshops on key elements of the recommended GHG reduction measures, including market mechanisms (ARB 2006). The regulations must be effective by January 1, 2011 and mandatory compliance commences on January 1, 2012. The mandatory reporting requirements are effective for electric generating facilities with a nameplate capacity equal or greater than 1 megawatt (MW) capacity if their emissions exceed 2,500 metric tonnes per year. The due date for initial reports by existing facilities was June 1, 2009.

Examples of strategies that the state might pursue for managing GHG emissions in California, in addition to those recommended by the Energy Commission and the Public Utilities Commission, were identified in the California Climate Action Team's Report to the Governor (CalEPA 2006). The scoping plan approved by ARB in December 2008 builds upon the overall climate policies of the Climate Action Team report and shows the recommended strategies to achieve the goals for 2020 and beyond. Some strategies focus on reducing consumption of petroleum across all areas of the California economy. Improvements in transportation energy efficiency (fuel economy), land use planning, and alternatives to petroleum-based fuels are slated to provide substantial reductions by 2020 (CalEPA 2006). The scoping plan includes a requirement for 33% of California's electrical energy to be provided from renewable sources by 2020 (implementing California's 33% RPS goal), aggressive energy efficiency targets, and a cap-and-trade system that includes the electricity sector (ARB 2008b).

It is likely that GHG reductions mandated by ARB will not be uniform across emitting sectors, in that reductions will be based on cost-effectiveness (i.e., the greatest effect for the least cost). For example, the ARB proposes a 40 percent reduction in GHG from the electricity sector, even though that sector currently only produces about 25 percent of the state's GHG emissions. In response, in September 2008 the Energy Commission and the Public Utilities Commission provided recommendations (CPUC 2008) to ARB on how to achieve such reductions through both programmatic and regulatory approaches, and identified regulation points should ARB decide that a multi-sector cap and trade system is warranted.

The Energy Commission's *2007 Integrated Energy Policy Report* (IEPR) also addressed climate change within the electricity, natural gas, and transportation sectors (CEC 2007). For the electricity sector, it recommended such approaches as pursuing all cost-effective energy efficiency measures and meeting the Governor's stated goal of a 33 percent renewable portfolio standard. The Energy Commission's *2009 Integrated*

[8] Governor Schwarzenegger has also issued Executive Order S-3-05 establishing a goal of 80% below 1990 levels by 2050.

Energy Policy Report continues to emphasize the importance of meeting greenhouse gas emissions reduction goals along with other important statewide issues such as backing out use of once-through cooling in coastal California power plants (CEC 2009d).

SB 1368[9], enacted in 2006, and regulations adopted by the Energy Commission and the Public Utilities Commission pursuant to the bill, prohibits California utilities from entering into long-term commitments with any base load facilities that exceed the Emission Performance Standard of 0.500 metric tonnes CO_2 per megawatt-hour[10] (1,100 pounds CO_2/MWh). Specifically, the SB 1368 Emission Performance Standard (EPS) applies to base load power from new power plants, new investments in existing power plants, and new or renewed contracts with terms of five years or more, including contracts with power plants located outside of California.[11] If a project, instate or out of state, plans to sell base load electricity to a California utility that utility will have to demonstrate that the project meets the EPS. *Base load* units are defined as units that operate at a capacity factor higher than 60 percent. As a renewable electricity generating facility, GSEP is determined by rule to be compliant with the SB 1368 EPS.

In addition to these programs, California is involved in the Western Climate Initiative, a multi-state and international effort to establish a cap and trade market to reduce greenhouse gas emissions in the Western United States and the Western Electricity Coordinating Council (WECC). The timelines for the implementation of this program are similar to those of AB 32, with full roll-out beginning in 2012. And as with AB 32, the electricity sector has been a major focus of attention.

ELECTRICITY PROJECT GREENHOUSE GAS EMISSIONS

Electricity use can be as simple as turning on a switch to operate a light or fan. The system to deliver adequate and reliable electricity supply is complex and variable. But it operates as an integrated whole to meet demand, such that the dispatch of a new source of generation generally curtails or displaces one or more less efficient or less competitive existing sources. Within the system, generation resources provide electricity, or energy, generating capacity, and ancillary services to stabilize the system and facilitate electricity delivery, or movement, over the grid. *Capacity* is the instantaneous output of a resource, in megawatts. *Energy* is the capacity output over a unit of time, for example an hour or year, generally reported as megawatt-hours or gigawatt-hours (GWh). Ancillary services[12] include regulation, spinning reserve, non-spinning reserve, voltage support, and black start capability. Individual generation resources can be built and operated to provide only one specific service. Alternatively, a resource may be able to provide one or all of these services, depending on its design and constantly changing system needs and operations.

[9] Public Utilities Code § 8340 et seq.

[10] The Emission Performance Standard only applies to carbon dioxide, and does not include emissions of other greenhouse gases converted to carbon dioxide equivalent.

[11] See Rule at http://www.cpuc.ca.gov/PUBLISHED/FINAL_DECISION/64072.htm

[12] See page CEC 2009b, page 95.

California is actively pursuing policies to reduce GHG emissions that include adding non-GHG emitting renewable generation resources to the system mix. The generation of electricity using fossil fuels, even in a back-up generator at a thermal solar plant, produces air emissions known as greenhouse gases in addition to the criteria air pollutants that have been traditionally regulated under the federal and state Clean Air Acts. Greenhouse gas emissions contribute to the warming of the earth's atmosphere, leading to climate change.

PROJECT CONSTRUCTION

Construction of industrial facilities such as power plants requires coordination of numerous equipment and personnel. The concentrated on-site activities result in short-term, unavoidable increases in vehicle and equipment emissions that include greenhouse gases. The construction would last approximately 37 months. The greenhouse gas emissions estimate, for the entire construction period, provided by the applicant[13] is below in **Greenhouse Gas Table 2**.

Greenhouse Gas Table 2
Estimated GSEP Potential Construction Greenhouse Gas Emissions

	CO_2-Equivalent (MTCO2E) [a,b]
Onsite Equipment	24,094
Gas Pipeline Equipment	1,544
Access Road Equipment	564
Transmission Line Equipment	1,185
Delivery Vehicles	3,520
Construction Worker Vehicles	22,067
Entire Construction Period Total	**52,974**

Source: TTEC 2010h, Table 2 and Table K.5-5.
[a] One metric tonne (MT) equals 1.1 short tons or 2,204.6 pounds or 1,000 kilograms
[b] The vast majority of the CO2E emissions, over 99 percent, is CO_2 from construction combustion sources.

PROJECT OPERATIONS

Operations GHG emissions, for both units, are shown in **Greenhouse Gas Table 3**. Operation of the GSEP would cause GHG emissions from the auxiliary boilers, fire water pump engines, emergency generator engines, maintenance fleet and employee trips, and sulfur hexafluoride emissions from new electrical component equipment.

[13] As noted in the Air Quality Section staff may be re-estimating certain construction emissions which would revise some of the values in **Greenhouse Gas Table 2**. If so, staff will provide a revised construction GHG emission estimate as part of a Staff Assessment Addendum.

Greenhouse Gas Table 3
Estimated GSEP Potential Operating Greenhouse Gas Emissions

	Annual CO_2-Equivalent (MTCO2E)[a]
Auxiliary Boilers [b]	3,520
Emergency Generators [b]	83.9
Fire Pumps [b]	17.5
Maintenance Vehicles [b]	194.1
Delivery Vehicles [b]	42
Employee Vehicles [b]	272.3
Equipment Leakage (SF_6)	3.4
Total Project GHG Emissions – MTCO2E [b]	**4,133**
Facility MWh per year	600,000
Facility GHG Emission Rate (MTCO2E/MWh)	0.007

Sources: GSEP 2009f, DR 34; TTEC 2010h, p. 22 to 25.
[a] One metric tonne (MT) equals 1.1 short tons or 2,204.6 pounds or 1,000 kilograms.
[b] The vast majority of the CO2E emissions, over 99 percent, is CO_2 from these emission sources.

Greenhouse Gas Table 3 shows what the proposed project, as permitted, could potentially emit in greenhouse gases on an annual basis. All emissions are converted to CO_2-equivalent and totaled. Electricity generation GHG emissions are generally dominated by CO_2 emissions from the carbon-based fuels; other sources of GHG are typically small and also are more likely to be easily controlled or reused/recycled. For this solar project the primary fuel, solar energy, is greenhouse gas free, but there is natural gas used in the two auxiliary boilers used for morning startup and HTF freeze protection, and gasoline and diesel fuel use in the maintenance vehicles, offsite delivery vehicles, staff and employee vehicles, the two emergency fire water pump engines, and two emergency generator engines. Another GHG emission source for this proposed project is SF_6 from electrical equipment leakage.

The proposed project is estimated to emit, directly from primary and secondary emission sources on an annual basis, over 4,000 metric tonnes of CO_2-equivalent GHG emissions per year. GSEP, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]). Regardless, GSEP has an estimated GHG emission rate of 0.007 MTCO2E/MWh, well below the Greenhouse Gas Emission Performance Standard of 0.500 MTCO2/MWh.

Solar Project Energy Payback Time

The beneficial energy and greenhouse gas impacts of renewable energy projects can also be measured by the *energy payback time*[14]. **Greenhouse Gas Tables 2** and **3** provide an estimate of the onsite construction and operation emissions, employee transportation emissions, and the final segment of offsite materials and consumables transportation. However, there are additional direct transportation and indirect manufacturing GHG emissions associated with the construction and operation of the

[14] The energy payback time is the time required to produce an amount of energy as great as what was consumed during production, which in the context of a solar power plant includes all of the energy required during construction and operation.

proposed project, which are all considered in the determination of the energy payback time. A document sponsored by Greenpeace estimates that the energy payback time for concentrating solar power plants, such as GSEP, to be on the order of 5 months (Greenpeace 2005, Page 9); and the project life for GSEP is on the order of 30 years. Therefore, the proposed project's GHG emissions reduction potential from energy displacement would be substantial[15].

Natural Carbon Uptake Reduction

This proposed project would cause the clearing of land and removal of vegetation, which would reduce the ongoing natural carbon uptake by vegetation. A study of the Mojave Desert indicated that the desert may uptake carbon in amounts as high as 100 grams per square meter per year (Wohlfahrt et. al. 2008). This would equate to a maximum reduction in carbon uptake, calculated as CO_2, of 1.48 MT of CO_2 per acre per year for areas with complete vegetation removal. For this 1,887 acre proposed project, which does require the complete removal of vegetation over most of the project site, the maximum equivalent loss in carbon uptake would be 2,793 MT of CO_2 per year, which would correspond to 0.005 MT of CO_2 per MW generated. Therefore, the natural carbon uptake loss is negligible in comparison with the reduction in fossil fuel CO_2 emissions, which can range from 0.35 to 1.0 MT of CO_2 per MW depending on the fuel and technology, that is enabled by this proposed project.

CLOSURE AND DECOMMISSIONING

Closure and decommissioning, as a one-time limited duration event, would have emissions that are similar in type and magnitude, but likely lower than, the construction emissions as discussed above.

ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Staff assesses four kinds of impacts: construction, operation, closure and decommissioning, and cumulative effects. As the name implies, construction impacts result from the emissions occurring during the construction of the proposed project. The operation impacts result from the emissions of the proposed project during operation. Cumulative impacts analysis assesses the impacts that result from the proposed project's incremental effect viewed over time. The impact of GHG emissions caused by this solar facility is characterized by considering how the power plant would affect the overall electricity system. The integrated electricity system depends on non-fossil and fossil-fueled generation resources to provide energy and satisfy local capacity needs. As directed by the Energy Commission's adopted order initiating an informational (OII) proceeding (08-GHG OII-1) (CEC 2009a), staff is refining and implementing the concept of a "blueprint" that describes the long-term roles (i.e., retirements and displacement) of

[15] The GHG displacement for the project would be similar to, but not exactly the same as, the amount of energy produced after energy payback is achieved multiplied by the average GHG emissions per unit of energy displaced. The average GHG emissions for the displaced energy over the project life is not known but currently fossil fuel fired power plants have GHG emissions that range from 0.35 MT/MWh CO2E for the most efficient combined cycle gas turbine power plants to over 1.0 MT/MWh for coal fired power plants.

fossil-fueled power plants in California's electricity system as we move to a high-renewable, low-GHG electricity system, which will include projects like GSEP.

PROPOSED PROJECT

Construction Impacts

Staff concludes that the GHG emission increases from construction activities would not be CEQA significant for several reasons. First, the period of construction would be short-term and the emissions intermittent during that period, not ongoing during the life of the proposed project. Second, best practices control measures that staff recommends, such as limiting idling times and requiring, as appropriate, equipment that meets the latest emissions standards, would further minimize greenhouse gas emissions since the use of newer equipment would increase efficiency and reduce GHG emissions and be compatible with low-carbon fuel (e.g., bio-diesel and ethanol) mandates that will likely be part of the ARB regulations to reduce GHG from construction vehicles and equipment. And lastly, these temporary GHG emissions are necessary to create this renewable energy source that would provide power with a very low GHG emissions profile, and the construction emissions would be more than offset by the reduction in fossil fuel fired generation that would be enabled by this proposed project. If the project construction emissions were distributed over the estimated 30 year life of the proposed project they would only increase the project life time annual facility GHG emissions rate by 0.0029 MT CO2E per MWh.

Direct/Indirect Operation Impacts and Mitigation

The proposed Genesis Solar Energy Project promotes the state's efforts to move towards a high-renewable, low-GHG electricity system, and, therefore, reduces both the amount of natural gas used by electricity generation and greenhouse gas emissions.

Net GHG emissions for the integrated electric system will decline when new renewable power plants are added to: 1) move renewable generation towards the 33 percent target; 2) improve the overall efficiency, or GHG emission rate, of the electric system; or 3) serve load growth or capacity needs more efficiently, or with fewer GHG emissions.

The Role of GSEP in Renewables Goals/Load Growth

As California moves towards an increased reliance on renewable energy by implementing the Renewables Portfolio Standard (RPS), non-renewable energy resources will be displaced. These reductions in non-renewable energy, shown in **Greenhouse Gas Table 4**, are targeted to be as much as 36,500 GWh. These assumptions are conservative in that the forecasted growth in electricity retail sales assumes that the impacts of planned increases in expenditures on (uncommitted) energy efficiency are already embodied in the current retail sales forecast[16]. Energy Commission staff estimates that as much as 18,000 GWh of additional savings due to

[16] Energy efficiency savings are already represented in the current Energy Commission demand forecast adopted December 2009 (CEC 2009c).

uncommitted energy efficiency programs may be forthcoming.[17] This would reduce non-renewable energy needs by a further 12,000 GWh given a 33 percent RPS.

Greenhouse Gas Table 4
Estimated Changes in Non-Renewable Energy Potentially Needed to Meet California Loads, 2008-2020

California Electricity Supply	**Annual GWh**	
Statewide Retail Sales, 2008, actual [a]	264,794	
Statewide Retail Sales, 2020, forecast [a]	289,697	
Growth in Retail Sales, 2008-20	24,903	
Growth in Net Energy for Load [b]	29,840	
California Renewable Electricity	**GWh @ 20% RPS**	**GWh @ 33% RPS**
Renewable Energy Requirements, 2020 [c]	57,939	95,600
Current Renewable Energy, 2008	29,174	
Change in Renewable Energy-2008 to 2020	28,765	66,426
Resulting Change in Non-Renewable Energy	176	(36,586)

b. 2009 IEPR Demand Forecast, Form 1.5a.
c. RPS requirements are a percentage of retail sales.

The Role of GSEP in Retirements/Replacements

Genesis Solar Energy Project would be capable of annually providing 600 GWh of renewable generation energy to replace resources that are or will likely be precluded from serving California loads. State policies, including GHG goals, are discouraging or prohibiting new contracts and new investments in high GHG-emitting facilities such as coal-fired generation, generation that relies on water for once-through cooling, and aging power plants (CEC 2007). Some of the existing plants that are likely to require substantial capital investments to continue operation in light of these policies may be unlikely to undertake the investments and will retire or be replaced.

Replacement of High GHG-Emitting Generation

High GHG -emitting resources, such as coal, are effectively prohibited from entering into new long-term contracts for California electricity deliveries as a result of the Emissions Performance Standard adopted in 2007 pursuant to SB 1368. Between now and 2020, more than 18,000 GWh of energy procured by California utilities under these contracts will have to reduce GHG emissions or be replaced; these contracts are presented in **Greenhouse Gas Table 5**.

[17] See *Incremental Impacts of Energy Efficiency Policy Initiatives Relative to the 2009 Integrated Energy Policy Report Adopted Demand Forecast* (CEC-200-2010-001-D, January, 2010), page 2. Table 1 indicates that additional conservation for the three investor-owned utilities may be as high as 14,374 GWh. Increasing this value by 25 percent to account for the state's publicly-owned utilities yields a total reduction of 17,967 GWh.

Greenhouse Gas Table 5
Expiring Long-term Contracts with Coal-fired Generation 2009 – 2020

Utility	Facility [a]	Contract Expiration	Annual GWh Delivered to CA

		TOTAL	18,522

Source: Energy Commission staff based on Quarterly Fuel and Energy Report (QFER) filings.
Notes:
a. All facilities are located out-of-state except for the Miscellaneous In-state Qualifying Facilities.
b. Estimated annual reduction in energy provided to LADWP by Utah utilities from their entitlement by 2013.
c. Contract not subject to Emission Performance Standard, but the Department of Water Resources has stated its intention not to renew or extend.

This represents almost half of the energy associated with California utility contracts with coal-fired resources that will expire by 2030. If the State enacts a carbon adder[18], all the coal contracts (including those in **Greenhouse Gas Table 5**, which expire by 2020 and, other contracts that expire beyond 2020 and are not shown in the table) may be retired at an accelerated rate as coal-fired energy becomes uncompetitive due to the carbon adder or the capital needed to capture and sequester the carbon emissions. Also shown are the approximate 500 MW of in-state coal and petroleum coke-fired capacity that may be unlikely to contract with California utilities for baseload energy due to the SB1368 Emission Performance Standard. As these contracts expire, new and existing generation resources will replace the lost energy and capacity. Some will come from renewable generation such as this proposed project; some will come from new and existing natural gas fired generation. All of these new facilities will have substantially lower GHG emissions rates than coal and petroleum coke-fired facilities which typically averages about 1.0 $MTCO_2$/MWh without carbon capture and sequestration. Thus, new renewable facilities will result in a net reduction in GHG emissions from the California electricity sector.

Retirement of Generation Using Once-Through Cooling

The State Water Resource Control Board (SWRCB) has proposed major changes to once-through cooling (OTC) units, shown in **Greenhouse Gas Table 6**, which would likely require extensive capital to retrofit, or retirement, or substantial curtailment of dozens of generating units. In 2008, these units collectively produced almost 58,000 GWh. While the more recently built OTC facilities may well install dry or wet cooling towers and continue to operate, the aging OTC plants are not likely to be retrofit to use

[18] A carbon adder or carbon tax is a specific value added to the cost of a project for per ton of associated carbon or carbon dioxide emissions. Because it is based on, but not limited to, actual operations and emission and can be trued up at year end, it is considered a simple mechanism to assign environmental costs to a project.

dry or wet cooling towers without the power generation also being retrofit or replaced to use a more efficient and lower GHG emitting combined cycle gas turbine technology. Most of these existing OTC units operate at low capacity factors, suggesting a limited ability to compete in the current electricity market. Although the timing would be uncertain, new resources would out-compete aging plants and would displace the energy provided by OTC facilities and likely accelerate their retirements.

Any additional costs associated with complying with the SWRCB regulation would be amortized over a limited revenue stream today and into the foreseeable future. Their energy and much of their dispatchable, load-following capability will have to be replaced. These units constitute over 15,000 MW of merchant capacity and 17,800 GWh of merchant energy. Of this, much but not all of the capacity and energy are in local reliability areas, requiring a large share of replacement capacity – absent transmission upgrades – to locations in the same local reliability area. **Greenhouse Gas Table 6** provides a summary of the utility and merchant energy supplies affected by the OTC regulations.

New renewable generation resources will emit substantially less GHG emissions on average than other energy generation sources. Existing aging and OTC natural gas facility generation typically averages 0.6 to 0.7 $MTCO_2$/MWh, which is much less efficient, higher GHG emitting, than a renewable energy project like GSEP. A project like GSEP, located far from the coastal load pockets like the Los Angeles Local Reliability Area (LRA), would more likely provide energy support to facilitate the retirement of some aging and/or OTC power plants, but would not likely provide any local capacity support at or near the coastal OTC units. Regardless, due to its low greenhouse gas emissions, GSEP would serve to reduce GHG emissions from the electricity sector.

Closure and Decommissioning

Eventually the facility would close, either at the end of its useful life or due to some unexpected situation such as a natural disaster or catastrophic facility breakdown. When the facility closes, all sources of air emissions would cease to operate and thus impacts associated with those greenhouse gas emissions would no longer occur. The only other expected, albeit temporary, GHG emissions would be equipment exhaust (off-road and on-road) from dismantling activities. These activities would be of much a shorter duration than construction of the proposed project, equipment used to dismantle the facility are assumed to have lower comparative GHG emissions due to technology advancement, and would be required to be controlled in a manner at least equivalent to that required during construction. It is assumed that the beneficial GHG impacts of this facility, displacement of fossil fuel fired generation, would be replaced by the construction of newer more efficiency renewable energy or other low GHG generating technology facilities. Also, the recycling of the facility components (steel, concrete, etc.) could indirectly reduce GHG emissions from decommissioning activities. Therefore, while there would be temporary adverse greenhouse gas CEQA impacts during decommissioning they are determined to be less than significant.

Greenhouse Gas Table 6
Aging and Once-Through Cooling Units: 2008 Capacity and Energy Output [a]

Plant, Unit Name	Owner	Local Reliability Area	Aging Plant?	Capacity (MW)	2008 Energy Output (GWh)	GHG Emission Rate ($MTCO_2$/MWh)

a. OTC Humboldt Bay Units 1 and 2 are included in this list. They must retire in 2010 when the new Humboldt Bay Generating Station (not ocean-cooled), currently under construction, enters commercial operation.

b. Units are aging but are not OTC.

REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would essentially be Unit 1 of the proposed project, and would be a 125 MW solar facility located within the boundaries of the proposed project as defined by NextEra. This alternative is analyzed for two major reasons: (1) it eliminates about 50 percent of the proposed project area so all impacts are reduced, and (2) by removing the eastern solar field, it would reduce the water required for cooling by 50 percent. The boundaries of the Reduced Acreage Alternative are shown in **Alternatives Figure 1**.

This alternative is located entirely within the boundaries of the proposed project. It simply eliminates effects to the eastern 125 MW solar field and relocates the gas yard approximately 1.75 miles northwest of its present location. As a result, the environmental setting consists of the western portion of the proposed project, as well as the area affected by the linear project components.

The Reduced Acreage Alternative would reduce the total construction and operation GHG emissions of the proposed project (see **Greenhouse Gas Tables 2** and **3**) by somewhat less than 50 percent, due to lower efficiencies of the somewhat smaller project size.

The results of the Reduced Acreage Alternative would be the following:

- The impacts of the proposed project would not occur on the lands not used due to the smaller project size. However, the land on which the project is proposed would become available to other uses that are consistent with BLM's land use plan, including another solar project.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would be reduced. Both State and Federal law support the increased use of renewable power generation.

If the Reduced Acreage Alternative were approved, other renewable projects may be developed that would compensate for the loss of generation compared to the proposed project on other sites in the Riverside County, the Colorado Desert, or in adjacent states as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates.

DRY COOLING ALTERNATIVE

This section identifies the potential impacts of using air-cooled condenser (ACC) systems rather than the cooling towers proposed by NextEra for the Genesis project. It is assumed that the ACC systems would be located where the cooling towers are currently proposed for each of the two 125 MW power block, as illustrated in **Alternatives Figure 2** (see Section B.3). This alternative is analyzed because it would reduce the amount of water required for steam turbine cooling from 822 acre-feet per year (AFY) to 66 AFY. This reduction in water use would reduce impacts to water and biological resources.

The Dry Cooling Alternative would minimally impact the direct construction and operation GHG emissions of the proposed project. The construction of the ACC versus the construction of the cooling tower could very slightly increase construction GHG emissions from that of the proposed project shown in **Greenhouse Gas Table 2**. The use of the ACC could require an increase in auxiliary boiler use during daily plant startup increasing the direct GHG emissions from that of the proposed project shown in **Greenhouse Gas Table 3**, and the reduction in steam cycle efficiency would reduce total project generation and the indirect emission reductions caused by the project.

The results of the Dry Cooling Alternative would be the following:

- Direct GHG emissions similar to or slightly higher than the proposed project would occur.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would be slightly reduced due to a reduction in steam cycle efficiency. Both State and Federal law support the increased use of renewable power generation.

NO ACTION ALTERNATIVES

No Action On Proposed Project Application And On CDCA Land Use Plan Amendment

Under this alternative, the proposed project would not be approved by the CEC and BLM and BLM would not amend the CDCA Plan. As a result, no solar energy project would be constructed on the project site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended.

The results of this alternative would be the following:

- The impacts of the proposed project would not occur. However, the land on which the project is proposed would become available to other uses that are consistent with BLM's land use plan, including another renewable energy project.
- The benefits of the proposed project in displacing fossil fuel fired generation and reducing associated greenhouse gas emissions from gas-fired generation would not occur. Both State and Federal law support the increased use of renewable power generation.

If the proposed project is not approved, renewable projects would likely be developed on other sites in Riverside County, the Colorado Desert, or in adjacent states as developers strive to provide renewable power that complies with utility requirements and State/Federal mandates. For example, there are several pending solar and wind projects near the project area along the I-10 corridor including two thermal solar projects, the Palen Solar Power Project and Blythe Solar Power Project siting cases, which are currently being evaluated by the Energy Commission and BLM. Additionally, there are dozens of other wind and solar projects that have applications pending with BLM in the California Desert District.

No Action On Proposed Project And Amend The CDCA Land Use Plan To Make The Area Available For Future Solar Development

Under this alternative, the proposed project would not be approved by the CEC and BLM and BLM would amend the CDCA Land Use Plan of 1980, as amended, to allow for other solar projects on the site. As a result, it is possible that another solar energy project could be constructed on the project site.

Because the CDCA Plan would be amended, it is possible that the site would be developed with the same or a different solar technology. As a result, GHG emissions

would result from the construction and operation of the solar technology and would likely be similar to the GHG emissions from the proposed project. Different solar technologies require different amounts of construction and operations maintenance; however, it is expected that all the technologies would provide the more significant benefit, like the proposed project, of displacing fossil fuel fired generation and reducing associated GHG emissions. As such, this No Project/No Action Alternative could result in GHG benefits similar to those of the proposed project.

No Action On Proposed Project Application And Amend The CDCA Land Use Plan To Make The Area Unavailable For Future Solar Development

Under this alternative, the proposed project would not be approved by the CEC and BLM and the BLM would amend the CDCA Plan to make the proposed site unavailable for future solar development. As a result, no solar energy project would be constructed on the project site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended.

Because the CDCA Plan would be amended to make the area unavailable for future solar development, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, the greenhouse gas emissions from the site, including carbon uptake, is not expected to change noticeably from existing conditions and, as such, this No Project/No Action Alternative would not result in the GHG benefits from the proposed project. However, in the absence of this project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects would have similar impacts in other locations.

CUMULATIVE IMPACTS

Cumulative impacts are defined as “two or more individual effects which, when considered together, are considerable or . . . compound or increase other environmental impacts” (CEQA Guidelines § 15355). “A cumulative impact consists of an impact that is created as a result of a combination of the project evaluated in the EIR together with other projects causing related impacts” (CEQA Guidelines § 15130[a][1]). Such impacts may be relatively minor and incremental, yet still be significant because of the existing environmental background, particularly when one considers other closely related past, present, and reasonably foreseeable future projects.

Cumulative effects are defined by NEPA regulations as “…the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such actions” (40 CFR 1508.7).

This entire assessment is a cumulative impact assessment. The proposed project alone would not be sufficient to change global climate, but would emit greenhouse gases and therefore has been analyzed as a potential cumulative impact in the context of existing GHG regulatory requirements and GHG energy policies.

COMPLIANCE WITH LAWS, ORDINANCES, REGULATIONS, AND STANDARDS

The Genesis Solar Energy Project, as a solar energy generation project, is exempt from the mandatory GHG emission reporting requirements for electricity generating facilities as currently required by the California Air Resources Board (ARB) for compliance with the California Global Warming Solutions Act of 2006 (AB 32 Núñez, Statutes of 2006, Chapter 488, Health and Safety Code sections 38500 et seq.) (ARB 2008a).

The GSEP, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

Since the proposed project would have emissions that are below 25,000 MT/year of CO2E, the proposed project would not be subject to federal mandatory reporting of greenhouse gases. It would also be exempt from the state's greenhouse gas reporting requirements.

NOTEWORTHY PUBLIC BENEFITS

Greenhouse gas related noteworthy public benefits include the construction of renewable and low-GHG emitting generation technologies and the potential for successful integration into the California and greater WECC electricity systems. Additionally, the GSEP project would contribute to meeting the state's AB 32 goals.

CONCLUSIONS

The Genesis Solar Energy Project would emit considerably less greenhouse gases (GHG) than existing power plants and most other generation technologies, and thus would contribute to continued improvement of the overall western United States, and specifically California, electricity system GHG emission rate average. The proposed project would lead to a net reduction in GHG emissions across the electricity system that provides energy and capacity to California. Thus, staff concludes that the proposed project's operation would result in a cumulative overall reduction in GHG emissions from the state's power plants that would create a beneficial CEQA and NEPA, would not worsen current conditions, and would thus not result in CEQA impacts that are cumulatively significant or result in adverse NEPA impacts.

Staff concludes that the GHG emission increases typical from construction and decommissioning activities would not be CEQA significant for several reasons. First, the periods of construction and decommissioning would be short-term and not ongoing during the life of the proposed project. Second, the best practices control measures that staff recommends, such as limiting idling times and requiring, as appropriate, equipment that meets the latest emissions standards, would further minimize greenhouse gas emissions since the use of newer equipment would increase efficiency and reduce GHG emissions and be compatible with low-carbon fuel (e.g., bio-diesel and ethanol) mandates that will likely be part of the ARB regulations to reduce GHG from

construction vehicles and equipment. Finally, the construction and decommissioning emissions are miniscule when compared to the reduction in fossil-fuel power plant greenhouse gas emissions during project operation. For all these reasons, staff would conclude that the short-term emission of greenhouse gases during construction would be sufficiently reduced and would be offset during proposed project operations and would, therefore, not be CEQA significant.

The GSEP, as a renewable energy generation facility, is determined by rule to comply with the Greenhouse Gas Emission Performance Standard requirements of SB 1368 (Chapter 11, Greenhouse Gases Emission Performance Standard, Article 1, Section 2903 [b][1]).

MITIGATION MEASURES/PROPOSED CONDITIONS OF CERTIFICATION

No Conditions of Certification related to project greenhouse gas emissions are proposed because the proposed project would create beneficial GHG impacts. The project owner would have to comply with any future applicable GHG regulations formulated by the ARB or the U.S.EPA, such as GHG reporting or emissions cap and trade markets.

C.2 - BIOLOGICAL RESOURCES

Testimony of Heather Blair, Carolyn Chainey-Davis, Amy Golden, Sara Keeler, Mark Massar and Susan Sanders

C.2.1 SUMMARY OF CONCLUSIONS

Overview of Impacts to Biological Resources: The Genesis Solar Energy Project (Genesis Project or Project) would have significant impacts to biological resources, eliminating all of the Sonoran creosote bush scrub and other native plant and wildlife communities within the approximately 1,880-acre site. The Genesis Project would result in loss of an extensive network of desert washes comprising 91 acres of state jurisdictional waters, and would significantly alter the hydrology of the area by re-routing ephemeral drainages through engineered channels.

The Project site provides habitat for desert tortoise, a species listed as threatened under the federal and state endangered species acts. The Project would impact 1,786 acres of desert tortoise habitat, including 23 acres within the Chuckwalla Desert Critical Habitat Unit. Construction and operation of the Genesis Project would therefore require state and federal endangered species "take" authorization. In addition to direct loss of habitat the Project would fragment and degrade adjacent native plant and wildlife communities, and could promote the spread of invasive non-native plants and desert tortoise predators such as ravens.

The U.S. Bureau of Land Management (BLM) and California Energy Commission (Energy Commission) staffs (hereafter jointly referred to as staff unless otherwise noted) have concluded that without mitigation the Genesis Project would contribute to the cumulatively significant loss of biological resources within the Chuckwalla Valley and the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) area. Staff recommends compensatory mitigation to offset direct, indirect, and cumulative impacts to desert tortoise and other special-status species, and to assure compliance with state and federal laws such as the federal and state endangered species acts and regulations protecting waters of the state. With implementation of staff's proposed conditions of certification, Project impacts to biological resources would be reduced to less than significant levels.

Mitigation for Desert Tortoise: The measures in staff's proposed Conditions of Certification **BIO-9** through **BIO-11** would avoid and minimize potential take of desert tortoise during Project construction and operation. To offset the loss of 1,763 acres of desert tortoise habitat, staff's proposed Condition of Certification **BIO-12** recommends habitat compensation at a 1:1 ratio for desert tortoise (i.e., acquisition and preservation of one acre of compensation lands for every acre lost). For Project impacts to 23 acres of Chuckwalla Desert Critical Habitat Unit, the mitigation ratio would be 5:1. This compensatory mitigation is consistent with recommendations from the California Department of Fish and Game (CDFG), the U.S. Fish and Wildlife Service (USFWS), and BLM guidance in the NECO. Staff's proposed Condition of Certification **BIO-12** also requires that the land acquisitions be within the Colorado Desert Recovery Unit, and have potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise populations and designated critical habitat. These conditions

satisfy the California Department of Fish and Game's requirements under Section 2081 of the California Fish and Game Code.

Staff's proposed Condition of Certification **BIO-13** requires implementation of a Raven Monitoring, Management and Control Plan to address Project-related increases in ravens, a desert tortoise predator.

Interim DRECP Process for Desert Tortoise Mitigation: Federal and state agencies are currently collaborating as the Renewable Energy Action Team (REAT) to establish joint policies and plans to expedite development of California's utility scale renewable energy projects. To accomplish this goal these agencies are developing a Desert Renewable Energy Conservation Plan (DRECP), a science-based process for reviewing, approving, and permitting renewable energy applications in California. Once the DRECP is complete, anticipated in late 2012, the plan will provide tools to expedite coordination of federal and state endangered species act permitting and a framework for implementing regionally coordinated land acquisition and mitigation.

Impacts to Mojave Fringe-toed Lizards: The Genesis Project would directly impact 66 acres of Mojave fringe-toed lizard habitat (including 28 acres of dunes and 38 acres of playa with sand drifts) and indirectly affect 453 acres of habitat downwind of the Project Disturbance Area. The indirect impact results from the Project solar arrays extending into sand transport corridors, diminishing the input of sand to downwind areas and reducing the active sand layer that is crucial to Mojave fringe-toed lizard habitat. The Mojave fringe-toed lizards in the Chuckwalla Valley are at the southernmost portion of the species range, and the proposed Project could increase the risks of local extirpation of an already fragmented and isolated population. Staff's proposed Condition of Certification **BIO-20** recommends acquisition and protection of core populations of Mojave fringe-toed lizard habitat in the Chuckwalla Valley, which would reduce Project impacts to less than significant levels.

While the Project's impacts to sand dune habitat and Mojave fringe-toed lizards can be mitigated to less than significant levels, the cumulative impacts from all foreseeable projects in the Chuckwalla Valley and the NECO planning area remain significant. Development of proposed projects would result in the direct loss of over 16 percent of all Mojave fringe-toed lizard habitat in the NECO planning area, effects that are all the more significant when combined with the expected indirect effects to Mojave fringe-toed lizard habitat, including: interruption of wind sand transport processes; diversions of desert washes and interruption of fluvial transport of sand that contribute to the maintenance of habitat; an increase in predation from ravens and direct mortality from an increase of vehicles in previously undisturbed habitat, and the continuing spread of non-native, weedy species such as Sahara mustard and Russian thistle in the Chuckwalla Valley. Staff considers these cumulative direct and indirect effects of to the Chuckwalla Valley population of Mojave fringe-toed lizards and their habitat to be significant. The Project's contributions to significant impacts would be mitigated to less than significant levels with implementation of staff's proposed conditions of certification.

Ephemeral Drainages: The Project would directly impact 91 acres of state jurisdictional waters, including 16 acres of microphyllous riparian vegetation, eliminating the hydrological, biogeochemical, vegetation, and wildlife functions of this network of

ephemeral drainages. As many as 21 acres of ephemeral drainages downstream of the Project area could also be indirectly impacted by changes in upstream hydrology. Staff considers the direct, indirect, and cumulative impacts to ephemeral drainages to be significant. The measures in staff's proposed Condition of Certification **BIO-22** would minimize and offset direct and indirect impacts to state waters to less than significant levels and would assure compliance with CDFG codes that provide protection to these state waters. These measures include acquisition and enhancement of 132 acres of ephemeral dry washes within the Chuckwalla Valley watershed, as well as avoidance and minimization measures to protect drainages near the Project site.

Special-Status Plants: No federal or state-listed plant species occur within the Project Disturbance Area, but four special-status plants species were detected within the Study area during surveys including Harwood's milk-vetch, desert unicorn plant, Las Animas colubrina, and ribbed cryptantha. Harwood's milk-vetch (CNPS List 2.2) and desert unicorn plant (CNPS List 4.3) were identified in the Project Disturbance Area and ribbed cryptantha (CNPS List 4.3) and Las Animas colubrina (CNPS List 2) were identified in the buffer area and outside of the Project Disturbance Area.

One segment of the proposed Project linears was not included in spring 2009 surveys, and the Applicant has proposed surveys of this area in 2010. In addition to the species included on the target list for 2009 surveys, staff has identified additional species to include in the spring 2010 survey.

Four species, including Abram's spurge, flat-seeded spurge, lobed ground cherry, glandular ditaxis, and winged cryptantha have moderate to high potential to occur within the Project site. They were not detected during spring 2009 botanical surveys, but may have been missed because they are late season plants and are difficult or impossible to detect during spring surveys (no late season surveys were conducted). Project construction and operation could result in direct and indirect impacts to all of these species, and impacts to even a small population of any of these species would be significant. The California distribution of each of these species is currently documented

Staff has proposed late-summer/early-fall season floristic surveys for these species. If Abram's spurge, flat-seeded spurge, lobed ground cherry, or glandular ditaxis are found, compensatory mitigation would be required as specified in staff's proposed Condition of Certification **BIO-19** and would reduce impacts to less than significant levels. If results of surveys for Abram's spurge, flat-seeded spurge, lobed ground cherry, and glandular ditaxis are inconclusive due to low rainfall levels, then compensatory mitigation shall be required on the basis of habitat loss. Staff has determined that impacts to winged cryptantha would be less than significant and would not require compensatory mitigation. Staff's proposed Condition of Certification **BIO-19** would prevent accidental impacts to special-status plants in close proximity to construction and reduce direct and indirect impacts to special-status plant species to less than significant levels.

Impacts to Groundwater Dependent Vegetation Communities: The proposed Project's groundwater pumping would have an impact on groundwater levels in the Chuckwalla Valley Groundwater Basin (see **Soil and Water** section), with potential adverse effects to groundwater dependent sensitive plant communities and to wildlife.

Groundwater is also important to sustain vegetation for wildlife habitat in some areas where surface waters are not present. Groundwater-dependent vegetation is documented at Palen Lake, where near-surface groundwater has been observed. Phreatophytes also occur sporadically with smaller examples at Ford Dry Lake, where groundwater levels are deeper. The project has the potential to lower groundwater levels as a result of water production during both construction and operations. The lowering of groundwater levels could have a significant impact to biological resources in areas where deep-rooted phreatophytes occur. Considerable uncertainty remains as to the potential extent of Project impacts to groundwater (see **Soil and Water** section) and to groundwater dependent plant communities, but staff considers these impacts to be potentially significant.

Even modest drawdowns of 0.3 feet can adversely affect vegetation if groundwater drops below the effective rooting levels sustained over time (so that plants never have an opportunity to recover), or occurs not just in summer (when plants are dormant) but throughout early spring when plants need and utilize water most, and when they are least tolerant of drought.

To ensure that the Project's proposed use of groundwater does not lower groundwater levels in the basin so that biological resources are significantly and adversely affected, staff has proposed that the Applicant develop a vegetation monitoring program and identify what changes are occurring in basin water levels and in groundwater-dependent vegetation. Substantial changes to groundwater levels caused by the proposed Project and other pumping in the basin would be documented by the Groundwater Well Monitoring and Reporting program outlined in Condition of Certification **SOIL&WATER-5**. Substantial changes in the vigor of groundwater-dependent vegetation would be monitored and documented under the Vegetation Monitoring and Reporting Plan outlined in staff's proposed Condition of Certification **BIO-25**. Condition of Certification **BIO-26** specifies remedial action to be taken if adverse effects are detected. These measures would be sufficient to ensure that the groundwater pumping for the Project would not result in significant adverse impacts to groundwater-dependent ecosystems in the Chuckwalla Basin.

Migratory Birds/Burrowing Mammals: Sonoran creosote bush scrub and ephemeral drainages within the Project Area provide foraging, cover, and/or breeding habitat for migratory birds, including a number of special-status bird species potentially occurring at the site (including loggerhead shrike, western burrowing owl, and California horned lark). Migratory birds and their eggs and young are protected by the federal Migratory Bird Treaty Act and Fish and Game Code section 3503. Implementation of staff's proposed Conditions of Certification **BIO-8** (Impact Avoidance and Best Management Practices), **BIO-15** (Pre-Construction Nest Surveys), and **BIO-16** (Avian Protection Plan) would avoid these potentially significant impacts to nesting birds. Potential impacts to burrowing owls would be further mitigated by implementation of staff's proposed Condition of Certification **BIO-18**. This condition involves passive relocation of burrowing owls, as well as acquisition of off-site habitat suitable for burrowing owl.

American badgers and desert kit foxes occur throughout the Project area, and construction activities could crush or entomb these burrowing species. Staff's proposed Condition of Certification **BIO-17**, which requires preconstruction surveys and

avoidance measures to protect badgers and kit foxes, would avoid these potential impacts.

Impacts and Mitigation for Golden Eagles: Although golden eagles were not detected during the avian surveys conducted for the Project, no focused survey for nest sites or breeding pairs was conducted, nor was an assessment made of the use of the Project site by wintering golden eagles. Surveys for golden eagles were conducted by the BLM in the late 1970s throughout the California desert and there are no known historic records for golden eagle nests within 14 miles from the Project site. While staff considers the direct and indirect impacts of the Genesis Project to be less than significant, information from golden eagle nest surveys in nearby mountains could change this conclusion.

On November 10, 2009 the USFWS introduced new rules (74 FR 46835) requiring a permit for all activities that might result in take of golden or bald eagles, including activities that might cause decreased productivity or nest abandonment. Staff is awaiting further guidance from USFWS to determine whether a federal Eagle Act take permit is warranted for the Palen Project. The USFWS may require higher resolution data from the Project vicinity to make that determination.

Project Closure and Decommissioning: Staff's proposed Condition of Certification **BIO-23** requires the Applicant to develop a Decommissioning and Closure Plan and a cost estimate that meets the requirements of BLM's 43 CFR 3809.550 et seq. This plan would need to include a conceptual approach for removing the engineered channels and other Project facilities, restoration of the site's topography and hydrology, and a revegetation plan for restoring the function and values of the vegetation communities and wildlife habitat. Condition of Certification **BIO-23** also requires a cost estimate of the funding required to undertake those activities.

Alternatives: Staff analyzed two alternatives to the Proposed Project other than the No Project Alternative, the Reduced Acreage Alternative and the Dry Cooling Alternative. The smaller Reduced Acreage Alternative would have smaller impacts on many of the biological resources within the Project area, and substantially less impact on Mojave fringe-toed lizard habitat. The Reduced Acreage Alternative would use approximately 50 percent less groundwater than the Proposed Project. Because the linear facilities for the Proposed Project and the Reduced Acreage Alternatives share the same route, impacts associated with this corridor remain very similar, such as impacts to Couch's spadefoot toad and microphyll woodland. In addition, although the Reduced Acreage Project does represent fewer acres of impacts, it is the same overall length as the Proposed Project, and therefore indirect impacts to desert washes that currently flow through the area would be similar.

The Dry Cooling Alternative is located entirely within the boundaries of the Proposed Project. Because this alternative would occupy the same footprint as the Proposed Project, the impacts remain the same between the two except for impacts to groundwater-dependent ecosystems. The Dry Cooling Alternative would use over 95 percent less groundwater than the Proposed Project.

Staff considers direct, indirect, and cumulative impacts from the Proposed Project and both alternatives to be similar (aside from differences in impact acreage) for most biological resources, including impacts to desert tortoise habitat, Couch's spadefoot toad, microphyll woodland, and migratory birds. While impacts from the Reduced Acreage Alternative are substantially less to Mojave fringe-toed lizard habitat and desert wash, these impacts would still be considered significant under this alternative as well as under the Proposed Project and Dry Cooling Alternative. Staff currently has insufficient information to fully assess the indirect and cumulative impacts to groundwater-dependent vegetation, but these impacts may be considered significant under the Proposed Project and the Reduced Acreage Alternative. Impacts from the Dry Cooling Alternative are identical to those from the Proposed Project, except that this alternative would eliminate any potential Project impacts to groundwater-dependent vegetation.

Proposed conditions of certification under the Reduced Acreages Alternative are identical to those for the Proposed Project, except that the compensatory mitigation acreages recommended for desert tortoise habitat (staff's proposed Condition of Certification **BIO-12**), western burrowing owl (staff's proposed Condition of Certification **BIO-18**), sand dunes (staff's proposed Condition of Certification **BIO-20**), Mojave fringe-toed lizards (staff's proposed Condition of Certification **BIO-20**), and state waters (staff's proposed Condition of Certification **BIO-22**) are adjusted to reflect the reduced areas of impacts. Proposed conditions of certification under the Dry Cooling Alternative are identical to those for the Proposed Project, except that proposed Condition of Certification **BIO-25** and **BIO-26** would not be required. Staff concludes that with implementation of these conditions, impacts from both alternatives would be less than significant.

Proposed 2010 Surveys: In addition to pre-construction surveys, staff and the Applicant have indicated that additional special-status species surveys need to be conducted in 2010. The absence of the 2010 survey data has not precluded staff from coming to conclusions about the significance of potential impacts to biological resources or prevented development of appropriate mitigation; staff has incorporated avoidance, minimization, or compensation measures into proposed conditions of certification in a manner that accommodates the results of the surveys. The proposed 2010 surveys include the following:

Desert Tortoise. The Applicant proposes conducting protocol-level surveys for desert tortoise and special-status plant species within the northern portion of the transmission line route (north of I-10) that was not surveyed during 2009 field surveys (TTEC 2009c).

Plant Surveys. The following will be targeted for late summer/early fall 2010 focused botanical surveys: glandular ditaxis (CEC 2009d), Abram's spurge, lobed ground cherry, and flat-seeded spurge (CEC 2009d). Additional Spring 2010 surveys are planned for an unsurveyed segment of the proposed Project linear facilities route.

Couch's Spadefoot Toad: Staff has concluded that a potential breeding pond for Couch's spadefoot toad occurs along the linear facilities corridor, and is requiring surveys for potential breeding habitat along other portions of the linear facilities.

Cumulative Effects: Construction and operation of the Genesis Project will have effects on a number of biological resources that are individually limited but cumulatively considerable. The cumulative effects analysis employed a quantitative, GIS-based analysis of direct impacts to habitat, and a qualitative analysis of indirect effects (e.g., increases in predators, noxious weeds, etc.). In many cases, the anticipated indirect effects are more significant, or adverse, than the direct loss of habitat, but are more difficult to quantify. Geographic scope varied between biological resources, but most analyses were based on the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) boundaries (BLM-CDD 2002).

Significant cumulative effects (including indirect effects) were identified in a number of biological resource areas where the Project contributes—at least incrementally—to the cumulative effect. These include: desert washes in the Ford Watershed and the broader NECO planning area; desert tortoise habitat; golden eagle foraging habitat; Mojave fringe toed lizard and their habitat; habitat for American badger, desert kit fox, and burrowing owl; Le Conte's thrasher habitat; Couch's spadefoot toad range; habitat for Harwood's milk-vetch and other dune/playa-dependent special-status plants; wildlife habitat and connectivity within the Palen-Ford WHMA (for Mojave fringe toed lizard, dunes, and playa); Mojave and Sonoran creosote bush scrub; desert dry wash woodland (microphyll woodland); playa and sand drifts over playa, and dunes (active and stabilized).

Of particular concern are the cumulative effects of renewable energy projects within the geographic scope of the Chuckwalla Valley, which contains an isolated system of dunes and population of Mojave fringe-toed lizard. The direct loss of dune habitat and Mojave fringe-toed lizard is minor relative to the indirect downwind effects from obstructions within the active aeolian sand transport corridor, and the disruption of the fluvial processes that contribute sand to the system from the diversion of washes--approximately 63 miles of washes within the Ford watershed alone. In addition to the disruption of geomorphic processes, significant indirect effects that can be reasonably expected to occur in the Chuckwalla system from future projects include: fragmentation and its effects on connectivity and gene flow; spread of invasive non-native plants; increase in avian predators; and an increase in vehicle-related wildlife mortality.

Implementation of staff's proposed conditions of certification would reduce the Project's contribution to cumulative effects to a level that is not cumulatively considerable. There may be cumulative effects after mitigation is implemented by all projects, but due to the mitigation implemented by the Project, its contribution would be less than cumulatively considerable. These residual cumulative effects from all future projects could be addressed through a regional and coordinated planning effort aimed at preserving and enhancing large, intact expanses of wildlife habitat and linkages, including maintaining connections between wildlife management areas and other movement corridors.

Ongoing collaborative efforts by federal and state agencies to develop a Desert Renewable Energy Conservation Plan and BLM's Solar Energy Development Programmatic EIS offer an appropriate forum for such planning. Appendix B describes the Desert Wildlife Management Area management strategies that could achieve the goals of preservation and enhancement of wildlife connectivity in the NECO planning area. Staff supports these programmatic efforts and believes they represent an

excellent means of integrating the State's and BLM's renewable resources goals and environmental protection goals.

C.2.2 INTRODUCTION

This section of the Staff Assessment/Draft Environmental Impact Statement (SA/DEIS) provides the California Energy Commission and BLM staff analysis of potential impacts to biological resources from the construction and operation of the Genesis Project. This analysis describes the biological resources at the proposed Project site and addresses potential impacts to special-status species, sensitive natural communities, and other significant biological resources. This section discusses the need for mitigation, evaluates the adequacy of mitigation proposed by the Applicant, and specifies additional mitigation measures designed to reduce impacts. It also describes compliance with applicable laws, ordinances, regulations, and standards (LORS) and recommends staff's proposed conditions of certification.

This analysis is based, in part, upon information from the following sources: the Application for Certification (AFC) (GSEP 2009a); Data Adequacy Supplement (GSEP 2009c) and Data Adequacy Supplement 1A (GSEP 2009d); responses to staff data requests (GSEP 2009f, TTEC 2010f); staff workshops held on November 23 and 24, December 18 and 31, 2009 and January 6, 11, and 12, February 10 and 18, 2010; site visits by staff on October 27, 2009, December 10, 2009, January 12 and February 25, 2010; the Applicant's December 2009 Notification of a Lake or Streambed Alteration (TTEC 2009d) revisions to the Notification of a Lake or Streambed Alteration (TTEC 2010j, TTEC 2010l); the applicant's *Aeolian Transport Evaluation and Ancient Shoreline Delineation Report for the GSEP* (Worley Parsons 2010c); the applicant's *Interim Preliminary Aeolian Sand Source, Migration and Deposition Letter Report for GSEP* (Worley Parsons 2010d); PWA's Geomorphic Assessment of the Genesis Solar Project Site (**Soil and Water Appendix A**); the Applicant's *Incidental Take of Threatened and Endangered Species Permit Application* (TTEC 2009c); the Applicant's draft mitigation plans including the Draft Desert Tortoise Relocation/Translocation Plan (TTEC 2010a), Draft Weed Management Plan (TTEC 2010g), Draft Revegetation Plan (TTEC 2010i), and Draft Common Raven Monitoring, Control and Management Plan (TTEC 2010k); communications with representatives from the California Department of Fish and Game (CDFG) and the U.S. Fish and Wildlife Service (USFWS); and information contained within the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO).

Compliance with Laws, Ordinances, Regulations, and Standards

The Project developer would need to comply with the following laws, ordinances, regulations, and standards (LORS) during Project construction and operation, as listed in **Biological Resources Table 1**.

Biological Resources Table 1
Laws, Ordinances, Regulations, and Standards (LORS)

Applicable LORS	Description
Federal	
Federal Endangered Species Act (Title 16, United States Code, section 1531 et seq., and Title 50, Code of Federal Regulations, part 17.1 et seq.)	Designates and protects federally threatened and endangered plants and animals and their critical habitats.
Clean Water Act (Title 33, United States Code, sections 1251 through 1376, and Code of Federal Regulations, part 30, section 330.5(a)(26))	Requires the permitting and monitoring of all discharges to surface water bodies. Section 404 requires a permit from the U.S. Army Corps of Engineers (USACE) for a discharge of dredged or fill materials into waters of the U.S., including wetlands. Section 401 requires a permit from a regional water quality control board (RWQCB) for the discharge of pollutants. By federal law, every applicant for a federal permit or license for an activity that may result in a discharge into a California water body, including wetlands, must request state certification that the proposed activity will not violate state and federal water quality standards.
Eagle Act (Title 50, Code of Federal Regulations, section 22.26)	Would authorize limited take of bald eagles (*Haliaeetus leucocephalus*) and golden eagles (*Aquila chrysaetos*) under the Eagle Act, where the taking is associated with, but not the purpose of activity, and cannot practicably be avoided.
Eagle Act (Title 50, Code of Federal Regulations, section 22.27)	Would provide for the intentional take of eagle nests where necessary to alleviate a safety hazard to people or eagles; necessary to ensure public health and safety; the nest prevents the use of a human – engineered structure, or; the activity, or mitigation for the activity, will provide a net benefit to eagles. Only inactive nests would be allowed to be taken except in the case of safety emergencies.
Bald and Golden Eagle Protection Act (Title 16, United States Code section 668)	This law provides for the protection of the bald eagle and the golden eagle by prohibiting, except under certain specified conditions, the take, possession, and commerce of such birds. The 1972 amendments increased penalties for violating provisions of the Act or regulations issued pursuant thereto and strengthened other enforcement measures. Rewards are provided for information leading to arrest and conviction for violation of the Act.
Northern and Eastern Colorado Desert Coordinated Management Plan (NECO)	A regional amendment to the CDCA Plan approved in 2002, NECO protects and conserves natural resources while simultaneously balancing human uses in the northern and eastern portion of the Colorado Desert.
California Desert Protection Act of 1994 (CDPA)	An Act of Congress which established 69 wilderness areas, the Mojave National Preserve, expanded Joshua Tree and Death Valley National Monuments and redefined them as National Parks. Lands transferred to the National Park Service were formerly administered by the BLM and included substantial portions of grazing allotments, wild horse and burro Herd Management Areas, and Herd Areas.
Migratory Bird Treaty	Makes it unlawful to take or possess any migratory nongame bird (or

Applicable LORS	Description
(Title 16, United States Code, sections 703 through 711)	any part of such migratory nongame bird) as designated in the Migratory Bird Treaty Act.
Executive Order 11312	Prevent and control invasive species.
California Desert Conservation Area Plan	The California Desert Conservation Area (CDCA) comprises one of two national conservation areas established by Congress at the time of the passage of the Federal Land and Policy Management Act (FLPMA) in 1976. The FLPMA outlines how the BLM will manage public lands. Congress specifically provided guidance for the management of the CDCA and directed the development of the 1980 CDCA Plan.
Desert Tortoise (Mojave Population) Recovery Plan (USFWS 1994) and Draft Revised Recovery Plan (USFWS 2008a)	Describes a strategy for recovery and delisting of the desert tortoise.
State	
California Endangered Species Act of 1984 (Fish and Game Code, sections 2050 through 2098)	Protects California's rare, threatened, and endangered species.
Protected furbearing mammals (California Code of Regulations, Title 14, section 460)	Fisher, marten, river otter, desert kit fox and red fox may not be taken at any time.
California Code of Regulations (Title 14, sections 670.2 and 670.5)	Lists the plants and animals of California that are declared rare, threatened, or endangered.
Fully Protected Species (Fish and Game Code, sections 3511, 4700, 5050, and 5515)	Designates certain species as fully protected and prohibits the take of such species or their habitat unless for scientific purposes (see also California Code of Regulations Title 14, section 670.7).
Nest or Eggs (Fish and Game Code section 3503)	Protects California's birds by making it unlawful to take, possess, or needlessly destroy the nest or eggs of any bird.
Birds of Prey (Fish and Game Code section 3503.5	Unlawful to take, possess, or destroy any birds in the orders Falconiformes and Strigiformes or to take, possess, or destroy the nest or eggs of any such bird.
Migratory Birds (Fish and Game Code section 3513)	Protects California's migratory birds by making it unlawful to take or possess any migratory nongame bird as designated in the Migratory Bird Treaty Act or any part of such migratory nongame birds.
Nongame mammals (Fish and Game Code section 4150)	Makes it unlawful to take or possess any non-game mammal or parts thereof except as provided in the Fish and Game Code or in accordance with regulations adopted by the commission.
Significant Natural	Designates certain areas such as refuges, natural sloughs, riparian

Applicable LORS	Description
Areas (Fish and Game Code section 1930 and following)	areas, and vernal pools as significant wildlife habitat.
California Environmental Quality Act (CEQA), CEQA Guidelines section 15380	CEQA defines rare species more broadly than the definitions for species listed under the state and federal Endangered Species Acts. Under section 15830, species not protected through state or federal listing but nonetheless demonstrable as "endangered" or "rare" under CEQA should also receive consideration in environmental analyses. Included in this category are many plants considered rare by the California Native Plant Society (CNPS) and some animals on the CDFG's Special Animals List.
Streambed Alteration Agreement (Fish and Game Code sections 1600 and following)	Regulates activities that may divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake in California designated by CDFG in which there is at any time an existing fish or wildlife resource or from which these resources derive benefit. Impacts to vegetation and wildlife resulting from disturbances to waterways are also reviewed and regulated during the permitting process.
California Native Plant Protection Act of 1977 (Fish and Game Code section 1900 and following)	Designates state rare, threatened, and endangered plants.
California Desert Native Plants Act of 1981 (Food and Agricultural Code section 80001 and following and California Fish and Game Code sections 1925-1926)	Protects non-listed California desert native plants from unlawful harvesting on both public and private lands in Imperial, Inyo, Kern, Los Angeles, Mono, Riverside, San Bernardino, and San Diego counties. Unless issued a valid permit, wood receipt, tag, and seal by the commissioner or sheriff, harvesting, transporting, selling, or possessing specific desert plants is prohibited.
Porter-Cologne Water Quality Control Act	Regulates discharges of waste and fill material to waters of the State, including "isolated" waters and wetlands.
Local	
Riverside County General Plan	Protection and preservation of wildlife for the maintenance of the balance of nature.

Desert Renewable Energy Conservation Plan – Interim Planning

In addition to the federal, state, and local LORS summarized above, federal and state agencies are currently collaborating to establish joint policies and plans to expedite development of California's utility-scale renewable energy projects. On October 12, 2009, the State of California and the U.S. Department of Interior entered into a Memorandum of Understanding (MOU) on renewable energy, building on existing efforts by California and its federal partners to facilitate renewable energy development in the state. The MOU stems from California and Department of Interior energy policy directives, and California's legislative mandate to reduce greenhouse gases to 1990 levels by 2020, and meet the goal of 33 percent of California's electricity production from renewable energy sources by 2020.

The California-Department of Interior MOU expands on several MOUs issued in 2008 to establish the activities of the California Renewable Energy Action Team (REAT). The REAT was established with California Executive Order S-14-08 (issued November 18, 2008), to "*establish a more cohesive and integrated statewide strategy, including greater coordination and streamlining of the siting, permitting, and procurement processes for renewable generation* …."

The Energy Commission and CDFG are the primary state collaborators in the REAT, operating under a November 18, 2008 MOU between the two agencies to create a "one-stop process" for permitting renewable energy projects under their joint permitting authority. The BLM and the USFWS also participate in the REAT under a separate MOU signed in November 2008, which outlines the state and federal cooperation of the group. The October 12, 2009 MOU between California and the Department of Interior reiterates several tasks of the REAT provided for in S-14-08 and the Energy Commission-Fish and Game MOU.

The REAT's primary mission is to streamline and expedite the permitting processes for renewable energy projects in the Mojave and Colorado Desert ecoregions within the State of California, while conserving endangered species and natural communities at the ecosystem scale. To accomplish this goal the REAT Agencies are developing a Desert Renewable Energy Conservation Plan (DRECP), a science-based process for reviewing, approving, and permitting renewable energy applications in California. Once the DRECP is complete, anticipated in late 2012, the plan will provide tools to expedite coordination of federal and state endangered species act permitting. The DRECP will also offer a unified framework for state and federal agencies to oversee mitigation actions, including land acquisitions, for listed species.

The REAT Agencies recognize that some renewable energy projects are scheduled to be approved prior to completion of the DRECP. Section 8.9 of the October 2009 Draft Planning Agreement for the DRECP <www.energy.ca.gov/2009publications/...2009.../REAT-1000-2009-034.PDF> provides explicit guidance for such interim projects, and directs the REAT Agencies to ensure that permitting for these projects: be consistent with the preliminary conservation objectives for the DRECP; not compromise successful completion and implementation of the DRECP; facilitate Federal Endangered Species Act, California Endangered Species Act, National Environmental Policy Act, and California Environmental Quality Act compliance; and not be unduly delayed during preparation of the DRECP.

Recognizing that the necessary components of the DRECP are not likely to be in place by the time the Genesis Project is ready for certification, this section also provides an option for implementing desert tortoise compensatory mitigation consistent with past policies and practices of BLM, the Energy Commission, and CDFG.

C.2.3 METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The analysis of proposed Project effects must comply with both CEQA and NEPA requirements given the respective power plant licensing and land jurisdictions of the

California Energy Commission (Energy Commission) and U.S. Bureau of Land Management (BLM). CEQA requires that the significance of individual effects be determined by the Lead Agency, but the use of specific significance criteria is not required by NEPA. This document is intended to meet the requirements of both NEPA and CEQA; therefore the method used for determining environmental impacts of the proposed Project incorporates guidance provided by both laws.

CEQA requires a list of criteria that are used to determine the significance of identified impacts. A significant impact is defined by CEQA as “a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project” (State CEQA Guidelines Section 15382).

Thresholds for determining CEQA significance in this section are based on Appendix G of the CEQA Guidelines (CCR 2006) and performance standards or thresholds identified by the Energy Commission staff. The determination of whether a project has a significant effect on biological resources is based on the best scientific and factual data that staff could review for the project. In this analysis the following impacts to biological resources are considered significant if the project would result in: a substantial adverse effect to plant species considered by the California Native Plant Society (CNPS), CDFG, or USFWS to be rare, threatened, or endangered in California or with strict habitat requirements and narrow distributions; a substantial impact to a sensitive natural community (i.e., a community that is especially diverse; regionally uncommon; or of special concern to local, state, and federal agencies); a substantial adverse effect to wildlife species that are federally-listed or state-listed or proposed to be listed; a substantial adverse effect to wildlife species of special concern to CDFG, candidates for state listing, or animals fully protected in California; substantial adverse effects on habitats that serve as breeding, foraging, nesting, or migrating grounds and are limited in availability or that serve as core habitats for regional plant and wildlife populations; substantially interferes with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; substantial adverse effect on important riparian habitats or wetlands and any other “Waters of the U.S.” or state jurisdictional waters; and conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan.

In contrast to CEQA, “significantly” as used in NEPA requires considerations of both context and intensity (40 CFR 1508.27). According to the NEPA Regulations adopted by the President’s Council on Environmental Quality (CEQ) (40 CFR 1500-1508), context means the affected environment in which a proposed action would occur; it can be local, regional, national, or all three, depending upon the circumstances. In determining the intensity of an impact, the following factors are considered: adverse effects of a project even though the overall proposed action is beneficial; effects on public health or safety; unique characteristics of the geographic area, such as historic resources, park lands, prime farmland, wetlands, wild and scenic rivers, ecologically critical areas; degree of controversy; degree of highly uncertain effects or unique or unknown risks; precedent-setting effects; cumulative effects; adverse effects on scientific, cultural, or historical resources; adverse effects on endangered or threatened species or designated critical

habitat (pursuant to the Endangered Species Act); and violations of federal, state, or local environmental law.

For NEPA, thresholds serve as a benchmark for determining if a project action would result in a significant adverse environmental impact when evaluated against the baseline. NEPA requires that an Environmental Impact Statement (EIS) be prepared when the proposed federal action (project) as a whole has the potential to "significantly affect the quality of the human environment."

C.2.4 PROPOSED PROJECT

C.2.4.1 SETTING AND EXISTING CONDITIONS

Proposed Project

Genesis Solar, LLC (Genesis Solar) is proposing development of their 250-megawatt (MW) solar generating facility within a 4,640-acre right-of-way (ROW) grant application from the Bureau of Land Management. Approximately 1,768 acres within the proposed ROW would be used for the solar power plant facility and 84 acres would be used for the linear facilities, collectively referred to as the Project Disturbance Area throughout the remainder of this Biological Resources Section (CEC 2010d). The Project Disturbance Area encompasses all areas to be temporarily and permanently disturbed including the following:

- "plant site" described by the applicant as the solar arrays, power blocks, power equipment, support facilities and evaporation ponds (TTEC 2009c);
- "linear facilities" including the access road, transmission line, natural gas pipeline (TTEC 2009c); and
- All areas disturbed by temporary access roads, fence installation, construction work lay-down and staging areas or by any other activities resulting in disturbance to soil or vegetation.

Linear facilities would include a 6.1-mile long access road from Interstate 10 (I-10), a 7.5-mile long transmission line which would extend south of I-10, and a 5.9-mile long natural gas pipeline, all sited in a single 6.5-mile long linear facility corridor. The generation tie-line would cross I-10 and tie into the Blythe Energy Project Transmission Line and existing pole structures in order to interconnect with the Colorado River substation to the east (TTEC 2009c).

Interstate-10 is located approximately 2 miles south of the southernmost boundary of the ROW. The Project site occurs at elevations ranging from approximately 350 to 450 feet above mean sea level, approximately 25 miles west of the community of Blythe and 27 miles east of Desert Center, California in eastern Riverside County. . The proposed Project would be located within the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) area. A detailed description of the Project is provided in section B.1. The Genesis Project would be located on the alluvial fan on the southern flank of the Palen Mountains in the eastern portion of the Chuckwalla Valley.

Regional Setting

The Genesis Solar Energy Project (Project) would be located within the northeastern portion of Chuckwalla Valley, an area east of Palm Springs in the remote Colorado Desert, a subsection of the Sonoran Desert. The range of the Chuckwalla Valley is from 400 feet above mean sea level at Ford Dry Lake to approximately 1,800 feet above mean sea level along some of the bajadas that occur west of Desert Center, California with the surrounding mountains rising to over 3,000 above mean sea level (GSEP 2009a).

Hydrologically, the proposed Project site occurs in the Colorado River Basin within the Chuckwalla Valley Drainage Basin. This is an internally drained basin and all surface water flows to Palen Dry Lake in the western portion of Chuckwalla Valley and Ford Dry Lake in the eastern section of Chuckwalla Valley. Palen Dry Lake is characterized as a "wet playa" since it supports significant groundwater discharge at the ground surface by evaporation. Ford Dry Lake is characterized as a "dry playa" with groundwater sources occurring well below the surface of the dry lake bed and as a result receives occasional inflow of surface water (GSEP 2009a,f).

A number of Areas of Critical Environmental Concern (ACECs) and federally-designated Wilderness Areas occur within the vicinity of the Project site. The 236,488-acre Palen-McCoy Wilderness area abuts the plant site to the north. Within this wilderness area, there are five distinct mountain ranges with characteristic sloping bajadas: the Granite, McCoy, Palen, Little Maria, and Arica Mountains (BLM 2009). Two additional Wilderness Areas occur in the Project vicinity, the Little Chuckwalla Mountains and Chuckwalla Mountains wilderness areas (GSEP 2009a). The 3,632-acre Palen Dry Lake ACEC occurs about 10 miles west of the Project site and is managed for protection of its prehistoric resources. The 2,273-acre Chuckwalla Valley Dune Thicket ACEC occurs approximately immediately west of the southern terminus of the proposed Project transmission line, and is managed for its wildlife habitat use, specifically for birds.

Vegetation and Wildlife

Natural Communities

The Study area supports five major natural communities. The majority of the Project Disturbance Area supports Sonoran creosote bush scrub; the eastern portion of the Project Disturbance Area also supports stabilized and partially stabilized desert dunes. A small amount of playa and sand drifts over playa occur within the Project Disturbance Area along the margins of Ford Dry Lake. The larger surveyed area, the Study area, supports chenopod scrub, and desert wash woodland in addition to the two vegetation communities mentioned above (GSEP 2009a). All of these communities except the Sonoran creosote bush scrub are considered sensitive according to the NECO plan. These communities are discussed in more detail below and acreages are summarized in **Biological Resources Table 2**. Additionally, the southern linear facility route was determined by the applicant to support wash-associated, microphyll riparian woodland communities (GSEP 2009f, BIO-DR-70) which are discussed in more detail below.

Sonoran Creosote Bush Scrub

A total of 1,787 acres of Sonoran creosote bush scrub occurs within the Project site; 1,727 acres occur in the solar power plant Disturbance Area and 60 acres occur along the linear Disturbance Area (CEC 2010d). Sonoran creosote bush scrub occurs on well-drained, secondary soils of slopes, fans, and valleys and is the basic creosote scrub community of the Colorado Desert (Holland 1986). Within this community in the Project site, soils are generally sandy-loams with scattered to 90 percent cover of fine gravel. The dominant plant species within this community are creosote bush (*Larrea tridentata*), white bursage (*Ambrosia dumosa*), brittlebush (*Encelia farinosa*), white ratany (*Krameria grayi*), and cheesebush (*Hymenoclea salsola*).

Stabilized and Partially Stabilized Desert Dunes

A total of 28 acres of stabilized and partially stabilized desert dunes occur within the Project site; 27 acres occur in the southeastern corner of the solar power plant Disturbance Area and 1 acre occurs along the linear Disturbance Area along I-10 (CEC 2010d). These dune systems are described as accumulations in the desert which are stabilized or partially stabilized by evergreen and/or deciduous shrubs and scattered, low grasses. These dunes typically occur lower than active dune systems and retain water just below the sand surface which allows deep-rooted, perennial vegetation to survive during longer drought periods. Shrub cover is lower in this community compared to Sonoran creosote bush scrub community in the Project site and shrubs become less sparse the closer to Ford Dry Lake. Where partially stabilized desert dunes intergrade with playas and the margins of Ford Dry Lake, fine sand drifts occur (GSEP 2009a, Appendix C). The dominant plant species associated with this community include four-wing saltbush (*Atriplex canescens*), desert croton (*Croton californicus*), and Colorado desert buckwheat (*Eriogonum deserticola*) (Holland 1986).

Playa and Sand Drifts Over Playa

A total of 38 acres of playa and sand drifts over playa occurs within the Project site in association with Ford Dry Lake; over 14 acres occur in the solar power plant Disturbance Area and over 23 acres occur within the linear Disturbance Area (CEC 2010d). There is not a formal description of this natural community according to CDFG, Holland (1986), or Sawyer and Keeler-Wolf (1995). This community occurs in close association with stabilized and partially stabilized desert dunes within the Study area and shrub cover continues to decrease towards Ford Dry Lake. There are intermittent, shallow sand drift deposits along the margins of the playa within the Study area. Playas and sand drifts over playas provide food and foraging opportunities for many species of wildlife and also provide habitat for several common and special-status plant species.

Chenopod Scrub

A portion of chenopod scrub occurs within the Study area; since this vegetation community does not occur within the Project Disturbance Area, an acreage was not determined (GSEP 2009f). Holland identifies two types of chenopod scrub, desert saltbush scrub and desert sink scrub. These communities are usually comprised of low-growing, grayish, with microphyllous (small-leaved) shrubs and some succulent species. The total vegetative cover is often low with bare ground between widely spaced shrubs. Both types of chenopod scrub occur on poorly-drained soils with high alkalinity or

salinity. These communities often occur on the margins of dry lake beds in the Colorado, Sonoran, Mojave, and Great Basin deserts typically below 4,000 feet in elevation (Holland 1986). Chenopod scrub provides habitat for many species of common and special-status plants, mammals, and reptiles as dispersal, foraging and cover habitat especially in association with other upland and desert wash communities.

Biological Resources Table 2
Upland Natural Communities within the GSEP Study Area

Natural Community Types within Study Area	Solar Power Plant Site (Acres)	Linear Facilities (Acres)	Buffer Area (Acres)[1]	Total Surveyed (Acres)[2]
Upland				
Sonoran creosote bush scrub	1,727	60	14,384	16,170
Stabilized and partially stabilized desert dunes	27	1	3,930	3,958
Playa and sand drift over playa	14	23	4,781	4,819
Chenopod scrub	0	0	370	370
Total Upland	**1,768**	**84**	**23,465**	**25,317**

[1] For the purposes of this table and this Biological Resources Section, the portion identified within the buffer area of this table is the difference between the total surveyed area less the sum of plant site acreage and linear facilities acreages.
[2] Includes natural community types observed during field surveys out to one mile buffer from the Project ROW and 2,400 feet of linear facilities.

Waters of the State

A formal jurisdictional delineation for regulated waters was conducted by the Applicant to determine the extent of potential jurisdictional waters of the U.S. and/or waters of the State within the Project. This includes waters (and/or wetlands) regulated under the federal Clean Water Act and/or streams and associated habitat regulated under the California Fish and Game Code. The Applicant is requesting a jurisdictional determination of isolated waters (non-jurisdictional waters of the U.S.) from the U.S. Army Corps of Engineers (USACE) and U.S. Environmental Protection Agency and submitted an application for a Streambed Alteration Agreement (TTEC 2009d). The application to the USACE assumed there are no potential jurisdictional waters of the U.S. because the features occur in a closed basin with no identifiable outlet and have no direct hydrologic connection to any navigable waters. The USACE has not yet completed their jurisdictional determination.

The Applicant submitted a Notification of a Lake or Streambed Alteration (TTEC 2009d) in December 2009 to CDFG, and in response to data requests from staff, submitted a revised jurisdictional delineation report and application in January 2010 (TTEC 2010j). The revised delineation also included waters and wash-dependent vegetation downstream of the project footprint that are likely to be indirectly affected by the diversion of waters. CDFG staff conducted a field verification of the delineation of state waters on February 17, 2010, and made some recommendations for adjustments to the boundaries (CDFG 2010).These revised boundaries (TTEC 2010l) resulted in a minor increase in the acreage of state waters, and are included below.

The total (91 acres) area of all waters of the state delineated within the Project Disturbance Area includes 16 acres of microphyllous riparian vegetation, also called desert dry wash woodland, and 74 acres of other ephemeral desert washes. A total of 21 acres of jurisdictional state waters, consisting of unvegetated ephemeral dry washes, were delineated downstream of the Project Disturbance Area, encompassing the full

downstream reach of waters that would likely be indirectly affected by the diversion of waters at the upstream edge of the Project Disturbance Area.

Hydrology

The Project area is within the Chuckwalla Valley-Ford Dry Lake watershed. The primary hydrologic feature in the watershed is Ford Dry Lake, a closed basin, which is the receiving basin for 1,503 miles of unnamed desert washes, including the many smaller ephemeral desert washes that pass through the Project site and drain the southeastern flank of the Palen Mountains. The “Palen Wash” is the larger feature that drains the alluvial fan between the Palen and McCoy mountains and supports an old growth forest of ironwood on its upper reaches. The lower reaches of this feature passes through the western portion of the transmission line, natural gas line and access road alignment. The entire study area is crossed by numerous ephemeral washes ranging from small, weakly expressed erosional features to broad (over 10 feet wide) channels. The active flow channels are generally devoid of vegetation and typically have a sandy-gravel substrate, although some washes also contained cobble and scattered larger rocks. Small- to medium-sized washes are common and widespread throughout the entire Project area. The larger washes tend to dissipate into smaller, more braided channels as they progress downslope. The majority of the channels terminate prior to reaching Ford Dry Lake as well-defined conveyance features diminish and transition into broad, shallow surface flow. All of the ephemeral washes identified in the Project area flow only in response to storm events.

Unvegetated Ephemeral Washes

The majority of washes identified throughout the study area are associated with Sonoran creosote bush scrub habitat. Species such as white bursage are common in some medium to large-sized washes, especially in braided channels that contain slightly elevated areas intermixed with the active flow channels. The larger washes (typically over 6 feet) that contain sandy, gravelly substrate and well-defined banks typically include big galleta grass and scattered desert wash tree species such as ironwood and palo verde. Ironwood and palo verde trees are sparsely scattered throughout the Project area and are associated with areas of heavier sheet flow.

Desert Dry Wash Woodland/Microphyllous Riparian Vegetation

Desert dry wash woodland is a sensitive vegetation community recognized by the CNDDB, BLM, and is also designated as state waters by CDFG (CDFG 2003, BLM CDD 2002). Desert dry wash woodland is an open to dense woodland of microphyllous desert riparian trees (Holland 1986).The Applicant has identified a stand of desert dry wash woodland as occurring east of the Project area, within the large Palen Wash, but had described this habitat type as absent from the Project area (GSEP 2009a). In their revised delineation the Applicant describes areas of areas of microphyllous riparian vegetation occurring in washes along the linear Disturbance Area. The microphyllous vegetation identified in these washes consists of three tree species (palo verde, ironwood, and honey mesquite) and totals 16 acres (TTEC 2010). Within the proposed Project area ironwood and palo verde occur in low densities but one wash along the linear facility route, identified as Wash 24-26 in the jurisdictional delineations report (TTEC 2010l) supports a relatively dense concentration of 270 palo verde trees. Wash 31 consists of honey mesquite and is also relatively dense.

Habitat Function and Value of State Waters

The Project area's ephemeral washes, both vegetated and unvegetated, provide unique habitat that is distinct from the surrounding uplands, providing more continuous vegetation cover and microtopographic diversity than the surrounding uplands, migration corridors, and refuge, for a variety of wildlife. Both the wash-dependent and upland vegetation along these washes drive food webs, provide seeds for regeneration, habitat for wildlife, access to water, and create cooler, more hospitable microclimatic conditions essential for a number of plant and animal species. The vegetation, whether dominated by woodland trees or shrubs and perennial herbs, contributes channel roughness that reduces the velocity of floodwaters and provides organic matter for soil development and nutrient cycling (USEPA 2008).

Because ephemeral and intermittent stream channels have a higher moisture content and more abundant vegetation than the surrounding areas, they are very important to wildlife. Frequently, these streams may retain the only available water in the area, with permanent pools interposed wherever hydrogeological conditions allow (USEPA 2008). The short duration and episodic flood pulses of surface and overbank flow is important as it allows some species to complete important life-history developmental stages. The habitat provided by desert streams contracts and expands dramatically in size due to the extreme variations in flow, which can range from high-discharge floods to periods when surface flow is absent. This spatial variation in habitat or ecosystem size is a fundamental, defining feature of these streams (Smith et al. 1995, USEPA 2008).

Groundwater-Dependent Vegetation Communities Outside the Project Area

Groundwater elevation contour mapping done by Steinemann (1989) suggests that groundwater levels are very close to the ground surface beneath the northwestern 25 percent of Palen Dry Lake (Worley Parsons 2009), approximately three to six miles from the Project's proposed groundwater pumping well and at Ford Dry Lake, near the Project, the water table was measured at 80 feet, extending to a depth of 200 feet. The groundwater-dependent plant communities in this area are included because they are potentially vulnerable to water table drawdowns caused by groundwater pumping, and because these are sensitive communities recognized by the California Natural Diversity Data Base (CDFG 2003) and BLM.

Mesquite Bosque and Other Phreatophytes

In the Chuckwalla Valley Groundwater Basin the groundwater is too deep to support shallow marshes and meadows, but it does support communities of deeper-rooted, groundwater-dependent "phreatophytes", most notably the shrubby "bosques" (groves) of honey mesquite around the open, unvegetated playa. Mesquite bosques are a rare and sensitive community recognized by BLM and the CNDDB (CDFG 2003). They occur in areas with access to permanent and stable groundwater; the deep roots can tap water supplies up 40 feet below the surface, although tap roots as long as 190 feet have been documented (Sosebee & Chan 1989). When available, mesquite will exploit sources of deep water by growing a taproot. Mesquite can also persist on sites that have little or no ground water by growing lengthy shallow lateral roots. In some parts of their range they are considered "facultative phreatophytes" that function as phreatophytes if unlimited water is available, but are capable of surviving on sites with limited soil water. In California, however, they are very rare outside of washes or areas

with available groundwater; they also occur as a decumbent or running bush found on coppice dunes (vegetated sand mounds). These adaptations allow honey mesquite to retain most leaves in all but the most severe droughts (Ansley et al 2004). In the Project vicinity, they are found along the northwest and southwest margins of Palen Dry Lake on small coppice dunes. They have also been documented elsewhere in Chuckwalla Valley (Evans and Hartman 2007).

The fruit of honey mesquite is valuable forage for wildlife; it is quite predictable, even in drought years, annually providing an abundant and nutritious food source for numerous wildlife species upon ripening in summer (Steinberg 2001). The fruit's pericarp is high in sugars and the seeds contain large amounts of protein. Where they occur, honey mesquite seeds form an important part of the diet of mice, kangaroo rats, ground squirrels, quail, black-tailed jackrabbit, mule deer, and many other wildlife. Mesquite flowers are eaten by numerous bird species. Quail and many other birds eat mesquite buds and flowers in the spring and seeds during the fall and winter. Western honey mesquite communities often attract large numbers of birds that feed on the mistletoe fruit.

Microphyll Woodland

Other known phreatophytes in the Project area includes the native trees ironwood, palo verde, and cat's claw; the invasive exotic salt cedar (tamarisk), and the native chenopod shrub bush seep-weed. Most of the microphyllous trees (ironwood, palo verde, cat's claw) occur along the many desert washes in the Project area. The best examples are described under "Desert Dry Wash Woodland/Microphyllous Riparian Vegetation", above. However, these deep-rooted trees also occur away from the streams on portions of the bajada (above and below the Project) where they have access to deep groundwater. Desert phreatophytes are legendary for their deep-rooting. One mesquite was documented to root to a depth of over 250 feet in a mine shaft, although most are documented to root at depths up to 40 feet (Sosebee & Chan 1989). They are also observed to occur sporadically around the perimeter of Ford Dry Lake, where the water table is measured at 80 feet. It is unclear at this time whether they are supported by the shallow groundwater table under Ford Dry Lake or by the mountain front aquifer, or surface runoff.

Bush Seep-Weed Alkali Sink Scrub

Other known phreatophytes observed within the zone potentially influenced by Project or cumulative groundwater pumping include succulent chenopod scrubs dominated by bush seep-weed, which forms pure stands over large areas around the margins of Palen Dry Lake. It also occurs sporadically around Ford Dry Lake, where it co-occurs with the xerophyte saltbush. Bush seep-weed is a characteristic component of alkali sinks, a phreatophyte (Barbour et al. 2007) occupying fine-textured saline soils on or around the playa margins, and rooting to depths of several meters to access groundwater (Patten et al. 2007).

Sand Transport System

This subsection provides a brief explanation of wind transport of sand relative to the creation, preservation and destruction of sand dunes in the Project area. **Soil & Water Appendix A** provides a more detailed explanation, as does the "*Aeolian Transport Evaluation and Ancient Shoreline Delineation Report, Genesis Solar Energy Project, Riverside County, California*" (Worley Parsons 2010). Movement of sand by wind and water is relevant to sensitive biological resources because these geomorphic processes create and maintain habitat for Mojave fringe-toed lizards and other species dependent on fine, wind-blown sand.

Two sand migration corridors occur in the vicinity of the Project. The Palen-Dry Lake (PDL) -Chuckwalla Valley Sand Corridor is located immediately to the south of the Project site, and is a major aeolian sand transport moving sand east along the Chuckwalla Valley toward the Colorado River (see Plate 5 in Worley Parsons 2010c). This is a regionally-significant geomorphic feature that provides sand to build and support sand dune habitat in the Project vicinity. To the east of the Project site is the Palen-McCoy Valley Sand Corridor, which moves sand to the south from the valley between the Palen and McCoy mountains. In addition to the regional wind transport system can also be transported locally by washes. These carry sediment from upstream sand corridors and distribute it on the alluvial fan where it is available for wind transport, creating smaller sand corridors around the main washes.

Noxious Weeds

Noxious weeds are species of non-native plants included on the weed lists of the California Department of Food and Agriculture (CDFA) (CDFA 2007), the California Invasive Plant Council (Cal-IPC), or those weeds of special concern identified by the Bureau of Land Management (BLM). They are of particular concern in wild lands because of their potential to degrade habitat and disrupt the ecological functions of an area (Cal-IPC 2006). Specifically, noxious weeds can alter habitat structure, increase fire frequency and intensity, decrease forage (including for special-status species, such as desert tortoise), exclude native plants, and decrease water availability for both plants and wildlife. Soil disturbance and gathering and channeling water create conditions favorable to the introduction of new noxious weeds or the spread of existing populations. Construction equipment, fill, and mulch can act as vectors introducing noxious weeds into an area.

Non-natives species were recorded as a part of Project surveys; additional baseline surveys to identify population locations and densities are pending (TTEC 2010g). Four noxious weed species were observed within the study area: Sahara mustard, Russian thistle, salt cedar, and Mediterranean grass. Each of these species is identified on a list of the region's worst weeds compiled by the Low Desert Management (NRCS 2005). Noxious weeds found in the study area are discussed further below.

Sahara Mustard

Sahara mustard (*Brassica tournefortii*) was widespread throughout the Project Study area, including in Sonoran creosote bush scrub, in and contributed to a relatively large portion of the plant biomass. There were patches of higher concentrations occurring within runnels, along the existing two-track road on the western side of the ROW, and

along the linear facility routes (TTEC 2010g). This species is of high concern; it is a BLM weed of special concern and Cal-IPC has declared this plant highly invasive (Cal-IPC 2006) and recommends that it should be eradicated whenever encountered. This species is associated with impacts to habitat for native wildlife as well as for native plants. It promotes the spread of fire by increasing fuel load and competes with native plants for moisture and nutrients. In addition, it increases cover and works to stabilize sand, thereby affecting wildlife species dependent on open sandy habitat (Brossard et al. 2000; Barrows and Allen 2007).

Russian Thistle

Russian thistle (*Salsola* sp.) was common in the dune areas on the east side of the Project area and along the linear facilities (TTEC 2010g). Although all invasive plants share the trait of being adapted to disturbed habitat, Russian thistle or tumbleweed particularly tends to be restricted to roadway shoulders and other sites where the soil has been recently disturbed. However, once an area is disturbed this species competes readily and can affect native plant ecosystems and increase fire hazard (Orloff et al. 2008; Lovich 1999). Dune habitat is particularly vulnerable to non-native species, which can stabilize sand or block sand movement, and Russian thistle is considered an invasive species of primary concern in this habitat (CDFG 2007). There is a high potential that Russian thistle could become established in the construction area and this species should be eradicated if observed. Cal-IPC has determined that this plant has a limited invasiveness rating in California (Cal-IPC 2006) and the CDFG has given it a “C” rating.

Mediterranean Tamarisk

Mediterranean tamarisk or salt cedar (*Tamarix ramosissima*) is a riparian plant and is therefore restricted to habitats where there is perennial saturation such as springs and seeps, or runoff from poorly maintained water pipelines or well pumps. It was observed south of the Project area on the edge of the dry lake bed (GSEP 2009a) and by staff south of I-10 along the transmission line route. Cal-IPC has declared this plant highly invasive (Cal-IPC 2006) and it is a CDFG “B” rated species. Salt cedar is associated with many ecological impacts including impacts to channel geomorphology, groundwater availability, plant species diversity, and fire frequency (Lovich 1999). Salt cedar can also affect sand dunes by blocking sand movement, a vital part of the natural function of these habitats (CDFG 2007).

Mediterranean Grass

Mediterranean grass (*Schismus arabicus, S. barbatus*) is prevalent throughout the Project area (TTEC 2010g). Mediterranean grass is an annual that reproduces by seed, and is widespread in arid and semi-arid California landscapes. This species competes effectively with native plants for nutrients and water and can provide cover that prevents native annuals from sprouting (VanDevender et al. 1997; Brossard et al. 2000) and contributes to dune stabilization (CDFG 2007). Fire, historically, was rare in the Colorado Desert. The presence of Mediterranean grass on other annual non-native grasses has provided a continuous and increased fuel load, influencing the extent, frequency, and intensity of fire in these ecosystems (Brooks and Pyke 2001; Brooks et al. 2004). BLM and other agencies recognize that because of the widespread

distribution of Mediterranean grass, this species is not considered feasible to eradicate, but is still subject to monitoring and control requirements.

Special-Status Species

Special-status species are plant and wildlife species that have been afforded special recognition by federal, state, or local resource agencies or organizations. Listed and special-status species are of relatively limited distribution and typically require unique habitat conditions. Special-status species are defined as meeting one or more of the following criteria:

1. Listed as threatened or endangered or candidates for future listing as threatened or endangered under CESA or FESA;

2. Protected under other regulations (e.g. Migratory Bird Treaty Act);

3. Listed as species of concern by CDFG;

4. A plant species considered by the CNPS to be "rare, threatened, or endangered in California" (CNPS List 1A, 1B, and 2) as well as CNPS List 3 and 4[1] plant species;

5. A plant listed as rare under the California Native Plant Protection Act[2];

6. Considered a locally significant species, that is, a species that is not rare from a statewide perspective but is rare or uncommon in a local context such as within a county or region or is so designated in local or regional plans, policies, or ordinances; or

7. Any other species receiving consideration during environmental review under CEQA.

The BLM designates Sensitive species as those requiring special management considerations to promote their conservation and reduce the likelihood and need for future listing under FESA. BLM Sensitive species include all Federal Candidate and Federally Delisted species which were so designated within the last 5 years, and CNPS List 1B species that occur on BLM lands. For the purposes of this analysis, Energy Commission staff considers all designated BLM Sensitive species as special-status species.

---

[1] List 3 plants may be analyzed under CEQA §15380 if sufficient information is available to assess potential impacts to such plants. Factors such as regional rarity vs. statewide rarity should be considered in determining whether cumulative impacts to a List 4 plant are significant even if individual project impacts are not. CNPS List 3 and 4 may be considered regionally significant if, e.g., the occurrence is located at the periphery of the species' range, or exhibits unusual morphology, or occurs in an unusual habitat/substrate. For these reasons, CNPS List 3 and 4 plants should be included in the field surveys. List 3 and 4 plants are also included in the California Natural Diversity Database's (CNDDB) Special Plants, Bryophytes, and Lichens List. [Refer to the current online published list available at: http://www.dfg.ca.gov/biogeodata.] Data on Lists 3 and 4 plants should be submitted to CNDDB. Such data aids in determining or revising priority ranking (CDFG 2009).

[2] As defined by the California Native Plant Protection Act, a plant is rare when, although not presently threatened with extinction, the species, subspecies, or variety is found in such small numbers throughout its range that it may be endangered if its environment worsens (Fish and Game Code §1901) (CDFG 2009).

Biological Resources Table 3 lists all special-status species evaluated during the analysis that are known to occur or could potentially occur in the Project area and vicinity. Special-status species (or their sign) observed during the 2009 field surveys are indicated by **bold-face type**. Special-status species listed in **Table 3** that were detected or considered likely to occur based on known occurrences in the vicinity and suitable habitat present within the Project area are discussed in more detail below. The rest of these species have low to moderate potential to occur in the project area and are described in **Biological Resources Table 4**.

Sources: CNDDB 2010

Status Codes:

Federal FE = Federally listed endangered: species in danger of extinction throughout a significant portion of its range
FT = Federally listed, threatened: species likely to become endangered within the foreseeable future
BCC: Fish and Wildlife Service: Birds of Conservation Concern: Identifies migratory and non-migratory bird species (beyond those already designated as federally threatened or endangered) that represent highest conservation priorities <www.fws.gov/migratorybirds/reports/BCC2002.pdf>

State CSC = California Species of Special Concern Species of concern to CDFG because of declining population levels, limited ranges, and/or continuing threats have made them vulnerable to extinction.
SE = State listed as endangered
ST = State listed as threatened
CFP = California Fully Protected
WL = State watch list
SR = State-listed rare; Plant species listed as rare under the California Native Plant Protection Act (Fish and Game Code §1900 et seq.). A plant is rare when, although not presently threatened with extinction, the species, subspecies, or variety is found in such small numbers throughout its range that it may be endangered if its environment worsens (Fish and Game Code §1901)

California Native Plant Society
List 1B = Rare, threatened, or endangered in California and elsewhere
List 2 = Rare, threatened, or endangered in California but more common elsewhere
List 3 = Plants which need more information
List 4 = Limited distribution – a watch list
0.1 = Seriously threatened in California (high degree/immediacy of threat)
0.2 = Fairly threatened in California (moderate degree/immediacy of threat)
0.3 = Not very threatened in California (low degree/immediacy of threats or no current threats known)

Bureau of Land Management
BLM Sensitive = Species requiring special management consideration to promote their conservation and reduce the likelihood and need for future listing under the ESA. BLM Sensitive species also include all Federal Candidate species and Federal Delisted species which were so designated within the last 5 years and CNPS List 1B plant species that occur on BLM lands.

Global Rank/State Rank
Global rank (G-rank) is a reflection of the overall condition of an element throughout its global range. Subspecies are denoted by a T-Rank; multiple rankings indicate a range of values
G2 = 6-20 EOs OR 1,000-3,000 individuals

G3 = 21-100 EOs OR 3,000-10,000 individuals
G4 = Apparently secure; this rank is clearly lower than G3 but factors exist to cause some concern; i.e., there is some threat, or somewhat narrow habitat.
G5 = Population or stand demonstrably secure to ineradicable due to being commonly found in the world.
State rank (S-rank) is assigned much the same way as the global rank, except state ranks in California often also contain a threat designation attached to the S-rank. An H-rank indicates that all sites are historical
S1 = Less than 6 EOs OR less than 1,000 individuals
S1.2 = threatened
S1.3 = no current threats known
S2 = 6-20 EOs OR 1,000-3,000 individuals
S2.1 = very threatened
S2.2 = threatened
S2.3 = no current threats known
S3 = 21-100 EOs or 3,000-10,000 individuals
S3.1 = very threatened
S3.2 = threatened
S3.3 = no current threats known

Special-Status Plant Species

As shown in **Biological Resources Table 3**, several special-status plant species have the potential to occur within the Study area. Six of these species were either observed during botanical and wildlife field surveys performed during spring 2009 and/or are considered very likely to occur within the Study area, including:
Harwood's milk-vetch
Ribbed cryptantha
Desert unicorn plant
Abram's spurge
Las Animas colubrina
White-margined penstemon

Harwood's Milk-vetch

Harwood's milk-vetch is a CNPS 2.2 species, meaning that is it fairly threatened in California, but more common elsewhere. It is also a covered species under NECO. It is an annual herb species that mainly occurs in Sonoran desert scrub habitat throughout the Colorado Desert (BLM CDD 2002). This species is found in desert dunes and sandy or gravelly areas throughout the Mojavean and Sonoran deserts covering portions of Imperial, Riverside, and San Diego counties (CNPS 2009). There are known occurrences of this species from Elephant Tree Nature Trail in San Diego County and Carrizo Station. Herbarium collections occur for this species from Ogilby Road in Imperial County and three locales west of Blythe, the Pinto Basin, and Chuckwalla Basin in Riverside County. Harwood's milk-vetch has also been reported from Baja California, Sonora Mexico, and portions of Yuma County, Arizona (Reiser 1994). There are several CNDDB records for this species within the Project area (CNDDB 2010) and a 10-mile radius of the Project area. There is a record in the Consortium of California Herbaria database from Wiley's Well Road between McCoy and Mule Mountains from 400 feet elevation (CCH 2010). The Harwood's milk-vetch populations on the southern deserts are presumed stable given limited disturbance to their desert habitats (Reiser 1994).

Twelve plants of Harwood's milk-vetch were found within the Study area, 2 within solar power plant Disturbance Area and 10 within linear Disturbance Area. All habitats within the Study area are suitable for this species.

Ribbed Cryptantha

Ribbed cryptantha is a CNPS 4.3 species, meaning that it has limited distribution in California, however it is not very threatened in California. It typically occurs in loose friable soils in the eastern Mojave and Sonoran deserts in Imperial, Riverside, San Diego, and San Bernardino counties and into Arizona and south to Baja California, Mexico (CNPS 2009). It commonly occurs in stabilized and partially stabilized desert dunes and sandy areas of Sonoran and Mojavean desert creosote bush scrub. There are 116 records of this species from several locations throughout Riverside, Imperial, San Diego, and Imperial counties in the Consortium of California Herbaria database; the nearest collection is from the Palen Valley approximately three miles east of the Desert Center Airport (CCH 2010).

A single population of a few ribbed cryptantha was observed northwest of the Wiley's Well rest area at approximately 380 feet elevation from in an area of mixed sand drifts, hummocks with Patton tank tracks with widely scattered shrubs (GSEP 2009f). This area occurs along the southern linear corridor route north of I-10. This species was identified in an area mapped as stabilized and partially stabilized desert dunes during March 2009 surveys and in close association with other areas mapped as playa and sand drifts and Sonoran creosote bush scrub with similar habitat qualities. Therefore, all habitats within the Study area are suitable for this species.

Desert Unicorn Plant

Desert unicorn plant is a CNPS List 4.3 plant species, meaning it has limited distribution, but is not very threatened in California. This is a covered species under NECO. This plant species occurs in sandy area within Sonoran desert scrub habitats in San Bernardino, Imperial, and Riverside counties of California. This is a low-growing, perennial species that occurs in sandy soils along washes. There are 13 records known from the NECO planning area in Milipitas Wash, Chuckwalla Valley, and Chemehuevi Valley (BLM CDD 2002). There are no records in the CNDDB for the entire state of California (CNDDB 2010). The blooming period for this species is from May to August (CNPS 2009) although is also known to flower between July and September after substantial summer rains (GSEP 2009a). It has a fleshy root system that can remain dormant in dry years.

There are 36 records in the Consortium of California Herbaria from Riverside, Imperial, San Bernardino, and San Diego Counties, several of which are from the Chuckwalla Mountains and Desert Center area. One record is from a large wash with sandy soils, one mile west of the Wiley Wells truck stop and approximately 5 miles north of Ford Dry Lake at approximately 350 feet above mean sea level (CCH 2010).
A total of 23 seed pods of this species were found within the Study area, 5 within the solar power plant Disturbance Area and 17 along the linear Disturbance Area (GSEP 2009f). According to the Biological Resources Technical Report, seed pods were found as evidence of this species occurring in the Project area (75 seed pods and 1 individual plant) (GSEP 2009a, Appendix C). Although only one plant was found during surveys, the number of seed pods found suggests that this species is present in the Study area and would likely germinate when growing conditions are suitable. All habitats within the Study area are suitable for this species.

Abram's Spurge

Abram's spurge is a CNPS List 2.2 species meaning it is fairly rare in California but more common elsewhere (CNPS 2009). Habitat consists of sandy flats in creosote bush scrub habitat from approximately 600 to 2,700 feet above mean sea level. This species occurs in halophytic scrub flats, playas, and along inlets and floodplains of playas and always seems to prefer the lower floodplain ecotone but can also extend higher up into floodplains where braided drainages nexus with dune-mesquite-saltbush-galleta associations (Silverman, pers. comm.). Based on fourteen (14) Consortium of California Herbaria database records for this species, habitats in Riverside, San Diego, and Imperial counties consist of sandy soil habitats often along dry lake margins, whereas record locations in San Bernardino County occur on coarser, possibly sandy loams. Abram's spurge occurs from San Bernardino County to Imperial and eastern San Diego counties to Arizona, Nevada, Mexico, and Baja California (GSEP 2009f). A recent 2000 CNDDB record is from a location approximately 0.50 mile east of Ford Dry Lake on Gasline Road just south of I-10 and the occurrence was reported as a "substantial population" (CNDDB 2010).

The blooming period is identified by CNPS as September through November (CNPS 2009). Since the Project site occurs in the Chuckwalla Valley of the Sonoran Desert, an area known for bi-modal rain patterns and late summer/fall rains, this species typically only blooms during summer or fall months following monsoonal rains (>+/- 0.10 inch) (Silverman pers. comm.). On average, August receives the most rainfall, although rainfall is also received during winter months of December, January, and February. Local botanical experts have concluded that significant findings may be missed if surveys are only conducted within the mid-March through mid-April window and that a full inventory at multiple temporal windows are necessary in order to capture all appropriate growing conditions (typically following 12 to 18 mm rain events) (CEC 2009d).

Abram's spurge is a late-summer, early-fall blooming plant species and was therefore not targeted or detectable during field surveys which were performed during March and April 2009. Given the presence of suitable habitat within the Study area, lack of targeting during field surveys, and a recent CNDDB record immediately south of the Project Disturbance Area near Ford Dry Lake, this plant species could be impacted by Project development. All habitats within the Project Disturbance Area are suitable for Abram's spurge.

Las Animas Colubrina

Las Animas colubrina is a CNPS List 2.3 species indicating it is not very endangered in California and more common elsewhere (CNPS 2009). This is a covered species under NECO. This species is an evergreen shrub and occurs in Mojavean and Sonoran desert scrub (creosote bush series) and occurs at elevations from approximately 30 to 3,000 feet above mean sea level. Dry canyonlands in Mojavean Desert scrub is the preferred habitat of this species (Reiser 1994). This species has also been reported from Joshua tree woodland habitats but primarily occurs in dry canyons with gravelly, sandy soils. The distribution of this species includes San Diego, Imperial, and Riverside counties; portions of Arizona; Baja California; and Sonora, Mexico. This species has been reported from isolated desert locales in Joshua Tree National Monument, the Eagle

Mountains, and Chuckwalla Mountains (Reiser 1994). There are approximately 27 occurrences primarily from the Chocolate Mountains area (BLM CCD 2002). The nearest CNDDB record is from McCoy Springs in the McCoy Mountains in 1976 from approximately 2,800 feet elevation (CNDDB 2010). This species typically blooms from April through June.

One Las Animas colubrina plant was found in the buffer area and not within the Project Disturbance Area. This species was observed approximately one mile north of the solar power plant Disturbance Area. All habitat types within the Study area are suitable for this species.

White-margined penstemon

White-margined penstemon is a perennial herb that is restricted to sandy substrates in desert dunes and Mojavean desert scrub habitats. This species occurs from approximately 2,000 feet elevation to 3,000 feet above mean sea level and appears to be restricted to the southeastern Mojave Desert ecoregion (BLM 2006, TNC 2007). White-margined penstemon typically blooms from March through May and flowering does not always appear to be dependent on the amount of rainfall (CNPS 2009, BLM 2006). It is believed that established plants may bloom even in very dry years by utilizing water and food resources that are stored in the large taproot (1 to 4 feet long); however rain probably affects germination rates of this species (BLM 2006, TNC 2007). In California, this plant often occurs in fine alluvial sand and in wide canyons within a creosote bush scrub community; sandy environments help establish and hold the deep taproot of this species. This species also occurs in deep, loose to stabilized sand, sometimes on sand dunes or in sandy to gravelly washes. Common associate plant species are white bursage, galleta grass, rice-grass, creosote bush, range rattany, goldenhead, and winterfat (TNC 2007).

White-margined penstemon occurs in southern Nevada, western Arizona, and in the western Mojave Desert in San Bernardino County (BLM 2006). Its distribution in the western Mojave Desert is restricted, occurring in a large four-mile long wash near Pisgah Crater and Lavic Lake, extending southwest from Sleeping Beauty Peak, crossing Interstate 40, and terminating in a flat spreading basin south of Interstate 40 (BLM 2006). There are 19 recent CNDDB records for the entire state of California all of which are from San Bernardino County near the vicinity of Highway 40 and Pisgah Crater (CNDDB 2010). There are 40 records of this species from the Consortium of California Herbaria database from the same general Ludlow and Lavic areas in San Bernardino County; most of these records are from sandy substrates associated with dry desert washes and desert scrub habitats (CCH 2010).

In Nevada, this species commonly grows along the base of hills and mountains in wind-blown sand dune-like areas, but are also found in deep loose sand in wash bottoms. Southern Clark County, Nevada appears to be its center of distribution while three arms define its spatial extent and radiate northwest into Nye County, southwest into California, and southeast into Arizona. In Arizona, it occurs in sandy loam uplands and sandy washes in broad alluvial plains; conversely, gravelly areas interspersed with the sandy places do not support this plant species (BLM 2006). Arizona's population of white-margined penstemon is the largest population known, but a total population estimate is not available.

The Genesis Project site occurs at elevations of approximately 400 feet above mean sea level which is a significantly lower elevation where this species has been reported; however given the location of the Project site in the distributional range of this species and presence of suitable habitats, this species has a potential to occur within the Genesis Project site. This species was not observed during spring 2009 field surveys although white-margined penstemon was not specifically targeted during botanical field surveys. This species will be a target species during spring 2010 focused botanical surveys.

Special-status Wildlife Species

Desert Tortoise

The desert tortoise was state-listed in California as threatened on August 3, 1989. The Mojave population was federally listed as threatened on April 2 1990, and critical habitat was designated on February 8, 1994. The Mojave population of the desert tortoise includes those animals living north and west of the Colorado River in the Mojave Desert of California, Nevada, Arizona, and southwestern Utah, and in the Sonoran (Colorado) Desert in California (USFWS 1990; USFWS 1994a). The desert tortoise's range, outside the listed Mojave population, extends into the Sonoran Desert, where tortoises occur in the lower Colorado River Valley, Arizona uplands, plains of Sonora, and the central Gulf Coast; the species has not been documented in northeastern Baja California (Germano et al. 1994).

Desert tortoises are well adapted to living in a highly variable and often harsh desert environment. They spend much of their lives in burrows, even during their seasons of activity, which generally coincides with the greatest annual forage availability. In late winter or early spring, they emerge from over-wintering burrows and typically remain active through fall. Activity does decrease in summer, but tortoises often emerge after summer rain storms to drink (Henen *et al.* 1998). During activity periods, desert tortoises eat a wide variety of herbaceous vegetation, particularly grasses and the flowers of annual plants (Berry 1974; Luckenbach 1982; Esque 1994). During periods of inactivity, they reduce their metabolism and water loss and consume very little food. Adult desert tortoises lose water at such a slow rate that they can survive for more than a year without access to free water of any kind and can apparently tolerate large imbalances in their water and energy budgets (Nagy and Medica 1986; Peterson 1996a, b; Henen et al. 1998).

The size of desert tortoise home ranges varies with respect to location and year (Berry 1986a) and also serves as an indicator of resource availability and opportunity for reproduction and social interactions (O'Connor *et al.* 1994). Females have long-term home ranges that may be as little or less than half that of the average male, which can range to up to 200 acres (Burge 1977; Berry 1986a; Duda et al. 1999; Harless et al. 2009). Core areas used within tortoises' larger home ranges depend on the number of burrows used within those areas (Harless et al. 2009). Over its lifetime, each desert tortoise may use more than 1.5 square miles of habitat and may make periodic forays of more than 7 miles at a time (Berry 1986a).

Tortoises are long-lived and grow slowly, requiring 13 to 20 years to reach sexual maturity, and have low reproductive rates during a long period of reproductive potential (Turner et al. 1984b; Bury 1987; Germano 1994). Mating occurs both during spring and fall (Black 1976; Rostal et al. 1994), and the number of eggs as well as the number of clutches (set of eggs laid at a single time) that a female desert tortoise can produce in a season is dependent on a variety of factors including environment, habitat, availability of forage and drinking water, and physiological condition (Turner et al. 1986, 1987; Henen 1997; McLuckie and Fridell 2002). Egg-laying occurs primarily from April to July (Rostal et al. 1994; USFWS 1994); the female typically lays 2-14 eggs (average 5-6) eggs in an earthen chamber excavated near the mouth of a burrow or under a bush (Woodbury and Hardy 1948; USFWS 1994). The eggs typically hatch 90 to 120 days later, between August and October. The success rate of clutches has proven difficult to measure, but predation, while highly variable (Bjurlin and Bissonette 2004), appears to play an important role in clutch failure (Germano 1994).

The majority of threats to the desert tortoise and its habitat are associated with human land uses. Many of those identified in the 1994 Recovery Plan, and that formed the basis for listing the species as threatened, continue to affect the tortoise today (USFWS 2008a). Some of the threats identified at the time of listing include urbanization, upper respiratory tract disease and possibly other diseases, predation by common ravens and domestic and feral dogs, unauthorized off-road vehicle activity, authorized vehicular activity, illegal collecting, mortality on paved roads, vandalism, drought, livestock grazing, feral burros, non-native plants, changes to natural fire regimes, and environmental contaminants (USFWS 1994).

Even though a wide range of threats are known to affect desert tortoises and their habitat, very little is known about their demographic impacts on tortoise populations or the relative contributions each threat makes to tortoise mortality (Boarman 2002a). Extensive research shows that all of these threats can directly kill or indirectly affect tortoises; research has also clarified many mechanisms by which these threats act on individuals. While current research results can lead to predictions about how local tortoise abundance should be affected by the presence of threats, quantitative estimates of the magnitude of these threats, or of their relative importance, have not yet been developed. Thus, the revised recovery plan focuses on expanding the knowledge of individual threats and places emphasis on understanding their multiple and combined effects on tortoise populations (USFWS 2008a).

The original *Desert Tortoise (Mojave Population) Recovery Plan* identified 6 recovery units (Upper Virgin River, Northeastern Mojave, Eastern Mojave, Eastern Colorado, Northern Colorado, and Western Mojave) and recommended the establishment of 14 DWMAs throughout the recovery units (USFWS 1994). Since 1994, greater insight into patterns of both ecological and genetic variation within the Mojave desert tortoise population has been gained. While the revised recovery plan has not yet been finalized, based on this new information, the revision redefines the recovery units to balance both distinctiveness and variability within the population. Given the generally continuous variation in genetic structure and biomes across the Mojave desert tortoise's range, the approach in delineating revised recovery units stresses identification of geographic discontinuities or barriers that coincide with any observed variation among tortoise populations. Several potential barriers are evident from topographic maps, the U.S.

Geological Survey habitat model (Nussear et al. 2009), and landscape genetic analyses (Hagerty 2008). Differences in genetic, ecological, and physiological characteristics to help highlight boundaries or other differences between units were used in the delineation. In doing this, the USFWS considered demographic, ecological, and behavioral considerations to be of greater importance than genetic issues alone, as have been suggested by researchers providing recommendations on the formulation of conservation plans for threatened or endangered species (Avise 2004; Mace and Purvis 2008). The draft revised recovery plan reduces the number of recovery units from six to five, which reflects the newly obtained information and ensures that local adaptations and critical genetic diversity are maintained (USFWS 2008a).

According to the 1994 Recovery Plan, the Project is located within Eastern Colorado Recovery Unit, which was merged with the Northern Colorado Recovery Unit in the draft revised recovery plan and referred to simply as the Colorado Desert Recovery Unit (USFWS 2008a). Within this recovery unit desert tortoise are found primarily in "well-developed washes, desert pavements, piedmonts, and rocky slopes characterized by relatively species-rich succulent scrub, creosote bush scrub, and blue palo verde-ironwood-smoke tree communities" (USFWS 1994). Habitat within this recovery unit has been described as being in excellent condition despite declines in tortoise densities over the past several decades; disturbance was estimated at less than 1.3 percent throughout (USFWS 2005). The highest desert tortoise densities within this recovery unit occur in Chemehuevi and Ward valleys, on the Chuckwalla Bench within the Chuckwalla Desert Wildlife Management Area (DWMA and associated Critical Habitat Unit) and in Joshua Tree National Park. Desert tortoise densities at the Chuckwalla Bench in 1992 were estimated between 22 and 49 adults per square kilometer (approximately 57–127 adults per square mile) but have shown declining trends (Berry 1997; Tracey et al. 2004).

According to the 1994 Recovery Plan, tortoise densities in the Eastern Colorado Recovery Unit were estimated between 5 and 175 adult tortoises per square mile and the area was given a threat level of 4 out of 5 (5 = extremely high) (USFWS 1994). Density estimates based on range-wide line distance sampling monitoring from 2001–2005 (USFWS 2006) are lower than estimates from earlier studies (Luckenbach 1982; Berry 1984), but these simple comparisons cannot be taken at face value when the historical monitoring efforts were conducted using different techniques at different scales and with different goals. Differences may reflect a difference in scale between methods, with relatively large historical tortoise densities estimated in small, local areas being smoothed over larger areas with range-wide sampling. However, low tortoise densities across recovery units from 2001-2005 may also represent continued decline of populations throughout the Mojave Desert since the species was listed (USFWS 2006).

Protocol-level surveys of most of the Study Area were conducted between March 17 – 25 and April 6 – 13, 2009 (Study area except south of I-10) and October 30, 2009 (transmission line south of I-10). The transmission line route changed after spring surveys; the northern alignment was included in spring surveys, but not to the same level of intensity as the rest of the Study area, and further surveys are scheduled for Spring 2010 (TTEC 2010a). Survey results of the Project Disturbance Area include 19 mineralized and 9 non-mineralized carcass fragments

The Applicant indicates that the Project Disturbance Area is currently unoccupied by desert tortoise. They conclude that the northwestern portion of the Project site is suitable or marginally suitable habitat, while the remainder of the site is not habitat for desert tortoise. They also conclude that the Sonoran creosote bush scrub and wash habitat north and west of the Project site is higher quality habitat (GSEP 2009a, TTEC 2009c). Energy Commission, BLM, CDFG and USFWS staff agree that the habitat within the Project Disturbance Area is of lower quality closer to the Ford playa and is higher quality toward the upper bajadas, but consider the entire Project site to contain suitable habitat for desert tortoise (e.g., Sonoran creosote bush scrub with friable soils for burrowing and appropriate forage plants) and could potentially be occupied by this species in the future.

Mojave Fringe-toed Lizard

The Mojave fringe-toed lizard is endemic to southern California and a small area of western Arizona, where it is restricted to aeolian (wind-blown) sand habitats in the deserts of Los Angeles, Riverside, and San Bernardino Counties in California and La Paz County in Arizona (Hollingsworth and Beaman 1999; Stebbins 1985). Nearly all records for this species are associated with present-day and historical drainages and associated sand dune complexes of the Mojave and Amargosa Rivers (Norris 1958).

The distribution of Mojave fringe-toed lizards is naturally fragmented because of its obligate habitat specificity to loose sand, a patchy habitat type (Murphy et al. 2007). Many local populations of this species are quite small, with small patches of sand supporting small populations of lizards. This fragmented pattern of distribution leaves the species vulnerable to local extirpations from additional habitat disturbance and fragmentation (Murphy et al. 2007). The loose wind-blown sand habitat, upon which the species is dependent, is a fragile ecosystem requiring the protection against both direct and indirect disturbances (Weaver 1981; Barrows 1996). Environmental changes that stabilize sand, affect sand sources, or block sand movement corridors will also affect this species (Turner et al. 1984; Jennings and Hayes 1994). Additional threats to this species include habitat loss or damage from urban development, off-highway vehicles (OHV), and agriculture. Aside from the direct loss of land, development can also increase predators, such as the common raven, to occupied habitat.

Murphy et al. (2006) identified two maternal lineages of this species; the northern lineage is associated with the Amargosa River drainage system, and the southern with the Mojave River drainage system, Bristol Trough, Clark's Pass (including Palen Lake and Pinto Wash), and the Colorado River sand transport systems.

The Mojave fringe-toed lizard is found in arid, sandy, sparsely vegetated habitats and is associated with creosote bush scrub throughout much of its range (Norris 1958;

Jennings and Hayes 1994). This species is totally restricted to habitats of fine, loose, aeolian sand, typically with sand grain size no coarser than 0.375 mm in diameter (Turner et al. 1984; Jennings and Hayes 1994; Stebbins 1944). It burrows in the sand for both cover from predators and protection from undesirable temperatures (Stebbins 1944), though it will also seek shelter in rodent burrows. They are primarily insectivorous, but also eat plant food including leaves, seeds, and buds (Stebbins 1944).

Mojave fringe-toed lizards normally hibernate from November to February, emerging from hibernation sites from March to April. The breeding season is April to July, and adult Mojave fringe-toed lizards reach sexual maturity two summers after hatching. Females deposit 2-5 eggs in sandy hills or hummocks May through July (Mayhew 1964, Jennings and Hayes 1994). April to May, while temperatures are relatively cool, this species is active during mid-day; from May to September, they are active in mornings and late afternoon, but seek cover during the hottest parts of the day. Common predators of the Mojave fringe-toed lizard include burrowing owls, leopard lizards, badgers, loggerhead shrikes, roadrunners, various snakes, and coyotes (Jennings and Hayes 1994).

Thirty-nine Mojave fringe-toed lizards were observed during Project surveys. The Project Disturbance Area contains suitable Mojave fringe-toed lizard habitat wherever stabilized and partially stabilized sand dune habitat (28 acres) and playa/sand drift over playa habitat (37 acres) occur. Mojave fringe-toed lizard habitat preferences are more closely tied to the landform than to the vegetation community, and Sonoran creosote bush scrub habitat with an active sand layer can also support this species. This species was detected south of I-10 in Sonoran creosote bush scrub because this area supports a layer of wind-blown sand from the adjacent dunes.

Couch's Spadefoot Toad

Couch's spadefoot toad is found in southeastern California east through Arizona, New Mexico, Texas, and Oklahoma, south to San Luis Potosi, Nayarit, Mexico, at the southern tip of Baja California, Mexico, and an isolated population in Colorado. In California, it is found in the extreme southeast, including southeastern San Bernardino County and eastern Riverside and Imperial Counties (Jennings and Hayes 1994). The Project area is west of the range for this species as the range is described in the Northern & Eastern Colorado Desert Coordinated Management Plan (BLM CDD 2002) and Amphibian and Reptile Species of Special Concern in California (Jennings and Hayes 1994); however, Dimmitt (1977) identifies the Palen Dry Lake area as a place of interest for further surveys.

They are found in a variety of plant communities, including desert dry wash woodland, creosote bush scrub, and alkali sink scrub. They require habitat with substrate capable of sustaining temporary pools for breeding, and loose enough to permit burial in subterranean burrows (Jennings and Hayes 1994, BLM CDD 2002). Breeding habitat includes temporary impoundments at the base of dunes as well as road or railroad embankments, temporary pools in washes or channels, pools that form at the downstream end of culverts, and playas (Morey 2005; Morey, pers. comm.; Mayhew 1965). Natural scour sites in washes with breeding toads (included in Dimmitt 1977) had washed down to a hardpan, which enabled ponding (Dimmitt, pers. comm.). The majority of known Couch's spadefoot toad breeding ponds are artificial, though this may be because of the difficulty of locating natural ponds within the limited amount of time ponds may retain water. Couch's spadefoot toads require a food source, primarily alate termites, but they also eat beetles, ants, grasshoppers, solpugids, scorpions, and centipedes.

This species is dormant from 8-10 months of the year, emerging from burrows at the onset of warm summer rains. Emergence appears to be triggered by the low frequency sound caused by falling rain, though it appears to be inhibited by low soil temperatures.

Threats to Couch's spadefoot include loss of habitat from urbanization and agriculture and impacts from off-highway vehicles, which can destroy potential pool habitat. There are also indications that the low-frequency sound created by off-highway vehicles may trigger emergence cues, and result in emergence in poor environmental conditions (Jennings and Hayes 1994). Emergence may also be triggered by construction vehicle noise (Dimmitt, pers. com.).

No Couch's spadefoot toads were observed during surveys; however, because of the short time this species is above ground, and because the surveys were not conducted during the proper season (i.e., after summer rains), the lack of observations does not suggest the species is absent from the Project site. During Project surveys, the Applicant searched for artificial or temporary water catchments that could serve as breeding pools (GSEP 2009a). None were identified within the Study area. Staff reviewed Project site aerials, however, and has identified some areas that appear to sustain or that could potentially sustain surface water.

The closest known record for this species is from Dimmitt (1977) from a breeding pond near the intersection of I-10 and Wiley Well Road. While Dimmitt (1977) does not identify the exact location of this pond, a large ponded area (an old borrow pit) is visible in aerial photos in the same general area identified by Dimmit (1977). Aerial photos and a site visit by BLM staff indicate the borrow pit can sustain ponded water. This area is within the Project transmission line route.

Western Burrowing Owl

The western burrowing owl inhabits arid lands throughout much of the western United States and southern interior of western Canada (Haug et al. 1993) and is typically a year-round resident in much of California (Gervais et al. 2008).

Burrowing owls are unique among the North American owls in that they nest and roost in abandoned burrows, especially those created by California ground squirrels, kit fox, desert tortoise, and other wildlife. Burrowing owls have a strong affinity for previously occupied nesting and wintering habitats. They often return to burrows used in previous years, especially if they were successful at reproducing there in previous years (Gervais et al. 2008). The southern California breeding season (defined as from pair bonding to fledging) generally occurs from February to August with peak breeding activity from April through July (Haug et al. 1993).

In the Colorado Desert, western burrowing owls generally occur at low densities in scattered populations, but they can be found in much higher densities near agricultural lands where rodent and insect prey tend to be more abundant, including along the lower Colorado River (Gervais et al. 2008). Western burrowing owls tend to be opportunistic feeders. Large arthropods, mainly beetles and grasshoppers, comprise a large portion of their diet. Small mammals, especially mice and voles (*Microtus, Peromyscus,* and *Mus* spp.), are also important food items for this species. Other prey animals include reptiles and amphibians, young cottontail rabbits, bats, and birds, such as sparrows and

horned larks. Consumption of insects increases during the breeding season (Haug et al. 1993).

Threats to burrowing owls include habitat modification and destruction of ground squirrel burrows. Other threats include pesticide accumulation, burrow destruction from farming practices and canal and road maintenance, roadside shooting, and direct mortality from squirrel poisons (BLM CDD 2002; Gervais et al. 2008).

Protocol-level surveys of part of the Project Disturbance Area (except for part of the Study area associated with the newest transmission line route south of I-10) were conducted in winter of 2007 (Phase I) and spring of 2009 (GSEP 2009a). Because no burrowing owls were observed during Phase III surveys pre-construction clearance surveys are planned (GSEP 2009a, Appendix C). The entire Project Disturbance Area (1,852 acres) is considered burrowing owl habitat.

Golden Eagle

Golden eagles are typically year-round residents throughout most of their western United States range. They breed from late January through August with peak activity March through July (Kochert et al. 2002). Migratory patterns are usually fairly local in California where adults are relatively sedentary, but dispersing juveniles sometimes migrate south in the fall. This species is generally considered to be more common in southern California than in the northern part of the state (USFS 2008).
Habitats for this species typically include rolling foothills, mountain areas, and deserts. Golden eagles need open terrain for hunting and prefer grasslands, deserts, savanna, and early successional stages of forest and shrub habitats. Golden eagles primarily prey on lagomorphs and rodents but will also take other mammals, birds, reptiles, and some carrion (Kochert et al. 2002). This species prefers to nest in rugged, open habitats with canyons and escarpments, with overhanging ledges and cliffs and large trees used as cover.

Absent interference from humans, breeding density is determined by either prey density or nest site availability, depending upon which is more limiting (USFWS 2009b). A compilation in Kochert et al. (2002) of breeding season home ranges from several western United States studies showed an average home range of 20–33 square kilometers (7.7 to 12.7 square miles) that ranged from 1.9 to 83.3 square kilometers (0.7 to 32.2 square miles). In San Diego, a study of 27 nesting pairs found breeding ranges to be an average of 36 square miles with a range from 19 to 59 square miles (Dixon 1937). Other studies from within and outside the United States include ranges from 9 to

74.2 square miles (McGahan 1968; Watson et al. 1992 [range of 14.7 to 26.1 pairs per 1,000 square kilometers]). An Environmental Assessment (EA) and Implementation Guidance for take permits was issued under the Bald Eagle and Golden Eagle Protection Act (USFWS 2009b). The EA specifies that in implementing the resource recovery permit for take of inactive golden eagle nests (50 CFR 22.25), data within a 10-mile radius of the nest provides adequate information to evaluate potential effects.

The closest known historic golden eagle nests are within 14 miles of the Project site (BLM 1999). No recent survey information is available indicating whether these nests are currently active or have recently been used. Nearby Palen and McCoy mountains

may also provide suitable nesting habitat. No golden eagles were observed during surveys in the Study Area, including during avian point count surveys. The avian point count surveys were conducted in March and April, 2009 (GSEP 2009a). However, these surveys were conducted within the Project site only and therefore were not designed to survey potential golden eagle nesting habitat near the Project site, and did not assess the quality of foraging habitat or prey abundance for eagles.

Loggerhead Shrike

Loggerhead shrikes are uncommon residents throughout most of the southern portion of their range, including southern California. In southern California they are generally much more common in interior desert regions than along the coast (Humple 2008). Loggerhead shrikes initiate their breeding season in February and may continue with raising a second brood as late as July; they often re-nest if their first nest fails or to raise a second brood (Yosef 1996).

This species can be found within lowland, open habitat types, including creosote bush scrub and other desert habitats, sage scrub, non-native grasslands, chaparral, riparian, croplands, and areas characterized by open scattered trees and shrubs. Fences, posts, or other potential perches are typically present. In general, loggerhead shrikes prey upon large insects, small birds, amphibians, reptiles, and small rodents over open ground within areas of short vegetation, usually impaling prey on thorns, wire barbs, or sharp twigs to cache for later feeding (Yosef 1996). Loss of habitat to agriculture, development, and invasive species is a major threat; this species has shown a significant decline in the Sonoran Desert (Humple 2008).

Loggerhead shrikes were observed throughout the survey area during spring 2009 surveys as well as during avian point count surveys. The entire Project site is considered loggerhead shrike habitat (GSEP 2009a).

Le Conte's Thrasher

In California, Le Conte's thrasher is a resident in the San Joaquin Valley and the Mojave and Colorado deserts. It occurs in desert flats, washes and alluvial fans with sandy and/or alkaline soil and scattered shrubs. It rarely occurs in monotypic creosote bush scrub habitat, because creosote bush is unable to support a nest, or in massive Sonoran Desert woodlands (Prescott 2005). Preferred nest substrate includes thorny shrubs and small desert trees. Breeding activity occurs from January to early June, with a peak from mid-March to mid-April (BLM CDD 2002). Le Conte's thrashers forage for food by digging and probing in the soil. They eat arthropods, small lizards and snakes, and seeds and fruit; the bulk of their diet consists of beetles, caterpillars, scorpions, and spiders.

This species was observed during Project surveys. Although the entire project area may provide suitable habitat for this species, the best habitat is likely the microphyll woodland associated with the linear facilities.

Crissal thrasher

Crissal thrashers are non-migratory residents ranging from southern Nevada and southeastern California to western Texas and central Mexico. This species prefers

habitats characterized by dense, low scrubby vegetation, which, at lower elevations, includes desert and foothill scrub and riparian brush. Nests of this species typically consist of an open cup of twigs, lined with finer vegetation, and are placed in the middle of a dense shrub (Shuford & Gardali 2008).

Based on a review of the vegetation community descriptions provided by the Applicant, the Project site contains little, if any, of the dense scrub habitat preferred by this species. They are known from the area, including from McCoy Spring, Palen Valley, and Chuckwalla Well (Shuford & Gardali 2008). The closet occurrence based on the CNDDB (2010) is south of the Project site within one mile of the transmission line interconnection location.

California Horned Lark

The California horned lark is found throughout California except the north coast, and is less common in mountainous areas. This species prefers open areas that are barren or with short vegetation including deserts, brushy flats, and agricultural areas. Eggs are laid March to early June, and this species frequently lays a second clutch.

The Project site contains suitable habitat for this species, especially in creosote bush scrub. This species was observed frequently in the Project Disturbance Area during surveys, and was the most numerous species observed during avian point count surveys (GSEP 2009a).

Brewer's Sparrow

In California, Brewer's sparrow is a common breeding bird east of the Cascade-Sierra Nevada crest, in the mountains and higher valleys of the Mojave Desert, and, uncommonly, at high elevations in San Bernardino, Ventura, Kern, and San Luis Obispo counties. This species winters in the southeastern part of the state in sagebrush shrublands and brushy desert habitat, including desert scrub dominated by various saltbush species and creosote (Zeiner et al. 1990, Rotenberry et al. 1999).

Declines in this species have been noted in the breeding range, and may be attributable to loss and fragmentation of breeding habitat. Impacts due to degradation of wintering habitat have not been reported for this species (Rotenberry et al. 1999).

Brewer's sparrows were observed during Project surveys, and would be expected in the Project area as a winter resident.

Prairie Falcon

The prairie falcon inhabits dry environments in the North American west from southern Canada to central Mexico. It is found in open habitat from annual grasslands to alpine meadows at all elevations up to 3,350 m, but is associated primarily with perennial grasslands, savannahs, rangeland, some agricultural fields, and desert scrub areas. They require cliffs or bluffs for nesting though will sometimes nest in trees, on power line structures, on buildings, or inside caves or stone quarries. Ground squirrels and horned larks are the primary food source, but prairie falcon will also prey on lizards, other small birds, and small rodents.

The entire Project Disturbance Area (1,852 acres) is suitable foraging habitat for prairie falcon, and this species was observed on the Project site. The Project site does not contain suitable nesting habitat, although adjacent mountains may. There are numerous CNDDB (2010) records in the region for this species, including nest records from Little Maria Mountains to the northeast (1977) and the Chuckwalla Mountains to the southwest (1978).

Short-eared Owl

Short-eared owls breed through much of northern North America, and are year-round residents in some areas of California. Historically, this species bred throughout much of California, west of the southern deserts, in low numbers. Currently, small populations breed regularly in the Great Basin and in the Sacramento/San Joaquin River Delta area, but sporadically in other parts of its former range. Short-eared owls require open country that supports small mammal populations, and that also provides adequate vegetation to provide cover for nests. This includes salt- and freshwater marshes, irrigated alfalfa or grain fields, and ungrazed grasslands and old pastures (Shuford & Gardali 2008, Zeiner et al. 1990).

The Project area is not within the breeding range for short-eared owl as the range is described in CDFG publications (Zeiner et al. 1990, updated 2008; Shuford & Gardali 2008); in addition, the Project site does not provide suitable breeding habitat. The Project site does contain suitable wintering habitat for the short-eared owl, and this species was observed during Project surveys..

Swainson's Hawk

Swainson's hawks require large areas of open landscape for foraging, including grasslands and agricultural lands that provide low-growing vegetation for hunting and high rodent prey populations. Swainson's hawks typically nest in large native trees such as valley oak, cottonwood, walnut, and willow, and occasionally in nonnative trees, such as eucalyptus within riparian woodlands, roadside trees, trees along field borders, isolated trees, small groves, and on the edges of remnant oak woodlands (CDFG 1993).

While there are historical breeding records of this species from the Colorado Desert (Woodbridge 1998), this species is now known from southern California only as a spring and fall migrant (CDFG 1993). This reduction in breeding range is believed to be from loss of nesting habitat (Zeiner et al. 1990, updated 2006).

The Project site may provide foraging habitat for migrating individuals, and this species was observed in the Project site during surveys.

Ferruginous Hawk

Ferruginous hawks do not breed in California, but are winter residents and in California are most common in grassland and agricultural areas in the southwest. Ferruginous hawks are found in open terrain from grasslands to deserts, and are usually associated with concentrations of small mammals. Threats to this species include loss of wintering habitat from urbanization and cultivation.

The Project site contains suitable wintering habitat for ferruginous hawks, and this species was observed during Project surveys.

Northern Harrier

In western North America, the northern harrier breeds from northern Alaska south to Baja California, Mexico. This species does not commonly breed in desert regions of California, where suitable habitat is limited, but winters broadly throughout California in areas with suitable habitat. Northern harriers forage in open habitats including deserts, pasturelands, grasslands, and old fields.

The Project site contains suitable wintering habitat for the northern harrier, and this species was observed during Project site surveys (GSEP 2009a). There are CNDDB (2010) nesting records for this species in eastern Riverside County

American Badger

American badgers were once fairly widespread throughout open grassland habitats of California. Badgers are an uncommon permanent resident with a wide distribution across California, except from the North Coast area. American badger is most abundant in the drier open stages of most shrub, forest, and herbaceous habitats with friable soils. Badgers are generally associated with treeless regions, prairies, parklands, and cold desert areas (Zeiner et al. 1990). Badgers inhabit burrows and often predate and forage on other small mammal burrows as evidenced by claw marks along the edges of existing burrows.

American badger sign was found during spring 2009 field surveys; burrow predation evidence by badgers was found in the buffer area west of the solar power plant Project Disturbance Area. Therefore, the entire Study area is considered suitable habitat for American badger.

Desert Kit Fox

Desert kit fox is an uncommon to rare permanent resident of arid regions of the southern portion of California. Kit fox occur in annual grasslands, or grassy open, arid stages of vegetation dominated by scattered herbaceous species. Kit fox occur in association with their prey base which is primarily cottontail rabbits, ground squirrels, kangaroo rats and various species of insects, lizards, or birds (Zeiner et al. 1990). California Code of Regulations 14 CCR § 460 stipulates that desert kit fox may not be taken at any time. Protection provided by kit fox dens for use as shelter, escape, cover, and reproduction is vital to the survival of the species.

Desert kit fox burrows, complexes and scat were observed throughout the Study area within desert wash and upland scrub habitats during 2009 field surveys. Over 65 kit fox burrow complexes, both active burrows with fresh scat present and inactive burrow complexes were observed throughout the solar power plant Project Disturbance Area and linear Disturbance Area (GSEP 2009a). The entire Study area is suitable habitat for desert kit fox.

Nelson's Bighorn Sheep

Nelson's bighorn sheep includes bighorns from the Transverse Ranges through most of the desert mountain ranges of California, Nevada, and northern Arizona to Utah. Essential habitat for bighorn sheep includes steep, rocky slopes of desert mountains, termed "escape terrain." Their agility on steep rocky terrain is an adaptation used to escape predators such as coyotes, eagles, and cougars (Wehausen 1992). Surface water is another element of desert bighorn habitat considered essential to population health. Male and female bighorn sheep inhabiting desert ecosystems can survive without consuming surface water (Krausman et al. 1985) and males appear to drink infrequently in many situations; however, there are no known large populations of bighorn sheep in the desert region that lack access to surface water. In the spring, when annual plants are available, bighorn tend to disperse downhill to bajadas and alluvial fans to forage. Desert bighorn have a long lambing season that can begin in December and end in June in the Mojave Desert, and a small percentage of births commonly occur in summer as well (Wehausen 1992).

Over the past 140 years, bighorn sheep have suffered considerable population declines throughout their range and metapopulations have been fragmented by roads and other barriers with a resulting decline in genetic diversity (Bleich et al. 1996, Epps et al. 2005). Disease, sometimes brought about by contacts with domestic sheep, drought and predation, interacting with other anthropogenic factors may also have contributed to declines in bighorn sheep populations (Wehausen 2005). Loss of surface water sources may also diminish the viability of existing populations (Wehausen 2005).

Two metapopulations of bighorn sheep occur within the NECO Planning Area, the Southern Mojave and Sonoran. Within these metapopulations, there are smaller, somewhat isolated subpopulations of bighorn sheep known as demes, with nine demes occuring in the Sonoran metapopulation (BLM CDD 2002). Bighorn sheep metapopulations have been fragmented by highways, roads, railroads, and aqueducts primarily by the construction of Interstate 10 and Interstate 40 which are major barriers to bighorn sheep movements. Transportation corridors of Highways 66, 62, 177, 95, and 78, the Atchison, Topeka &and Santa Fe Railroad (parallel to Old Highway 66) and the Eagle Mountain Railroad (scheduled for reactivation) inhibit bighorn sheep movements between demes. Nevertheless, bighorn sheep are known to cross these and other linear features such as transmission lines and fences.

The Project site is located southeast of an occupied bighorn Sheep WHMA in the Palen, Granite, and Coxcomb Mountains (BLM CDD 2002), and southwest of a currently unoccupied Bighorn Sheep WHMA in the McCoy Mountains. Recent surveys suggest bighorn sheep may occur in the Little Maria Mountains, farther northeast of the Project area, in an area designated by the NECO Plan as an unoccupied WHMA (Wehausen 2009). The CNDDB records for this species from the Project area indicate that bighorn sheep disperse through these mountain ranges typically whenever forage and water conditions permit.

No sign or evidence of Nelson's bighorn sheep were found during field surveys and bighorn sheep are not expected to occur in the Project area. The Project Area is not within a known bighorn sheep corridor as identified in the NECO Plan.

Burro Deer

Burro deer is a subspecies of mule deer (*Odocoileus hemionus*) found in the Colorado Desert of southern California. This species is found in the Colorado region of the Sonoran Desert near the Colorado River and within desert dry wash woodland communities. Some burro deer are resident along the Colorado River, but a significant portion move into desert areas in response to water and forage. During the hot summers, water is critical, and burro deer concentrate along the Colorado River or the Coachella Canal where water developments have been installed and where microphyll woodland is dense and provides good forage and cover. With late summer thundershowers and cooler temperatures, deer move away from the Colorado River and Coachella Canal and then up the larger washes into mountains or wash complexes in the foothills (BLM CDD 2002).

During spring 2009 field surveys, tracks of burro deer were found in one location south of I-10 along the southern transmission line route (GSEP 2009a, Appendix C). This species is expected to occur north of I-10 and within the Study area especially along desert washes and areas of dry desert wash woodland and other microphyllous riparian vegetated washes. Therefore, these habitat areas are considered suitable for burro deer within the Study area.

Biological Resources Table 4 lists all special-status species evaluated during the analysis that are not likely to occur or have a low to moderate potential for occurrence in the Project area. This table provides additional information on the species identified in **Biological Resources Table 3** and the determination of their potential for occurrence in the Project area such as the presence or absence of suitable habitat, nearby occurrence records, and survey efforts that have taken place.

Biological Resources Table 4
Special-Status Species with No, Low or Moderate Potential to Occur at the GSEP Study Area

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
Plants		
Angel trumpets *Acleisanthes longiflora*	This species occurs in Sonoran desert scrub habitats on carbonate soils from approximately 200 to 300 feet above MSL. There are two records from the Consortium of California Herbaria from the Colorado Desert, Palo Verde area (CCH 2010).	This species has low potential to occur in the Project area due to the presence of suitable habitat although the site being located above the elevation range of this species. Surveys will be conducted for this species in 2010. This species is not expected to occur in the Project area because it is above the elevation range of this species.
Argus blazing star *Mentzelia puberula*	This plant species occurs in desert scrub and desert woodlands with limestone and granitic slopes above 2,000 feet in elevation. This is a species of hot, rugged, rocky areas and should be distinguishable from M. multiflora on habitat characteristics alone. Argus blazing star was a proposed addition and is now a recent addition to CNPS List 2, In California, this species has been observed in good numbers in the Whipple, Chemehuevi and Turtle mountains, in southeastern San Bernadino and eastern Riverside counties along the Colorado River (Silverman, Pers. Comm. March 2010). Based on 13 Consortium of California Herbaria database records for this species, this species has been collected from Riverside, San Bernardino, and Imperial counties from the Little and Big Maria Mountains in Riverside County.	This species has low potential to occur in the study area; limestone and granitic slopes which are soil types preferred by this species are absent from the study area. The Project site is located at approximately 360 to 450 feet above MSL which is well below the typical elevation where this species typically occurs. This will be a target species during 2010 focused botanical surveys.
Arizona spurge *Chamaesyce arizonica*	This species occupies sandy, Sonoran desert scrub habitat areas and has been reported from Imperial, Riverside, San Diego counties and portions of Arizona and Baja, California (CNPS 2009) from approximately 150 feet to 1,200 feet above MSL. There are 7 database records from the Consortium of California Herbaria primarily from San Diego County but also Riverside and Imperial counties often from sandy areas and transition areas between chaparral and desert habitats. The record from Riverside County is near Palm Springs from Andreas Canyon (CCH 2010).	This species has a low potential to occur within the study area. Although suitable habitat is present and the project site is within the appropriate elevation range, there are no CNDDB occurrences within 10 miles of the site and the species is not known to occur in the area.
Bitter hymenoxys	Bitter hymenoxys grows in riparian scrub and Sonoran	This species has low potential to occur within the

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
Hymenoxys odorata	desert scrub habitats from 150 feet to 500 feet above MSL. This plant species blooms from February through November (CNPS 2009). There are five CNDDB records for this species for the entire state of California, two of which occur in Riverside County.	Sonoran creosote bush scrub habitats within the Project area. However, this species was not found during spring 2009 field surveys. There are no CNDDB occurrences within 10 miles of the site.
Bitter snakewood *Condalia globosa* var. *pubescens*	Another common name for this species is spiny abrojo. Bitter snakewood occurs in Sonoran desert scrub from approximately 400 feet to 3,000 feet above MSL. Bitter snakewood blooms from March through May (CNPS 2009). Based on 35 records Consortium of California Herbaria database, all records are from Imperial County except one from Riverside County, a record from 1,900 feet elevation from a relatively flat alluvial fan from Chuckwalla Bench (CCH 2010). There are no CNDDB records for this species for the state of California (CNDDB 2010).	The higher elevation levels of the Project site are within the appropriate elevation range where this species typically occurs. However, this species was not observed during spring 2009 field surveys. There are no CNDDB occurrences within 10 miles of the site.
California ayenia *Ayenia compacta*	This species occurs in Mojavean and Sonoran desert scrub habitats from approximately 500 to 3,300 feet above MSL. This species blooms from March through April. There are 29 records from the Consortium of California Herbaria database from the Anza Borrego area alone, one from Riverside County from a sandy wash in the Santa Rosa Mountains off Martinez Canyon (CCH 2010).	This species was not observed during spring 2009 field surveys. This species not expected to occur since the elevation range of the Project site is not appropriate for this species.
California ditaxis *Ditaxis serrata* var. *californica*	This species occupies Sonoran desert scrub habitat and has been reported as occurring from San Bernardino, Riverside, Imperial, San Diego, and Sonora, Mexico (CNPS 2009) from approximately 100 to 3,000 feet above MSL. There are 23 records from the Consortium of California Herbaria database primarily from Riverside County from sandy, open alluvial fans.	This species has moderate potential to occur within the study area due to the presence of suitable habitat and records from the Chuckwalla Valley and Desert Center areas. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
California satintail *Imperata brevifolia*	This species occurs in grassy areas found near chaparral, desert scrub, riparian scrubs, coastal scrub, wet springs, meadows, stream sides and floodplains from sea level to approximately 1,500 feet above MSL. There are 64 records from the Consortium of California Herbaria database from many northern and southern California counties. Records from Riverside County are from the Palm Springs and San Jacinto Mountains area along irrigation ditches or streams.	This species has low potential to occur within the study area due to the presence of suitable habitat. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Chaparral sand	This species occupies sandy soil areas of chaparral,	This species has low potential to occur within the

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
verbena *Abronia villosa* var. *aurita*	coastal sage scrub, and sandy desert dune habitats (CNPS 2009) from approximately 240 feet to approximately 4,800 feet above MSL. There are 147 records in the Consortium of California Herbaria database many from Riverside County in the San Jacinto Mountains area.	study area due to the presence of suitable habitat. However, this species was not observed during spring 2009 field surveys. There are no CNDDB occurrences within 10 miles of the site.
Coachella Valley milk-vetch *Astragalus lentiginosus* var. *coachellae*	The Coachella Valley Multiple Species Habitat Conservation Plan states that this species occurs on "dunes and sandy flats, along the disturbed margins of sandy washes, and in sandy soils along roadsides and in areas formerly occupied by undisturbed sand dunes. Within the sand dunes and sand fields, this milk-vetch tends to occur in the coarser sands at the margins of dunes, not in the most active blows and areas. As this species is strongly affiliated with sandy substrates, it may occur in localized pockets where sand has been deposited by wind or by active washes. It may also occur in sandy substrates in creosote bush scrub, not directly associated with sand dune habitat (CVAG 2007). This plant species blooms from February to May, producing pink to deep magenta-colored flowers. This species occurs on aeolian deposits with fewer than 25 occurrences in the Coachella Valley. Coachella Valley milk-vetch depends on natural disturbances from fluvial and aeolian processes for seedling establishment (BLM CDD 2002).	This species was not observed during spring 2009 surveys and does not have a potential to occur in the study area. The distribution of Coachella Valley milk-vetch is restricted to the Coachella Valley in Riverside County, between Cabazon and Indio. CVAG (2007) identifies six outlying occurrences within a 5-mile area along Rice Road in the Chuckwalla Valley north of Desert Center, California (CVAG 2007); however, USFWS staff has indicated that these occurrences are not of the listed taxon (Engelhard, personal communication).
Cove's cassia *Senna covesii*	This species occurs on dry, sandy desert washes and slopes, roadsides, alkaline flats in the Mojave Desert and northern Sonoran Desert between 1,600 to 2,000 feet above MSL (CNPS 2009).	This species is not expected to occur within the study area since the Project site is located below the typical elevation range where this species is known to occur. This species was not observed during spring 2009 field surveys.
Crucifixion thorn *Castela emoryi*	This species occurs in Sonoran Desert and Mojavean Desert in scrub habitats and playas with dry, gravelly washes, slopes, and plains from approximately 300 to 2,100 feet above MSL. There are 64 records in the Consortium of California Herbaria database from Riverside, San Bernardino and Imperial counties among others and often times prefers grassy or hayfield habitats. There is a record from a hayfield in Chuckwalla Valley.	This species has a low potential to occur within the study area due to the presence of suitable habitat and appropriate elevation range of the Project site. However, this species was not observed during spring 2009 field surveys. The nearest CNDDB record for this species is approximately 5 miles north of the Project site in the Palen Mountains.
Desert portulaca	This species occurs in Joshua tree woodlands and has	Given the lack of typical habitat associations and

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
Portulaca hamiloides	been reported from Riverside, San Bernardino, and portions of Arizona and Baja, California from 3,000 feet to 3,600 feet above MSL (CNPS 2009).	the Project site being located outside of the elevation range, this species has low potential to occur within the study area. This species was not observed during spring 2009 field surveys, and will be a target species for the 2010 botanical surveys.
Desert sand parsley *Ammoselinum giganteum*	This species occupies Sonoran creosote bush scrub habitat and has been reported from Riverside County, California and portions of Arizona (CNPS 2009) at approximately 1,200 feet elevation. There are 2 records from the Consortium of California Herbaria database from Riverside County from the Chuckwalla Valley where this species was observed growing in dry basins at 500 feet above MSL (CCH 2010).	This species has a low potential to occur within the study area due to presence of suitable habitat and reported occurrences from the Chuckwalla Valley. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Desert spike moss *Selaginella eremophila*	This is a dense, mat forming, non-flowering plant. This species occurs in Sonoran creosote bush scrub habitats in gravelly or rocky soils from approximately 600 to 2,700 feet above MSL. There are 56 records in the Consortium of California Herbaria database from Riverside and San Diego counties with several records from Anza Borrego State Park, Palm Springs, Palm Canyon, and San Jacinto Mountain Range. One collection from Riverside County is from the vicinity of the Chocolate-Chuckwalla Mountain region near the north side of the Orocopia Mountains from sloped rocky, shady surfaces in gravelly soils (CCH 2010).	This species has a low potential to occur within the study area given the presence of suitable desert scrub habitat, although the Project site is located below the typical elevation range of this species. This species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Dwarf germander *Teucrium cubense* ssp. *depressum*	This species occurs in desert dune, playa margins, and Sonoran desert scrub habitats from approximately 100 feet to 1,200 feet above MSL. This species typically blooms from March to May but may also bloom from September through November. This species typically occurs in sandy soils and wash habitats and is known from fewer than 10 occurrences in California (CNPS 2009). There are 15 records from Consortium of California Herbaria database from Riverside and Imperial counties; there are records from the Chuckwalla Valley in the Hayfield area and Palo Verde Valley. There is a CNDDB record from Wiley's Well Road (400 feet elevation) during 1979 (CNDDB 2010). Another CNDDB occurrence is a historical record from	This species has a low potential to occur due to the presence of suitable habitat and appropriate elevation range of the site. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	1912 located in Palo Verde Valley (CNDDB 2010).	
Flat-seeded spurge *Chamaesyce platysperma*	This species occurs in desert dunes and Sonoran desert scrub habitat types from approximately 200 to 300 feet above MSL. This species blooms from February through September and is considered a late-season fall blooming plant (CNPS 2009). There are four records of this species for the entire state of California, only one of which is from Riverside County; the closest CNDDB occurrences is a historical record mapped near the City of Thousand Palms during 1926 (CNDDB 2010).	This species has moderate potential to occur in the Project site. This species was not observed during spring 2009 field surveys. This species is a target plant species to be surveyed for during spring 2010 botanical surveys. There are no CNDDB occurrences within 10 miles of the site.
Foxtail cactus *Coryphantha alversonii*	This species occurs on rocky, granitic soils in Sonoran and Mojavean desert scrub habitats from 200 feet to 4,600 feet above MSL. Prior to conducting spring 2009 field surveys, a reference population was observed on April 9, 2009 at a gravel pit northwest of Blythe along State Route 95 and several individuals were observed in relatively undisturbed Sonoran creosote bush scrub on granitic rock, a preferred habitat type of this species (CNPS 2009). There are 25 records of this species from the Consortium of California Herbaria database from Riverside, Imperial, and San Bernardino counties. There are records from the Chuckwalla Valley from rocky, granitic slopes (CCH 2010).	This species has a low potential to occur within the Project area due to the presence of suitable desert scrub habitat and appropriate elevation of the site. However, there are no rocky, granitic soils, which is required for this species. This species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Glandular ditaxis *Ditaxis claryana*	This plant species grows in Mojavean and Sonoran desert scrub habitat. Glandular ditaxis blooms from October through March (CNPS 2009) and is also considered a late-season, fall blooming plant species. Glandular ditaxis grows in these types of habitats from sea level to approximately 1,400 feet above MSL.	This species has a moderate potential to occur within the Project site. The nearest CNDDB occurrence is from 1977 from Corn Springs Wash, south of I-10 near Chuckwalla Road in creosote bush scrub habitats with gravelly, sandy soils (CNDDB 2010). This occurrence is recorded approximately 6.5 miles east of the Project site, near the Chuckwalla Mountains. This species was not observed during spring 2009 surveys and will be a target species to be surveyed for during 2010 botanical surveys.
Harwood's phlox *Eriastrum harwoodii*	Harwood's phlox occupies desert dunes and slopes from approximately 600 to 2,700 feet above MSL. The blooming period for Harwood's phlox is from March through June (CNPS 2009). This species is known from eastern Riverside County and San Bernardino County; there are 12	This species has a low potential to occur due to the presence of suitable habitat although the Project site occurs below the typical elevation range of this species. This species was possibly observed during spring 2009 field surveys,

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	CNDDB records for this species all of which are from San Bernardino County except one record from 2008 from Riverside County located approximately 2.5 miles west of Blythe Junction (CNDDB 2010). There are 17 records from the Consortium of California Herbaria database primarily from San Bernardino County and 3 from Riverside County at Blythe Road near Rice from very sandy soils (CCH 2010).	however could not be positively identified. There are no CNDDB occurrences within 10 miles of the site.
Jackass clover *Wislizenia refracta* ssp. *refracta*	Jackass clover is an annual herb that occupies desert dunes, Mojavean desert scrub, playas and Sonoran desert scrub. The blooming period for jackass clover is April through November. Elevation range for this species is approximately 1,900 to 2,700 feet above MSL.	There is low potential for this species to occur given the presence of suitable habitat although the Project occurs well below the typical elevation range of this species. There is one CNDDB record of this species in Riverside County.
Lobed ground cherry *Physalis lobata*	Lobed ground cherry occurs in Mojavean desert scrub on decomposed granite soils, playas, and alkaline dry lake beds. This species occurs from approximately 1,500 feet to 2,400 feet above MSL. There are six records from the Consortium of California Herbaria database, all from San Bernardino County (CCH 2010).	This species has a moderate potential to occur in the Project area due to the presence of suitable habitat. This species was not found during spring 2009 field surveys, and will be a target species for the 2010 botanical surveys.
Mesquite nest straw *Stylocline sonorensis*	This species occupies Sonoran desert scrub habitats around 1,300 feet elevation and has been reported from Riverside County and portions of Arizona and Sonora, Mexico (CNPS 2009). There are 2 records from the Consortium of California Herbaria database from Riverside County both from the Chuckwalla Mountains, Hayfields region from 1930 (CCH 2010).	There is low potential for this species to occur given the presence of suitable habitat although the Project occurs well below the typical elevation range of this species. This species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Orocopia sage *Salvia greatae*	This species occurs in the southeastern Sonoran Desert and is associated with the Orocopia and Chocolate Mountains on alluvial slopes between 100 and 800 feet above MSL. There are 49 records from the Consortium of California Herbaria database several from the Chocolate, Chuckwalla, and Orocopia mountain areas (CCH 2010).	This species has a low potential to occur within the study area due to the presence of suitable habitat and appropriate elevation range of the site. This species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Palmer's jackass clover *Wislizenia refracta* ssp. *palmeri*	Palmer's jackass clover is a perennial herb that occupies sandy washes, and Sonoran desert scrub habitat from sea level to 650 feet above MSL. There are 5 records from the Consortium of California Herbaria database for this subspecies, 3 from Riverside County, one from San Diego	There is low potential for this species to occur due to the presence of suitable habitat and the Project site occurs within the typical elevation range of this species. Surveys will be conducted for this species in 2010.

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	County and one from San Bernardino County (CCH 2010). The Palmer's jackass clover is a proposed new addition to the CNPS inventory and is likely to be added to CNPS List 2 by the end of 2010 (Silverman, pers. comm.).	
Pink fairyduster *Calliandra eriophylla*	This species occurs in the Sonoran Desert in sandy washes, slopes and mesas from 350 to 5,000 feet above MSL. There are 62 records from the Consortium of California Herbaria database several from the Chocolate-Chuckwalla Mountains area in Imperial and San Diego counties (CCH 2010).	This species has a low potential to occur within the Project area due to the presence of suitable habitat and appropriate elevation range of the site. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Pink velvet mallow *Horsfordia alata*	This species occurs in the Sonoran Desert in California, Arizona, and Mexico. It occurs in Sonoran desert scrub habitats from approximately 300 to 1,500 feet above MSL.	This species was not observed during spring 2009 field surveys. There are no CNDDB records for this species for the entire state of California; the most recent collections have been from the Chocolate, Chuckwalla, and Cargo Muchacho Mountains approximately 50 miles south of the study area and are believed to be extant. Surveys will be conducted for this species in 2010.
Sand evening-primrose *Camissonia arenaria*	This species occupies sandy and gravelly areas of Sonoran desert scrub habitat and has been reported from Imperial and Riverside counties and areas of Arizona and Mexico from 200 feet to 2,700 feet above MSL (CNPS 2009). There are 13 records of this species in the Consortium of California Herbaria database several from the Chocolate-Chuckwalla Mountains, Palo Verde Valley, and Ogilby Pass area (CCH 2010).	This species has a low potential to occur within the study area due to the presence of suitable habitat and appropriate elevation of the site. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Slender woolly-heads *Nemacaulis denudata* var. *gracilis*	This species occupies desert sand dunes, coastal dunes, and Sonoran desert scrub (CNPS 2009) from 150 to 1,200 feet above MSL. There are 45 records in the Consortium of California Herbaria database from the Palm Springs, Indian Wells area in Riverside County (CCH 2010).	This species has a low potential to occur within the Project area due to suitable habitat and appropriate elevation range of the site. However, this species was not observed during spring 2009 field surveys and there are no CNDDB occurrences within 10 miles of the site.
Small-flowered androstephium *Androstephium breviflorum*	This species occurs in desert dune and Mojavean desert scrub habitats from approximately 700 feet to 2,000 feet above MSL (CNPS 2009). This species blooms from March through April and often occurs on desert bajadas.	This species has a low potential to occur within the study area given the presence of suitable desert scrub habitat, although the Project site is located below the typical elevation range of this species. The nearest CNDDB record for this

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
		species is from Cadiz Valley from Riverside and San Bernardino counties approximately one mile north of Highway 62 during 1995 from a sandy, Mojavean Desert shrub-land bajada (CNDDB 2010). This species was not observed during 2009 field surveys and will be a target species to be surveyed for during 2010 botanical surveys.
Spearleaf *Matelea parvifolia*	This species occurs on rocky ledges and slopes in Mojavean and Sonoran desert scrub habitats from 1,000 feet to approximately 6,000 feet above MSL. This species blooms from March through May (CNPS 2009). The nearest CNDDB record for this species is from the Chuckwalla Bench area during 1986 from desert dry wash woodland and creosote bush scrub habitats (CNDDB 2010).	This species is not likely to occur within the Project site. The Project site is located below the typical elevation range of this species. This species was not observed during spring 2009 field surveys.
Utah milkvine *Cynanchum utahense*	This species occurs in Mojavean and Sonoran desert scrub habitats often times with sandy or gravelly soils from approximately 500 feet to 4,300 feet in elevation (CNPS 2009). The distribution of this species covers San Diego, Imperial, Riverside, and San Bernardino counties and portions of Arizona, Nevada, and Utah. An occurrence of this species from Sentenac Canyon in San Diego County is from acid igneous rock and is a locale with arid, sandy slopes and relatively low-growing desert shrub cover. The Project is likely outside of the range of Utah milkvine (Silverman, pers. comm.).Utah cynanchum populations are likely stable on the southern deserts based on limited historical impacts to its habitat and although it is apparently more common elsewhere in southeastern California, populations within the western Colorado Desert are uncommon and should be protected (Reiser 1994).	This species was not observed during spring 2009 field surveys. It was originally thought to be present onsite, but this was due to a mis-identification (GSEP 2009f). There are no CNDDB records for this species from the entire state of California (CNDDB 2010). There are 58 records of this species from the Consortium of California Herbaria database primarily from San Bernardino and San Diego counties; there is one record from the Big Maria Mountains from wash and stabilized dune habitat at approximately 1,200 feet elevation (CCH 2010).
Wiggins' cholla *Cylindropuntia wigginsii* (syn=*Opuntia wigginsii*)	Wiggins' cholla is not believed to be a valid taxon and is considered a hybrid of silver cholla (C. echinocarpa) and pencil cholla (C. ramosissima) (GSEP 2009f); however, this species is covered under the NECO Plan and was targeted during spring 2009 field surveys. CNPS describes the	Since this is not a valid taxon recognized by local botanical experts; this species is not expected to occur in the Project site.

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	potential taxon as occurring in Sonoran creosote bush scrub in sandy areas between 100 feet and 2,600 feet elevation. There are two records of this species from the Consortium of California Herbarium from San Bernardino and Imperial counties (CCH 2010).	
Winged cryptantha *Cryptantha holoptera*	This species occurs in Mojavean and Sonoran desert scrub habitats from 300 feet to approximately 5,000 feet above MSL. This species blooms from March through April (CNPS 2009). Winged cryptantha is found in Mojavean and Sonoran deserts within California, Arizona, and Nevada. There are 79 records of this species in the Consortium of California Herbaria database from Riverside, Imperial, San Bernardino, and San Diego counties (CCH 2010).	This species has low to moderate potential to occur at the Project site. There are no CNDDB records for this species for the entire state of California (CNDDB 2010). This species was not observed during spring 2009 field surveys. Surveys will be conducted for this species in 2010.
Birds		
Bendire's thrasher *Toxostoma bendirei*	Bendire's thrashers are known in California from scattered locations in Kern, Inyo, San Bernardino, and Riverside counties. This species is a summer resident in southeastern California, and arrives at breeding grounds from mid-March through May, and departs by late August. This species favors open grassland, shrubland, or woodland with scattered shrubs, primarily in areas that contain large cholla, Joshua tree, Spanish bayonet, Mojave yucca, palo verde, mesquite, catclaw, desert-thorn, or agave. The status of populations of this species is poorly understood, but threats are believed to be loss of habitat due to urbanization, harvesting of yucca and Joshua trees, overgrazing, and off-road vehicle activity. In parts of the range, grazing may increase habitat suitability by increasing the area with scattered junipers.	The desert dry wash vegetation community provides potential habitat for this species, although it was not observed during surveys. There are CNDDB (2010) records near Desert Center from 2004.
Black-tailed gnatcatcher *Polioptila melanura*	A year round resident in southwestern United States and central and northern Mexico, in California the black-tailed gnatcatcher is found in the southeast desert wash habitat from Palm Springs and Joshua Tree National Monument south, and along the Colorado River. It is now rare in eastern Mojave Desert north to the Amargosa River, Inyo Co. This species nests primarily in wooded desert wash habitat, but also occurs in creosote bush scrub habitat during the non-breeding season.	Based on a review of the vegetation community descriptions provided by the Applicant, the Project site contains little, if any, of the dense scrub habitat preferred by this species. They are known from the area, including from McCoy Spring, Palen Valley, and Chuckwalla Well (Fitton 2008).

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
Gila woodpecker *Melanerpes uropygialis*	The Gila woodpecker's range is limited to a small area of southwestern United States and northwestern Mexico. In California, this species is found only along the Colorado River and in small numbers in Imperial County. In southeastern California, Gila woodpeckers were formerly associated with desert washes extending up to one mile from the Colorado River. Currently, they are found only in riparian areas along the Colorado River.	In California, this species is currently known only from the Colorado River; therefore this species is not expected in the Project site. The Project site does not contain suitable nesting habitat for this species. The closest CNDDB (2010) record for this species is a 1986 record east of the Project site at the Colorado River.
Gilded flicker *Colaptes chrysoides*	In California, the gilded flicker is known from the southeast; habitat includes stands of giant cactus, Joshua tree, and riparian groves of cottonwoods and tree willows in warm desert lowlands and foothills. Until the mid-1990's, this species was considered a subspecies of northern flicker (*C. atratus*). This species nests primarily in cactus, but also will use cottonwoods and willows of riparian woodlands. This species may be nearly extinct in California.	This species is not expected to regularly use the Project site due to lack of suitable habitat. The closest CNDDB (2010) records for this species are along the Colorado River.
Mountain plover *Charadrius montanus*	Mountain plovers do not breed in California, but are winter visitors primarily from September to mid-March. In California they are found in the Central Valley, Antelope Valley, San Jacinto Valley, Imperial Valley, and Palo Verde Valley. Mountain plover habitat includes short-grass prairie or their equivalents, and in southern California deserts are associated primarily with agricultural areas, though use of these areas is suspected to be because of loss of native grassland and playa habitats.	This species may use the dry lakebed and nearby agricultural areas as winter habitat. The closest CNDDB (2010) record for this species is in Imperial County at the southern end of the Salton Sea.
Peregrine falcon *Falco peregrinus*	The Peregrine falcon's year-round range includes coastal and northwestern California and the Sierra Nevada and other California mountains. Additionally, this species winters inland throughout the Central Valley and in northeastern California. They are rare in the arid southeast, but they occur and are suspected to breed in the lower Colorado River Valley. Peregrine falcons require open habitat for foraging, and prefer breeding sites near water. Nesting habitat includes cliffs, steep banks, dunes, mounds, and some human-made structures.	This species may forage on the Project site and nest in nearby mountains, but was not observed in the Project site during Project surveys. There are no CNDDB (2010) records for Riverside County.
Purple martin *Progne subis*	The historical breeding range of the purple martin includes southern California, though populations have shrunk dramatically. Neither the historical or current breeding	This species not expected to occur at the project site due to the lack of suitable foraging habitat. There are six CNDDB (2010) records for this

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	range, however, includes the Colorado Desert. Purple martins habitat requirements include adequate nest sites and availability of large aerial insects, and therefore are most abundant near wetlands and other water sources. Threats to this species include loss of large tree and snags and competition from European starlings.	species from western Riverside County, the most recent of which include nesting records from 1983 and 1993.
Vaux's swift *Chaetura vauxi*	This species is not known to breed in Riverside County or elsewhere in southern California. Very few nests have been found so their breeding range has been inferred from sightings of birds flying over potential nesting areas during their nesting season, in June and July. Vaux's swifts prefer to nest in the hollows formed naturally inside of large old conifer trees, especially snags, which are entirely lacking from the Project site.	This species was not observed during surveys and is not expected to occur due to a lack of nesting habitat on the Project site, any occurrences are expected to be of migrants only. There are no CNDDB occurrences within 10 miles of the site.
Vermilion flycatcher *Pyrocephalus rubinus*	Vermilion flycatchers are rare breeders or residents in localized areas of southern California, including along the Colorado River. They are usually found near water in arid scrub, farmlands, parks, golf courses, desert, savanna, cultivated lands, and riparian woodlands; nesting substrate includes cottonwood, willow, and mesquite.	Within the Project vicinity, occurrences of this species are limited to the Colorado River. This species is not expected in the Project site. The closest CNDDB (2010) records include a 1983 record from the Blythe golf course.
Yellow warbler *Dendroica petechia*	Yellow warblers historically bred throughout much of California except for high elevations, the Colorado Desert, and most of the Mojave Desert. Breeding abundance for this species has declined in much of California, as has the breeding range, especially in the Central Valley and parts of Owens Valley. In southeastern California, this species is known only from the lower Colorado River Valley from the middle of San Bernardino County through Riverside and Imperial Counties. Currently, this species no longer breeds in much of the Riverside County segment of the lower Colorado River Valley. This species commonly uses wet, deciduous thickets for breeding, and seeks a variety of wooded, scrubby habitats in winter.	This species was not observed during surveys, and is not expected to nest in the Project site due to lack of suitable habitat. The closest CNDDB (2010) records for this species are two 1986 records east of the Project site at the Colorado River.
Yellow-breasted chat *Icteria virens*	The yellow-breasted chat occurs as a summer resident and migrant in California. In the southeastern California, the yellow-breasted chat breeds primarily in scattered locations in Owen's Valley and the Mojave, from the Salton Sea, and from the lower Colorado River Valley. This species	In this region, this species is associated with the Colorado River only. The Project site does not contain suitable habitat for this species. CNDDB (2010) records in the region are associated with the Salton Sea or the Colorado River. The

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	occupies shrubby riparian habitat with an open canopy, and will nest in non-native species including tamarisk. Threats to this species include loss of riparian habitat, and, it is suspected, pressure from cowbird parasitism.	closest CNDDB records for this species are two 1986 records east of the Project site at the Colorado River.
Mammals		
Arizona myotis *Myotis occultus*	This species has been found from southeastern California through Arizona, New Mexico, and south into Chihauhau, Mexico. Arizona myotis is most commonly known from conifer forests from 6,000 to 9,000 feet in elevation, although maternity roosts are known from much lower elevations including areas along the Colorado River in California.	This species is not expected to occur due to lack of coniferous forests and low elevation of the study area. The closest CNDDB (2010) record is a historical occurrence from 1945 east of the Project site near the town of Ripley.
Big-free tailed bat *Nyctinomops macrotis*	This species ranges from most of South America northward to include Mexico, Arizona, New Mexico, southern and western Texas, southern California, southeastern Nevada, southern Utah, and north and western Colorado from generally sea level to 8,000 feet in elevation. This species occurs in desert shrub, woodlands, and coniferous forests. It roosts mostly in the crevices of rocks although big free-tailed bats may roosts in buildings, caves, and tree cavities	This species has the potential to forage within the project area. The nearest occurrences for this species in Riverside County are from the vicinity of Palm Springs and Joshua Tree National Park (CNDDB 2010). There are no CNDDB occurrences within 10 miles of the site.
Burro *Equus asinus*	The burro is found mostly in Inyo and San Bernardino counties and in the vicinity of the Colorado River, its range extends into eastern Lassen County, extreme southern Mono County and south to the California/Mexico border. This species occurs in a variety of habitats near water. Such habitats include; sagebrush, bitterbrush, alkali desert scrub, desert scrub, desert succulent scrub, desert riparian, desert wash, Joshua tree, pinyon-juniper, montane chaparral, and pasture.	This species is not expected to occur within the Project area due to the lack of water resources.
California leaf-nosed bat *Macrotus californicus*	California leaf-nosed bat is a species of concern and a BLM Sensitive species indicating it is covered under the NECO plan. California leaf-nosed bats occur in the deserts of California, southern Nevada, Arizona and south to northwestern Mexico. In California, they are now found primarily in the mountain ranges bordering the Colorado River Basin. In California, the two largest roosts (each sheltering 1,500 bats during winter months) are in mines in	All habitats within the Project area are suitable for this species. There are several CNDDB records in the vicinity of the Project area. The nearest record is from 1993 near the McCoy Mountains in creosote bush scrub habitat where approximately 300 adults were observed roosting (CNDDB 2010).

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	extreme southeastern California. This species depends on either caves or mines for roosting habitat. All major maternity, mating, and overwintering sites are in mines or caves (CDD 2002). Radio-telemetry studies of Macrotus in the California desert show that the California leaf-nosed bat forages almost exclusively among desert wash vegetation within 10 km of their roost (WBWG 2005-2009).	
Cave myotis *Myotis velifer*	The cave myotis occurs from western Texas, to southern Nevada, southeastern California (only along the Colorado River), southward into Mexico, and is also widely distributed in Arizona. This species is found primarily at lower elevations (the Sonoran and Transition life zones) of the arid southwest in areas dominated by creosote bush, palo verde, and cactus. This species is a "cave dweller" and caves are the main roosts although this species may also use mines, buildings, and bridges for roosts.	This species has a potential to occur within the study area, more likely as a foraging species than a roosting bat species. The nearest CNDDB record for this species is approximately 3 miles east of the Project site, near the McCoy Mountains.
Colorado Valley woodrat *Neotoma albigula venusta*	Occurs from southern Nevada, southeastern California, northeastern Baja California, to western Arizona. Colorado Valley woodrats are found in a variety of habitats including low desert, pinyon-juniper woodlands, and desert-transition chaparral. Suitable habitat elements for this species include washes where organic debris gathers, areas of prickly pear cactus and mesquite, rocky areas, and crevices in boulders which are used for cover and nest sites.	This species is not expected to occur on the Project site given the lack of suitable habitat. The nearest CNDDB record is from 1934 near Blythe (CNDDB 2010).
Hoary bat *Lasiurus cinereus*	Hoary bat is the most widespread of North American bats and are highly associated with forested habitats in the west. Hoary bats roost are usually located at the edge of a clearing although more unusual roosting sites have been reported in caves, beneath rock ledges, woodpecker holes, squirrel nests, and building sides.	This species may occur in the area as a forager and may roost within the project area. The closest CNDDB (2010) record is a historical occurrence from the town of Neighbors during 1919.
Pallid bat *Antrozous pallidus*	The pallid bat is a California species of concern and a BLM Sensitive species indicating it is covered under the NECO plan. Pallid bats inhabit low elevation (less than 6,000 feet) rocky, arid deserts and canyonlands, shrub/steppe grasslands, but also occur in higher elevation coniferous forests, greater than 7,000 feet in elevation. This species is	This species has a potential to roost and forage within the Project area. The nearest CNDDB (2010) record is approximately 8 miles north of the Project site near the McCoy Mountains.

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	most abundant in xeric landscapes including the Great Basin, Sonoran, and Mojave deserts (WBWG 2005-2009). Pallid bats are known from Cuba, Mexico, and throughout the southwestern and western United States. Population trends are not well known, but there are indications of decline. Pallid bats roost alone, in small groups (2 to 20 bats), or gregariously (100s of individuals). Day and night roosts include crevices in rocky outcrops and cliffs, caves, mines, trees with exfoliating bark, and various human structures such as bridges, barns, porches, bat boxes, and human-occupied as well as vacant buildings (WBWG 2005-2009).	
Pocketed free-tailed bat *Nyctinomops femorosaccus*	Pocketed free-tailed bat is a California species of concern. This species occurs in western North America, from southern California, central Arizona, southern New Mexico, western Texas, south into Mexico and Baja, California (WBWG 2005-2009). Despite only a limited number of records, pocketed free-tailed bats are known to occur in the desert from March through August, when they then migrate out of the area. In California, they are found primarily in creosote bush and chaparral habitats in proximity to granite boulders, cliffs, or rocky canyons.	This species has a potential to roost and forage within the Project site based on what is understood of its habitat requirements and roosting habits. The nearest CNDDB record for this species is from 2002 near the I-15 bridge over the Colorado River in Blythe.
Spotted bat *Euderma maculatum*	This species is known from all the states west of and including Montana, Wyoming, Colorado, New Mexico and Texas. Although broadly distributed, this species is rarely common, but may occur locally from southern British Columbia, northern Arizona, Arizona/Utah border, and western Texas from below sea level to 8,100 feet above mean sea level. Spotted bats occur in arid, low desert habitats to high elevation conifer forests and prominent rock features appear to be a necessary feature for roosting.	This species has a potential to roost and forage within the Project site based on what is understood of its habitat requirements and roosting habits. The nearest CNDDB record is a historical occurrence from 1907 in the Colorado Desert near Mecca (CNDDB 2010).
Townsend's big-eared bat *Corynorhinus townsendii*	This species has been reported in a wide variety of habitat types ranging from sea level to approximately 9,000 feet above MSL. Habitat associations include coniferous forests, deserts, native prairies, riparian communities, active agricultural areas, and coastal habitat types.	This species has a potential to forage within the study area although roosting is unlikely to occur since cave and abandoned buildings do not occur within the study area. There are no CNDDB occurrences within 10 miles of the site.

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
	Foraging associations include edge habitats along streams, adjacent to and within a variety of wooded habitats.	
Western mastiff bat *Eumops perotis*	The subspecies that occurs in North America*, E. p. californicus*, ranges from central Mexico across the southwestern United States including parts of California, southern Nevada, Arizona, southern New Mexico and western Texas. Recent surveys have extended the previously known range to the north in both Arizona with several localities near the Utah border and California. It is found in a variety of habitats, from desert scrub to chaparral to oak woodland and into the ponderosa pine belt and high elevation meadows of mixed conifer forests. Surveys in northern Arizona have documented roosts at approximately 3,600 feet elevation and foraging bat species at 7,500 feet above MSL (WBWG 2005-2009).	The Project site does not support suitable roosting habitat for western mastiff bat but this species may utilize the study area for foraging. There are no CNDDB occurrences within 10 miles of the site
Yuma mountain lion *Puma concolor browni*	In the NECO planning area, mountain lions primarily inhabit the low mountains and extensive wash systems in and around Chuckwalla Bench, Chuckwalla Mountains, Chocolate Mountains, Picacho Mountains, Milpitas Wash, Vinagre Wash, and other washes in that area. Mountain lions typically occur in habitat areas with extensive, well-developed riparian or shrubby vegetation interspersed with irregular terrain, rocky outcrops, and community edges. Mountain lions are restricted to the southern Colorado Desert from Joshua Tree National Park south and east to the Colorado River. Burro deer, the primary prey item, are known to spend the hot summer and fall in riparian areas along the Colorado River and in dense microphyll woodlands near the Coachella Canal.	This species likely uses the Project site but no definitive sign for this species was observed during 2009 spring surveys.
Yuma myotis *Myotis yumanensis*	This species ranges across the western third of North America from British Columbia, Canada, to Baja California and southern Mexico. Yuma myotis is usually associated with permanent sources of water, typically rivers and streams, feeding primarily on aquatic emergent insects, but Yuma myotis also use tinajas in the arid west. It occurs in a variety of habitats including riparian, arid scrublands and deserts, and forests. The species roosts in bridges, buildings, cliff crevices, caves, mines, and trees.	This species has a potential to roost and forage within the Project site. The nearest CNDDB record is from 2002 near the Blythe bridge over the Colorado River where individual bats of this species were detected acoustically during April 2002 (CNDDB 2010).

Species	Habitat Requirements and Geographic Range	Potential to Occur or Presence On Site
Reptiles/Amphibians		
Desert rosy boa *Charina (Lichanura) trivirgata*	In California, desert rosy boas are found only in the southern part of the state south of Los Angeles, from the coast to the Mojave and Colorado deserts (Zeiner et al. 1990, updated 1997; BLM CDD 2002). It is uncommon throughout its range. Desert rosy boas are found in habitats with moderate to dense vegetation and rocky cover, such as desert canyons, washes, and mountains. They have been found under rocks, in boulder piles and along rock outcrops and vertical canyon walls. Their diet consists of small mammals and birds. Rosy boas are primarily nocturnal, but may be out in the evening or morning in the spring and may appear during the day. The greatest activity occurs in late spring to early or mid-summer. They hibernate in winter. Desert rosy boas are not listed, but are included in the NECO and the Project area is within the range of this species.	There are 4 CNDDB records of this species from Riverside County, the majority of which are reported from western Riverside County near Cabazon, Lake Matthews, Lake Elsinore, and Hemet areas from disturbed sage scrub habitats with rocky soils and outcroppings. This species was not observed during spring 2009 field surveys; however temperatures may have been too low and therefore not during an optimal time to identify this species in the field. The Project site does not contain the preferred substrate, and therefore the site is not expected to provide important habitat for this species.

C.2.4.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

CONSTRUCTION AND OPERATION - DIRECT IMPACTS, INDIRECT IMPACTS, AND MITIGATION

Direct impacts are those resulting from a project and occur at the same time and place. Indirect impacts are caused by a project, but can occur later in time or farther removed in distance while still reasonably foreseeable and related to the project. The potential impacts discussed in this analysis are those most likely to be associated with construction and operation of the Project.

Impact analyses typically characterize effects to plant communities as temporary or permanent, with a permanent impact referring to areas that are paved or otherwise precluded from restoration to a pre-project state. In the desert ecosystems the definition of permanent impacts needs to reflect the slow recovery rates of its plant communities. Natural recovery rates from disturbance in these systems depend on the nature and severity of the impact. For example, creosote bushes can resprout a full canopy within five years after damage from heavy vehicle traffic (Gibson et al. 2004), but more severe damage involving vegetation removal and soil disturbance can take from 50 to 300 years for partial recovery; complete ecosystem recovery may require over 3,000 years (Lovich and Bainbridge 1999). In this analysis, an impact is considered temporary only if there is evidence to indicate that pre-disturbance levels of biomass, cover, density, community structure, and soil characteristics could be achieved within five years.

Summary of Impacts

Biological Resources Table 5 summarizes the direct, indirect, and cumulative impacts to biological resources and includes the proposed conditions of certification that would mitigate these impacts. **Biological Resources Table 6** provides a summary of acreage impacts and recommended mitigation.

Biological Resources Table 5
Summary of Impacts and Mitigation

Biological Resource	Impact/Mitigation
Sonoran Creosote Bush Scrub & Associated Wildlife	**Direct Impacts**: Permanent loss of 1,786[a] acres; fragmentation of adjacent wildlife habitat and native plant communities **Indirect Impacts**: Disturbance (noise, lights, dust) to surrounding plant and animal communities; spread of non-native invasive weeds; changes in drainage patterns downslope of Project; erosion and sedimentation of disturbed soils. **Cumulative Impacts**: Contributes 0.7% to cumulative loss from future projects within the NECO planning area (**Table 17**). **Mitigation**: Off-site habitat acquisition and enhancement (**BIO-12**); implement impact avoidance and minimization measures (**BIO-8)** and weed control plan (**BIO-14**)
Waters of the State & Associated Sensitive Plant Communities	**Direct Impacts**: Loss of hydrological, geomorphic, and biological functions and values of 91[b] acres of State waters(73 acres permanent loss, 18 acres temporary loss) including 16[b] acres of microphyll woodland

Biological Resource	Impact/Mitigation
	Indirect Impacts: Permanent loss of hydrological connectivity downstream of the Project, including 21[c] acres unvegetated ephemeral wash; head-cutting on drainages upslope and erosion/sedimentation downslope; * **Cumulative Impacts**: Contributes 0.3% to cumulative loss from future projects within the NECO planning area (Table 10); contributes 4.6% to cumulative loss from future projects within the Ford watershed (**Table 11**). **Mitigation**: Acquisition and enhancement of 132 acres ephemeral desert washes (**Table 6**), implementation of avoidance and minimization measures to protect state waters (**BIO-22**); implement weed plan (**BIO-14**)
Desert Tortoise	**Direct Impacts**: Potential take of individuals during operation and construction; permanent loss of 1, 786[d] acres (including 23[d] acres of critical habitat) of desert tortoise habitat and fragmentation of surrounding habitat. **Indirect Impacts**: Increased risk of predation from ravens, coyotes, feral dogs; disturbance from increased noise and lighting; introduction and spread of weeds; increased road kill hazard. **Cumulative Impacts**: Contributes to cumulative loss of low to moderate value desert tortoise habitat (2.0% to 0.1 habitat value, 2.9% to 0.2 habitat value, 0.1% to 0.3 habitat value) from future projects in the NECO planning area (**Table 12**); **Mitigation**: Implement avoidance and minimization measures (**BIO-6** through **BIO-11**) and acquire 1,878 acres of desert tortoise habitat (**BIO-12**).
Mojave Fringe-Toed Lizard	**Direct impacts**: Mortality to individuals during construction and permanent loss of 66[a] acres of fringe-toed lizard habitat; increased road kill hazard from construction traffic; potential accidental direct impacts to adjacent preserved habitat during construction and operation. **Indirect impacts**: Disruption of sand transport corridor resulting in downwind impacts to 453[e] acres of sand dunes; introduction and spread of invasive plants; erosion and sedimentation of disturbed soils; fragmentation and degradation of remaining habitat; increased road kill hazard from construction and operations traffic; harm from accidental spraying/drift of herbicides and dust suppression chemicals. **Cumulative Impacts**: Contributes 0.2% to cumulative loss from future projects within the NECO planning area (**Table 10**); contributes 2.0% to cumulative loss from future projects within the range of the Chuckwalla Valley population (**Table 15**). **Mitigation**: Implement **BIO-20**, Mojave fringe-toed lizard compensation, and **BIO-8**, impact avoidance and minimization measures; **BIO-14** weed management plan.
Couch's Spadefoot Toad	**Direct Impacts:** loss of breeding and upland habitat, mortality of individuals; disturbance to breeding ponds, **Indirect Impacts:** reduced flow to breeding areas, increased flow to upland habitat, construction noise could trigger emergence when conditions are not favorable. **Cumulative Impacts**: Contributes 1.6% to cumulative loss of

Biological Resource	Impact/Mitigation
	habitat from future projects within the NECO planning area (**Table 15**). **Mitigation**: Conduct surveys and implement impact avoidance and minimization measures, avoidance and protection of breeding habitat **BIO-27**.
Western Burrowing Owl	**Direct Impacts**: Permanent loss of foraging habitat; potential loss of eggs and young; degradation and fragmentation of remaining adjacent habitat from edge effects; disturbance of nesting and foraging activities for nesting pairs near the plant site and linear facilities; **Indirect Impacts**: increased road kill hazard from operations traffic; potential collision with mirrors; increased predation from ravens; disturbance of nesting activities from operations. **Cumulative Impacts**: Contributes 0.5% to cumulative loss from future projects within the NECO planning area (**Table 15**). **Mitigation:** Implement burrowing owl impact avoidance and mitigation measures, including habitat acquisition if owls are displaced by the Project (**BIO 18**)
Golden Eagle	**Direct/Indirect Impact**: Loss of foraging habitat. **Cumulative Impacts**: Contributes 6.8% to cumulative loss of Sonoran creosote bush scrub and 2.4% to loss of dry desert wash woodland, and 29.2% to loss of sand dune foraging habitat from future projects within the NECO planning area within 10 miles of the Project. Contributes 0.7% to cumulative loss of Sonoran creosote bush scrub and 0.3% to loss of dry desert wash woodland, and 28% to loss of sand dune foraging habitat from future projects within 10 miles of the nearest mountains (**Table 16**). **Mitigation**: Off-site habitat acquisition and enhancement for desert tortoise would protect eagle foraging habitat (**BIO-12**); additional mitigation may be required pending USFWS guidance.
Special-Status Birds & Migratory Birds	**Direct Impacts**: Permanent loss of breeding and foraging habitat, including loss of 1, 786[a] acres of Sonoran creosote bush scrub and 16[b] acres of microphyll woodland; potential loss of eggs and young; disturbance of nesting and foraging activities for populations on and near the plant site and linear facilities; degradation and fragmentation of remaining adjacent habitat from edge effects. **Indirect Impacts**: increased road kill hazard from operations traffic and collision with mirrors; increased predation from ravens; disturbance from operations. **Cumulative Impacts**: Contributes 0.6% to cumulative loss of habitat from future projects within NECO planning area (**Table 15**, Le Conte's Thrasher). **Mitigation**: Implement impact avoidance and minimization measures (**BIO-8**); pre-construction nest surveys (**BIO-15**); avian protection plan (**BIO-16**) off-site habitat acquisition and enhancement (**BIO-12** and **BIO-22**)
Desert Kit Fox & American Badger	**Direct Impacts**: Permanent loss of 1,852 [a] acres of foraging and denning habitat; fragmentation and degradation of remaining habitat, loss of foraging grounds, crushing or

Biological Resource	Impact/Mitigation
	entombing of animals during construction; increased risk of road kill hazard from construction traffic. **Indirect Impacts**: Disturbance from increased noise and lighting; introduction and spread of weeds; increased risk of road kill from operations traffic. **Cumulative Impacts**: Contributes 0.5% to cumulative loss of habitat from future projects within the NECO planning area (**Table 15**). **Mitigation:** Implementation of impact avoidance and minimization measures (**BIO-8**), conduct pre-construction clearance surveys (**BIO-17**); off-site habitat acquisition and enhancement (**BIO-12** and **BIO-22**)
Nelson's bighorn sheep	**Direct Impacts:** None **Indirect Impacts:** harassment from elevated construction noise **Cumulative Impacts**: None **Mitigation:** Implementation of noise-related avoidance and minimization measures (**BIO-8**).
Bats	**Direct/Indirect/Cumulative Impacts**: Loss of foraging habitat. **Mitigation:** off-site habitat acquisition and enhancement (**BIO-12** and **BIO-22**)
Special Wildlife Management Areas	**Chuckwalla DWMA/Desert Tortoise Critical Habitat:** Impacts to 23[d] acres **ACEC**: None **WHMA:** Impacts to1,852[a] acres **Mitigation**: Mitigate loss of critical habitat with acquisition and preservation of suitable desert tortoise at a 5:1 ratio (**BIO-12**).
Special-status Plants • Ribbed cryptantha • Las Animas colubrina • Desert unicorn • Harwood's milk-vetch • Abram's spurge • Glandular Ditaxis • Lobed ground cherry • Flat-seeded spurge	**Direct Impacts:** Loss of desert unicorn (CNPS List 4.3) and two Harwood's milk-vetch (CNPS List 2.2) plants during site grading. **Indirect impacts:** Introduction and spread of invasive plants; erosion and sedimentation of disturbed soils; potential disruption of sand transport systems that maintain habitat below the Project; alteration of drainage patterns; herbicide drift; disruption of photosynthesis and other metabolic processes from dust **Cumulative Impacts:** Contributes 0.7% to cumulative loss of Harwood's milk-vetch habitat from future projects within the NECO Planning Area. Contributes cumulative loss of dune-, playa-, and wash habitat for other special-status species: 1.7% active dunes; 0.2% playa, and 1.1% riverwash (**Table 14, 18**). **Mitigation:** Implement weed management plan (**BIO-14**); Best Management Practices (**BIO-8**); special-status plant impact avoidance and minimization measures and potential habitat compensation (**BIO-19**), acquisition of sand dune habitat (**BIO-20**).
Groundwater-Dependent Plant Communities	**Direct:** None **Indirect/Cumulative:** Degradation of groundwater-dependent plant communities (e.g., mesquite bosque, bush seep-weed) from water table drawdown **Mitigation:** Conduct long-term monitoring of groundwater-dependent vegetation (**BIO-25**) and implement adaptive

Biological Resource	Impact/Mitigation
	management, if necessary (**BIO-26**).

Waters of the State: Impacts and Mitigation

Biological Resources Table 6 summarizes the direct and indirect impacts to waters of the state as a result of Project construction, and includes recommendations from Energy Commission staff and CDFG for compensatory mitigation ratios for these impacts.

Grading within the Project Disturbance Area and its ephemeral drainages would directly impact 91 acres of state jurisdictional waters, and for 73 of these acres would permanently eliminate their hydrological, biogeochemical, vegetation and wildlife functions. Eighteen acres of drainages would be temporarily impacted by construction of linear facilities and access roads associated with those facilities.

Desert washes downstream from the Project area, comprising approximately 21 acres of state waters, would also be indirectly impacted as a result of changes to upstream hydrology, with downstream vegetation in washes deprived of flows or receiving lower or higher volumes and velocities of water than current conditions at discharge points along the stormwater conveyance channel. Diversions could significantly alter the hydrology and wash-dependent vegetation of any features that may occur downstream of the Project area, an effect that is quite apparent below Interstate 10 (I-10) near the Corn Springs Exit. On the northern side of I-10 broad expanses of desert wash trees and shrubs have died in response to the construction of I-10 and the diversion of smaller channels into collector ditches on the southern side of I-10.

The Applicant has provided drainage plans that conceptually discuss how diffusers at the downstream end of the engineered channels would restore sheet flow downslope of the Project Disturbance Area. However, as discussed in the **Soil & Water,** the drainage report does not provide sufficient information to establish the post-Project flooding conditions or to determine the potential impacts to vegetation downstream. Other potential indirect effects of the changed proposed drainage plans are erosion and resulting root exposure leading to the eventual death of vegetation. Washes upstream of the Project area may also be impacted by head-cutting and erosion; however, bank stabilization measures are proposed for the intake portion of the channel that would minimize or avoid this potential effect. Staff assumes that all 21 acres of the ephemeral washes occurring downstream of the Project boundaries would be adversely affected by the proposed Project.

Staff considers direct impacts of the Project to 91 acres of state jurisdictional waters and indirect impacts to as many as 21 acres to be significant. The extensive ephemeral drainage network at the Project site currently provides many functions and values, including landscape hydrologic connections, stream energy dissipation during high-water flows that reduces erosion and improves water quality, water supply and water-quality filtering functions, surface and subsurface water storage, groundwater recharge, sediment transport, storage, and deposition aiding in floodplain maintenance and development, nutrient cycling, wildlife habitat and movement/migration; and support for vegetation communities that help stabilize stream banks and provide wildlife habitat. The Project would eliminate all of these functions and values on at least 73 acres of ephemeral washes, and would temporarily impact these functions on another 18 acres.

To replace the flood conveyance function and some of the biogeochemical functions of the impacted desert washes, the Applicant has proposed to replicate the existing flow patterns and volume with three channels that would be constructed adjacent to, through, or across the site. Channel design, in particular the proposed plans for restoring sheet flow to the terrain downslope of the Project boundaries, has yet to be finalized.

The engineered channels would not replace the biological resource values and functions of the Project's ephemeral washes. Staff and CDFG agree that off-site acquisition and enhancement of off-site state waters would mitigate Project impacts to waters. Staff and CDFG have proposed mitigation at a 1:1 ratio for unvegetated ephemeral drainages, and at a 3:1 mitigation ratio for microphyll woodlands, the higher ratio reflecting the high wildlife values and scarcity of this habitat type. Indirect impacts to state waters would be mitigated at half the ratio of direct impacts, as detailed in **Biological Resources Table 6**. The lesser mitigation ratio for indirect impacts to drainages downgradient of the Project site reflects staff's expectation that while the wash-dependent vegetation downslope of altered drainages would eventually be lost, that loss would be slow and gradual. Staff anticipates that the wash-dependent vegetation downstream of the Project deprived of flows would continue to provide habitat for years and possibly decades after the Project is constructed, although eventually it would die (if deprived of flows) or be indirectly affected by erosion and sedimentation along reaches below the stormwater channel discharge points.

Staff's proposed Condition of Certification **BIO-22** recommends off site acquisition of 132 acres of waters of the state within the Chuckwalla Valley watershed, with at least 48 acres of that consisting of microphyllous riparian vegetation. This condition also provides the specifics of avoidance and mitigation measures for impacts to ephemeral drainages within and downslope of the Project Disturbance Area. Implementation of Condition of Certification **BIO-22** would reduce Project impacts to state waters to less than significant levels, and would satisfy CDFG codes relating to protection of state waters.

Impacts to Sand Transport Corridor and Mojave Fringe-toed Lizard Habitat

The Project's western solar array is located on land surface units that are relatively geomorphically stable and are not within an active wind transport corridor. The eastern solar array, however, intrudes into the outer edges of two sand transport corridors that deliver sand to Mojave fringe-toed lizard habitat downwind. The Applicant estimates that the easternmost end of the Project's eastern solar array extends approximately 1000 feet (19 percent) of the width of the Palen-McCoy Valley Sand Transport Corridor (Worley Parsons 2010c). The southwestern corner of the eastern solar array also extends into the PDL-Chuckwalla Valley Sand Transport Corridor by approximately 1,600 feet at a point where the corridor is 24,000 feet wide, approximately 7 percent of the width of the corridor (Worley Parsons, 2010c). Staff agrees with the Applicant's estimates on the extent of the Project intrusion into the two sand transport corridors.

Staff has concluded that the Project intrusion within these two sand transport corridors would not result in a substantial reduction in sand transport capacity. However, the presence of the Project solar arrays would diminish the input of sand to downwind areas, with adverse effects to the active sand layer that is crucial to Mojave fringe-toed lizard habitat. Staff estimates that an area of 157 acres of vegetated sand dune habitat downwind of the intrusion within the PDL-Chuckwalla Valley Sand Transport Corridor would be adversely affected; the area affected downwind of the Palen-McCoy Valley Sand Transport Corridor would be 309 acres (see **Figure 17** in **Soil and Water Appendix A**). With a 13-acre overlap between these two "sand shadows", the Mojave

fringe-toed lizard habitat potentially affected by the project would total 453 acres. This downwind area would received reduced sand input because of interference from Project features, deflating downwind sand dunes and gradually diminishing their depth and extent over time as sand output exceeds sand input. Habitat suitability for Mojave fringe-toed lizards would be gradually degraded as wind-borne sand is depleted and not replaced within these downwind areas. Project impacts to Mojave fringe-toed lizard as a result of these indirect habitat impacts are discussed below in the subsection on Special-Status Species: Impacts and Mitigation.

The Project would also have an indirect impact on the creation and maintenance of sand transport as a result of rerouting of the ephemeral drainages in the Project area. More than a hundred ephemeral washes cross the site from north to south. The boundaries of these shallow channels are typically subtle, and the presence of these channels in areas of desert varnish and soil horizons suggests that these channels are relatively stable (i.e., do not cut and fill vertically) The channels in the western portion of the Project area do not appear to transport much sediment, as evidenced by their shallow depth and the absence of scour features (**Soil and Water Appendix A**). However, larger washes at the eastern side of the Project area have braided channels that show more evidence of active sediment transport, with better-defined banks and some sand in the channel bottom. Unlike the small washes that cross the western solar array site, the larger washes appear to supply a large amount of sand to the surrounding area. The Applicant has not provided a quantitative or qualitative assessment of the changes in fluvial sand transport as a result of re-routing the ephemeral drainages in the project area, but staff anticipates that Project would result in a reduction in the water-borne sand available for transportation to downwind sand dunes systems.

In contrast to the Project's eastern solar array, which is located at the outer edges of the sand transport corridors, the Project linear facilities would pass through the core of the Palen-McCoy Valley Sand Transport Corridor, where considerable sand transport occurs (Worley Parsons 2010c, Soil and Water Appendix A). Staff has concluded that the Project should be able to avoid or minimize impacts created by the linear facilities within this zone; most wind-borne transport of sand occurs within three feet of the ground, so the buried gas pipeline and at-grade access roads would be flush with the surrounding ground surface and would not create ground level obstructions. Transmission line supports should not pose a problem due to their small surface area at ground level.

Special-status Species: Impacts and Mitigation

Mojave Fringe-toed Lizard

The Genesis Project would directly impact 28 acres of stabilized/partially stabilized sand dune habitat and 38 acres of playa/sand drifts over playa (CEC 2010d). In addition to this direct and immediate loss of habitat, the project would indirectly affect 453 acres of Mojave fringe-toed lizard habitat downwind of the Project Disturbance Area(see **Soil & Water Appendix A**). As discussed above, the easternmost portion of the Project's eastern solar extends into the Palen-McCoy Valley Sand Transport Corridor, and the southwestern corner of the eastern solar array extends south into the PDL-Chuckwalla Valley Sand Transport Corridor (Worley Parsons, 2010c).

The Mojave fringe-toed lizard relies on vegetated sand dunes and a regular supply of fine wind-blown sand for its habitat. Active sand dunes (i.e., dunes that have an active layer of mobile sand) exist in a state of dynamic equilibrium, continuously losing sand downwind due to erosion and transport and gaining new supplies from upwind. If the upwind sand supply is cut off the dunes deflate, losing sand downwind and shrinking in size and depth. The finest sand (which is most easily transported) is lost first with coarser sand and gravel being left behind to form an armor or lag. This lag does not support Mojave fringe-toed lizard habitat.

As discussed above, the Project may also have an impact on sand transport and Mojave fringe-toed lizard habitat by eliminating the network of desert washes throughout the site and replacing them with engineered channels (**Soil & Water Appendix A**). Project construction on the alluvial fans and alteration of stream channels by channelization may reduce the amount of fluvial sediment reaching the depositional areas upwind of sand dunes and Mojave fringe-toed lizard habitat. Similar effects have been observed in the Coachella Valley, with adverse consequences for Coachella Valley fringe-toed lizard habitat (Griffiths et al. 2002). The extent of the Project impact to fluvial sand transport is unknown, but is expected to contribute at least incrementally to loss of Mojave fringe-toed lizard habitat.

Other potential indirect impacts of the Project to Mojave fringe-toed lizards include mortality from vehicle strikes; introduction and spread of invasive plants; erosion and sedimentation of disturbed soils; fragmentation and degradation of remaining habitat; increased road kill hazard from operations traffic; harm from accidental spraying or drift of herbicides and dust suppression chemicals; and an increase in access for avian predators (such as loggerhead shrikes) due to new perching structures.

As described in subsection C.2.8, Cumulative Impacts, future proposed projects would cumulatively cause losses over a substantial portion of Mojave fringe-toed lizard habitat. Approximately 16 percent of the Mojave fringe-toed lizard habitat in the NECO planning areas would be affected if all proposed projects were constructed (see subsection C.2.8, Cumulative Impacts). The Genesis Project’s contribution to the direct loss of habitat for the Chuckwalla Valley population of Mojave fringe-toed lizard is 2 percent. These effects are exacerbated when combined with the expected indirect effects to Mojave fringe-toed lizard habitat from interruption of aeolian sand transport; diversions of desert washes and interruption of fluvial transport of sand that contribute to the maintenance of habitat; and the continuing spread of non-native weedy species such as the Sahara mustard and Russian thistle in the Chuckwalla Valley.

The distribution of Mojave fringe-toed lizards is naturally fragmented because of its obligate habitat specificity to a patchy habitat type, and many local populations of this species are quite small, with small patches of sand supporting small populations of lizards. This fragmented pattern of distribution leaves the species vulnerable to local extirpations from additional habitat disturbance and fragmentation (Murphy et al. 2007). The Mojave fringe-toed lizard population in the Chuckwalla Valley, along with a very small population in Joshua Tree National Park's Pinto Basin, represents the southernmost distribution of this species (Barrows pers. comm.). This southern population may represent an important gene pool in light of the likely warming and drying that will occur in this region as a result of climate change; these southernmost

lizards that may already be adapted to hotter and drier conditions than those further north and could represent a source of genetic variation that could stave off extinction of this species in selected refugia (Barrows pers. comm.).

Staff considers the direct, indirect, and cumulative direct of the Project to be significant for the Chuckwalla Valley Mojave fringe-toed lizard population. The cumulative impact of all the proposed projects would be to increase the already fragmented distribution of the Mojave fringe-toed lizards, and to increase the risk of extirpation of isolated populations within the Chuckwalla Valley. Staff's proposed Condition of Certification **BIO-20** recommends acquisition and protection of core populations of Mojave fringe-toed lizard habitat elsewhere in the Chuckwalla Valley. Staff has concluded that the habitat acquisition and protection proposed in Condition of Certification **BIO-20** would, if implemented, reduce Project impacts to Mojave fringe-toed lizards to less than significant levels.

Desert Tortoise

Direct Impacts

During construction of the Genesis Project desert tortoises may be harmed during clearing, grading, and trenching activities or may become entrapped within open trenches and pipes. Construction activities could also result in direct mortality, injury, or harassment of individuals as a result of encounters with vehicles or heavy equipment. Other direct effects could include individual tortoises being crushed or entombed in their burrows, collection or vandalism, disruption of tortoise behavior during construction or operation of facilities, disturbance by noise or vibrations from the heavy equipment, and injury or mortality from encounters with worker's or visitor's pets. Desert tortoises may also be attracted to the construction area by application of water to control dust, placing them at higher risk of injury or mortality. Increased human activity and vehicle travel would occur from the construction and improvement of access roads, which could disturb, injure, or kill individual tortoises. Also, tortoises may seek shade by taking shelter under parked vehicles and be killed, injured, or harassed when the vehicle is moved.

The Applicant has recommended impact avoidance and minimization measures to reduce these direct impacts to desert tortoise, including installation of exclusion fencing to keep desert tortoise out of construction areas, relocating/translocating the resident desert tortoise from the Genesis Project site, reducing construction traffic and speed limits to reduce the incidence of road kills and worker environmental awareness training programs.

Staff has incorporated these recommendations into conditions of certification. These include staff's proposed Conditions of Certification **BIO-1** through **BIO-5,** which requires qualified biologists, with authority to implement mitigation measures necessary to prevent impacts to biological resources, be on site during all construction activities. Staff's proposed Condition of Certification **BIO-6** requires the development and implementation of a Worker Environmental Awareness Program to train all workers to avoid impacts to sensitive species and their habitats. Staff's proposed Condition of Certification **BIO-7** requires the project owner to prepare and implement a Biological Resources Mitigation Implementation and Monitoring Plan that incorporates the

mitigation and compliance measures required by local, state, and federal LORS regarding biological resources. Staff's proposed Condition of Certification **BIO-8** describes Best Management Practices requirements and other impact avoidance and minimization measures.

Staff's proposed Conditions of Certification **BIO-9** through –**BIO**-**11** are specific to desert tortoise; proposed Condition of Certification **BIO-9** would require installation of security and desert tortoise exclusionary fencing around the entire Project Disturbance Area (including access roads), and **BIO-10** recommends the development and implementation of a desert tortoise translocation plan to move the tortoises currently living in the Project Disturbance Area to identified translocation sites. Staff's proposed **BIO-11** requires verification that all desert tortoise impact avoidance, minimization, and compensation measures have been implemented.

Implementation of staff's proposed Conditions of Certification **BIO-9** and **BIO-10** have inherent risks and could themselves result in direct effects such as mortality, injury, or harassment of desert tortoises due to equipment operation, fence installation activities, removal of tortoise burrows, and tortoise translocation. These impacts are described in more detail below.

Impacts to Critical Habitat

The Project area overlaps with a portion of the 1,020,600-acre Chuckwalla Desert Tortoise Critical Habitat Unit. Critical habitat is defined as the specific areas supporting those physical and biological features that are essential for the conservation of the species and that may require special management considerations or protection (USFWS 2008a). The Project transmission line (2.8 miles), gas line (1 mile) and access road (1.8 miles) would intersect the edge of designated desert tortoise critical habitat (TTEC 2009c). Approximately 23 acres of critical habitat would be directly impacted by construction of these facilities (TTEC 2009c). The Applicant proposed compensation at a 5:1 ratio for all impacts in critical habitat and/or Desert Wildlife Management Areas. Staff concurs with this recommendation, as described in proposed Condition of Certification **BIO-12**.

Impacts of Relocation/Translocation

Capturing, handling, and relocating desert tortoises from the proposed site after the installation of exclusion fencing could result in harassment and possibly death or injury. Tortoises may die or become injured by capture and relocation if these methods are performed improperly, particularly during extreme temperatures, or if they void their bladders. Averill-Murray (2001) determined that tortoises that voided their bladders during handling had significantly lower overall survival rates (0.81-0.88) than those that did not void (0.96). If multiple desert tortoises are handled by biologists without the use of appropriate protective measures, pathogens may be spread among the tortoises, both resident and translocated animals. For those tortoise near but not within the Project Disturbance Area, removal of habitat within a tortoise's home range or segregating individuals from their home range with a fence would likely result in displacement stress that could result in loss of health, exposure, increased risk of predation, increased intraspecific competition, and death. Tortoises moved outside their home ranges would likely attempt to return to the area from which they were moved,

therefore making it difficult to isolate them from the potential adverse effects associated with Project construction.

The risks and uncertainties of translocation to desert tortoise are well recognized in the desert tortoise scientific community. The Desert Tortoise Recovery Office (DTRO) Science Advisory Committee (SAC) has made the following observation regarding desert tortoise translocations (DTRO 2009, p. 2):

> "*As such, consensus (if not unanimity) exists among the SAC and other meeting participants that translocation is fraught with long-term uncertainties, notwithstanding recent research showing short-term successes, and should not be considered lightly as a management option. When considered, translocation should be part of a strategic population augmentation program, targeted toward depleted populations in areas containing "good" habitat. The SAC recognizes that quantitative measures of habitat quality relative to desert tortoise demographics or population status currently do not exist, and a specific measure of "depleted" (e.g., ratio of dead to live tortoises in surveys of the potential translocation area) was not identified. Augmentations may also be useful to increase less depleted populations if the goal is to obtain a better demographic structure for long-term population persistence. Therefore, any translocations should be accompanied by specific monitoring or research to study the effectiveness or success of the translocation relative to changes in land use, management, or environmental condition.*"

The Applicant has prepared a draft Desert Tortoise Relocation/Translocation Plan as part of the Incidental Take Permit application (TTEC 2010a) which includes measures to avoid and minimize adverse impacts to resident and translocated desert tortoise. This plan would be reviewed and approved by CDFG, USFWS, BLM and Energy Commission staff, and would be implemented to move any tortoises detected during clearance surveys. The Desert Tortoise Relocation/Translocation Plan includes an analysis to determine whether relocation or translocation is an appropriate action; the identification and prioritization of potentially suitable locations for translocation; desert tortoise handling and transport considerations (including temperature); animal health considerations; a description of translocation scheduling, site preparation, and management; and specification of monitoring and reporting activities for evaluating success of translocation. With implementation of staff's proposed Condition of Certification **BIO-10**, adverse impacts associated with desert tortoise relocation/translocation would be minimized.

Mitigation for Desert Tortoise Habitat Loss

A significant impact of the Genesis Project is loss of approximately 1,786 acres of desert tortoise habitat, including 23 acres of critical habitat. Fragmentation and disturbance to adjacent desert tortoise habitat contributes to the significance of this impact. Desert tortoise are known to use lower-quality intermountain habitat, such as that present across most of the Project area, as dispersal routes over time, providing connectivity between higher-quality habitat areas (Averill-Murray and Averill-Murray 2005).

In consultation with USFWS and CDFG, staff has concluded that habitat compensation at a 1:1 ratio through land acquisitions or an assessed financial contribution based on

the final construction footprint would mitigate for desert tortoise habitat loss within the Project Disturbance Area. This mitigation is consistent with measures in Incidental Take Permits issued by CDFG for projects in the region, and with requirements described in the NECO (BLMCCD 2002). The NECO specifies the following desert tortoise compensation requirements (from page D-2, Appendix D, BLM-CCD 2002):

> "*A mitigation fee based on the amount of acreage disturbed shall be required of proponents of new development. Within Desert Wildlife Management Areas (DWMAs) (Category I) the lands delivered or equivalent fee shall be an amount that achieves a ratio of 5 acres of compensation land for every 1 acre disturbed. Outside DWMAs (Category III) the lands delivered or equivalent fee shall be an amount that achieves a ratio of one 1 acre of compensation land for every 1 acre disturbed. Funds may be expended as approved by the Management Oversight Group in 1991. Lands will be acquired or enhanced within the same recovery unit as the disturbance. CDFG may require additional fees for management of lands and for rehabilitation of lands.*"

In its Incidental Take Permit application (TTEC 2009c) the Applicant described the desert tortoise habitat within the Project Disturbance Area as marginal, and did not recommend mitigation for any desert tortoise habitat loss. Instead the Applicant proposed acquisition of off-site habitat to compensate for possible incidental take of six desert tortoises over the course of construction and operation, as well as compensatory mitigation of impacts to portions of the Desert Wildlife Management Area and critical habitat.

Staff, CDFG, and USFWS agree that the Project Disturbance Area does not include any high quality desert tortoise habitat, but all of it is suitable for desert tortoise and all could potentially be occupied by this species. The Project would eliminate desert tortoise habitat, fragment adjacent habitat and adversely affect connectivity for desert tortoise and other wildlife. Staff recommends a mitigation ratio of 1:1 for loss of 1,763 acres of Sonoran creosote bush scrub within the Project Disturbance Area, and a 5:1 ratio for the 23 acres within critical habitat.

Integrating State and Federal Desert Tortoise Mitigation

Staff from BLM, Energy Commission, USFWS, and CDFG agrees that compensatory mitigation at a 1:1 ratio is appropriate for Project impacts to desert tortoise habitat. However, some differences remain between the federal and state approach to desert tortoise mitigation that currently preclude a complete integration of desert tortoise mitigation requirements. One difference is the state requirement for permanent protection of acquired mitigation lands. Energy Commission staff and CDFG require that mitigation lands acquired for endangered species be maintained and protected in-perpetuity for the benefit of those species. The BLM cannot always make the same commitment to protecting acquired mitigation lands because their multiple use mandate restricts their ability to designate lands solely for conservation purposes and to exclude potentially incompatible development and activities.

The Renewable Energy Action Team (REAT) Agencies (BLM, CDFG, USFWS, and the Energy Commission) are currently developing an interagency agreement that would address the in-perpetuity protection requirement on BLM lands so that state and federal

mitigation requirements could be integrated (Fesnock pers. comm., Flint pers. comm.). The REAT Agencies also note that protection could be achieved by buying private in-holdings within BLM's Desert Wildlife Management Areas (DWMAs) so that the surrounding protective land management would prevail and meet the requirement for in-perpetuity protection. If other mitigation lands were acquired that were not within such protected areas, the REAT Agencies have proposed mechanisms such as deed restrictions, conservation easements, or right-of-way exclusion areas that would provide permanent protection for acquired mitigation lands under BLM management. Staff anticipates that a mechanism for in-perpetuity protection of BLM mitigation lands will be established before the end of 2010 (Fesnock pers. comm., Flint pers. comm.).

The BLM has also indicated that for any land enhancement actions or recovery actions implemented on existing BLM-owned lands, BLM would develop a Memorandum of Understanding (MOU) with CDFG containing provisions for notification of any proposed Projects affecting those lands (BLM 2009a). The BLM agreed that future Projects authorized on these mitigation lands that might degrade or diminish the desert tortoise recovery value would be compensated at a higher rate (BLM 2009a).

Calculation of Security for Desert Tortoise Compensatory Mitigation

To satisfy section 2081 of the California Endangered Species Act an applicant must provide financial assurances to guarantee that an adequate level of funding is available to implement all impact avoidance, minimization, and compensation measures. These financial assurances are generally provided in the form of an irrevocable letter of credit, a pledged savings account, or another form of security prior to initiating ground-disturbing Project activities. Staff's proposed conditions of certification typically specify the dollar amount of the security, and include a provision for adjusting that security amount when parcel-specific information is available. This security amount is calculated by multiplying the acreage of the impact area by the total per acre costs, a figure which represents the sum of the costs required for: (1) land acquisition, (2) initial habitat improvements, and (3) an endowment to support long-term management of the acquired lands.

The latter cost for the long-term management endowment is typically the largest component of the mitigation fee. Interest from the endowment creates a funding source that provides enough income to cover annual stewardship costs on the acquired lands and includes a buffer to offset inflation. The amount for the endowment is established by a Property Analysis Record (PAR), a computerized database methodology developed by the Center for Natural Lands Management (<www.cnlm.org/cms>) which calculates the costs of land management activities for a particular parcel. These activities include development of a desert tortoise management plan tailored for each parcel of mitigation land to assess habitat status, identify desired conditions, and develop plans to achieve conditions that would best support desert tortoise. Once the management plan is developed and approved by the appropriate resource agencies, implementation of enhancement actions such as fencing, road closure, weed control, habitat restoration as well as monitoring can begin. The goal of these activities is to increase the carrying capacity of the acquired lands for desert tortoise and increase their population numbers by enhancing survivorship and reproduction.

Funding for the initial habitat improvements supports those actions needed immediately upon acquisition of the property to secure it and remove hazards. These activities might include fencing or debris clean-up, or other urgent remedial action identified prior to when the parcels were acquired. When the management plan is completed for the acquired parcel activities like these are thereafter funded from the interest produced by the long-term management endowment described above.

Staff's proposed Condition of Certification **BIO-12** specifies acquisition of 1,878 acres and provides an estimate of associated costs. These costs include acquisition fees of $500 per acre, a figure that reflects recent land sale in the Chuckwalla Bench area (Nicol pers. comm.). Initial habitat improvement costs (for example, fencing, debris removal) are estimated at $330 per acre, and long-term management endowment is estimated at $1,450 per acre based on a Property Analysis Record prepared for land in the Chuckwalla area (Nicol pers. comm.) The estimated composite mitigation cost to meet staff's recommendation for establishing the security would be $2,280 per acre. This security amount may change when a Property Analysis Record is prepared for the parcels that have been selected for acquisition. It is important to note that these are estimates based on current costs; the requirement is defined in terms of acres, not dollars per acre, and actual costs may vary.

In contrast to the state mitigation approach, the BLM does not require an endowment fee or other funding to manage the acquired desert tortoise mitigation lands because they pursue recovery goals through implementation of region-wide management plans and land use planning as described in the NECO and the Desert Tortoise Recovery Plan rather than through parcel by parcel acquisitions and management. The BLM typically requires a cash payment (proffer) prior to initiating ground-disturbing activities, which generally includes a per acre cost reflecting current land value and recent purchase prices, as well as additional acquisition and indirect costs and funding for appraisals, environmental site assessments, property cleanup, and an inflation contingency. However, as noted by the REAT agencies, other methods may be employed which would satisfy both BLM and the state agency legal requirements.

Indirect Impacts

Ravens and Other Predators

Construction and operations activities associated with the Genesis Project could provide food or other attractants in the form of trash, road-killed animals, and water, which would draw unnaturally high numbers of desert tortoise predators such as the common raven, kit fox, and coyote to the Project area. Project structures would also provide new nesting and perching sites for ravens such as new transmission line towers and perimeter fencing. Development of new elevated perching sites as a result of Project construction could increase raven numbers locally, including the probability that young ravens remain in the area after maturing, which, in turn, could result in increased predation on desert tortoise in the vicinity of the Project Disturbance Area.

Common raven populations in some areas of the Mojave Desert have increased 1,500 percent from 1968 to 1988 in response to expanding human use of the desert (Boarman 2002). Since ravens were scarce in this area prior to 1940, the current level of raven predation on juvenile desert tortoises is considered to be an unnatural occurrence (BLM

1990, USFWS 2008a) and one of many anthropogenic contributors to desert tortoise population declines.

In addition to ravens, feral dogs have emerged as major predators of the tortoise. Dogs may range several miles into the desert and have been found digging up and killing desert tortoises (USFWS 1994; Evans 2001). Dogs brought to the Project site with visitors may harass, injure, or kill desert tortoises, particularly if allowed off leash to roam freely in occupied desert tortoise habitat. The worker environmental awareness training (**BIO-6**) and restrictions on pets being brought to the site required of all personnel (**BIO-8**) would reduce or eliminate the potential for these impacts.

Construction and operation of the Genesis Project would increase raven and coyote presence in the Project area. Ravens capitalize on human encroachment and expand into areas where they were previously absent or in low abundance. Ravens habituate to human activities and are subsidized by the food and water, as well as roosting and nesting resources that are introduced or augmented by human encroachment. Road kill along I-10 provides an additional attractant and subsidy for opportunistic predators/scavengers such as ravens. Road kills would mount with increased Genesis Project construction and operations traffic, further exacerbating the raven/predator attractions and increasing desert tortoise predation levels. Staff's proposed Condition of Certification **BIO-8** provides measures to minimize the number of road-kill that might attract desert tortoise predators.

Regional Approach to Raven Control

The USFWS is developing a comprehensive, regional raven management and monitoring program in the California Desert Conservation Area to address the regional, significant threat that increased numbers of common ravens pose to desert tortoise recovery efforts, The regional raven program will implement recommendations in the USFWS E*nvironmental Assessment to Implement a Desert Tortoise Recovery Plan Task: Reduce Common Raven Predation on the Desert Tortoise* (USFWS 2008). Project applicants would contribute to this region-wide program with a fee that reflects the anticipated level of adverse impacts from their project on desert tortoise populations from predation by ravens (Engelhard pers. comm.). The USFWS has not yet finalized the specific components of the raven management and monitoring program, but anticipate establishing a fee based on a cost-per-acre for the project footprint, to be assessed each year for the life of the project (Engelhard pers. comm.).

The draft Common Raven Monitoring, Management and Control Plan (TTEC 2010k) includes methods and best management practices to avoid and minimize raven attractants and subsidies on the project site, and these methods and practices have been incorporated into staff's proposed Condition of Certification **BIO-13**. Implementation measures in **BIO-13** would avoid or minimize the contributions of the Project to increased desert tortoise predation from ravens to less than significant levels. Staff also recommends that the Applicant integrate the agreement for payment of the USFWS fee into their draft Common Raven Monitoring, Management and Control Plan. The USFWS will be coordinating with the Applicant to develop the specific components of the fee for raven control (Engelhard pers. comm.).

Increased Risk from Roads/Traffic

Vehicle traffic would increase as a result of construction and improvement of access roads, increasing the risk of injuring or killing desert tortoise. The potential for increased traffic-related tortoise mortality is greatest along paved roads where vehicle frequency and speed is greatest though tortoises on dirt roads may also be affected depending on vehicle frequency and speed. Census data indicate that desert tortoise numbers decline as vehicle use increases and that tortoise sign increases with increased distance from roads (Nicholson 1978; Hoff and Marlow 2002). Additional unauthorized impacts that may occur from casual use of the access roads in the Project area include unauthorized trail creation.

To minimize the risks of increased traffic fatality and other hazards associated with roads at the Genesis Project site, the Applicant has proposed a variety of minimization measures which staff has incorporated into staff's proposed Condition of Certification **BIO-8**. These measures include confining vehicular traffic to and from the Project site to existing routes of travel, prohibiting cross country vehicle and equipment use outside designated work areas, and imposing a speed limit of 25 miles per hour.

Other Indirect Impacts

Indirect impacts to desert tortoise could result from construction-related introduction of invasive plants that out compete native plants, or from increased incidence of accidental wildfires (potentially caused by construction or downed new transmission wires, but the potential for this is low due to the relatively small length of transmission lines proposed as part of the Project), both of which could reduce adjacent habitat quality for desert tortoise. Potential deposition of sediment loads as a result of construction-related sediment mobilization during heavy rain events and flooding downstream would impact existing desert tortoise burrows outside of the Project Disturbance Area.

Conclusion – Impacts and Mitigation for Desert Tortoise

Staff's proposed Conditions of Certification **BIO-6** through –**BIO**-**11** describe measures that would avoid and minimize direct impacts to desert tortoise and other sensitive biological resources, and staff has concluded that implementation of these measures would reduce potential direct impacts to less than significant levels. To address the loss of 1,786 acres of desert tortoise habitat, including impacts to 23 acres of critical habitat, and associated fragmentation and loss of connectivity, staff's proposed Condition of Certification **BIO-12** requires acquisition and enhancement of 1,878 acres of desert tortoise habitat within the Colorado Desert Recovery Unit. Staff recommends a 5:1 compensatory mitigation ratio for impacts to desert tortoise critical habitat, and 1:1 for the 1,763 acres of Sonoran creosote bush scrub within the Project Disturbance Area. The compensatory mitigation acquisitions must be in areas that have potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise populations. Staff has concluded that these mitigation measures would reduce impacts to desert tortoise to less than significant levels.

Couch's Spadefoot Toad

Couch's spadefoot toads were recorded breeding in a pond south of I-10 near Wiley Well Road (Dimmitt 1977) that apparently overlaps with the Project's proposed

transmission line corridor; in the absence of survey information indicating otherwise, staff considers this species to be extant at this location. Couch's spadefoot toads require aquatic habitat for breeding and upland habitat for burrowing. This species does not breed every year, and therefore potential breeding habitat does not necessarily need to sustain surface water for an extended period of time (minimum approximately 9 days) every year. Burrowing habitat is considered any area with friable soil within the adult or juvenile dispersal distance for this species. This dispersal distance is largely unknown, though there is one record from Mayhew (1965) of a juvenile 0.25 miles from the closest breeding pond. Therefore, in the absence of more conclusive information, upland Couch's spadefoot toad habitat is considered to be all areas with friable soils within 0.25 miles of a potential breeding pond and other observations place them at least one mile from ponds (Dimmitt, pers. comm.). While little is known about the location and proximity of subterranean refuge sites, there is some indication that they are widely distributed and that breeding pond habitat is the limiting factor in their distribution (Dimmitt, pers. comm.).

Impacts to Couch's spadefoot toads could include loss of breeding habitat and direct mortality during grading or construction. Disturbance to breeding ponds, including new ponds incidentally created during construction activities, could also impact this species. In addition, construction, maintenance, and operation traffic could result in direct mortality on Project area roads. Indirect impacts could result from hydrology changes that reduce flow to breeding areas. In addition, construction noise could trigger emergence when conditions are not favorable. As discussed above, the Project transmission line corridor overlaps a recorded breeding site. While the exact location of the breeding pond is unknown, a review of aerial photos and a site visit identified a pond southwest of the intersection of Wiley Well Road and I-10 the area mapped in Dimmitt (1977). In addition, staff has reviewed aerial photos of the linear route and solar facility site north of I-10. Staff agrees with the Applicant that it is unlikely the solar facility site supports breeding pond habitat thought it may provide habitat for subterranean burrows if there is a breeding pond within dispersal distance. Staff has identified areas along the linear route, however, that need further study to determine whether these areas are capable of sustaining surface water and therefore provide breeding habitat.

Without species-specific survey results and with limited occurrence information, it is difficult to assess the potential for direct and indirect impacts to Couch's spadefoot toads. However, based on a known occurrence in the Project area, and surface water visible in Project aerials and verified in the field, staff concludes that the pond southwest of Wiley Well Road and I-10 is breeding habitat for Couch's spadefoot toad. Further, based on a review of aerial photography staff believes that additional breeding habitat for this species may occur north of I-10 along the proposed linear facility route.

The Genesis Project is located at the western border of the Couch's spadefoot toad range. Staff considers the impacts to one of the few known breeding ponds for this species at the western boundary of its range to be a significant impact. Staff's proposed Condition of Certification **BIO-27** requires development and implementation of a Couch's Spadefoot Toad Protection and Mitigation Plan, which requires avoiding impacts to all spadefoot toad breeding habitat along the Project linear corridors, or requires construction of replacement habitat if impacts are unavoidable. In order to complete this plan, habitat surveys in 2010 would be required to identify potential

spadefoot toad breeding habitat along the linear alignment. Staff will work with the Applicant to develop the appropriate survey methods and gain appropriate approvals prior to survey initiation from agency staff. Elements to consider in developing the survey methods would include a discussion of available food sources, identifying potential breeding pond characteristics, and an appropriate buffer to protect these potential breeding sites.

Staff anticipates that construction activities could avoid the known breeding pond south of I-10 near Wiley Well Road. The Protection and Mitigation Plan would provide detailed guidance to implement the protection of the I-10 pond during Project construction and operation, and would extend that protection to any other ponds detected during habitat surveys conducted north of I-10 along the linear corridor. Staff's proposed Condition of Certification **BIO-27** also requires that the new breeding pond habitat be created if ponds are impacted during construction. The avoidance, minimization and compensatory mitigation described in **BIO-27** would reduce Project impacts to Couch's spadefoot toad to less than significant levels.

Western Burrowing Owl

The 2009 biological field surveys indicated two burrowing owls were present within the Study area and burrowing owl sign (burrows, whitewash, feathers, and pellets) was observed at several locations throughout the Study area (GSEP 2009a, Appendix C). However, the 2009 surveys did not reveal the presence of burrowing owls or active burrows within in the Project Disturbance Area. Since owls and owl sign were found just outside of the Project Disturbance Area, staff has concluded that there is some potential for burrowing owls to move into Project site to nest, and therefore could be directly impacted. In addition, burrowing owls near but not within construction areas could be impacted during construction activities. The potential for direct impacts to burrowing owl includes the loss of nest sites, eggs, and/or young (unless the birds are evicted prior to construction); permanent loss of breeding and foraging habitat; and disturbance of nesting and foraging activities for burrowing owl pairs within the Project site, buffer, or immediately surrounding area. Indirect impacts to burrowing owls during construction and operation can include increased road kill hazards, modifications to foraging and breeding activities, and loss of prey items and food sources due to a decreased number of fossorial mammals.

If burrowing owls were detected nesting within the Project Disturbance Area, they would need to be relocated prior to the nesting season to avoid direct impacts. There is much debate among state, federal, local, and private entities over the most practicable and successful relocation/translocation methods for burrowing owl. When passive relocation is used solely as an impact avoidance measure, it is generally only effective when burrowing owl nesting territories are directly adjacent to permanently protected lands (i.e. military reservation, airport, wildlife reserve, agricultural reserve with appropriate crop type such as alfalfa) (Bloom 2003). Passive relocation has been criticized as a relocation method because relocated or displaced owls are tenacious about returning to their familiar burrows and are inclined to move back to the impact site if the impact site is still visible to the owl and/or if the impact site is not completely graded (Bloom pers. comm.). Burrowing owls are put at increased risk when they are introduced to a new environment. The owls are naturally preyed upon by numerous diurnal and nocturnal

avian and mammalian species and evicting owls from their familiar burrow, territory, and home range without a safe opportunity to become familiar with their new habitat increases the potential for predation (Pagel pers. com.). Thus, many burrowing owls likely die during passive relocations used for permanent owl eviction.

For successful active or passive relocation, breaking the owl's site fidelity is of utmost importance (Bloom 2003). The off-site location for the relocated owls should ideally have an existing burrowing owl colony and a large ground squirrel colony. Should

neither colony already exist at the translocation site, artificial burrows should be installed if significant grassland or appropriate agricultural crop type is present (Bloom 2003). Active translocation of owls involves trapping owls, temporarily holding them in enclosures with supplemental feeding, and releasing at a suitable off-site location with existing or artificial burrows prior to breeding.

While active translocation might be a better solution than passive relocation for moving owls from large sites like the Genesis Project site, California Fish and Game Code 3503.3 prohibits the active relocation of burrowing owls unless the effort is designed as a research project. Staff therefore recommends implementation of passive relocation if burrowing owls are detected within the Project Disturbance Area and need to be relocated to avoid direct impacts. Staff requests that the applicant coordinate with CDFG on the approval of the color-banding of any burrowing owls to be passively relocated (in accordance with the guidance provided by USGS bird banding lab (http://www.pwrc.usgs.gov/bbl) in order to document the success of the burrowing owl relocation and monitoring program. Staff would also support a cooperative research effort with the Applicant, CDFG and USFWS to develop a research protocol to assess the efficacy of an active translocation program., The California Burrowing Owl Consortium (CBOC 1993) guidelines state that offsite suitable habitat for use by burrowing owl must be acquired at one of the following ratios:

- Replacement of occupied habitat with occupied habitat at 9.75 acres (6.5 acres times 1.5 acres) per pair or single bird;
- Replacement of occupied habitat with habitat contiguous to currently occupied habitat at 13.0 (6.5 acres times 2) acres per single pair or single bird, or;
- Replacement of occupied habitat with suitable unoccupied habitat at 19.5 (6.5 acres times 3) acres per pair or single bird.

The USFWS notes that the above guidelines were developed for owls nesting in coastal habitats, and their efficacy in desert environments has not been ascertained (Sorenson pers. comm.). No documentation is available to statistically evaluate the success of passive relocation in southern California. Passive relocations in Western Riverside County have not involved banded birds, so information on rates of success and direct/indirect mortality are not available. Reports elsewhere (Trulio 1995; 1997) do not provide long term analyses associated with passive relocation efforts to determine if passively relocated burrowing owls are present in the area after one or more years. The lack of documented success of passive translocations raises concerns regarding the fate of evicted owls.

Acquisition of the appropriate amount of offsite habitat for burrowing owl should take into consideration the number of owls being displaced as a result of the Project, the amount of foraging habitat being impacted by the Project, and the average home ranges and foraging distances of breeding and non-breeding owls. Diurnal home range for owls can be 150 feet on both sides of burrow. Nocturnal home range is much larger, 1 square mile per owl pair, and several owls can overlap in that 1 square mile (Bloom pers. comm.). The mean home range for 11 male burrowing owls in 1998 and 22 males in 1999 was 177 ha (437 acres) and 189 hectares (467 acres), respectively, at naval Air Station in Lemoore, California which is located south of Fresno (Bloom 2003). Male burrowing owls often move greater than 1,000 meters when foraging in the breeding season and home ranges can often times overlap (Bloom 2003).

Staff has concluded that while no burrowing owls were detected in the Project Disturbance Area during the 2009 surveys, they could be found there when construction occurs because they have been recorded nearby. Staff has proposed Condition of Certification **BIO-18** (Burrowing Owl Impact Avoidance and Minimization Measures) which requires a pre-construction survey to determine the current number of owls occupying the Project Disturbance Area and surrounding buffer area. **BIO-18** recommends avoidance and minimization measures to protect owls nesting near but not within the Project Disturbance Area. In addition, staff has conservatively assumed that one burrowing owl pair might occur within the Project, and has required acquisition of up to 39 acres of compensatory mitigation to offset the loss of habitat if pre-construction surveys indicate that owls are using the Project site for breeding. If no burrowing owls are detected nesting within the Project Disturbance Area during pre-construction surveys, then the recommendation for acquisition of 39 acres of burrowing owl habitat would not apply. With implementation of **BIO-18,** direct and indirect impacts to burrowing owls resulting from construction of the Project would be mitigated to less than significant levels through pre-construction surveys and acquisition of compensatory habitat if it is determined that owls will be displaced as a result of construction following surveys.

Golden Eagle

Golden eagles are often sensitive to human activity (Anderson et al. 1990; USFWS 2009b), and studies reviewed in a report commissioned by the Scottish Natural Heritage (Whitfield et al 2008) suggest adverse effects are possible from various human activities up to nearly one mile from a nest site. While golden eagles are known to occur in the region, there are no known nests within 14 miles of the Project site (BLM 1999) and this species was not incidentally observed during avian point count surveys or field surveys conducted for other plant and wildlife species (GSEP 2009a). However, no historic or recent surveys have been conducted for golden eagle nests near the Project area, and the USFWS recommends that the Applicant conduct nest surveys for this species in Spring 2010 (Engelhard pers. comm.).

The status of golden eagle populations in the United States is not well known, though there are indications populations may be in decline (USFWS 2009b, Kochert et al. 2002). Accidental death from collision with man-made structures, electrocution, gunshot, and poisoning are the leading causes of mortality for this species, and loss

and degradation of habitat from agriculture, development, and wildfire continues to put pressure on golden eagle populations (Kochert et al. 2002; USFWS 2009b).

Staff reviewed historic nest data, Project survey data, and information on home range size available in the literature. Relying on the limited available data, staff has concluded that the Project would not result in direct or indirect disturbance of golden eagle nesting activities. As part of the cumulative impacts analysis staff analyzed foraging impacts within 10 miles of potential nest habitat based on USFWS guidance. Staff has concluded that this Project would contribute to the cumulative loss of golden eagle foraging habitat within the NECO planning area. Surveys for breeding and wintering eagles within a 10 mile radius of the project footprint would provide data on use of the Project area by eagles. With current interpretation of the literature, staff has concluded that the Project would reduce the availability of foraging habitat in the Project area and could degrade foraging habitat by the introduction and spread of noxious weeds and an increase in human activity in the area. As discussed in the cumulative impact subsection, the Project contributes 0.7 percent to cumulative loss of Sonoran creosote bush scrub habitat within 10-miles of potential nest habitat from future projects (see **Biological Resources Table 15**). The potential for impacts to golden eagle foraging habitat can be minimized by the implementation of staff's proposed Conditions of Certification **BIO-12** (acquisition of desert tortoise compensatory mitigation lands), **BIO-22** (acquisition of state waters compensatory mitigation lands) and **BIO-14** (implementation of weed management plan).

The USFWS is the primary federal authority charged with the management of golden eagles in the United States. A permit for take of golden eagles, including take from disturbance such as loss of foraging habitat, may be warranted for this Project. USFWS guidance on the applicability of current Eagle Act statutes and mitigation is currently under review. On November 10, 2009, the USFWS implemented new rules (74 FR 46835) governing the "take" of golden and bald eagles. The new rules were released under the existing Bald and Golden Eagle Act which has been the primary regulation protecting unlisted eagle populations since 1940. All activities that may disturb or incidentally take an eagle or its nest as a result of an otherwise legal activity must be permitted by the USFWS under this act. The definition of disturb (72 FR 31132) includes interfering with normal breeding, feeding, or sheltering behavior to the degree that it causes or is likely to cause decreased productivity or nest abandonment. Because large-scale solar Projects would result in the loss of large amounts of golden eagle foraging habitat, there are concerns about the cumulative impacts to golden eagles resulting from loss of foraging habitat.

In February 2010, the USFWS issued interim guidance on the minimum inventory and monitoring effort recommended for evaluating potential golden eagle use of habitat during breeding and non-breeding periods, which in turn will provide information on the baseline circumstances for evaluating permit applications and a baseline for permit conditions (Pagel et al. 2010); however, this guidance is still under review. Although Energy Commission staff is awaiting guidance from USFWS on this subject as to whether an Eagle Act permit may be warranted for this and other renewable energy Projects, the USFWS may not be able to determine the need for a permit without higher resolution data from the Project vicinity. The lack of Project-specific data on golden eagle could be remedied by conducting surveys this spring for (1) nesting eagles within

an approximate 10-mile radius of the Project perimeter, and (2) prey abundance and foraging habitat value (Engelhard pers. comm.). If a permit is warranted, due to take and compounded by the current uncertainty on the status of golden eagle populations in western United States, it is expected permits would only be issued for safety emergencies or if conservation measures implemented in accordance with a permit would result in a reduction of ongoing take or a net take of zero (USFWS 2009c). Staff has not proposed a condition of certification for golden eagles in this Staff Assessment, but may do so in the Staff Assessment Addendum if the USFWS determines that a federal Eagle Act take permit is warranted for this Project.

Migratory/Special-status Bird Species

Several special-status species, such as black-tailed gnatcatchers, yellow warblers, and crissal thrashers, breed in the region, but would not breed on the site due to lack of suitable habitat. This region does not provide breeding habitat for Swainson's hawks, northern harriers, short-eared owls, ferruginous hawks, or Brewer's sparrows but may provide overwintering habitat or the species may be present during migration. The Project impacts to Sonoran creosote bush scrub and microphyll woodland would contribute to loss of foraging habitat, cover, and roost sites for these species on their migratory or wintering grounds, but would not contribute to loss of breeding habitat. The Project would have more substantial adverse effects to the resident breeding birds at the site, which include loggerhead shrike, California horned lark, and Le Conte's thrasher among others. These species would be adversely affected by the loss of 16 acres of microphyll woodland and 1,786 acres of Sonoran creosote bush scrub. Le Conte's thrasher, loggerhead shrikes and other wash-dependent species would in particular be affected by the loss of the cover, foraging and nesting opportunities provided by the structurally diverse and relatively lush dry washes and microphyll woodland. Dry washes contain less than five percent of the Sonoran Desert's area, but are estimated to support ninety percent of Sonoran Desert birdlife (CalPIF 2006). As discussed in the cumulative impact subsection, staff considers the Genesis Project to be a substantial contributor to the cumulative loss of the NECO Planning Area's biological resources, including habitat for these special-status birds. Staff's proposed Condition of Certification **BIO-12**, the desert tortoise compensatory mitigation plan and **BIO-22**, mitigation for impacts to state waters, would offset the cumulative loss of habitat for these species.

The loss of active bird nests or young is regulated by the federal Migratory Bird Treaty Act and Fish and Game Code section 3503, which protects active nests or eggs of California birds. The Applicant has proposed mitigation measures to avoid and minimize impacts to nesting birds that have been incorporated into staff's proposed Conditions of Certification including: **BIO-8** (Impact Avoidance and Minimization Measures); **BIO-15** (Pre-construction Nest Surveys); which describes guidelines for performing pre-construction surveys and **BIO-16** (Avian Protection Plan) which provides a mechanism to monitor for bird collisions and implement adaptive management measures to minimize impacts. Implementation of staff's proposed conditions of certification would avoid direct impacts to nests, eggs, or young of migratory birds, and would minimize the impacts to less than CEQA significant levels for construction disturbance to resident and migratory birds.

Bats

The Project site supports foraging and roosting habitat for several special-status bat species. Roosting opportunities for bats are available in tree cavities, soil crevices and rock outcroppings primarily within dry desert wash woodland habitats. Bats likely utilize habitats throughout the study area for foraging but forage more commonly when water is present within the desert washes when insects are more abundant. Implementation of the Project would result in loss of these foraging and roosting habitat opportunities for special-status bats that might occur in the Project area.

As discussed in the cumulative impact subsection, staff considers the Genesis Project to be a substantial contributor to the cumulative loss of in the NECO Planning Area's biological resources, including habitat for these special-status bats. Staff's proposed Condition of Certification **BIO-12**, the desert tortoise compensatory mitigation plan and **BIO-22**, mitigation for impacts to state waters, would offset the cumulative loss of habitat for these species.

American Badger and Desert Kit Fox

Construction of the Project could kill or injure American badgers by crushing with heavy equipment or could entomb them within a den. Construction activities could also result in disturbance or harassment of individuals. Like badgers, desert kit fox are burrow dwellers and are similarly at risk of death or injury from construction activities. The desert kit fox is not a special-status species, but it is protected under Title 14, California Code of Regulations (section 460), and potential impacts to individuals of this species must be avoided. Badger burrows and kit fox burrow complexes were detected within the Project Disturbance Area, and the site includes suitable foraging and denning habitat for these species. Construction activities could also result in disturbance or harassment of individuals. Staff's proposed Condition of Certification **BIO-17** requires that concurrent with the desert tortoise clearance survey, a qualified biologist perform a preconstruction survey for kit fox dens and American badgers in the Project area, including areas within 250 feet of all Project facilities, utility corridors, and access roads.

The Genesis Project would permanently remove approximately 1,852 acres of foraging and denning habitat for American badgers and kit foxes and would fragment and reduce the value of foraging and denning habitat adjacent to the Project site. This habitat loss and degradation could adversely affect American badger and kit fox populations within the NECO Planning Area. As discussed in the cumulative impact subsection, staff considers the Genesis Project to be a substantial contributor to the cumulative loss of the NECO Planning Area biological resources, including American badgers and kit fox. Staff's proposed Condition of Certification **BIO-12**, the desert tortoise compensatory mitigation plan, and **BIO-22**, compensatory mitigation for state waters, could offset the loss of habitat for this species and reduce the impact to less-than-significant.

Nelson's Bighorn Sheep

The Project site is south of a bighorn sheep connectivity corridor between the Palen and McCoy Mountains, identified in the NECO (BLM CDD 2002). However because the distance from the mountain ranges, and the width of the valley at the Project site, staff agrees with the Applicant that the Project site is not expected to be an important movement corridor for this species. The Society for Conservation of Bighorn Sheep has

recommended a one mile buffer from the upper edge of any solar development to the base of the mountains to protect spring foraging habitat. The Genesis Project site is over one mile from the base of either the McCoy Mountains or Palen Mountains, and the Project site is not expected to provide spring foraging habitat.

Also of interest are the potential impacts from Project groundwater extraction to seeps, springs, or other water resources that are currently available to bighorn sheep that occupy the Palen Mountains or could occupy the McCoy Mountains in the future. The Applicant has provided information (GSEP 2009f) about the closest water features, and has concluded that groundwater extraction for the Project would not affect these features. After reviewing the data provided in the Data Responses, staff agrees with the Applicant that the Project is unlikely to affect springs and seeps available for use by bighorn sheep.

As discussed in the Cumulative Impact subsection C.2.9, the Genesis Project would not directly affect habitat within any NECO connectivity corridors and would not conflict with Desert Bighorn Sheep Conservation goals and objectives outlined in the NECO. In addition, staff has concluded that the Genesis Project site does not represent significant direct or indirect impacts to bighorn sheep habitat connectivity or foraging. Bighorn sheep may be impacted by construction noise, as discussed in the Construction Noise subsection below.

Construction Noise

Construction activities would result in a temporary, although relatively long-term (37 months) increase in the ambient noise level. Animals rely on hearing to avoid predators, obtain food, and communicate. Excessive construction noise could interfere with normal communication, potentially interfering with maintenance of contact between mated birds, obscuring warning and distress calls that signify predators and other threats, and affecting feeding behavior and protection of the young. High noise levels may also render an otherwise suitable nesting area unsuitable. Behavioral and physiological responses to noise and vibration have the potential to cause injury, energy loss (from movement away from noise source), a decrease in food intake, habitat avoidance and abandonment, and reproductive losses (Hunsaker 2001; National Park Service 1994).

The Palen/McCoy Wilderness Area, immediately north of the proposed Project, and a bighorn sheep Wildlife Habitat Management Area (WHMA), approximately four miles north of the proposed Project, are especially sensitive noise receptors due to the presence of breeding wildlife (e.g., migratory birds and Nelson’s bighorn sheep). Sensitive bird nesting habitat also occurs in the adjacent creosote bush scrub to the south and east of the Project site as well as in the desert dry wash woodland approximately one mile east of the Project site. Studies have shown that noise levels over 60 A-weighted decibels (dBA) can result in nest abandonment by birds and intense, long-lasting noise can mask bird calls, which can reduce reproductive success (Dooling and Popper 2007; Hunsaker 2001). Noise impact studies on bighorn sheep have not identified numerical noise impact thresholds. Weisenberger et al. (1996) found that bighorn sheep responded to aircraft over-flights (92-112 dBA) with increased heart rates and altered behavior; however, animal response decreased with increased exposure.

Assuming an average construction noise of 93 dBA at 50 feet from the noise center (the upper range of noise levels for construction equipment), project construction noise would attenuate to 30 dBA at a distance of five miles from the noise center (GSEP 2009a). Using sound extrapolation, project construction noise should attenuate to 60 dBA at approximately 2,300 feet (0.43 mile) from the noise center of construction activities (Bright pers. comm.). The majority of the construction activities would occur within the powerblocks located approximately 3,200 feet (0.6 mile) from the project boundary. Therefore, it is anticipated that average construction noise levels would typically be less than 60 dBA in the Palen/McCoy Wilderness Area and surrounding the project site. The infrequent occasions when construction activities would occur near the project boundary and resultant noise levels would be temporarily elevated beyond 60 dBA surrounding the project would not significantly impact sensitive wildlife.

Although average construction noise levels would usually attenuate to 60 dBA at the Project boundary, steam blows and pile driving produce short-term, sporadic, and loud noise that could substantially elevate noise levels in the Palen/McCoy Wilderness Area and bighorn sheep DWMA. The loudest proposed construction activity would be the steam blows required to prepare a steam turbine for startup during the final phase before operation. This process cleans the piping and tubing which carry steam to the turbines; starting the turbines without cleaning these systems would destroy the turbine. A series of short steam blows, lasting two or three minutes each, would be performed several times daily over a period of two or three weeks. These steam blows can produce noise as loud as 130 dBA at a distance of 100 feet. This would attenuate to about 82 dBA at a distance of five miles from the project site, and 77 dBA at nine miles from the project site. Staff recommends that a continuous low-pressure technique be used for steam blows, which would release steam over a continuous period of about 36 hours and would result in noise levels of about 80 dBA at 100 feet. Another relatively loud and short-term construction activity is pile driving. If required, noise from this activity could be expected to reach 101 dBA at a distance of 50 feet and attenuate to 47 dBA at distance of five miles from the project site.

Elevated noise from steam blows and pile driving could adversely affect the breeding, roosting, or foraging activities of sensitive wildlife proximate to the project area. To minimize these potential noise impacts, staff proposes Condition of Certification **BIO-8**, which recommends avoidance of loud construction activities (i.e., steam blowing and pile driving) between February 15 and April 15, which is the height of the local bighorn lambing and bird breeding season. With implementation of this condition, impacts to project construction activities would be less than significant. Employing the low-pressure steam blow technique recommended by staff would further reduce noise levels and hence the potential for impacts to wildlife. For a complete analysis of construction noise impacts, refer to the **Noise** section of this SA/DEIS.

Special-status Plant Species

Harwood's milk-vetch and other Special-status Plants Found During the 2009 Surveys

The Genesis Project would directly impact two special-status plant species, Harwood's milk-vetch (CNPS List 2.2) and desert unicorn plant (CNPS List 4.3). Construction of the solar fields, the access road, and linear corridor north of I-10 would destroy 5 individual

Harwood's milk-vetch plants and an estimated 13 desert unicorn plants (estimate based on location of seed pods, and not individual plants). In addition 7 Harwood's milk-vetch plants and 7 desert unicorn plants were found outside of but close to the Project footprint (GSEP 2009f). Potential indirect impacts to these plants include: accidental harm during construction; erosion and sedimentation of disturbed soils; alteration of the drainage patterns; disruption of the aeolian and fluvial sand transport systems; spread of noxious weeds; herbicide and other chemical drift; disruption of photosynthesis and other metabolic processes from fugitive dust during construction and operation; increased risk of fire; impacts to pollinators; and habitat fragmentation and the effects of isolation on population viability.

Staff considers impacts to a total of 12 Harwood's milk-vetch to be a significant effect. The Project also contributes, at least incrementally, to a significant cumulative impact to Harwood's milk-vetch and it's habitat in the Chuckwalla Valley and vicinity from proposed renewable energy projects. The avoidance and minimization measures specified in staff's proposed Condition of Certification **BIO-19** would minimize the Project's impacts to Harwood's milk-vetch to a level less than significant. Staff considers the impacts to desert unicorn plant to be less than significant because its population in California is relatively stable and the occurrences in the Project area are neither distinctive nor occur at the periphery of its range. However, staff recommends that the same avoidance and minimization measures contained in **BIO-19** be applied to desert unicorn plant to address the cumulative impacts to this species from other projects in the vicinity.

Three additional species were identified outside of the Project Disturbance Area: ribbed cryptantha (CNPS List 4.3), Las Animas colubrina (CNPS List 2), and an unconfirmed occurrence of Harwood's phlox (CNPS List 1B). The nearest Las Animas colubrina plant was found 1.5 miles north of the Project, and the Harwood's phlox occurs 6 miles to the west; therefore, the Project is not expected to directly or indirectly affect either species. A single ribbed cryptantha was found on the linear corridor north of I-10; it would not be directly affected by construction of the solar arrays but could be subject to many of the indirect effects listed above during construction and operation of the Project. Staff considers that the impacts to a single ribbed cryptantha would be less than significant because its population in California is relatively stable and many new occurrences have recently been found in the vicinity. The occurrences in the Project area are not distinctive and do not occur at the periphery of its range; however, it is characteristically found in loose sandy soils—a habitat that is already limited in distribution and subject to significant cumulative effects. Staff recommends that the same avoidance and minimization measures contained in **BIO-19** be applied to ribbed cryptantha as many of the new occurrences and a portion of its habitat would be impacted (directly, indirectly, and cumulatively) by the proposed renewable energy projects and other future projects.

The 2009 surveys also detected a total of 26 cacti that were tentatively identified as Wiggins' cholla. Staff and the Applicants consulted regional botanical experts and recognized experts in the cacti of California about the validity of the taxon. The consensus opinion was that the Wiggin's cholla is not a valid taxon and is instead merely a dwarf form of the common silver cholla. Staff considers that impacts to 26 silver cholla would not be an impact to a special-status species; however, the Applicant has submitted a plan for native cacti avoidance and minimization (including the dwarf

silver cholla) to ensure the Project's consistency with the California Desert Native Plants Act (CDNPA), which was passed in 1981 to protect non-listed California desert native plants from unlawful harvesting on both public and privately owned lands (see discussion below).

Abram's spurge and Other Special-status Plants That May be Detected During 2010 Surveys

Abram's spurge (CNPS List 2), which is documented to occur on Ford Dry Lake just south of I-10, has a very high potential to occur within the Project site. It was not detected during the 2009 surveys; however, the surveys were not conducted at a time of year adequate for detecting this species. Staff consulted with regional botanical experts before and after Staff's data requests (CEC 2009d), reviewed the Applicant's data responses (GSEP 2009f), and spoke with regional agency staff and has concluded that three additional species could also possibly occur within or near the Project Disturbance Area based on the presence of suitable habitat. Like Abram's spurge, these species may have been missed during the spring 2009 surveys because they are late season plants that are difficult or impossible to detect during spring surveys, and no late season surveys were conducted. Staff is proposing as part of Condition of Certification **BIO-19** that late season 2010 botanical surveys be conducted within the entire Project Disturbance Area in summer/fall 2010, which would target the following late summer/early fall species:

Abram's spurge (*Chamaesyce abramsiana*) – CNPS List 2.1, CNDDB state rank S1.2 (8 occurrences in CNDDB, including Ford Dry Lake)

Flat-seeded spurge (*Chamaesyce platysperma*) – BLM Sensitive, CNPS 1B.2, CNDDB state rank S1.2 (4 occurrences in CNDDB)

Lobed ground cherry (*Physalis lobata*) – CNPS List 2.3, CNDDB state rank S1.3 (4 occurrences in CNDDB, southernmost at Ward Valley)

Glandular ditaxis (*Ditaxis claryana*) – CNPS List 2.2, CNDDB state rank S1/S2 (8 occurrences in CNDDB, including Corn Springs Wash near I-10)

The Applicant has already proposed additional 2010 field work to cover the portion of the northern transmission line route that had not previously been surveyed because the alignment had not yet been finalized (TTEC 2009c). Spring 2010 surveys of the previously unsurveyed portions of the Project should include the following species in addition to those species contained on the target list for the 2009 surveys (GSEP 2009a): winged cryptanta, Palmer's jackass clover, small-flowered androstephium, spiny abrojo, white-margined penstemon, angel trumpets, argus blazing star, bitter Hymenoxys, pink velvet mallow, and desert portulaca.

Of the species listed above, staff has concluded that winged cryptantha, Abram's spurge, flat-seeded spurge, lobed ground cherry, and glandular ditaxis have moderate to high potential to occur. However, staff has concluded that if 2010 surveys detect the CNPS List 4.3 winged cryptantha, impacts would be less-than-significant because its distribution is relatively stable and an occurrence in the Project area would not be at the periphery of its range. Staff has reviewed the occurrence records of Abram's spurge,

flat-seeded spurge, lobed ground cherry, and glandular ditaxis and has determined that impacts to even small occurrences of these CNPS List 2 species would be significant, if present, based on their rarity in California and status. All of these species have less than 10 documented occurrences in California (many of which are historical collections that may no longer be extant), and they have a CNDDB state rank of 'S1' ("Critically imperiled due to extreme rarity, imminent threats, or and/or biological factors") or 'S2' ("Imperiled due to rarity and/or other demonstrable factors"). Although some of these are more common outside of California, the occurrences in the region are located at the western periphery of the species' global range, and some of these occurrences, or their habitat, which is already limited in extent, may be cumulatively affected by the recent push for renewable energy development.

To ensure that the development of the Project would not result in significant impacts to special-status plants potentially occurring on the Project (and for which absence cannot be adequately concluded), staff's proposed Condition of Certification **BIO-19** requires development and implementation of a Sensitive Plant Protection and Mitigation Plan ("Plan"). The objectives of the Plan are to:

1. Protect preserved plants near the Project Disturbance Area from direct and indirect effects of construction and operation;

2. Ensure that any special-status plants that may have been missed during the 2009 surveys are detected; and

3. Provide detailed specifications and performance standards to compensate for unavoidable impacts to special-status plants.

To compensate for potential significant impacts to Abram's spurge, glandular ditaxis, flat-seeded spurge, and lobed ground cherry, the Plan recommends acquisition of compensatory mitigation land for habitat directly impacted by the project as follows:

- Abram's spurge: playa (38 acres); dunes (28 acres); desert washes (91 acres)
- Glandular ditaxis: desert washes (91 acres)
- Flat-seeded spurge: playa (38 acres); dunes (28 acres)
- Lobed ground cherry: playa (38 acres)

The criteria need to be met on a species by species basis; the acreages totals for these special-status species are 114 acres of playa and sand drift over playa habitat, 56 acres of dune habitat, and 182 acres of desert wash habitat (including at least 16 acres of microphyll woodland). Habitat acquisition for these species may also be integrated with habitat compensation for other species if the criteria listed below are met.
The compensatory lands acquired for each of these species must meet at least one of the following criteria:

1. Contain occupied habitat for an occurrence anywhere in the species' range in California;

2. Contain unoccupied habitat that is in the immediate watershed of an extant occurrence in California and considered to have a high potential for occurrence, or;

3. Provide watershed protection to extant and protected occurrences on federal land regardless of the habitat the acquired lands support.

Acquisition of lands that meet these criteria would expand the level of protection and connectivity of extant occurrences on federal land and/or prevent impacts to these special status plants from future development on private lands. The compensatory mitigation specified in staff's proposed Condition of Certification **BIO-19** would not be required if 2010 botanical surveys definitively rule out potential presence of these species (i.e., surveys were conducted at the appropriate time of year and under appropriate environmental conditions). Habitat acquisition for special status plants may also be integrated with compensatory mitigation described in Conditions of Certification **BIO-12**, **BIO-20**, and **BIO-22** if the criteria listed above are met.

Staff also recommends that the Plan shall include avoidance and minimization measures for any additional species detected during the 2010 surveys that occur near the Project Disturbance Area. The Applicant has already provided draft avoidance and minimization measures (GSEP 2009f) that minimize impacts of the following species to a level less than significant: Harwood's milk-vetch, desert unicorn plant, and ribbed cryptantha, and staff recommends that these measures be integrated into the Plan and that these avoidance and minimization measures be expanded to include any other special-status plant species detected during the 2010 surveys. Staff also recommends implementation of the following conditions of certification to minimize the potential indirect effects of the Project: Weed Management Plan (**BIO-14**); Best Management Practices during construction, operation, and closure of the Project (**BIO-8)**; and the Revegetation Plan for Temporarily Disturbed Areas (**BIO-24**). With implementation of these conditions of certification, and with staff's proposed Condition of Certification **BIO-19**, Project impacts to special-status plants would be reduced to less than significant levels.

Cacti, Yucca, and Native Trees

As indicated in **Biological Resources Table 1**, the California Native Plant Protection Act (Fish and Game Codes 1900-1913) and the California Desert Native Plant Act of 1981 (i.e. Food and Agricultural Code 80001, et . seq. and Fish and Game Codes 1925-1926) were passed to prevent unlawful harvesting of non-listed native desert plants of the state.

The applicant conducted stratified sampling plots for cacti, yucca, and native trees in the Study area and found that two cacti species (beavertail cholla and Wiggins cholla) and three tree species (palo verde, cat-claw acacia, and ironwood) occur within the Project area. Other cacti and native trees identified during field surveys include buckhorn cholla (*Cylindropuntia acanthocarpa*), silver cholla (*C.=Opuntia echinocarpa*), pencil cholla (*C.=Opuntia ramosissima*), ocotillo (*Fouquieria splendens*), fish-hook cactus (*Mammillaria tetrancistra*), honey mesquite (*Prosopis glandulosa*), and smoke tree (*Psorothamnus spinosus*) (GSEP 2009a, Appendix C Biological Resources Technical Report). To the extent practical, the Applicant would salvage native desert plants during construction of the Project and would use the salvaged plants for revegetation of temporarily disturbed areas. The Applicant has prepared a draft Revegetation Plan that addresses the salvaging of cacti and native trees during initial vegetation grubbing of the Project site, as well as proper storage of salvaged plant material and seed

collection, replanting of salvaged materials, and monitoring parameters including revegetation success criteria and performance standards for salvaged materials (TTEC 2010i). Staff's Condition of Certification **BIO-24** requires the applicant finalize the draft Revegetation Plan prepared for the Project which would address the salvaging of topsoil and native desert plants to aid in the revegetation of temporarily disturbed area following Project construction.

Noxious Weed Spread Due to Construction

Construction activities and soil disturbance could introduce new noxious weeds to lands adjacent to the Genesis Project plant site and its linear facilities, and could further spread weeds already present in the Project vicinity. The spread of invasive plants is a major threat to biological resources in the Colorado Desert because non-native plants can displace native plants, increase the threat of wildfire, and supplant wildlife foods that are important to herbivorous species.

Salt cedar, Russian thistle, Sahara mustard, and Mediterranean grass are already present in the Project vicinity and are expected to increase as a result of construction- and operation-related disturbance. The proliferation of these and other non-native species has dramatically increased the fuel load and frequency of fire in many desert ecosystems (Lovich & Bainbridge 1999). Unlike other ecosystems in California, fire was not an important part of the Colorado Desert ecosystems and most perennials are poorly adapted to even low-intensity fires, and the animals that coevolved are not likely to respond favorably to fire either. The potential spread or proliferation of non-native annual grasses, combined with the proximity to ignition sources could potentially increase the risk of fire, and the effects to these poor-adapted desert communities would be harmful, particularly to cacti and most native shrubs species. Burned creosote bush and other native shrubs are typically replaced by short-lived perennials and non-native grasses (Brown & Minnich 1986).

To avoid and minimize the spread of existing weeds and the introduction of new ones, an active weed management strategy and control methods must be implemented. The Applicant has submitted a draft Weed Management Plan (TTEC 2010g) to avoid and minimize the spread of noxious weeds. Staff has incorporated recommendations from the Applicant into proposed Condition of Certification **BIO-14** (Weed Management Plan). The Weed Management Plan includes a discussion of weeds targeted for eradication or control and a variety of weed control measures such as establishing weed wash stations for construction vehicles and revegetation of disturbed areas with native seed mix. Implementation of this condition/weed management plan would reduce potential impacts from introduction and spread of noxious weeds to less than significant levels under CEQA.

Construction Impacts of Dust on Plants

Disturbance of the soil's surface caused by construction traffic and other activities would result in increased wind erosion of the soil. Aeolian transport of dust and sand can result in the degradation of soil and vegetation over a widening area (Okin et al. 2001). Dust can have deleterious physiological effects on plants and may affect their productivity and nutritional qualities. The destruction of plants and soil crusts by windblown sand and dust exacerbates the erosion of the soil and accelerates the loss of nutrients (Okin

et al. 2001). Soil erosion from construction activities and vehicle activity, which affects vegetation and soil properties, could have an adverse effect on both foraging and burrowing potential for Mojave fringe-toed lizards. The impacts of increased dust and other construction impacts can be minimized with implementation of staff's proposed Condition of Certification **BIO-8** (Impact Avoidance and Minimization Measures).

Additional Operation Impacts

Operation Lighting

Collision hazards at the Genesis Project site would include several ancillary buildings (e.g., water treatment building, administration building, control room, steam turbine generator building) that range in height from 30 to 50 feet. The structures would be located within the power block, approximately in the center of each solar field and surrounded by solar arrays. The solar collection assemblies would vary in height depending on their position while tracking the sun; the tallest configuration would be approximately 25 feet tall. The tallest proposed structures are the transmission line monopoles, which are approximately 75 feet tall.

Operation of the Genesis Project would require onsite nighttime lighting for safety and security at the site. Existing sources of artificial lighting at night in the project vicinity include intermittent vehicles traveling along Interstate 10 as well as fixed light sources at the California State Prisons south of I-10 at the Wiley's Well Road Exit and at the Wiley's Well Rest Stop. Given the lack of night lighting in this remote area, the overall change in ambient lighting conditions at the Project site may be substantial when viewed from nearby offsite locations. Night lighting close to the ground at the Genesis Project site could disturb the resting, foraging, or mating activities of wildlife and make wildlife more visible to predators.

To reduce lighting impacts, the applicant proposed several design features (GESP 2009a, Visual Design Feature 5). Lighting at the facility would be restricted to areas required for safety, security, and operation. Exterior lights would be shielded and oriented to focus illumination on the desired areas and minimize additional nighttime illumination in the site vicinity (GESP 2009a). Switched lighting would be provided for areas where continuous lighting is not required for normal operation, safety, or security. Implementation of these applicant-proposed measures would allow areas surrounding the project to remain un-illuminated (dark) most of the time, thereby minimizing the amount of lighting potentially visible off site and minimizing the potential for lighting impacts to proximate wildlife. These features have been incorporated into Condition of Certification **VIS-3** (Temporary and Permanent Exterior Lighting) and BIO-8. Staff concludes that bird collisions occurring at night would be less than significant and no mitigation is proposed.

Collisions

Bird collisions with structures typically result when the structures are invisible (e.g., bare power lines or guy wires at night), deceptive (e.g., glazing and reflective glare), or confusing (e.g., light refraction or reflection from mist) (Jaroslow 1979). Collision rates generally increase in low light conditions, during inclement weather (e.g., fog, which is rare in the desert), during strong winds, and during panic flushes when birds are startled

by a disturbance or are fleeing from danger, or diving after prey. Numerous golden eagle fatalities have been documented near transmission lines where collisions apparently occurred from striking unmarked wires while diving for prey (Kerschner pers. comm.).

Lighting plays a substantial role in collision risk because lights can attract nocturnal migrant songbirds and major bird kill events have been reported at lighted communication towers (Manville 2001) with most kills from towers taller than 300 to 500 feet (Kerlinger 2004). Many of the avian fatalities at communication towers and other tall structures have been associated with steady-burning, red incandescent L-810 lights, which seem to attract birds (Gehring et al. 2009). Longcore et al. (2008) concluded that use of strobe or flashing lights on towers resulted in less bird aggregation, and, by extension, lower bird mortality, than use of steady-burning lights.

As described above, operation of the Genesis Project would require onsite nighttime lighting for safety and security at the site. The transmission line support structures would not be lit and no red incandescent lighting is proposed. With implementation applicant-proposed visual design features and staff-proposed conditions of certification (i.e., **VIS-3** and **BIO-8**) pertaining to minimization of night lighting, lighted Project facilities would not pose a significant collision hazard at night.

However, relative to nighttime collisions with lighted facilities, the risk of bird collisions and other injuries from solar facilities during daytime is unstudied. In particular, bird response to glare from the proposed solar trough technology is not well understood. Although the proposed Project facilities are significantly shorter than 350 feet (the height above which is considered a collision danger for migrating birds), there is concern that the mirrors may appear to a bird as a no-hazard flight area. The mirrors reflect light and take on the color of the image being reflected (Ho et al. 2009). When viewed from an angle near the current direction of the sun, at a distance or an elevated position, the solar field at its most reflective point may appear like a waterbody or lake (GSEP 2009a). Diurnal birds could also be at risk of injury and fatality from burns if they flew into the reflected sunlight between parabolic troughs or landed on the collector tubes of heat transfer fluid.

Staff has concluded that the risk of such impacts is probably low, although very little research has been conducted on the risks of bird collisions at solar facilities. The only such research available is the bird fatality studies at the Solar One facility near Daggett, San Bernardino County (McCrary et al. 1986). Results of that study indicated that much of the bird mortality consisted predominantly of collisions with mirrors, in large part resulting from increased numbers of birds attracted to the adjacent evaporation ponds and agricultural fields. For the Genesis Project, staff has concluded that without such a nearby attractant, bird numbers, and hence likelihood of bird collisions, would be low.

Although staff does not think it likely that mirrors and other structures within the Project Disturbance Area pose a significant collision risk to resident or migratory birds at the Project site, there is insufficient information available to conclude with certainty that the Genesis Project would not be an ongoing source of mortality to birds for the life of the project. Given the lack of research-based data on the impacts of glare and collision threats to birds, staff has proposed Condition of Certification **BIO-16**, which requires

implementation of an Avian Protection Plan. The Avian Protection Plan would provide the information needed to determine if operation of the Project posed a collision risk for birds, and would provide adaptive management measures to mitigate those impacts to less than significant levels.

Lighting – Glare

The proposed solar mirrors and heat collection elements (HCEs or receiver tubes) are sources of bright light caused from the diffuse reflection of the sun. Glint and glare studies of solar trough technology found that pedestrians standing within 20 meters (60 feet) of the perimeter fence when the mirrors rotate from the stowed position to a vertical position may see a light intensity equal or greater to levels considered safe for the human retina (URS 2008). Staff concludes that any wildlife on the ground at a distance of 20 meters or closer could experience similar hazards from unsafe light intensity. Slatted fencing is recommended in the **Visual Resources** section of this analysis to mitigate the problem of bright spots on motorists. Implementation of Condition of Certification **VIS-4** (Reduction of Glint and Glare), which requires that slatted fencing be used as the perimeter fencing primarily to mitigate for impacts to motorists, would prevent glare exposure to wildlife on the ground within 20 meters of the project boundary, thereby reducing the potential for a significant impact. For a complete analysis of glare impacts, refer to the **Visual Resources** section of this SA/DEIS.

Electrocution

Large raptors such as golden eagle, red-tailed hawk, and great horned owl, can be electrocuted by transmission lines if the bird's wings simultaneously contact two conductors of different phases, or a conductor and grounded hardware. This happens most frequently when a bird attempts to perch on or take off from a structure with insufficient clearance between these elements. The majority of bird electrocutions occur on distribution lines between 1- and 60-kV; however, configurations greater than 60 kV typically do not present an electrocution potential because phase-to-phase and phase-to-ground clearances for lines greater than 60-kV are typically sufficient to prevent bird electrocution (APLIC 2006). The proposed transmission lines would be 230 kV; therefore, phase-to-phase and phase-to-ground clearances are expected to be sufficient to avoid bird electrocutions.

Potential impacts to wildlife resulting from electrocution by transmission lines would be minimized by incorporating the construction design recommendations provided in *Suggested Practices for Raptor Protection on Power Lines: The State of the Art in 2006* (APLIC 2006). Specifically, the phase conductors shall be separated by a minimum of 60 inches and bird perch diverters and/or specifically designed avian protection materials should be used to cover electrical equipment where adequate separation is not feasible (APLIC 2006). This is further described in staff's proposed Condition of Certification **BIO-8** (Impact Avoidance and Minimization Measures); with implementation of Condition of Certification **BIO-8** staff concludes that the proposed transmission lines would not pose a substantial electrocution threat to birds.

Operation Noise

The majority of operational noise would originate from the power blocks, which would be roughly centered at each site and surrounded by solar fields; this creates a buffer for

noise to attenuate before reaching the Genesis Project property boundary and the Palen/McCoy Wilderness Area. Other minor operational noise sources include mirror rotation and maintenance activities (e.g., mirror washing). Excessive noise could disrupt the nesting, roosting, or foraging activities of sensitive wildlife. The Palen/McCoy Wilderness Area, immediately north of the proposed Project, is an especially noise-sensitive biological receptor.

Because the proposed project is located more than nine miles from a human noise-sensitive receptor, the applicant determined that a full acoustic modeling analysis of project operations was not warranted (GSEP 2009a). However, data provided for nearby proposed solar projects of similar size and technology (i.e., Palen and Blythe Solar Power Projects) serve as a proxy for anticipated operational noise levels of the Genesis Project. As such, operational noise is expected to typically range from 90dBA and for certain equipment to approximately 50 to 60 dBA at greater linear distances from the power generation equipment (GSEP 2009a). Based on these estimates, staff concludes there would be no significant impacts to surrounding wildlife from increased operational noise and no mitigation is proposed. For a complete analysis of operation noise impacts, refer to the **Noise** section of this SA/DEIS.

Evaporation Ponds

The proposed Project includes six, eight-acre evaporation ponds that would collect blowdown water from the cooling towers (GSEP 2009a). A variety of waterfowl and shorebirds seasonally inhabit or utilize evaporation ponds as resting, foraging, and nesting areas. Evaporation ponds in the Sonoran Desert pose several threats to wildlife. First, creation of a new water source to an area where water is scarce would attract ravens to the Genesis Project, potentially increasing predation rates on juvenile desert tortoise in adjacent habitat. Second, waterfowl, shorebirds, and other resident or migratory birds that drink or forage at the ponds could be harmed by selenium or hyper-saline conditions resulting from high total-dissolved-solids concentrations (EPTC 1999; Lemly 1996; Windingstad et al. 1987). Staff, CDFG, and USFWS are concerned about these threats to wildlife posed by the evaporation ponds.

Dry cooling is being evaluated by staff as an alternative to wet cooling (refer to the **Alternatives** section of this Staff Assessment) and zero liquid discharge (ZLD) remains a viable wastewater disposal alternative to evaporation ponds (refer to the **Soil & Water Resources** section of this Staff Assessment for a detailed analysis of ZLD). These alternatives would eliminate impacts from wildlife exposure to the evaporation ponds and is recommended by staff, CDFG, and USFWS. If either of these alternatives is not adopted and evaporation ponds would be constructed for the Genesis Project, staff proposes Condition of Certification **BIO-21**, which requires installation of netting over the evaporation ponds to exclude birds and other wildlife as well as a monitoring program to ensure the effectiveness of exclusion. Implementation of this measure would reduce evaporation pond impacts to birds to less-than-significant levels.

Impacts to Groundwater-Dependent Vegetation During Construction and Operation

Project pumping during construction and operation could lower groundwater levels (**Soil and Water Resources**, Section C.7.4.2.3) which could have a significant impact if it

lowered the water table below the reach of the deep-rooted, groundwater-dependent plants ("phreatophytes") that are within the Project pumping impact zone. This zone includes an area extending 2 to 3 miles from the Project pumping well during construction and approximately 10 miles by the end of Project operation (Worley Parsons 2009, Figure 3).

The Applicant predicted that the maximum drawdown in the shallow water table (the water table that supports phreatophytes) associated with the Project is approximately 0.3 feet in the area of the pumping well. The area where drawdown exceeds 0.25 foot is limited to within approximately 2.5 to 3.5 miles of the Project wells (see **Soil and Water Figure 16**). The Applicant's analysis showed a minor drawdown in the deep water aquifer of 0.5 foot as much as 10 miles away at the end of Project operation (33 years); drawdown in the shallow aquifer would be considerably less (Worley Parsons 2009, Figure 3).

The proposed groundwater pumping is not expected to significantly affect the health or status of the creosote bush scrub, which dominates the drier portions of the valley floor and surrounding alluvial fans and pediments, because this plant community is hundreds of feet above the groundwater level. These drought-adapted and shallow-rooted species are supported by precipitation, not shallow or deep groundwater. The phreatophytic communities potentially affected by the proposed Project are described below.

Groundwater-Dependent Plants and Communities in the Project Pumping Zone

Phreatophytes are groundwater-dependent plants with deep root systems that can extend tens of feet below the ground surface to the underlying water table. The communities of desert phreatophytes found in the 10 mile radius around the Project pumping well include mesquite bosques, bush seep-weed-dominant chenopod scrubs (succulent chenopod scrubs), and ironwood and palo verde woodlands (microphyll woodlands). The dune scrubs occurring in areas of near-surface groundwater may also be affected by lowered groundwater tables. All of these communities are designated as rare natural communities by the CNDDB (CDFG j2003) and the desert dry wash woodland (a microphyll woodland), chenopod scrubs, and dune habitats are recognized sensitive plant communities in the BLM NECO Plan (BLM CDD 2002).

Ground waters are important to sustain vegetation for wildlife habitat in some areas where surface waters are not present (RWQCB 2006). Special-status wildlife has been documented within these phreatophytic communities in the Project area and around Palen Dry Lake including Mojave fringe-toed lizard, American badger, western burrowing owl, desert kit fox, and loggerhead shrike (GSEP 2009a; Solar Millennium 2009a). Two special-status plants, jack-ass clover and Palmer's jack-ass clover, occur among the mesquite dunes around Palen Dry Lake and are known from only a few occurrences in California (CNDDB 2010; Silverman pers. comm.). CNPS List 2 Harwood's milk-vetch also occurs in the dunes around Palen Dry Lake.

Plant communities dominated by bush seep-weed (a phreatophyte) and allscale (a "xerophyte", or drought-tolerant plant) are found sporadically along the northeastern margins of Ford Dry Lake (TTEC 2009d) with scattered woody phreatophytes such as blue palo verde and ironwood. It is uncertain whether these phreatophytes are supported by the basin aquifer (from which the Project would draw its water) or

mountain front aquifer, which the Applicant has stated would be essentially unaffected by pumping from the deeper—and at least partially contained—basin aquifer. Shallow water tables at Ford Dry Lake were measured at 80 feet in depth in the test well on site. Almost 10 miles away at Palen Dry Lake, where groundwater is near surface, two phreatophytic communities were documented: Mesquite bosque (at the southwest margins of the lakebed) and a succulent alkali sink scrub/chenopod scrub dominated by bush seep-weed. BLM has identified an ironwood woodland community approximately 5 miles north of the Project site. Predicted water table drawdowns beneath this woodland are in the range of 0.05 to 0.2 feet (See **Soil and Water Figure 16**).

Groundwater can also be held near the ground surface in dune systems through capillarity and can influence both the vegetative cover and the morphology of the dunes. Recent research in New Mexico has confirmed that groundwater is one feature that influences dune morphology; dune fields are shaped by feedback between aeolian dynamics and groundwater chemistry (Langford et al. 2009). Consequently, some dune scrubs, if present in the dunes off the northeast corner of the Palen project where the groundwater is much nearer to surface than Ford Dry Lake, could also be affected by a drop in groundwater levels if the levels drop below the effective rooting depth of these shallower rooted species.

Preliminary investigations conducted at the Project site suggest that the aquifer that is proposed for development is under confined to semi-confined conditions and is separated in part from the shallow alluvial groundwater system by low permeability sediments (Worley Parsons 2009). Correspondingly, the Applicant's assessment of impacts to these layers is based on the assumption that the confining layers are laterally continuous and maintain hydraulic separation away from the proposed pumping wells. Staff, however, is concerned about the level of uncertainty in such a prediction and the potential influence of groundwater pumping in the shallow aquifer if the low permeability layers are fractured, as they often are (Deacon et al 2007).

Groundwater-Dependent Plant Responses to Lowered Groundwater Levels

A plant affected by competition for water displays signs of stress (e.g. Manning and Barbour 1988), and stress can be manifested as anything from diminished physiological processes to plant death. Shallower rooted herbs are the first affected and least able to withstand drought-stress; deep-rooted woody phreatophytes (such as mesquite) can take decades to die. Staff expects that stress to woody species, such as mesquite, from declines in groundwater levels would be detected in measures of plant vigor, such as die-back, long before plant cover changes might be measurable in an aerial photo. As Elmore et al. (2006) and Manning (2007) show, total live plant abundance (plant cover) on a site decreases as the water table is lowered. This in turn increases wind and water erosion to soil, and the void left behind by the receding native plants is often colonized by invasive exotic plants (Patten et al 2007; Lovich 1999; Manning 2006). Lowering the local water table from groundwater pumping has also been demonstrated to induce habitat conversions (Manning 2006; 2007). Even modest drawdowns of 0.3 feet can adversely affect vegetation if groundwater drops below the effective rooting level; if the drop is sustained (so that plants never have an opportunity to recover); or if the groundwater lowering occurs not just in summer (when plants are dormant) but also

occurs throughout early spring when plants need and utilize water most (Manning pers. comm.).

Increased soil erosion induced by the decreasing vegetative cover leads to a loss of nutrients, minerals, and the structure necessary for seed germination of plants that are adapted to prior groundwater conditions on the site. Non-native opportunistic “weed” species (e.g., Russian thistle) are better adapted to nutrient-poor soils and a wider variety of soil moisture regimes or conditions, and demonstrate a competitive edge. Animals, including mammals, reptiles, birds, and invertebrates, who may require certain plant species or a certain vegetation structure, may no longer find suitable food or living space. Local extirpations are compounded if the displaced animal is an important food source for another animal. The complex below-ground systems of bacteria, algae, and fungi, which provide many valuable ecosystem services (e.g. breakdown of organic matter, nitrogen fixation, carbon storage, and recycling of nutrients), are also disrupted when water tables are lowered. Ultimately, when groundwater levels are lowered beyond the normal reach of groundwater-dependent ecosystems, the decline in plant cover and change in species abundance can result in severe consequences, depending on the organism(s) involved or the prevailing ecosystem processes.

Importance of Spring Water Table in Maintaining Groundwater Dependent Plant Communities

The Applicant stated that water table drawdowns of 0.3 feet or less are similar to or less than expected normal climatic, seasonal, or diurnal water table fluctuations (Worley Parsons 2009). However, inter-annual measurements or averages of water table fluctuations are misleading in predicting the effects of water level declines to groundwater-dependent plant communities, and do not take into account the ecological and physiological traits of arid region plant communities. In forecasting a plant community’s response to lowering groundwater tables, it is necessary to identify the quantity and timing of water availability necessary for healthy ecologic functioning (Eamus and Froend 2006) . The extent to which water tables drop during the summer and fall dormant seasons is irrelevant for such forecasts; the only relevant measure of a plant community’s ability to withstand water table declines is the annual water table year-to-year fluctuations in early spring because the growing season is when plants need and utilize water most. In arid regions, most plants are dormant in summer and fall, and measures of fluctuating groundwater levels made during this time will not provide information about the ability of groundwater dependent plant communities to withstand reduced water tables. If, for example, water tables in April were reduced to the low levels associated with summer and fall (as a result of groundwater pumping), then adverse consequences would be expected (Manning pers. comm.) Groundwater dependent ecosystems experience measurable plant losses and other adverse changes when water tables fail to fully.

Conclusions and Mitigation

As discussed in subsection C.7.4.2 in the **Soil and Water** section, the calculations and assumptions used to evaluate potential Project impacts to groundwater levels are imprecise and have limitations and uncertainties associated with them. Given this uncertainty, the magnitude of potential Project impacts that could occur to groundwater dependent plant communities cannot be determined precisely. To ensure that the

Project's proposed use of groundwater does not significantly impact the groundwater levels in the Project area to the extent that biological resources are significantly and adversely affected, staff recommends in proposed Condition of Certification **BIO-23** the design and implementation of a Groundwater-Dependent Vegetation Monitoring Plan (Plan). This condition specifies monitoring for: 1) groundwater-dependent vegetation (measurements of plant vigor) within the area potentially affected by groundwater pumping, and 2) water table levels at the Project pumping well and other wells within the Project pumping zone (a 10-mile radius of the Project pumping well; Worley Parsons 2009, Figure 3).

The "Project pumping zone at end of Project Operation" depicted in Figure 3 of the cumulative effects analysis in the technical memorandum *Groundwater Resources Cumulative Impact Analysis for Genesis Solar Power Project, Riverside County, CA* (Worley Parsons 2009), is an approximate 10-mile radius area centered on the Project pumping well. After reviewing the groundwater analysis and pumping zone for the Palen Solar Power Project, it appears there may be an overlap between the Project's pumping zone and the northeast corner of the Palen Project's pumping zone (AECOM 2010a, Figures DR-ALT-207-1 & 2). Staff therefore infers that there may be a cumulative effect from the impacts of these two projects on the phreatophytic community of bush seep-weed and scattered stands of mesquite within the overlapping area of effect. Numerous occurrences of Mojave fringe-toed lizard and other special-status plants and animals have been documented in this area (Solar Millennium 2009a).

Project effects would be distinguished from the effects of drought or climate change by comparing monitoring data collected within the area of potential effect (Near-Project Monitoring Sites) to data collected at controls sites in areas not affected by groundwater pumping or hydrologic alterations (Reference Monitoring Sites). The Reference Monitoring Sites would be established within the Sonoran or Colorado Desert regions of California (i.e. regions with similar bi-modal precipitation pattern) and in areas containing examples of the target groundwater-dependent plant communities. Mesquite, ironwood, and palo verde stands along rivers or dependent on surface flows would not be included, and bush seep-weed communities would only be selected where they occur in sinks on or around the margins of playas. Reference Monitoring Sites should not be selected in areas influenced by groundwater pumping or altered hydrology; national park lands, monuments, and other private and public preserves are good sources for Reference Monitoring Sites.

Baseline data would be collected at all sites prior to the start of pumping, and then data collected annually for the life of the project. A statistician shall be retained to use the first year of baseline data to conduct a "prior power analysis" and evaluate the adequacy of the sampling design. The results of the first year baseline data, prior power analysis, and recommended changes shall be submitted for approval to the CPM and BLM Authorized Officer by December 31 of the first baseline year.

Staff Condition of Certification **BIO-25** provides guidelines for the development of a detailed, objective-driven Groundwater-Dependent Vegetation Monitoring Plan. **BIO-25** specifies that the Plan be prepared by a qualified plant ecologist and be consistent with guidelines contained in *Measuring and Monitoring Plant Populations* (Elzinga et al. 1998), including: sampling objectives (target/threshold, change/trend-based); attributes

measured; field techniques; minimum standards for monitoring personnel; data management; statistical analysis; monitoring schedule; reporting requirements, and responsible parties. Field techniques for measuring drought response include: percent dieback; live crown density; percent cover of live (versus dead) vegetation, percent cover/frequency of associated phreatophytic species; changes over time in percent composition of native versus non-native species, and facultative wetland plants present. Conditions of Certification **SOIL&WATER-3** through **SOIL&WATER-5**, provided in Section C.7.12, specifies sampling and reporting guidelines for groundwater level monitoring. The primary objective for the monitoring is to establish pre-construction and Project related groundwater levels and water quality trends that can be quantitatively compared against observed and simulated trends near the Project pumping wells and near potentially impacted existing wells. **SOIL&WATER-5** also specifies monitoring of area seeps and springs within a mile of the Project well.

Water table depths must be measured in early spring (March 15- April 1) to assess water table conditions, project summer vegetation conditions, and compare the effects of pumping or runoff from one year to the next (Manning 2006). Normal year-to-year variability in spring water tables can be projected from a review of historical data from area well logs. The analysis would also compare estimated to actual water table declines and perform a statistical trend analysis to refine future predictions of effect. If a decline in plant vigor (that is not also detected at the Reference Monitoring Sites) and changes in the spring groundwater levels and are detected, then remedial action would be implemented according to the specifications in staff proposed Condition of Certification **BIO-26.** The threshold for remedial action would be based on an analysis of: 1) groundwater-dependent vegetation (measures of plant vigor, compared against the control sites); 2) data on water usage and its effects on the water table at the Project pumping well, and; 3) the indirect effects of project pumping on water tables from area wells within the Project pumping zone.

If the analysis detects: 1) declining spring water tables—in any amount greater than the normal year-to-year variability—combined with 2) indicators of a decline in plant vigor, that 3) are not detected in the Reference Monitoring Sites, then the Applicant would prepare a detailed proposal for remedial action. The analysis and proposal must clearly demonstrate how the proposed remedial action would restore the spring groundwater tables to a level necessary to sustain healthy ecological functioning in the affected plant communities, as defined by the trigger described above, and be informed by data on Project water usage. The Applicant may choose the most feasible method of accomplishing this, providing it meets the performance standard above. Some possible remedial actions that could be considered include:

1. Relocating the Project pumping well to another location farther from the groundwater-dependent vegetation (and where the dependent vegetation is no longer within the drawdown cone of depression), or—alternatively—constructing a new well farther away and reducing water usage in the well closest to the dependent plant communities.

2. Reducing the Project's impacts by reducing groundwater usage elsewhere within the zone of potential effect of the Project well. This might include: acquiring or reducing water usage on agricultural or other lands.

3. Reducing the Project water usage through water conservation methods or new technologies.

4. Providing an alternative water source other than #1 above, if one became available at some future time (vegetation impacts may not be felt for a decade or more). For example, if non-potable, treated, or recycled water were available from the Blythe area and could feasibly be brought to the site.

For the purposes of this impact analysis, it is assumed that any withdrawals that exceed the average natural recharge and cause a decline in the normal average year-to-year fluctuations in the spring groundwater levels are significant, causing harm not only to biological resources but to area wells (see **Soil and Water Resources**, Section C.7.4.2 Assessment of Impacts and Discussion of Mitigation). Based on the performance standards for remedial action described above, staff has concluded that with implementation of Conditions of Certification **BIO-25** and **BIO-26**, indirect and cumulative impacts to groundwater-dependent plant communities would be reduced to less than significant levels.

PROJECT CLOSURE AND DECOMMISSIONING

The Applicant submitted a Draft Decommissioning and Closure Plan (Worley Parsons 2010b) in response to staff's data request for a conceptual decommissioning plan that addressed the fate of the engineered channels and reclamation of the site to native plant communities (CEC 2009d). Staff requested a conceptual plan for filling the re-created channels and restoring drainages on the Project site, including a description of a revegetation plan for restoring the function and values of the ephemeral drainages. Staff also requested a cost estimate, adjusted for inflation, for implementing the closure, including the revegetation component of the closure activities for the drainages, and asked for a conceptual plan and funding mechanism for monitoring and maintenance of the ephemeral drainages until existing functions are reestablished.

The Applicant's Draft Decommissioning and Closure Plan (Worley Parsons 2010b) provides some of the information requested by staff, but does not include a conceptual revegetation plan that could be used to guide reclamation of the Project site after closure and decommissioning, nor does it provide sufficient information to develop an estimate of the funding needed for those activities.

Regulations promulgated by BLM at 43 CFR 3809.550 et seq. require a more detailed reclamation plan and a funding estimate. Page 5 of BLM's Instructional Memo for Oregon/Washington BLM Policy for 43 CFR 3809 Notice and Plan-level Occupations, 43 CFR 3715 Use and Occupancy and Reclamation Cost Estimates (BLM 2009b) lists the requirements for a reclamation plan as follows:

"(c) Reclamation Plan. A plan for reclamation to meet the standards in §3809.420 with a description of the equipment, devices, or practices proposed for use including, where applicable, plans for:

i. drill-hole plugging;

ii. regrading and reshaping;

iii. mine reclamation, including information on the feasibility of pit backfilling that details economic, environmental, and safety factors;

iv. riparian mitigation;

v. wildlife habitat rehabilitation;

vi. topsoil handling;

vii. revegetation;

viii. isolation and control of acid-forming, toxic, or deleterious materials;

ix. removal or stabilization of buildings, structures, and support facilities; and

x. post-closure management."

Page 3 of the same document also explicitly requires an estimate of the costs of reclamation, as follows:

> "*Reclamation Cost Estimate. An estimate of the cost to fully reclaim disturbances created during the proposed operations as required by §3809.552. The reclamation cost estimate must be developed as if the BLM were to contract with a third party to reclaim the operations according to the reclamation plan*."

Staff's proposed Condition of Certification **BIO-23** requires the Applicant to develop a Decommissioning and Closure Plan and cost estimate that meets the requirements of BLM's 43 CFR 3809.550 et seq. Staff acknowledges the uncertainty in planning for conditions 30 to 50 years in the future, but the Decommissioning and Closure Plan cannot defer establishing reasonable performance standards and goals until that time. The plan must explicitly state that the goals of reclamation include restoration of the site's topography and hydrology to a relatively natural condition and restoration of native plant communities. The plan must also provide guidelines for developing milestones and specific, quantitative success criteria for parameters such as native plant density and diversity and percent cover for weeds, thresholds that would trigger remedial actions, and information about what those remedial actions would be. The plan should also provide an approximate outline and schedule for monitoring the success of the reclamation effort. Staff recommends that the reclamation plan establish at least a 10-year monitoring period to achieve revegetation success criteria because of the slow pace of restoration in a desert environment.

C.2.5 REDUCED ACREAGE ALTERNATIVE

The Reduced Acreage Alternative would essentially be Unit 1 of the Proposed Project, including a 125 MW solar facility located within the boundaries of the Proposed Project as defined by NextEra. This alternative is analyzed for two major reasons: (1) it eliminates about 50 percent of the Proposed Project area so all impacts are reduced, and (2) by eliminating the eastern solar field, it would reduce the water required for wet cooling by 50 percent. The boundaries of the Reduced Acreage Alternative are shown in **Alternatives Figure 1** in the Alternatives section.

The Reduced Acreage Alternative would have a net generating capacity of approximately 125 MW and would occupy approximately 1,080 acres of land. This

alternative would retain 50 percent of the Proposed Project's generating capacity, and would affect 50 percent of the land affected by the Proposed Project. Specifically, the alternative would retain the Unit 1 solar field, including the construction parking, construction trailers, and temporary construction laydown area; the administration building and warehouse; the solar collector assembly area; the western evaporation pond area (approximately 24 acres); and the land farm area (approximately 10 acres). The alternative would require relocating the switchyard, from the Unit 2 power block to the Unit 1 power block. The eastern evaporation pond area (approximately 24 acres) that corresponds with Unit 2 would not be included in the Reduced Acreage Alternative. This area could be used for the relocated gas yard if needed.

Similar to the Proposed Project, the Reduced Acreage Alternative would transmit power to the grid through the Colorado River Substation. It would require infrastructure including groundwater wells, transmission line, road access, administration building, and evaporation ponds. The required infrastructure and transmission line for the Reduced Acreage Alternative would follow the routes defined for the Proposed Project, even though Unit 1 would not be constructed. The linear facilities would require approximately 90 acres. The gas pipeline would be approximately 1 mile longer than for the Proposed Project.

Dry cooling is being evaluated as an alternative to the Proposed Project, so could also be used with this configuration; however, if wet cooling were retained, water usage for the Reduced Acreage Alternative would be approximately 822 acre-feet per year.

C.2.5.1 SETTING AND EXISTING CONDITIONS

This alternative is located entirely within the boundaries of the Proposed Project. It simply eliminates approximately 800 acres from the Proposed Project. As a result, the environmental setting is similar to that of the Proposed Project (see **Biological Resources Table 7**). There are fewer acres of unvegetated ephemeral dry wash, stabilized and partially stabilized sand dune, and Sonoran creosote bush scrub plant communities. However, there are similar acres of playa and microphyll woodland, in part because the linear facilities route is the same for the Proposed Project and the alternative.

C.2.5.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

The smaller Reduced Acreage Alternative would have smaller impacts on many of the biological resources within the Project area, including desert tortoise habitat, unvegetated ephemeral dry washes, and migratory birds. The Reduced Acreage Alternative would have substantially less impact on Mojave fringe-toed lizard habitat both because of a decrease in impacts to stabilized and partially stabilized sand dunes and because the Reduced Acreage Alternative does not extend into the sand transport corridor, and therefore has no indirect downwind impact to sandy habitats outside of the Disturbance Area (**Biological Resources Table 8)**. In addition, the Reduced Acreage Alternative would use approximately 50 percent less groundwater than the Proposed Project, though it would still use a substantial amount. Both the Proposed Project and the Reduced Acreage Alternative would impact groundwater-dependent ecosystems through this use of groundwater. Because the linear facilities for the Proposed Project

and the Reduced Acreage Alternatives share the same route, impacts associated with this corridor are very similar. Impacts to Couch's spadefoot toad and microphyll woodland remain the same for both the Proposed Project and this alternative for this reason. In addition, although the Reduced Acreage Alternative does represent fewer acres of impacts, it is the same overall length as the Proposed Project, and therefore indirect impacts to desert washes that currently flow through the area remain similar. Staff considers direct, indirect, and cumulative impacts from the Proposed Project and the Reduced Acreage Alternative similar (aside from differences in impact acreage) for most impacts associated with the Proposed Project including to desert tortoise habitat, Couch's spadefoot toad, microphyll woodland, and migratory birds. While impacts from the Reduced Acreage Alternative are substantially less to Mojave fringe-toed lizard habitat and desert wash, these impacts would still be considered significant under this alternative as well as under the Proposed Project and Dry Cooling Alternative. Staff currently has insufficient information to fully assess indirect and cumulative impacts to groundwater-dependent vegetation, but these impacts may be considered significant under the Proposed Project and the Reduced Acreage Alternative.

Proposed conditions of certification under the Reduced Acreages Alternative are identical to those for the Proposed Project, except that the compensatory mitigation acreages recommended for desert tortoise habitat (staff's proposed Condition of Certification **BIO-12**), western burrowing owl (staff's proposed Condition of Certification **BIO-18**), sand dunes (staff's proposed Condition of Certification **BIO-20**), Mojave fringe-toed lizards (staff's proposed Condition of Certification **BIO-20**), and state waters (staff's proposed Condition of Certification **BIO-22**) are adjusted to reflect the reduced areas of impacts. Aside from the pending issue related to groundwater-dependent ecosystems, staff concludes that with implementation of these conditions, impacts from this alternative, as with the Proposed Project, would be less than significant.

C.2.5.3 CEQA LEVEL OF SIGNIFICANCE

Direct, indirect and cumulative impacts of the Reduced Acreage Alternative to desert tortoise, Mojave fringe-toed lizard, and other special-status species, as well as sensitive biological resources such sand dunes and desert washes are significant, as with the Proposed Project.

Biological Resources Table 7
Comparison of Impacts to Vegetation Communities from the Proposed Project and Reduced Acreage Alternative

	Proposed Project/Dry Cooling Alternative (acres)	**Reduced Acreage Alternative** (acres)
Riparian – Direct Impacts[1]		
Microphyll woodland	16	16
Unvegetated, ephemeral dry wash	74	51
Riparian – Indirect Impacts[2]		
Unvegetated, ephemeral dry wash	21	21
Total State Waters	*111*	*88*
Upland[3]		
Sonoran creosote bush scrub	1,786	1,039
Playa and sand drifts over playa	38	44
Stabilized and partially stabilized desert dunes	28	1.3
Total Upland	*1,852*	*1,083*

1 Proposed Project: From the memo "Revisions to Jurisdictional Waters for the Genesis Solar Energy Project" (TTEC 2010l).
Reduced Acreage Alternative: Estimate only - from TTEC 2010l, with the area impacted by Unit 2 removed.

2 Proposed Project: From Appendix D, Lake and Streambed Alteration Agreement Application (TTEC 2009d); the Reduced Acreage Alternative intercepts the same features as the Proposed Project, and therefore indirect impacts would be the same.

3 Proposed Project: From CEC 2010d (TetraTech table "Anticipated Direct and Indirect Impacts to Vegetation Communities").
Reduced Acreage Alternative: Estimate only - from **Biological Resources, Appendix A** and linear facility acreages included in CEC 2010d).

Biological Resources Table 8
Comparison of Mitigation Requirements for Proposed Project, Reconfigured Alternative, and Reduced Acreage Alternatives

Resource	Mitigation Ratio	Proposed Project/Dry Cooling Alternative (acres)	Reduced Acreage Alternative (acres)
Microphyll woodland – Direct Impacts	3:1	48	48
Unvegetated, ephemeral dry wash – Direct Impacts	1:1	74	51
Unvegetated, ephemeral dry wash – Indirect Impacts	0.5:1	10	10
Total state waters mitigation		**132**	**109**
DT habitat within CHU[1]	5:1	115	115
DT habitat outside CHU[2]	1:1	1,763	1,016
Total desert tortoise mitigation		**1,878**	**1,131**
MFTL habitat (sand dunes) – Direct Impacts[3]	3:1	84	4
MFTL habitat (playa and sand drifts over playa) – Direct Impacts	3:1	114	132
MFTL habitat (sand dunes, playa, other) – Indirect Impacts[4]	0.5:1	226	0
Total sand dune/MFTL mitigation		**424**	**136**

2 Proposed Project: From CEC 2010d (TetraTech table "Anticipated Direct and Indirect Impacts to Vegetation Communities").
Reduced Acreage Alternative: Estimate only, from **Biological Resources, Appendix A** and TTEC 2009d.
3 Stabilized and partially stabilized sand dunes, see source information for **Biological Resources Table 7**
4 From **Soil and Water, Appendix A**

C.2.6 DRY COOLING ALTERNATIVE

There are two types of dry cooling systems: direct dry cooling and the lesser used indirect dry cooling. In both systems, fans blow air over a radiator system to remove heat from the system via convective heat transfer (instead of once-through cooling or evaporative heat transfer). In the direct dry cooling system, also known as an air-cooled condenser (ACC), steam from the steam turbine exhausts directly to a manifold radiator system that rejects heat to the atmosphere, condensing the steam inside the radiator. Direct dry cooling is analyzed as alternative to the wet cooling proposed by NextEra for the Proposed Project.

Dry cooling is the best choice of cooling technologies for a steam power plant to conserve water and minimize wastewater. However, this technology can create both environmental and economic concerns, depending on the location and specific situation.

Advantages and Disadvantages of Dry Cooling

The following is a general list of the general advantages and disadvantages of dry cooling.

Advantages of Dry Cooling Systems

Dry cooling allows a power plant location to be independent of a water source. It has essentially no water intake or water discharge requirements.

Dry cooling minimizes the use of water treatment chemicals.
Dry cooling minimizes the generation of liquid and solid wastes.
Dry cooling does not generate visible plumes that are commonly associated with wet cooling towers.
Dry cooling eliminates impacts to aquatic biological resources.
Dry cooling eliminates the need for discharge permits.
Dry cooling eliminates the need for disturbance of wetland/aquatic substrate habitat.

Disadvantages of Dry Cooling Systems

Dry cooling requires air-cooled condensers that could have negative visual effects.

Compared to once-through cooling, dry cooling requires the disturbance of a larger area for the air-cooled condensers than that required for cooling towers.

Dry cooling can have noise impacts that are greater than once-through or wet cooling systems because of the number of fans and the considerably greater total airflow rate. New quieter fans and other mitigation measures are available to reduce these impacts.

Using dry cooling, the power plant steam cycle efficiency and output can be slightly reduced, depending on site conditions and seasonal variations in ambient conditions. Also, extra power is needed to operate the cooling fans.

Capital costs for building air-cooled condensers are generally higher than capital costs for once-through cooling.

While the area required for a dry cooling system would require about 40 to 50 percent more land area than the proposed wet cooling system, from the site layout, it appears that such a system would fit in the approximate current Project location as there is unused space between the power block and the solar collector assembly (GSEP 2009a). This unused space would have been previously graded as it is designed to be used for construction parking and construction trailers. Therefore, this alternative could be located entirely within the boundaries of the Proposed Project.

C.2.6.1 SETTING AND EXISTING CONDITIONS

This alternative is located entirely within the boundaries of the Proposed Project. It simply eliminates the use of wet-cooling towers and incorporated the use of air-cooled condensers in the same location. As a result, the environmental setting would be the same as for the Proposed Project.

C.2.6.2 ASSESSMENT OF IMPACTS AND DISCUSSION OF MITIGATION

Because this alternative would occupy the same footprint as the Proposed Project, the impacts remain the same between the two except for impacts to groundwater-dependent ecosystems. The Dry Cooling Alternative would use over 95% less groundwater than the Proposed Project. Impacts to groundwater-dependent ecosystems, through use of groundwater, are expected to be substantial under the Proposed Project, but would not under the Dry Cooling Alternative.

Staff considers direct, indirect, and cumulative impacts from the Proposed Project and this alternative the same for most impacts associated with the Proposed Project including to desert tortoise habitat, Couch's spadefoot toad, microphyll woodland, and migratory birds. Impact to groundwater-dependent ecosystems would not be considered significant under this alternative, while there is currently not enough information to determine the status of indirect and cumulative impacts from the Proposed Project on this resource.

Proposed conditions of certification under the Dry Cooling Alternative are identical to those for the Proposed Project, except that proposed Condition of Certification **BIO-25** (monitoring groundwater-dependent vegetation) and **BIO-26** (Remedial action for adverse effects to groundwater-dependent biological resources) would not be required. Aside from the pending issue related to groundwater dependent ecosystems, staff concludes that with implementation of these conditions, impacts from both alternatives would be less than significant.

C.2.6.3 CEQA LEVEL OF SIGNIFICANCE

Direct, indirect and cumulative impacts of the Dry Cooling Alternative to desert tortoise, Mojave fringe-toed lizard, and other special-status species, as well as sensitive biological resources such sand dunes and desert washes are significant, as with the Proposed Project.

C.2.7 NO PROJECT/NO ACTION ALTERNATIVE

C.2.7.1 NO ACTION ON PROPOSED PROJECT APPLICATION AND ON CDCA LAND USE PLAN AMENDMENT

Under this alternative, the Proposed Project would not be approved by the Energy Commission and BLM and BLM would not amend the CDCA Plan. As a result, no solar energy project would be constructed on the site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended.

Because there would be no amendment to the CDCA Plan and no solar project approved for the site under this alternative, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site, and no impacts to sensitive biological resources. However, the land on which the Project is proposed would become available to other uses that are consistent with BLM's land use plan, including another solar project requiring a land use plan amendment. In addition, in the absence of this Project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects may have some similar impacts in other locations.

C.2.7.2 NO ACTION ON PROPOSED PROJECT APPLICATION AND AMEND THE CDCA LAND USE PLAN TO MAKE THE AREA AVAILABLE FOR FUTURE SOLAR DEVELOPMENT

Under this alternative, the Proposed Project would not be approved by the Energy Commission and BLM and BLM would amend the CDCA Land Use Plan of 1980, as

amended, to allow for other solar projects on the site. As a result, it is possible that another solar energy project could be constructed on the site.
Because the CDCA Plan would be amended, it is possible that the site would be developed with the same or a different solar technology. As a result, sensitive biological resources would be impacted from the Proposed Project. Different solar technologies require different amounts of land, placement, grading and maintenance; however, it is expected that all the technologies would require a large use of land. As such, this No Project/No Action Alternative could result in biological resource impacts similar to the impacts under the Proposed Project.

C.2.7.3 NO ACTION ON PROPOSED PROJECT APPLICATION AND AMEND THE CDCA LAND USE PLAN TO MAKE THE AREA UNAVAILABLE FOR FUTURE SOLAR DEVELOPMENT

Under this alternative, the Proposed Project would not be approved by the Energy Commission and BLM and the BLM would amend the CDCA Plan to make the proposed site unavailable for future solar development. As a result, no solar energy project would be constructed on the site and BLM would continue to manage the site consistent with the existing land use designation in the CDCA Land Use Plan of 1980, as amended. Because the CDCA Plan would be amended to make the area unavailable for future solar development, it is expected that the site would continue to remain in its existing condition, with no new structures or facilities constructed or operated on the site. As a result, new impacts to biological resources would not occur, as such, this No Project/No Action Alternative would not result in impacts to biological resources that would occur under the Proposed Project. However, in the absence of this Project, other renewable energy projects may be constructed to meet State and Federal mandates, and those projects may have some similar impacts in other locations.

C.2.8 CUMULATIVE IMPACT ANALYSIS

C.2.8.1 CEQA AND NEPA DEFINITIONS

A cumulative impact analysis is required under both CEQA and NEPA. “Cumulative impact” is the impact on the environment which results from the incremental impact of the proposed Project when considered with other past, present, and reasonably foreseeable future actions regardless of which agency (federal or non-federal) or person undertakes such other actions (40 CFR §1508.7).

Under CEQA Guidelines, “a cumulative impact consists of an impact which is created as a result of the combination of the project evaluated in the EIR together with other projects causing related impacts” (Title 14 Cal Code Regs §15130(a)(1)). Cumulative impacts must be addressed if the incremental effect of a project, combined with the effects of other projects is “cumulatively considerable” (Title 14 Cal Code Regs §15130(a)). Such incremental effects are to be “viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects” (Title 14 Cal Code Regs §15164(b)(1)). Together, these projects comprise the cumulative scenario which forms the basis of the cumulative impact analysis.
NEPA states that cumulative effects can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR §1508.7). Under NEPA,

both context and intensity are considered. When considering intensity of an effect, we consider “whether the action is related to other actions with individually minor but cumulatively significant impacts. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.” (40 CFR §1508.27(b)(7))

Analysis of Cumulative Effects to Biological Resources

Staff used the following steps to develop the cumulative effects analysis described in this subsection:
Identified the biological resources to consider in the analysis from a review of the impact analysis;
Defined the geographic Study area for each resource;
Described the current health and historical context for each resource;
Identified direct and indirect impacts of the proposed project that might contribute to a cumulative impact;
Identified other reasonably foreseeable projects that affect each resource;
Assessed potential cumulative impacts;
Reported the results; and
Assessed the need for mitigation.

C.2.8.2 GEOGRAPHIC SCOPE

This cumulative impact analysis makes a broad, regional evaluation of the impacts of existing and reasonably foreseeable future projects that threaten plant and animal communities within the context or geographic scope of the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) (BLM-CDD 2002). The NECO planning area is located in the southeastern California Desert Conservation Area (CDCA). It occurs primarily in the Sonoran Desert region, but includes a smaller portion of the southern Mojave Desert region. For some resources, a different geographic scope was warranted, such as the use of watershed boundaries to analyze cumulative effects to desert washes, or the Chuckwalla Valley region of the I-10 corridor for populations or dune systems restricted to that geographic area.

C.2.8.3 REGIONAL OVERVIEW

This overview of regional impacts is followed by a more detailed discussion of the effects of past, present, and future projects to biological resources of the Project vicinity, with an emphasis on resources found within the Chuckwalla Valley of eastern Riverside County.

The California Desert remained a desolate area for the first few decades of the 20th century. Disturbance was more or less restricted to highways, railroad, and utility corridors, scattered mining, and sheep grazing. In the 1940s, several large military reservations were created for military training, testing, and staging areas. The deserts of eastern Riverside County comprise 40 percent of the County’s land area but less than 1 percent of its population. Outside of the small urban-agricultural center of Blythe, near the Colorado River and Arizona border, there are only a few scattered, small residential and agricultural areas between Indio (to the west) and Blythe; most of the lands are in BLM ownership.

Populations of many of the desert's sensitive plants and animals were considered relatively stable until recently, as the push for renewable energy development has placed many populations at risk. Climate change is inarguably one of the biggest environmental challenges of our time and energy developers have submitted project applications that would collectively cover more than one million acres of the region (BLM 2010). However, renewable energy development has its own ecological consequences and portions of the Sonoran and Mojave deserts of California are bearing the brunt of these effects. Poorly planned development could contribute to habitat loss and fragmentation and barriers to species movement and gene flow. Although project permitting and regional planning evaluate basic environmental impacts of such projects, rarely do they consider impacts on connectivity or conduct thorough cumulative effects analyses.

Some of the many sensitive biological resources at risk In the areas identified for renewable energy development in the NECO planning area include desert washes and desert dry wash woodland, desert tortoise habitat, foraging habitat for golden eagle, Mojave fringe-toed lizard, western burrowing owl, American badger, riparian habitat for Le Conte's thrasher and other desert birds in decline, fragile dune ecosystems, burro deer range, the special-status plants Las Animas colubrina and Harwood's milk-vetch, and groundwater dependent vegetation. The Project also lies within a proposed Wildlife Habitat Management Area (Palen-Ford Wildlife Habitat Management Area). These resources will not only be affected by significant direct and indirect effects from the proposed Project, but will experience similar effects from over 20 reasonably foreseeable future projects within the NECO planning area alone.

The incremental, direct loss of habitat and individuals is more significant when considered with the significant indirect effects of fragmentation, disrupted wildlife movement and connectivity, introduction and spread of non-native plant species, and increases in predators such as ravens. These effects have contributed to population declines and range contractions for many special-status plant and animal species (Boarman 2002a). Combined with the effects of historical grazing and military training, agriculture, and highway and aqueduct construction, the proposed wind and solar energy projects have the potential to further reduce and degrade native plant and animal populations.

C.2.8.4 MAKING CONCLUSIONS ABOUT THE SEVERITY OR SIGNIFICANCE OF THE EFFECT

"No net loss" does not necessarily mean there are no cumulative impacts; the analysis of each resource also describes the indirect and cumulative effects that cannot be quantified through a Geographic Information System (GIS) analysis of habitat impacts. Similarly, even seemingly minor impacts can be significant if they affect an extremely rare or limited resource, and the cumulative impact may be substantial.

For each cumulative effect the following questions were considered in making conclusions about the severity or significance of an effect:

The health, status, or condition of the resource as a result of past, present, and reasonably foreseeable impacts;

The contribution of the proposed project to the overall cumulative impact to the resource;

The project's mitigated effect, when added to the effects of these planned future projects; and

Impact avoidance and minimization: any project design changes that were made, or additional opportunities that could be taken, to avoid and minimize potential impacts in light of cumulative impact concerns.

The standard for a cumulative impacts analysis is defined by the use of the term "collectively significant" in the CEQA Guidelines section 15355; the analysis must assess the collective or combined effect of development. Cumulative impact assessments cannot conclude that contributions to cumulative impacts are not significant because the contributions represent a small percentage of the overall problem. Doing so could improperly omit facts relevant to an analysis of the collective effect that the Project and other related projects would have upon biological resources. The result could be approval of projects based on an analysis that avoided evaluating the severity of impacts which, when taken in isolation appear insignificant, but when viewed together appear significant.

C.2.8.5 ANALYTICAL TOOLS AND STUDY LIMITATIONS

This cumulative effects analysis employed a combination of quantitative and qualitative analyses; a Geographic Information System (GIS)-based quantitative analysis for assessing the direct cumulative effects to habitat loss, and a qualitative analysis of the cumulatively considerable indirect effects, based on consultations with agency biologists and regional experts, as well as a literature review of the threats to species and their habitats.

GIS-Based Quantitative Analysis of Habitat Loss

The GIS-based analysis of direct habitat loss was used for this cumulative effects analysis to:

- Identify the overlap between existing and future projects and various biological data layers (e.g. landforms, soils, species occurrences, hydrographic data, vegetation mapping, wildlife habitat models, ownership and management layers);

- Compile digital map information about each resource for purposes of display and analysis; and

- Create statistical tables to summarize the direct impacts to these resources from existing and anticipated future projects, and the Project's contribution to those effects. Information on the datasets used, the sources of the data, and any limitations of the data, are provided in each biological resource section.

Qualitative Analysis of Indirect Effects

GIS is a widely used and effective tool for analyzing large amounts of spatial data, for documenting and quantifying assumptions about direct habitat loss, and the value of the

habitat (where habitat models are available). However, the indirect impacts of projects are not easily captured in GIS and thus were only addressed qualitatively. This is important to note because many of these indirect effects (i.e., effects following construction) have greater significance and greater ecological consequences than the original habitat loss. Of particular concern are the effects of habitat fragmentation and its consequences for population viability and the effects of disrupted wildlife movement and connectivity and its effects on gene flow, subjecting populations of species such as bighorn sheep to isolation and inbreeding depression, and reducing their adaptability to climate change.

Other common themes that arose in this qualitative analysis of indirect cumulative effects include: increased vehicle-related mortality; disturbance from noise, lighting and increased human activity; increase in predators such as ravens; spread of invasive non-native plants; downwind effects of facilities and wind fencing on sand transport corridors; bird collisions and electrocutions; climate change and its accompanying increased risk of drought, fire the and spread of invasive exotic plants; and the downstream effects of channel diversions on fluvial sediment transport and riparian vegetation.

Limitations of the Cumulative Project Data and Datasets

The large renewable projects proposed on BLM and private land that made up the dataset of future projects in the cumulative analysis for Biological Resources (**Biological Resources Table 9**) represent only those projects that had applications to the BLM, the Energy Commission, or eastern Riverside County as of January 2010 (the time of the analysis). **Biological Resources Figures 1** and **2** include projects for which staff had no GIS-based shapefiles at the time of the analysis; thus, they were not included in the quantitative analysis. The project list changes frequently; updates to the data used are presented below and in Section B.3.2, **Cumulative Scenario**. Further, not all of the projects shown on the table will complete the environmental review, and not all projects will be funded and constructed. Alternatively, it is possible, even likely, that new projects will be proposed in the near future that are not reflected in this analysis. See Section B.3.2 (Cumulative Scenario) for a discussion on the likelihood of development of the renewable projects on BLM and private lands listed in **Biological Resources Table 9** and illustrated in **Biological Resources Figures 1** and **2**.

This analysis does not compare the loss of individuals against the total known metapopulation; population data are incomplete for many or most species or occurrences and for some species can vary widely from year to year in response to drought.

Finally, in the GIS-based analysis, which requires the use of datasets that encompass the entire geographic scope of the analysis, the Project-specific survey data could not be compared against data for the region that was derived from different methodologies. For example, the Project survey data for waters and habitat is generally based on field surveys. Conversely, the NECO datasets for plant communities and habitats are based largely on aerial photo interpretation. Consequently, the GIS analysis of impacts to plant communities, landforms, and habitats is based on region-wide datasets for those resources (primarily NECO datasets), and not on Project survey data. Acreages listed in

the analysis below, for example desert wash woodland or sand dunes, will not match the Project-specific survey results. Where there are such differences, they are noted in a footnote to the table or in the summary of a specific analysis. Notwithstanding the challenges presented by comparing region-wide and Project-specific datasets, the GIS-based datasets for vegetation and landforms still provide a powerful and efficient tool for conducting large-scale, region-wide analyses.

C.2.8.6 PROJECTS CONTRIBUTING TO CUMULATIVE EFFECTS TO BIOLOGICAL RESOURCES

This analysis evaluates the impacts of the proposed Project in addition to the current baseline of past effects, present (existing) projects, and reasonably foreseeable or probable future projects in the I-10 corridor as well as the greater NECO Planning Area. **Biological Resources Figure 1**, located at the end of this section, illustrates the numerous proposed renewable projects on BLM, State and private land in the I-10 corridor between Desert Center and the Colorado River, near Blythe, in eastern Riverside County. **Biological Resources Figure 2** encompasses the entire NECO planning area, an area that is roughly equivalent to the boundaries of the Northern and Eastern Colorado Desert Recovery Unit for desert tortoise. **Biological Resources Table 9** lists the existing and foreseeable future projects (proposed) that were included in the quantitative analysis of cumulative effects. See Section B.4, **Cumulative Scenario Figures 2** and **3** and **Cumulative Scenario Tables 2** and **3** for descriptions of these existing and future proposed projects.

Biological Resources Table 9
Existing and Proposed Future Projects Considered in Cumulative Effects Analysis

Existing Projects (analyzed quantitatively)	ROW Area* (ac)	Foreseeable Future Projects * [Proposed] (analyzed quantitatively)	ROW Area* (ac)
Chuckwalla State Prison	**1,044**	**Genesis Solar Power Project (GSEP)**	**3,001****

Pipeline (NECO pipelines dataset)	**4,392**	**Red Bluff Substation –** for Genesis Solar Power Project	**90**
Projects Considered Qualitatively	**Area (ac)**	**Colorado Substation –** for Blythe Solar Power Project	**44**
Existing		**EnXco 2 Mule Mountain**	**~2,021**
BLM Grazing – Cattle and sheep allotments (Lazy Daisy, Chemehuevi, Rice Valley, and Ford Dry Lake (recently closed)	**n/a**	**Paradise Valley** (Residential "New Town" development)	**6,724**
BLM Multiple Use – Intensive multiple-use classes	**n/a**	**Blythe Airport Solar I Project**	**639**
Gen. Patton military training areas	**n/a**	**Eagle Mountain Landfill**	**1,633**
Colorado Aqueduct – open portions	**n/a**	**Blythe Energy Project II**	**153**
Chocolate Mountains Aerial Gunnery Range	**n/a**	**DPV2 Proposed Roads** (2-foot width) **and towers** (100 sq ft/tower)	**256**
Four approved commercial and 12 residential developments near Blythe	**n/a**	**Genesis Solar Project Access Road**	**29**
Solar Projects at Arizona border	**n/a**	**Blythe Energy Project Transmission Line Towers**	**148**
BLM Renewable Energy Study Areas (future, proposed)	**n/a**		
BLM Transmission Corridors	**n/a**		
		Genesis Solar Project Gas Line (100 foot width)	**85**
		Total Future Projects* 02/05/2010	**339,704 acres**
		Total Existing Disturbances*	**134,750 acres**

* Includes only renewable energy projects that had submitted a Plan of Development (POD) as of the time of the analysis (02/05/2010) and projects for which area data was available. Acreage shown for existing disturbances reflects only those projects for which area data was available.

** Acreage impacts depicted reflect the project footprint only; not the entire ROW. The unused portions of the ROW will be returned to BLM and not included in the final ROW permit
*** UFWS issued a BO for this project in 2001 and it's currently being constructed.
**** Not all of the projects depicted here will complete the environmental review, not all projects will be funded and constructed, and many will not use the entire ROW area.

Project Information Updates

Since **Biological Resources Table 9** was compiled and the GIS analysis conducted, several project changes have occurred, as follows:
The Altera Black Hills project included in the impact calculations has been denied by the BLM.
The LightSource Renewables – Mule Mountain II project, which is an active application in to the BLM, was not included in the impact calculations.
The Pacific Solar Investments – Ogilby project has refined the project boundaries from those used in the impact calculations.

C.2.8.7 ANALYSIS OF CUMULATIVE EFFECTS TO BIOLOGICAL RESOURCES

Waters of the State

The geographic scope for the analysis of cumulative impacts to desert washes include: the Chuckwalla-Ford Dry Lake watershed (the watershed encompassing the project) and the entire NECO planning area. The watershed area analysis (**Biological Resources Figure 3**) was based on the USGS National Hydrographic Dataset (2010) within the watershed boundary as defined by the California Interagency Watershed Map of 1999 (California Interagency Watershed Mapping Committee 1999). All figures are provided at the end of the cumulative effects analysis.

The primary hydrologic feature in the watershed is Ford Dry Lake, a depressional sink and dry playa. It is a closed basin, and the receiving basin for 1,504 miles of unnamed desert washes, including the many smaller ephemeral desert washes that pass through the Project site and drain the southeastern flank of the Palen Mountains. The "Palen Wash" is the larger feature that drains the alluvial fan between the Palen and McCoy Mountains. McCoy Spring and an an old growth forest of ironwood occur on its upper reaches. The lower reaches of this feature passes through the western portion of the transmission line, natural gas line, and access road alignment.

The Chuckwalla-Ford Dry Lake watershed is relatively unaffected by existing impacts with one notable exception that was not analyzed quantitatively – the construction of I-10 and a series of wing dikes south of I-10. These permanently diverted surface flows from miles of small ephemeral desert washes and desert dry wash woodland north of 1-10, leaving miles of scattered dead ironwood trees and poor creosote bush desert scrub in their wake. Plant cover is very sparse, and diversity very low in these affected areas; they are also a testament to the downstream effects that channel diversions, including small channels, can have on both upland and riparian plant communities. For the Project, these effects would be minimized somewhat by the proposed redistribution of flows below the Project into many (not all) of the delineated channels downstream of the Project, but it is unclear to what extent sediment transport in the diverted channels would be affected.

Portions of the I-10 corridor were also disturbed historically for military training exercises during World War II, and later by jojoba farming and various transmission corridors (gas and electric). There are several large infestations of Sahara mustard in this area but the watershed is otherwise little affected by existing impacts. **Biological Resources Table 10** summarizes the direct loss of desert washes that would result from anticipated future projects within the Ford Dry Lake watershed. These effects are also illustrated spatially in **Biological Resources Figure 3.** Proposed future projects would affect approximately 63 miles of desert washes (4.2 percent). Based on the USGS National Hydrographic Dataset (2010) that was used to quantify existing and future impacts throughout the watershed, the Project would affect 2.9 miles (4.6 percent of all future impacts). The ground-based and field-verified delineation of state waters (TTEC 2010l) is provided as a footnote to **Biological Resources Table 10**. Staff considers these effects significant..

The direct loss of channels (**Biological Resources Table 10**) is only part of the bigger picture of cumulative effects to desert washes, however. Significant indirect cumulative effects to these features that are not reflected in the quantitative analysis include impacts to sediment transport from the numerous channel diversions, impacts to wind sand transport processes from the loss of sediment input, impacts to water quality from culverts and road crossings, fragmentation of habitat, and the corresponding loss of habitat function and values.

Cumulative impacts to washes adjacent to dune systems may also have unanticipated consequences to dune habitat and the special-status plants and animals that depend on them. Recent geomorphology studies of the sand transport systems of the Chuckwalla Valley dune systems (**Soil & Water Appendix A**) suggest that the affected washes around the Chuckwalla dunes are also an important contributor to the sand transport system; the potential indirect effects of channel diversions and redistribution below the various solar project sites are not well understood. The downstream indirect impacts of the Project would be minimized, at least in part, through the Applicant's revisions to the drainage plan, which would discharge diverted flows into existing flow paths between the Project and Ford Dry Lake (See **Soil and Water** section for a discussion of Channel Maintenance requirements).

The contribution of the Project to cumulative effects from future projects provided shown in **Biological Resources Table 10** is based on the USGS National Hydrographic Dataset (2010) within the watershed boundary as defined by the California Interagency Watershed Map of 1999 (Calwater 2.2.1); the results of the ground-based delineation of washes is shown as a footnote to **Biological Resources Table 10**.

With the Project design changes, described above, and implementation of staff's proposed Conditions of Certification (**BIO-22, BIO-7, BIO-8**, **BIO-14** and **BIO-23**), staff has concluded that the Project's contribution to cumulative impacts would be reduced to a level less than significant. Staff's proposed Condition of Certification **BIO-22** requires compensation through acquisition of desert washes within or adjacent to the Ford watershed); **BIO-7** specifies mitigation monitoring and reporting requirements; **BIO-8** requires implementing avoidance and minimization measures; **BIO-14** requires finalizing and implementing a detailed weed management plan, and **BIO-23** requires implementing a closure and decommissioning plan for restoring the site topography and hydrology to a more natural condition and revegetating with the locally native species.

Biological Resources Table 10
Cumulative Effects: Desert Washes in Ford Lake Watershed

Total Desert Washes* in Genesis Watershed	**Impacts to Habitat from Existing Projects**** (Percent of total watershed)	**Impacts to Habitat from Foreseeable Future Projects***** (Percent of total watershed)	**Contribution of GSEP to future cumulative impacts** (Percent of total impacts from Future projects)
1,503 miles	**13 miles (0.9%)**	**63 miles (4.2%)**	**2.9 miles (4.6%)** (based on USGS dataset)

*Based on the USGS National Hydrographic Dataset (2010) and CalWater Version 2.2.1 (California Interagency Watershed Mapping Committee 1999).
** Includes only those existing projects for which GIS-based spatial data was available at the time of the analysis; see **Biological Resources Table 9**.
***The ground-based, field-verified delineation of state waters concluded that 90 acres of desert washes would be directly affected and 21 acres would be indirectly affected downstream of the Project (TTEC 2010l, TTEC 2009d).

Biological Resources Table 11 and **Biological Resources Figure 4** illustrate the potential cumulative impacts to all desert washes within the entire NECO planning area, as depicted in the USGS National Hydrographic Dataset (USGS 2010). Cumulative impacts to desert washes from all foreseeable future projects within NECO are significant. Within the NECO planning area, the northern Palo Verde Mesa watershed (near Blythe) and the watersheds immediately north of Highway 62 near Cadiz Valley and Danby Lake are particularly hard-hit by proposed future projects. The cumulative projects' direct effects are compounded by the fact that they also cause impairment of hydrologic, geochemical, geomorphic, and habitat function and values of the remaining reaches downstream of the impact.

Although the Project's contribution to cumulative effects is relatively smaller in the context of the entire NECO planning area, it nevertheless contributes to a significant cumulative effect. With implementation of conditions of certification **BIO-22** for compensatory mitigation of desert washes within the immediate watersheds, avoidance and minimization measures described in **BIO-8**, monitoring and reporting requirements contained in **BIO-7**, and the channel decommissioning and reclamation efforts required by **BIO-23**, the Project's contribution to cumulative impacts would be reduced to a level less than significant.

Biological Resources Table 11
Cumulative Effects: Desert Washes in the NECO Planning Area

Total Desert Washes* in NECO	Impacts to Habitat from Existing Projects** (Percent of total washes in NECO)	Impacts to Habitat from Foreseeable Future Projects*** (Percent of total washes in NECO)	Contribution of GSEP to future cumulative impacts (Percent of total impacts from Future projects)
18,596 miles	**190 miles (1.0%)**	**1,122 miles (6.0%)**	**2.9 miles (0.3%) (based on USGS dataset)**

*Based on the USGS National Hydrographic Dataset (USGS 2010).
** Includes only those existing projects for which GIS-based spatial data was available at the time of the analysis; see **Biological Resources Table 9**.
***The ground-based, field-verified delineation of state waters concluded that 90 acres of desert washes would be directly affected and 21 acres would be indirectly affected downstream of the Project (TTEC 2010l, TTEC 2009d).

Special-Status Wildlife

Desert Tortoise

This analysis addresses cumulative impacts to desert tortoise habitat as defined by the current USGS Desert Tortoise Habitat Model (Nussear et al. 2009). It is a predictive model for mapping the potential distribution of desert tortoise habitat and is useful tool for evaluating different land-use issues that tortoises face at a landscape scale. **Biological Resources Figure 5** is a spatial representation of the predicted habitat potential index values for desert tortoise, based on the 2009 model. The model is not intended to be used, or viewed, as a substitute for ground-based and site-specific field surveys. Model scores reflect a hypothesized habitat potential given the range of environmental conditions where tortoise occurrence was documented. Nussear et al. (2009, p. 15) specifically states:

> "*As such, there are likely areas of potential habitat for which habitat potential was not predicted to be high, and likewise, areas of low potential for which the model predicted higher potential. Finally, the map of desert tortoise potential habitat that we present does not account either for anthropogenic effects, such as urban development, habitat destruction, or fragmentation, or for natural disturbances, such as fire, which might have rendered potential habitat into habitat with much lower potential in recent years*".

GIS-based files for the boundaries of the Eastern and Northern Colorado Recovery Units of the 1994 Desert Tortoise Recovery Plan were not available from the USFWS and the proposed new boundaries as depicted in the USFWS 2008 Draft Revised Recovery Plan had not been adopted as of the time of this analysis. Consequently, the NECO planning area boundary was used for this analysis. The NECO boundary closely approximates the boundaries of the two USFWS recovery units; however, the USFWS boundaries extend slightly to the north and west of the NECO boundary.

The Project's unmitigated effects to desert tortoise habitat (based on the 2009 USGS habitat model) are quantified below in **Biological Resources Table 12** (and **Biological Resources Figure 5**). Most of the proposed projects in the NECO area would impact lower quality desert tortoise habitat, according to the predictive model. Across the NECO planning area, the cumulative effects to moderate quality desert tortoise habitat from proposed future projects is particularly significant but even seemingly minor effects

to higher quality habitat are significant given the species' decline and the present and future direct and indirect threats from habitat fragmentation and its associated impacts on population viability, the effects of increased predation from ravens, and other reasonably foreseeable future threats.

One of the objectives for desert tortoise recovery in the NECO is to "*mitigate effects on desert tortoise populations and habitat outside DWMAs to provide connectivity between DWMAs*." Maintaining connectivity is particularly important given the threats posed by global climate change, according to the USFWS 2008 Draft Revised Recovery Plan. Probable desert tortoise linkages between the Chuckwalla and Chemehuevi Critical Habitat Units and DWMAs are shown in **Biological Resources Figure 6.** The linkages depicted represent areas of the best habitat quality for tortoises between the DWMAs and critical habitat, and therefore represent the most probable linkages and most important areas to protect to maintain connectivity between the Chemehuevi and Chuckwalla DWMAs. The identified linkages are based on a review of information on existing vegetation and landform data (NECO datasets and Project-specific survey data) and depicted in the USGS habitat model. The location of available lands in "probable" linkages is a useful tool for identifying potential acquisition lands for desert tortoise mitigation, and for evaluating different land-use issues that tortoises face at a landscape scale. **Biological Resources Figure 6** identifies these linkages based on the areas of moderate and high quality habitat between management areas for a qualitative analysis of cumulative effects; however, the impacts are not quantified here as the linkages have not been formalized or created as shape layers suitable for GIS analysis. Along with the linkages depicted in **Biological Resources Figure 6**, additional linkages through areas currently considered lower quality habitat that could be restored may also be important for long-term connectivity between the Chemehuevi and Chuckwalla DWMAs. The Project would not contribute significantly to loss of desert tortoise connectivity between the Chuckwalla and Chemehuevi Desert Wildlife Management Areas (DWMAs) and Critical Habitat Units.

While impacts to higher quality habitat are small (approximately 3 percent) relative to cumulative effects to moderate and low quality habitat, this nevertheless represents over 53,000 acres of habitat and over 150,000 acres of moderate and moderately high quality habitat that would be lost to proposed future projects. Although the project contributes a relatively small percentage of lower quality habitat, it contributes to a significant cumulative effect to an imperiled species.

With the implementation of staff's proposed Condition of Certification **BIO-12** (acquisition of compensation lands), desert tortoise-specific avoidance and minimization measures **BIO-1** through **BIO-6**, and monitoring and reporting requirements in **BIO-7,** staff believes that the Project's contribution to cumulative impacts to desert tortoise habitat would be reduced to a level less than significant. Condition of Certification **BIO-12** specifies that compensation habitat acquisitions occur within the Colorado Desert Recovery Unit in areas that have potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise designated critical habitat, known populations of desert tortoise, and/or other preserved lands. Indirect effects to desert tortoise from ravens and the degradation of habitat quality from the spread of noxious weeds would be minimized through the detailed raven and weed management plans required under **BIO-13** and **BIO-14.**

Biological Resources Table 12
Cumulative Effects: Desert Tortoise Habitat*

Habitat Value*	Total Desert Tortoise habitat* in NECO	Impacts to Habitat from Existing** Projects (Percent of total in NECO)	Impacts to Habitat from Foreseeable Future*** Projects (Percent of total in NECO)	Contribution of GSEP to future cumulative impacts (Percent of total impacts from Future projects)

*** Includes only BLM Renewables that had submitted a Plan of Development at the time of the analysis and those additional future projects listed in **Biological Resources Table 9**.

Implementation of staff's proposed conditions of certification would reduce the Project's contribution to cumulative impacts to desert tortoise habitat, movement, and connectivity to a level that is not cumulatively considerable. There may be cumulative impacts after mitigation is implemented by all projects, but due to the mitigation implemented by the Project, its contribution is less than cumulatively considerable. These residual cumulative effects from all future projects could be addressed through a regional and coordinated planning effort aimed at preserving and enhancing large, intact expanses of wildlife habitat and linkages, including maintaining connections between wildlife management areas and other movement corridors.

Nelson's bighorn sheep

The distribution and extent of the NECO-designated bighorn sheep WHMAs (occupied and unoccupied range) and connectivity corridors, overlaid with past and foreseeable future projects within the NECO Planning Area, are quantified in **Biological Resources Table 13** and illustrated in **Biological Resources Figure 7-a**. The GIS analysis of the NECO bighorn sheep WHMAs and connectivity corridors indicates that occupied and unoccupied ranges and connectivity corridors are unaffected by the proposed Project. However, large-scale renewable energy development in the region north of Highway 62 could significantly impact gene flow between sheep populations through significant cumulative impacts to connectivity corridors, potentially decreasing the viability of the metapopulation of bighorn sheep. The Genesis Project itself, however, has no direct contribution to the loss of habitat within the identified connectivity corridors or the WHMAs.

The Genesis project is located within the proposed Palen-Ford multi-species WHMA (BLM CDD 2002; map 2-21); but is mainly located outside the sensitive habitats for which the WHMA was primarily established (i.e., dunes and playas). The Project is not located within a bighorn sheep WHMA or corridor (BLM CDD 2002). The cumulative effects of all other proposed future projects on bighorn sheep connectivity can only be addressed through a regional and coordinated effort aimed at preserving and enhancing large, intact expanses of wildlife habitat and linkages, including maintaining connections between wildlife management areas and other movement corridors.

Biological Resources Table 13
Cumulative Effects: Bighorn Sheep WHMAs and Connectivity Corridors

Another consideration of this analysis was whether the proposed future projects would cumulatively and significantly affect bighorn sheep through the loss of spring forage on the upper bajadas adjacent to occupied range. Based on recommendations from the Society for Conservation of Bighorn Sheep, staff analyzed the impact of existing and future projects within a one-mile buffer from the base of occupied ranges (or potentially restored populations in unoccupied ranges) on plant communities to assess the potential impacts to bighorn foraging habitat. These impacts are depicted in **Biological Resources Figure 7-b** and summarized in **Biological Resources Table 14**, below. No direct or cumulative effects to bighorn sheep WHMAs or spring foraging habitat would result from the proposed Project and thus no mitigation measures relating to bighorn sheep are proposed by staff. Impacts to spring foraging habitat in other affected portions of NECO remain significant, however. Playa and sand drifts over playa are hardest hit but this would not be considered preferred forage as these habitats are characteristically sparse. Approximately 4.5 percent of all spring forage in Sonoran creosote bush scrub and an additional 3.3 percent of Mojave creosote bush scrub within

a mile of bighorn sheep WHMAs would be affected from all other foreseeable future projects.

Mojave Fringe-toed Lizard

The geographic scope for the first of two cumulative effects analyses for Mojave fringe-toed lizard is the entire NECO planning area; the second analysis looked only at the habitat for the Chuckwalla Valley population. The NECO habitat dataset for Mojave fringe-toed lizard, which included all but the highest portions of the mountain ranges, was refined to reflect the species restriction to sandier substrates. Using the NECO landforms dataset, staff created a habitat model by selecting the following landforms: crescentic dunes, longitudinal dunes, undifferentiated dunes, sandy dissected fans, sandy plains, and dry playas. Playas were included because they often have at least a veneer of sand. The selected landforms were overlaid with documented occurrences of

Mojave fringe-toed lizard from CNDDB and the detailed field survey data from four renewable energy projects within the NECO boundary. The occurrence data was in considerable agreement with the selected landforms; no corrections were necessary and no attempt was made to rank habitat value. **Biological Resources Figure 8** and **Biological Resources Table 15** present the results of the Mojave fringe-toed lizard habitat mapping overlaid with the existing and future projects within the NECO planning area to quantify the cumulative effects of all projects on habitat loss. **Biological Resources Table 15** also summarizes the cumulative loss of habitat for six additional plant and animal species discussed later in this section (American badger and desert kit fox, burrowing owl, Le Conte's thrasher, burro deer, Couch's spadefoot toad, and Harwood's milk-vetch),

However, there are also significant indirect cumulative effects to Mojave fringe-toed lizard that are not reflected in this quantitative analysis of habitat loss. These include impacts to sand transport systems and the maintenance of dunes from renewable energy projects (wind fencing and the obstruction of sand-carrying winds and water-deposited sands); premature stabilization of dunes by the spread of noxious weeds, which also fuel wildfires; increased risk of fire from transmission lines and increased ignition rates and vehicle-related mortalities from the introduction of vehicles into formerly undisturbed habitats; the effects of past and future grazing and off-road vehicle use; fragmentation of the remaining habitat and the accompanying isolation and reduced population viability; and an increase in predation by ravens and other predators from an increase in perching structures. Staff considers these indirect cumulative effects significant.

Future (proposed) projects alone will cumulatively cause a direct loss of over 103,000 acres (16 percent) of all Mojave fringe-toed lizard habitat. Although the Project's contribution to these NECO-wide effects is relatively minor it nevertheless contributes, at least incrementally, to a significant cumulative effect.

Within Chuckwalla Valley (**Biological Resources Table 15** and **Biological Resources Figures 9**), nearly 13,000 acres (12.9 percent) of the Mojave fringe-toed lizard habitat would be directly impacted by the construction of all proposed projects. The Project's contribution to the direct loss of habitat for the Chuckwalla Valley population of Mojave fringe-toed lizard is somewhat more substantial in the local context (2 percent). These effects are far more significant when combined with the expected indirect effects to Mojave fringe-toed lizard habitat in Chuckwalla Valley described above. Of particular concern with all proposed projects within the aeolian (wind-deposited) sand transport corridor is the indirect downwind loss of dune habitat and habitat quality from obstructions (structures and wind fencing). Studies and examples in nearby Coachella Valley suggest that such effects can be acute and occur quickly (Katra et al. 2009; Turner et al. 1984). Staff considers these cumulative direct and indirect effects to the Chuckwalla Valley population of Mojave fringe-toed lizard, to which the Project contributes, to be significant.

To minimize the Project's contribution to significant cumulative effects to a level less than significant, staff proposes compensatory mitigation for both the direct and indirect (downwind) effects of the project on Mojave fringe-toed lizard habitat through Condition of Certification **BIO-20**, which requires implementation of impact avoidance and

minimization measures and acquisition of habitat to mitigate for the Project-related loss of sand dune and other sandy habitats that support Mojave fringe-toed lizards. Condition of Certification **BIO-20** specifies that the acquisitions would need to be targeted for sand dune or partially stabilized sand dune habitat within the Chuckwalla Valley. Impacts to desert washes in Chuckwalla Valley, some of which contribute sand to the aeolian transport corridor, would be offset through Condition of Certification **BIO-22** by acquiring and preserving private lands in the valley containing desert washes that are not currently protected under a conservation easement and could be developed in the future. Indirect effects from ravens and the spread of Sahara mustard and other noxious weeds would be minimized through **BIO-13** and **BIO-14.** Implementation of all mitigation measures would be assured through Condition of Certification **BIO-7**.

Golden Eagle

Staff conducted four different analyses of cumulative effects on golden eagle foraging habitat: 1) the entire NECO planning area (**Biological Resources Figures 10**); 2) foraging habitat within 10 miles of the base of all mountain landforms within NECO (**Biological Resources Figures 11-a**); 3) a 10-mile radius around the Project (**Biological Resources Figures 11-b**), and 4) a 140-mile radius around the Project (**Biological Resources Figures 11-c**).

The model of foraging habitat adjacent to mountain landforms was based on an assumption that the mountainous areas were the most likely sites for golden eagle nests. The 140-mile analysis (**Biological Figure 11-c**) used the California GAP vegetation mapping dataset (Davis et al. 1998), a project of the Biogeography lab at UC Santa Barbara. The original GAP mapping of desert dry wash woodlands and dunes was improved for the NECO plant communities dataset used in **Biological Figures 11-a and 11-b** (BLM CDD; Appendix H); however, both datasets are based largely on aerial photo interpretation and would not be considered as accurate as a ground-based and field-verified delineation of habitats. The number of mapping units in NECO was reduced (from the original GAP classifications) by organizing types into broader categories. The 140-mile analysis (which was limited by a lack of compatible vegetation mapping data for Mexico and Arizona) was based on an analysis of band recovery data provided by the U.S. Bird Banding Laboratory which showed that 90 percent of mature golden eagles re-encountered during the breeding season were within 140 miles of their natal site (USFWS 2009). Currently, no nests have been documented within 10 miles of the Project. Surveys may be warranted to identify whether eagle nests are present within 10 miles of the Project site. **Biological Resources Table 16** summarizes the impacts to foraging habitat for **Biological Resources Figures 11-a** through **11-c**. Please see **Biological Resources Table 18** and **Figure 19-a** for a summary and map of impacts to plant communities within entire NECO planning area.

All analyses defined the foraging habitat by plant community and all analyses assumed that all habitat is potential foraging habitat, including dry playas and sand drifts over playa. However, the GAP dataset (**Biological Resources Figure 11-c**) distinguishes row crop agriculture from, for example, orchards and vineyards.

All of the golden eagle foraging habitat figures depict the locations of currently known and documented golden eagle nest locations. The source of this information include the "nest card" database, desert-wide helicopter surveys conducted in 1978 and 1979, and locations depicted in a 1984 BLM California Desert Conservation Area (CDCA) map of “Sensitive, Rare, Threatened and Endangered Fish and Wildlife” that were digitized for this analysis (BLM 1999). It is unknown whether these nests are still active and/or present; this analysis assumes that they could be active and, at a minimum, that the site is suitable for nesting. The nest locations depicted are approximate (with a margin of error +/- 1-2 miles) and the map should not be viewed as a substitute for site-specific nest surveys to assess project impacts.

The loss of foraging habitat quantified in the GIS analysis is but one picture of the range-wide cumulative effects that have contributed to a sharp decline in recent years. The USFWS and others (USFWS 2009b; Kochert et al. 2002) estimate there are approximately 30,000 golden eagles in the western U.S., down from an estimated

100,000 in the late 1970s. Survey data from 2003 and 2006-2008 indicate a decline of 26 percent since 2003. Climate change is also expected to impact golden eagle by increasing drought severity, and the CO_2 concentrations are expected to exacerbate the spread of invasive weeds, which displace native species and habitats, fuel wild fires, and alter fire regimes. Wind energy development may also be particularly harmful to golden eagles; however, the proposed transmission lines for this and other proposed future projects are also expected to increase raptor collisions and electrocutions. Lead poisoning and the loss of prey species are also important contributors to golden eagle mortality and the overall decline in habitat function and value from human activities.

Proposed future projects within 10 miles of all mountains (**Biological Resources Figure 11-a and Biological Resources Table 16**) would cumulatively affect over 325,000 acres of foraging habitat (not including agriculture). The entire Project area would be considered a loss of foraging habitat, and although it is a relatively minor contribution, it nevertheless contributes to a significant cumulative effect. Proposed future projects within 10 miles of the Project site (**Biological Resources Figures 11-b**) would cumulatively affect over 31,780 acres of foraging habitat (not including agriculture)—nearly 10 percent of all potential foraging habitat. The Project contributes, at least incrementally, to the overall significant cumulative loss and degradation of foraging habitat of a species in sharp decline.

The substantial cumulative loss of foraging habitat within 10 miles of the NECO mountain ranges—and the Project's contribution to that significant cumulative effect—is more significant when combined with the reasonably foreseeable indirect effects described above.

The Project's contribution to the cumulative loss of foraging habitat would be minimized to level less than significant by implementing staff's proposed conditions of certification that would compensate for habitat loss and minimize many of the indirect effects. As specified in staff's proposed Condition of Certification **BIO-12**, the Applicant shall acquire and protect 1,878 acres of Sonoran creosote bush scrub within the Colorado Desert Recovery Unit (for desert tortoise), 424 acres of Mojave fringe-toed lizard habitat (**BIO-20**), and 132 acres of ephemeral desert washes within or adjacent to the Ford watershed (**BIO-22**). While acquisition does not address the net loss of foraging habitat in the immediate future, it is expected to prevent future losses of habitat by placing a permanent conservation easement and deed restrictions on private lands that could otherwise be converted for urban or agricultural uses, or energy development. The Project's contribution to the indirect cumulative effects to foraging habitat from the spread of invasive non-native plants would be reduced to a level less than significant through implementation of staff's proposed Condition of Certification **BIO-14** (weed management plan.

Implementation of staff's proposed conditions of certification would reduce the Project's contribution to cumulative impacts to golden eagle foraging habitat to a level that is not cumulatively considerable. There may be cumulative impacts after mitigation is implemented by all other projects, but due to the mitigation implemented by the proposed Project, its contribution is less than cumulatively considerable. These residual cumulative effects from all future projects could be addressed through a regional and coordinated planning effort aimed at preserving and enhancing large, intact expanses of

foraging habitat, limiting development near nest sites, developing guidelines for minimizing collisions and electrocutions, and other programmatic efforts.

+++Based on the California GAP Analysis of Vegetation (Davis et al 1998)

American Badger and Desert Kit Fox

The geographic scope for the cumulative analysis for these two species encompasses the entire NECO planning area. Using the NECO landforms dataset, the extent of suitable habitat depicted in the NECO plan was refined somewhat by excluding the following landforms: playas, badlands (steep erosional features), lava flows, and mountains. It was then overlaid by existing and foreseeable future projects to quantify cumulative impacts to badger and kit fox habitat (**Biological Resources Table 15** and **Biological Resources Figure 12**).

This quantitative analysis of habitat loss does not address use of the Project site and adjacent habitat for both foraging and movement pathways. Other reasonably anticipated cumulative effects not quantified here include habitat fragmentation and the diminished habitat values of remaining habitat from increased noise; disruption from night lighting; exotic plant invasion (which fuels wildfires and alters fire regimes); dust and air pollution; an increase in predators; agriculture and urban development, and; the consequences of human intrusion into previously undisturbed habitats (such as hunting, use of rodenticides and other poisons, road kills, trapping, and human disturbance).

An estimated 339,704 acres of American badger and desert kit fox habitat would be displaced by the proposed future projects within the NECO planning area, representing approximately 7 percent of the total habitat mapped in NECO (based on the simple habitat model described above). Staff considers this a significant cumulative effect, particularly when viewed in combination with the anticipated indirect effects of habitat fragmentation and degradation to remaining habitat and other threats described above. The Project contributes—at least incrementally—to this significant cumulative effect. Staff's proposed Condition of Certification **BIO-12** for acquisition of 1,878 acres of Sonoran creosote bush scrub within the Colorado Desert Recovery Unit (for desert tortoise), 424 acres of Mojave fringe-toed lizard habitat **(BIO-20)** within Chuckwalla Valley, and 132 acres of desert washes **(BIO-22)** within the immediate or adjacent watershed, would also be expected to benefit American badger and desert kit fox. This habitat acquisition (**BIO-12, 20, and 22**), and the avoidance and minimization measures for American badger and desert kit fox contained in **BIO-17** would reduce the Project's contribution to these cumulative effects to habitat less to a level less than significant by preventing future losses of habitat through conservation easements and deed restrictions on private lands that could otherwise be converted for urban or agricultural uses, or energy development. A programmatic and multi-agency approach to address the cumulative effects of all projects, after implementation of the Project-specific mitigation measures, is currently in progress.

Western Burrowing Owl

Using the NECO landforms dataset, the extent of suitable habitat for burrowing owl in the NECO planning area was refined by excluding the following landforms: dunes, mountains, playas, badlands (steep erosional features) and lava flows. The results were then overlaid by existing and foreseeable future projects to quantify cumulative impacts

to burrowing owl habitat **(Biological Resources Table 15** and **Biological Resources Figure 13)**.

The Project's contribution to the cumulative loss of habitat to western burrowing owl is comparable to the cumulative loss of badger and kit fox habitat, described above. The analysis does not quantify the significant cumulative effects of habitat fragmentation and its impacts on population viability, increased road kills, increased risk of fire from weed invasion and ignition sources, and the degradation of remaining habitat function and values. Staff considers the effects of all proposed future projects (339,704 acres or 7.1 percent loss of all habitat in the NECO planning area) to be a significant cumulative effect, and to which the Project contributes both directly and indirectly. The Project's contribution to cumulative effects would be reduced to a level less than significant through the following conditions of certification: acquisition of 1,878 acres of Sonoran creosote bush scrub within the Colorado Desert Recovery Unit for desert tortoise (**BIO-12)**, 424 acres of Mojave fringe-toed lizard habitat **(BIO-20)** within Chuckwalla Valley, and 132 acres of desert washes **(BIO-22)** within the immediate or adjacent watershed. This proposed habitat replacement would also be expected to benefit burrowing owl by preventing future losses of habitat that is currently zoned for energy or other development. The Raven Management Plan **(BIO-13)** and Weed Management Plan **(BIO-14)** are also expected to minimize the Project's contribution to the indirect effects of increased avian predators and the spread of invasive plants, and **BIO-18** contains measures specifically for avoiding and minimizing impacts to burrowing owl.

Le Conte's Thrasher

The scope of this analysis includes the entire NECO planning area and utilized the NECO Le Conte's thrasher habitat dataset to quantify cumulative effects of habitat loss from existing and foreseeable future projects (**Biological Resources Table 15** and **Biological Resources Figure 14)**. The NECO habitat model for this species is applicable to several other special-status bird species that inhabit desert dry wash woodland and adjacent upland habitat, including loggerhead shrike, phainopepla, ash-throated flycatcher, and northern mockingbird. The cumulative impacts to migratory birds not addressed in the quantitative analysis of habitat loss include habitat fragmentation, and degradation, and impacts to riparian and groundwater-dependent vegetation and riparian vegetation from water overdrafts and diversions.

The cumulative effects from foreseeable future projects on habitat loss are substantial; 300,139 acres of desert scrubs and desert wash woodland would be lost to future renewable energy development within the NECO planning area alone; this represents 8.1 percent of all potential habitat in NECO. Staff believes that the Project's contribution to the cumulative loss of habitat would be minimized to a less than significant level through implementation of proposed Condition of Certification **BIO-22**, which requires acquisition and enhancement of desert dry wash woodland and unvegetated ephemeral washes within the same watershed as the Genesis Project. Condition of Certification **BIO-12** requires compensatory habitat acquisition for desert tortoise habitat, which is also expected to benefit Le Conte's thrasher, and **BIO-15** requires pre-construction nesting bird surveys. Proposed Conditions of Certification **BIO-25** and **BIO-26** would require monitoring for impacts to groundwater-dependent vegetation within 10 miles of the Project pumping well and require remedial action if adverse effects are

detected. These additional mitigation measures would also minimize the Project contributions to the anticipated cumulative indirect effects to habitat for Le Conte's thrasher habitat and other desert birds occupying similar habitat.

Burro Deer

Burro deer is a subspecies of mule deer found in the Colorado Desert of Southern California, primarily along the Colorado River and in desert dry wash woodland communities away from the river. During the hot summers, water is critical, and deer concentrate along the Colorado River where water developments have been installed and where the microphyll woodland is dense and provides good forage and cover. Impacts are most important within 1/4 mile of natural or artificial watering sites; these sites are depicted in the bighorn sheep WHMA map, **Biological Resources Figure 7a,** are based on the NECO dataset for natural and artificial water sources.

Biological Resources Table 15 summarizes the anticipated cumulative effects to burro deer range; these effects are also illustrated in **Biological Resources Figure 15.** Using the NECO dataset for burro deer range, approximately 5.4 acres of burro deer range would be displaced by the Project. Proposed future projects would cumulatively affect 7.5 percent of the burro deer range, as the range is documented in NECO (BLM CDD 2002). Staff's proposed Condition of Certification **BIO-22** for acquisition of 132 acres of desert washes within or adjacent to the Ford watershed, and Condition of Certification **BIO-12** for acquisition of 1,878 acres of Sonoran creosote bush scrub would be expected to offset the Project contributions to the cumulative loss of burro deer range to a level less than significant. The Project's contribution to indirect cumulative effects would be minimized through **BIO-14** (detailed weed management plan), **BIO-24** (revegetation of temporarily disturbed areas), and **BIO-25** and **26** (monitoring for impacts to groundwater-dependent vegetation within 10 miles of the Project pumping well and remedial action if adverse effects are detected).

Burro deer movement between the eastern portion of Ford Dry Lake and the Palen Wash ironwood forest, which is depicted in **Biological Resources Figure 15** as burro deer range, would be impacted by the proposed Project. This is not expected to be a significant impact because the important of this linkage is already compromised in part by OHV and other human disturbance related to the Wiley Well Rest Stop, and because the western portion of the ROW will be returned to BLM, thus allowing continued movement upslope into the Palen Wash and Palen mountains from the west.
The cumulative effects of all future projects on wildlife movement and connectivity are discussed below and addressed in part through a proposed coordinated, multi-agency approach to preserving important linkages in the Chuckwalla Valley outlined in **Biological Resources Appendix B.**

Couch's Spadefoot Toad

The NECO Couch's spadefoot toad range dataset was used in this analysis to quantify cumulative impacts to potential habitat (**Biological Resources Table 15** and **Biological Resources Figure 16**). Based on the dataset's depiction of the range the GIS analysis indicates that the cumulative effects of all proposed future projects would affect 115,218 acres of Couch's spadefoot toad range in California, or 7.4 percent of its total range in California. Staff considers this a significant cumulative effect to which the

Project would contribute. The Project's contribution to this significant cumulative effect would be minimized to a level less than significant through implementation of staff's proposed Condition of Certification **BIO-27**, which specifies avoidance and minimizations measures for the known breeding pond south of I-10 along the interconnecting transmission line. The Project's contribution to an increase in invasive non-native plants and avian predators would be minimized to a level less than significant through staff's proposed conditions of certification **BIO-13** (raven management plan) and **BIO-14** (weed management plan).

Wildlife Movement and Connectivity

Connectivity refers to the degree to which organisms can move among habitat patches and populations. Individuals must be able to move between patches to meet their resource needs, and in the long term populations must be connected to allow for dispersion, gene flow, and re-colonization. This discussion includes a qualitative discussion of cumulative effects to wildlife movement and connectivity. The probable desert tortoise linkages between the Chuckwalla DWMA and Chemehuevi DWMA are depicted spatially in **Biological Resources Figure 6** "Desert Tortoise DWMAs & Connectivity Corridors", displayed on a base map of USGS desert tortoise habitat modeling (Nussear et al. 2009).

Biological Resources Table 13 and **Figures 7-a** and **7-b** summarize cumulative effects to bighorn sheep WHMAs and connectivity corridors as depicted in the NECO Plan (BLM CDD 2002). **Biological Resources Table 17** and **Biological Resources Figure 17** and **18** look at the cumulative effects to plant communities and landforms within three Multi-Species WHMAs in the Project vicinity: Big Maria Mountains WHMA, Palen-Ford WHMA, and the DWMA Continuity WHMA, which provides connectivity between the Chuckwalla DWMA/ACEC south of I-10 and the Palen-Ford WHMA north of I-10. This analysis utilized the NECO Plant Communities and Landforms datasets to describe the type of habitat affected within each separate WHMA.

Two other solar projects are currently proposed within the Palen-Ford WHMA: Palen Solar Power Project and Chuckwalla Solar One. **Biological Resources Table 5** and **Figure 17** and **18** indicates the Genesis Project is an important contributor to the loss of Sonoran creosote bush scrub (29 percent) and dunes and playa (sand drifts at the playa margins). The actual ground-delineated and field-verified impact for desert dry wash woodland is 16 acres (see also **Biological Resources Table 5**); the NECO datasets are based on aerial photo interpretation and as such are considered less reliable than verified ground survey results.

However, the Palen-Ford WHMA, and all other WHMAs within the NECO planning area, was specifically designated to form the NECO Multi-species Conservation Zone, along with the wilderness areas, DWMAs, ACECs, Joshua Tree National Park, and the military bases, to protect the species considered in NECO. The Palen-Ford WHMA was specifically established to protect the dunes and playas (NECO sensitive habitat types) and the Mojave fringe-toed lizard.

The Genesis solar fields are located largely out of the dune system, and the linears moved slightly to avoid dune habitat occupied by Mojave fringe-toed lizard. The Project

will not substantially impair the connectivity for those species for which the Palen-Ford WHMA was designated. However, there is a small direct impact to dunes (28 acres) and sand drifts over playa (38 acres) that will have a significantly larger indirect effect because of the position of the impact within the edges of an active wind sand transport corridor. The cumulative effect of all future projects on dunes, Mojave fringe-toed lizard habitat, and connectivity within Chuckwalla Valley and the Palen-Ford WHMA is significant and thus the Project will contribute, at least incrementally, to a cumulative effect.

The Project's contribution to this effect would be minimized to a level less than significant through Condition of Certification **BIO-20** which specifies the acquisition and permanent protection of 424 acres of dune and Mojave fringe-toed lizard habitat in Chuckwalla Valley to compensate for the direct loss of habitat and the downwind effect of construction within the edge of the sand transport corridor. Staff's proposed Conditions of Certification **BIO-22** requires acquisition of 132 acres of desert washes and desert wash woodland within the Ford watershed or adjacent watersheds; desert washes also play an important role in the maintenance of dunes as a source of the sand.

Rerouting washes from the Palen Mountains around the Genesis site would not represent a significant disruption to wildlife movement as the washes lead only to Ford Dry Lake and I-10; an area that is also disturbed by human and unauthorized vehicle use around the Wiley Well Rest Area.

Staff also believes that the Genesis site will not significantly impact—individually or cumulatively—desert tortoise connectivity; staff has identified the area west of Desert Center and HWY 177 as being the most valuable area for tortoise connectivity based on existing habitat conditions, tortoise densities, and the USGS habitat modeling for the Project vicinity (see **Biological Resources Figure 6**). Additionally, the dunes and playas form a north-to-south barrier to tortoise movement. The Project is also located outside the DWMA Connectivity WHMA. Although the WHMA was not established to specifically serve desert tortoise, it does contribute to the loss of habitat (Sonoran creosote bush scrub) within the WHMA. Proposed Condition of Certification **BIO-12** would require acquisition and protection of 1,878 acres of Sonoran creosote bush scrub within the Chuckwalla Desert Tortoise Critical Habitat Unit. Mitigation for cumulative effects to connectivity could be enhanced if desert tortoise acquisitions were targeted for areas that would enhance wildlife connectivity within the same WHMA and corridor, or the DWMA Connectivity WHMA, as described in **Biological Resources Appendix B**. Kit foxes, coyotes, and badgers are not NECO species and were not the reason for the establishment of the WHMAs. Staff considers the Project impact to movement and connectivity to kit foxes, badgers, and coyotes a less-than-significant impact.

**** Acreages shown based on the NECO plant communities and landforms datasets and do not reflect the field-verified, ground-based delineation of desert wash woodland and other habitats (see Biological Resources Table 5). Acreages shown in parenthesis reflect the ground-based and field-verified surveys (TTEC 2010-l).

Natural Communities

The geographic scope of the analysis of cumulative effects on plant communities included: 1) the entire NECO planning area (**Biological Resources Figure 19-a),** and 2) Chuckwalla Valley (**Biological Resources Figure 19-b)**. The NECO plant communities dataset was used for this analysis; it is based on the California Gap Analysis Project (Davis et al. 1998), a project of the Biogeography lab at UC Santa Barbara. The accuracy and resolution of the GAP mapping was improved for the NECO plant communities dataset (BLM CDD; Appendix H) using aerial photos and helicopter surveys but should not be viewed as a substitute for site-specific habitat mapping. **Biological Resources Table 18** quantifies the cumulative effects to plant communities based on the NECO dataset and stratified by community type; the results of the ground-based and field-verified mapping and delineation are shown in parentheses under the acreage calculations based on the NECO mapping. “Mojave creosote scrub” refers to the creosote bush-dominant desert scrubs that occur within the Mojave Desert region of the California Desert geographic subdivision (Hickman 1993). The transition to Sonoran Desert is mapped at the Bristol Mountains near the Twenty-Nine Palms Marine Corps Base and extends east and south through the NECO planning area.

Significant cumulative effects to plant communities from all proposed future projects (before mitigation) across the NECO planning area are seen in many community types: 228,363 acres of Sonoran creosote scrub (5.9 percent of the total habitat type in NECO), 43,320 acres of Mojave creosote bush scrub (5.4 percent), 48,167 acres of desert dry wash woodland (7.1 percent), and 18,634 acres of playa (21.1 percent). Project-specific avoidance, minimization, and compensatory mitigation measures of all future projects could be expected; however, the direct impacts to habitat reflected in **Biological Resources Table 18** do not address the significant cumulative indirect effects to remaining habitat that can be expected from all or most past, present, and future projects: fragmentation; alteration of the surface drainage patterns (which support many common and rare species); interruption of the fluvial and aeolian transport systems that maintain dune ecosystems; groundwater pumping impacts to groundwater-dependent mesquite groves and other phreatophytes; and an increase in the risk of fire and the introduction and spread of noxious weeds. The potential for spread of Sahara mustard is major concern because it is already infesting many areas on and adjacent to the Project and it has the potential to spread explosively if not carefully managed. Sahara mustard has been reported to be toxic to desert tortoise and other herbivores, and is an immediate threat to several special-status plant occurrences. Climate change is expected to exacerbate the effects of drought and noxious weed spread.

The Project contributes at least incrementally to the cumulative impacts of existing and future projects to Sonoran creosote bush scrub across NECO. Sonoran creosote bush scrub is a common and widespread community in the southeastern deserts of California; however, this broad designation does not reflect the uncommon and even rare plant assemblages within creosote bush scrub that have been documented and are monitored by the CNDDB; nor does it reflect the reasonably anticipated indirect effects described above. To minimize the Project’s contribution to the cumulative loss of habitat

to a level less than significant, staff proposes the following conditions of certification: **BIO-12** for acquisition of 1,878 acres of Sonoran creosote bush scrub; **BIO-21** for acquisition and protection of 132 acres of desert washes and desert dry wash woodland within or adjacent to the Ford watershed; and **BIO-20** for the acquisition and protection of 424 acres of dunes or other sandy landforms within Chuckwalla Valley to compensate for both the direct and downwind effects on dunes from interrupted wind-sand transport. Acquisition would prevent future losses of habitat by placing a permanent conservation easement and deed restrictions on private lands that could otherwise be converted for urban, agricultural, or energy development.

Staff recommends implementation of the following conditions of certification to minimize the Project's contribution to indirect cumulative effects to a level less than significant: **BIO-14** for weed management; **BIO-24** for revegetation of temporarily disturbed areas using locally native seed, and; **BIO-25 and BIO-26** for monitoring of groundwater-dependent vegetation and remedial action in the event of adverse effects.

** Includes only those existing projects between Desert Center and the Colorado River for which GIS-based spatial data was available at the time of the analysis; see Biological Resources Table 9

*** Includes only BLM Renewables that had submitted a Plan of Development (POD) at the time of the analysis and those additional future projects listed in Biological Resources Table 9

****Acreages shown are based on the NECO plant communities dataset and do not reflect the field-verified, ground-based delineation of desert wash woodland and other habitats (see Biological Resources Table 5). Acreages shown in parenthesis reflect the ground-based and field-verified surveys (TTEC 2010-l).

Landforms

Biological Resources Table 19 reflects the cumulative impacts to landforms within the NECO planning area, stratified by landform and based on the NECO landforms dataset. There is some overlap with the GAP Analysis/NECO Plant Communities dataset (dunes and playa); differences in extent reflect the different data sources and mapping methodology. Like the NECO plant communities mapping dataset, the landforms dataset was also based on aerial photo interpretation with some ground-truthing, but should be viewed as a substitute or superior to ground-based and field-verified delineations of habitat. The Project's survey data is shown in parentheses below the acreages generated by the NECO landforms dataset.

As illustrated below, and illustrated spatially in **Biological Resources Figure 20,** the cumulative effects of all future (proposed) projects to dunes, playas, and plains are significant. Dunes and sandy plains also provide habitat for several rare plants and animals in the Chuckwalla region, most notably Mojave fringe-toed lizards, Harwood's milk-vetch, Abram's spurge, and jack-ass clover. The Project contributes—at least incrementally—to these significant cumulative effects. The Project also contributes to significant indirect effects to these sensitive habitats, including interrupted aeolian (wind-deposited) and fluvial (water-deposited) sand transport systems, both of which contribute to the maintenance and sustainability of dune habitats; groundwater pumping (lowering groundwater tables has also been demonstrated to influence dune morphology [Langford et al 2009]); habitat fragmentation and degradation from roads and increased vehicle and human disturbance; an increase in avian predators of dune species from the increase in perching sites; and the spread of invasive non-native plants such as Sahara mustard, which is believed to be toxic to desert tortoise and other herbivores and can spread explosively in response to disturbance.

The Project's contribution to the significant cumulative loss of sandy plains, sand drifts over playa, and dunes will be mitigated to a level less than significant through staff's proposed Condition of Certification **BIO-20.** This requires acquisition of 424 acres of these landforms within Chuckwalla Valley to compensate for both the direct habitat loss and the indirect downwind effects of obstructing the wind-sand transport corridor. The project's contribution to the cumulative loss of alluvial fans and bajadas is addressed through **BIO-12**, which requires protection of 1,878 acres of Sonoran creosote bush scrub, which inhabits these landforms that occur between the valley floor and the base of the adjacent mountains. The project's contribution to the cumulative loss of desert washes will be addressed through **BIO-22**; 132 acres of desert washes and desert dry wash woodland would be protected within the Ford watershed or adjoining watersheds. The Project's contribution to other significant indirect effects shall be reduced to a level less than significant through conditions of certification **BIO-13** (raven management plan), **BIO-14** (weed management plan), **BIO-24** (revegetation of temporarily disturbed areas using locally native seed), and **BIO-25 and BIO-26** (monitoring of groundwater-dependent vegetation and remedial action in the event of adverse effects).

*Based on the NECO Landforms dataset (BLM CDD 2002); acreages for dunes and playa from this dataset differ from the acreages based on an analysis using the NECO plant communities dataset, due to differences in methodology, minimum mapping polygons, etc. Actual project-specific field survey data concluded that the project would directly affect 28 acres of stabilized and partially stabilized dunes.
** Includes only those existing projects between Desert Center and the Colorado River for which GIS-based spatial data was available at the time of the analysis; see T Biological Resources Table 9
*** Includes only BLM Renewables that had submitted a Plan of Development (POD) at the time of the analysis and those additional future projects listed in T Biological Resources Table 9
****Acreages shown are based on the NECO plant communities dataset and do not reflect the field-verified, ground-based delineation of desert wash woodland and other habitats (see Biological Resources Table 5). Acreages shown in parenthesis reflect the ground-based and field-verified surveys (TTEC 2010-l).

Desert Dry Wash Woodland

Biological Resources Table 20 highlights the cumulative effects of existing and future projects to desert dry wash woodland within the immediate watershed encompassing

the Project (**Biological Resources Figure 21**). The NECO plant communities dataset was used for this analysis, which is based largely on aerial photo interpretation. The Project's field-verified, ground-based delineation (TTEC 2010l)) documented 16 acres of desert dry wash woodland (a microphyll woodland) along jurisdictional state waters features in the project footprint that would be directly impacted and reflects the field-verified, ground-based delineation of waters of the state. A large polygon of desert dry wash woodland was mapped just outside of the Project footprint along the Palen Wash and may account for the difference in acreage between the field-based delineation and the mapping of woodland in the NECO plant communities dataset.

According to CEQ guidance for the preparation of joint CEQA-NEPA cumulative effects analyses, "seemingly minor impacts can be significant if they affect an extremely rare or limited resource, and the cumulative impact may be substantial". Desert dry wash woodland is a sensitive natural community recognized under many LORS and area plans. Because it has a limited distribution (relative to common and widespread communities such as Sonoran creosote bush scrub) and carries an ecological importance that is disproportionate to its limited extent, staff considers a loss of approximately 7 percent to be a significant cumulative effect—an effect to which the Project contributes at least incrementally. Desert dry wash woodland and other wash-dependent habitat that occurs within the stream environment is regulated under Section 1600 of the California Fish and Game Code. These habitats are also recognized as sensitive communities in the NECO plan (BLM CDD 2002) and CNDDB (CDFG 2003).

This GIS analysis of direct habitat loss does not reflect the equally significant indirect effects that could be reasonably expected to occur with all or most of the proposed future projects, including the Genesis Project: interrupted geomorphic processes downstream of the stream diversions; diverted stream flows and deprived stream reaches; fragmentation of the remaining habitat and diminished habitat function and value for wildlife; and invasion by tamarisk (a highly invasive noxious weed that displaces native riparian vegetation and depletes shallow groundwater). Miles of standing dead ironwood trees north of I-10 in the Corn Springs Area are a testament to the effects of channel diversions—even small channels—on desert riparian trees.

The Project's contribution to the cumulative loss of desert dry wash woodland would be mitigated to less than significant through a variety of measures. The original engineered

channel design, which provided for only three discharge points on the downstream side of the project, was revised to ensure that the discharge points would align with the existing natural drainages delineated between the Project and Ford Dry Lake. Condition of Certification **BIO-22** specifies acquisition and enhancement of 48 acres of desert dry wash woodland (16 acres mitigated at a 3:1 ratio) within or adjacent to the Ford Dry Lake watershed. The Weed Management Plan (**BIO-14**) would include tamarisk as a target for management.

Acreages shown in parenthesis reflect the ground-based and field-verified surveys (TTEC 2010-l). Active Dune Habitat in Chuckwalla Valley

This analysis highlights the cumulative effects of existing and proposed future projects on the dune ecosystem in Chuckwalla Valley, a dune system that is distinct from other dunes in the NECO, and, like the Palo Verde mesa and Cadiz Valley areas, it is an area that may be disproportionately affected by proposed renewable energy projects.

Dunes provide habitat for a variety of special-status plants and animals; locally these include Mojave fringe-toed lizard, Harwood's milk-vetch, jack-ass clover, and Abram's spurge. In nearby Coachella Valley, the dune ecosystems are home to a wide variety of rare and endemic, threatened and endangered plants and animals, including several rare dune endemic invertebrates. Dunes are also BLM NECO sensitive communities and recognized as rare natural communities in the CNDDB (CDFG 2003). Even seemingly minor impacts may be considered significant if they affect an extremely rare or limited resource, according to CEQ guidance.

The NECO landforms dataset was used for this analysis. The following attributes were selected from the NECO landforms dataset to build a model of dune habitat: crescentic

dunes, longitudinal dunes, and undifferentiated dunes. **Biological Resources Table 21** and **Biological Resources Figure 20** quantifies the cumulative effects of the BLM renewable energy projects and other existing and future projects on “active” dune formations in the NECO planning area; the extent of other less active aeolian-deposited and stream-deposited sands are better reflected in the habitat model for Mojave fringe-toed lizard (**Biological Resources Figure 8** and **9**, and **Biological Resources Table 14**). The habitat model for Mojave fringe-toed lizard includes also sandy plains and sand-covered alluvial fans; all or portions of these landforms may be located within the wind-sand transport corridor but occur in the less active outer portions beyond the more active dunes.

The direct impacts to dune habitat quantified in **Biological Resources Table 21** are only part of the picture of cumulative effects; staff also considers the Project’s likely indirect effects, which, when combined with the similar indirect effects from other reasonably foreseeable future projects. For example, approximately 66 acres of the Project footprint occurs within the active aeolian sand transfer corridor (Worley Parsons 2010c; **Soil & Water Appendix A**). Even though this direct effect is located within the less active portion of the sand transport corridor, the obstruction (from the solar field) would indirectly affect approximately 453 acres of dune habitat downwind of the obstruction, thus depriving the dunes downwind of the fine windblown sands that build and maintain the habitat and ensure its suitability for Mojave fringe-toed lizard. In the absence of regular fresh input of fine, windblown sands, the deprived dunes quickly become stabilized, vegetate, compact, and develop a surface lag of coarse sand or gravel that combine to render the habitat unsuitable for the many plants and animals that have evolved to the unique, always shifting, natural disturbance regime of the dunes. Similar effects can be reasonably expected from other future projects located in dune habitats. Staff considers these direct and indirect cumulative effects to sand dunes significant, and an effect to which the Project contributes both directly and indirectly.

Other reasonably foreseeable indirect cumulative effects to dune habitat not reflected in this quantitative analysis include fragmentation and degradation of remaining habitat by roads, development, off-road vehicles, altered drainage patterns, and the spread of noxious weeds and other invasive plants, such as Russian thistle and Sahara mustard. Habitat values for dependent wildlife are also affected by increased predation from avian predators, which benefit from the new perching structures that the solar facilities provide. Additionally, recent research in New Mexico has confirmed that groundwater is a key feature that contributes to dune morphology; dune fields are shaped by feedback between aeolian dynamics and groundwater chemistry (Langford et al. 2009). Consequently, groundwater pumping may also indirectly affect dune habitat.

Biological Resources Table 21 illustrates the significant cumulative effects to active dunes expected to occur in the Chuckwalla Valley; over 1,600 acres of active dunes would be directly affected by habitat loss alone. Please also see **Biological Resources Figure 8** and **9**, and **Biological Resources Table 15** for a summary of the Mojave fringe-toed lizard habitat model, which includes sandy plains and sand-covered alluvial fans (in addition to more active dune landforms). All or portions of these landforms may be located within the wind-sand transport corridor but occur in the less active outer portions beyond the more active dunes (barchan dunes, etc.).

The Project contributes 28 acres direct effects to dunes and approximately 453 acres of indirect Mojave fringe-toed lizard habitat loss (including playa and sand drifts over playa) by obstructing a portion of the aeolian sand transport corridor. The Project's contribution to direct and indirect cumulative effects would be reduced to a level less than significant through the following conditions of certification: **BIO-20** for acquisition and protection of 424 acres of dune habitat in Chuckwalla Valley; **BIO-13** (raven management plan); **BIO-14** (weed management plan); **BIO-24** (revegetation plan for temporary disturbance), and **BIO-25** and **BIO-26** for monitoring groundwater-dependent vegetation and remedial action in the event that adverse effects are detected.

SPECIAL STATUS PLANTS

Harwood's Milk-Vetch

New occurrences of Harwood's milk-vetch have been found at three of the proposed solar projects in the I-10 corridor; however, its range in California still appears to be restricted to less than 25 occurrences in eastern Riverside County, and a few occurrences in eastern San Diego County and Imperial County. On the Project site small populations of Harwood's milk-vetch were found in the stabilized and partially stabilized dunes along the transmission line, natural gas line, and access road alignment; very few plants would be directly impacted, but the Project may have indirect effects to the population from altered surface drainage patterns (where populations extend downslope of Project features). Populations of Harwood's milk-vetch, like many other rare plants of the eastern California deserts, were considered relatively stable until recently, as the push for renewable energy development has placed many plants and occurrences at risk. Because the occurrence records for this taxon are spotty in portions of its range, this analysis was based instead on threats to potential habitat. However, the mapping of habitat should not be misconstrued as potentially occupied; rare plants have very specific microhabitat requirements that are often poorly understood. Actual distribution within mapped habitat is often confined to small or scattered and infrequent occurrences within an already restricted range. Rare plants can also sometimes be locally abundant but highly restricted in their range.

Biological Resources Table 15 and **Biological Resources Figure 23** quantifies the cumulative effects of the BLM renewable energy projects and other existing and future projects to the very sandy substrates associated with this special-status plant. The NECO landforms dataset was used; landforms selected to create the simple model of potential habitat include sandy dissected fans; sandy plains; fans; dissected fans; undifferentiated plains, and undifferentiated dunes. This was based on a careful review of the landforms dataset overlaid with known occurrences of Harwood's milk-vetch from CNDDB occurrences and the Project-specific survey data. Staff expects that this model somewhat over-represents actual suitable habitat for Harwood's milk-vetch but cannot be refined until the more detailed soil mapping for the region is available (currently in development by the Natural Resources Conservation Service). **Biological Resources Figure 23** also shows the location of known or documented occurrences relative to proposed future projects, including those occurrences recently found on the I-10 corridor projects.

Harwood's milk-vetch habitat would be disproportionately affected (almost 9 percent of all its habitat in NECO) by the push for renewable development in eastern Riverside County, and the majority of this special-status plants' range in California is in eastern Riverside County. The actual effect to habitat may well be greater than 9 percent, assuming that the model over-estimates potential habitat; clearly the sandy plains and dunes that characteristically support this species have been disproportionately affected by proposed renewable energy development on Palo Verde mesa, and in Chuckwalla Valley. Although the few plants would be directly affected by the Blythe, Palen, and Genesis projects, the occurrences are in such close proximity to the project that many are likely to be affected by the indirect effects of altered drainage patterns, disrupted wind- or fluvial-sand transport processes, fragmentation of the dune habitat, the spread of non-native plants, and an increased risk of fire. Climate change is expected to exacerbate the effects of drought, and CO2 concentration has already been demonstrated to promote the spread of invasive plants. Staff considers this a significant cumulative effect and the Project would contribute to both the direct and indirect effects described above.

The Project's contribution to cumulative effects would be minimized to a level less than significant through a variety of conditions of certification for avoiding, minimizing, and compensating for direct and indirect effects to plants and their habitat. These are described in the Draft Special-Status Plant Protection Plan (GSEP 2009f) and in staff's proposed Condition of Certification **BIO-19**. Staff's proposed Condition of Certification **BIO-20**, which requires acquisition and protection of sand dune habitat in Chuckwalla Valley that would be otherwise subject to future development, is also expected to benefit Harwood's milk-vetch, as would staff's proposed Condition of Certification **BIO-22,** which requires protection of 132 acres of desert washes and woodland within the Ford watershed or adjacent watersheds. The Project's contribution to the indirect effects of invasive non-native plants would be minimized through **BIO-14**, the Weed Management Plan.

Groundwater-Dependent Vegetation

The groundwater cumulative impact analysis (see **Soil and Water Resources**, Section C.7.4.2) indicates that groundwater extraction during construction and operation of this

and other foreseeable projects would place the basin into an overdraft condition. This impact may be exacerbated by other unidentified renewable energy projects in the I-10 corridor, which has been targeted as a potential area for further renewable energy development. However, staff concluded that the amount of water that is stored in the basin greatly exceeds the amount of cumulative overdraft, rendering the project's contribution to this cumulative impact less than cumulatively considerable.

Nevertheless, the proposed Project would have an impact on the deep aquifer groundwater levels within the area immediately surrounding the proposed Project pumping well. The area of potential affect surrounding the well is estimated to extend approximately 10 miles out from the Project pumping well by the end of Project operation. The Applicant has stated that pumping from the deeper aquifer would not affect the shallow alluvial-fill aquifer that supports groundwater-dependent vegetation within this zone of potential effect based on the presence of low permeability clay layers between the shallow and deep aquifers observed at the test well onsite, and that characteristically occur around lakebeds. However, the calculations and assumptions used to evaluate potential groundwater level impacts are imprecise and have limitations and uncertainties associated with them such that the magnitude of potential impacts that could occur cannot be determined precisely.

To ensure that the Project's proposed use of groundwater does not significantly impact any groundwater-dependent vegetation within the area of potential effect, staff recommends the Applicant develop a monitoring program and identify what changes are occurring in basin water levels and if the anticipated lowering of groundwater levels is adversely affecting the ecosystems dependent on permanent groundwater availability within a narrow range of depth. Substantial changes to groundwater levels caused by the proposed Project and other pumping in the basin would be documented by this monitoring, and a mitigation and reporting program would be required in accordance with Conditions of Certification **SOIL& WATER-3**, **-4**, and **-5**. Staff's proposed Condition of Certification **BIO-25** specifies minimum standards for monitoring the groundwater-dependent vegetation and spring groundwater levels within the 10-mile area of effect around the Project pumping well, and details the reporting requirements. Condition of Certification **BIO-26** outlines the thresholds for remedial action in the event that adverse effects are detected and minimum success standards for the remedial action. These measures would be sufficient to ensure that significant impacts related to changes in groundwater levels do not occur and that the Project's contributions to cumulative effects are less than significant.

Overview: Cumulative Impacts to Biological Resources of the Chuckwalla Valley

The indirect effects of past, present, and foreseeable future development of the Chuckwalla Valley will contribute cumulatively to the overall loss of dune habitat, desert washes, and the fragmentation and degradation of the remaining habitat for Mojave fringe-toed lizard and several dune-dependent rare plant species. The indirect cumulative effects of development on dune ecosystems are not represented in the GIS analysis of direct habitat loss, but such effects are well documented in Coachella Valley--a comparable and suitable reference site from which conclusions may be reasonably drawn about the environmental stressors and their effects. The Chuckwalla Valley system, although not nearly as fragmented as Coachella Valley, has already been

adversely affected in many ways. Proposed renewable energy development in Chuckwalla Valley could threaten what remains of the habitat and places several populations at risk—most notably, the local Chuckwalla Valley population of the Mojave fringe-toed lizard. **Past and present impacts** in Chuckwalla Valley that have already contributed to a decline in the quality and extent of aeolian dune habitat, habitat for Mojave fringe-toed lizard and dune-dependent rare plant species, desert washes and wash-dependent vegetation, include:

- Compaction and habitat degradation from historic military training operations during World War II;
- Past off-road vehicle use and present/future unauthorized use around Ford Dry Lake and ;
- Past sheep grazing around Ford Dry Lake;
- Electric and Natural Gas Transmission line construction;
- Road construction associated with the transmission construction;
- Construction and operation of the Wiley Wells Rest Stop;
- Construction of Interstate 10 and the network of diversion dikes south of I-10;
- State Highway 177 and a network of both paved roads and unimproved roads;
- Urban and agricultural conversion around Desert Center (8,424 acres);
- Blythe Energy and DPV 1 transmission lines and access roads; and
- Construction of the Colorado Aqueduct;
- Chuckwalla Valley State Prison

Dikes associated with I-10 limit the depositional area of the Chuckwalla Mountains bajada to the south (upstream) of I-10 and concentrate the flows into three discrete channels, where historically numerous small channels fanned out over large areas contributing to fluvial sediment to the aeolian system. The downstream effects of these diversions are striking, severe, and very apparent throughout the I-10 corridor to the north, and in comparisons of current and historical photos. The perimeter stormwater conveyance channels proposed with nearly every solar project would closely mimic these downstream effects to fluvial transport systems. Russian thistle, a noxious weed, has replaced native plant diversity in some dune habitats. More recently, Sahara mustard has invaded the valley and spread explosively since it was introduced some decades ago. Invasive plants increase fire frequency and are correlated with population declines of milk-vetch and fringe-toed lizard in Coachella Valley (Barrows and Allen 2007).

Reasonably foreseeable future actions that will further contribute to the loss of habitat, desert washes and wash-dependent vegetation, and to the fragmentation and degradation of dunes and adjacent habitat for fringe-toed lizard and dune-dependent rare plant species include:

- Palen Solar Power Project (3,001 acres)
- Genesis Solar Energy Project (1,797 acres)

- Chuckwalla Solar 1 (4,091 acres)
- EnXco 2 (Solar Energy Project, 1,325 acres)
- First Solar – Desert Sunlight (5,119 acres)

On the dunes south of I-10:

- Colorado Substation (44 acres)
- DPV 2 and Desert Southwest transmission lines and access oads
- LightSource Renewables – Mule Mountain II
- Altera - Mule Mountain (6,618 acres).

In Coachella Valley, blocked sand/wind corridors have been shown to lead to sand compaction and premature stabilization of the dunes, increased mean grain size (which reduces habitat suitability for fringe-toed lizards), and aeolian habitat loss. Stabilization of the dunes is also aggravated by an increase in invasive exotic plants, introduced through soil disturbance and an increase in vectors (vehicles). Invasive plants are correlated with decreases in the rare dune-endemic species of milk-vetch, fringe-toed lizard, and endemic sand-treader crickets in Coachella Valley.

Road construction associated with new solar projects and their related transmission corridors further degrade and fragment the habitat, and lead to an increase in vehicle traffic and encroachment in previously undisturbed areas. Unpaved roads into the valley interior and historical grazing have led to a dramatic increase in noxious weed invasion over large areas of dunes and surrounding habitat. New roads into otherwise undisturbed portions of the valley also lead to an increase in vehicle-related mortality, and habitat destruction from unauthorized off-road vehicle use. Human encroachment, agriculture, and development around Desert Center are also accompanied by an increase in predators, such as ravens. These indirect cumulative effects on dune-dependent species are particularly acute in isolated, fragmented habitats that lack the buffering effects of connectivity to larger populations. All of these stressor and effects are documented to have led to the decline of dune ecosystems in Coachella Valley and can reasonably be expected to occur in Chuckwalla Valley with future development.

C.2.8.8 CONCLUSION

Construction and operation of the Genesis Project will impact a number of biological resources that are individually limited but cumulatively considerable. “Cumulatively considerable” means that the incremental effects of an individual project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects. Cumulative impact assessments cannot conclude that contributions to cumulative impacts are not significant because the contributions represent a small percentage of the overall problem.

The biological resources cumulative effects analysis employed a quantitative, GIS-based analysis of direct impacts to habitat and a qualitative analysis of indirect effects (e.g., increases in predators, noxious weeds, etc.). In many cases, the anticipated indirect impacts are more significant, or adverse, than the direct loss of habitat, but are more difficult to quantify. The qualitative assessment of indirect cumulative effects relied

on consultations with regional experts and agency biologists, a literature review of the threats to species and their habitats, and documented observations and studies from Coachella Valley, a dune system west of Chuckwalla Valley that supports many related species and similar habitats (Barrows 1996; Barrows & Allen 2007; CVAG 2007; Griffiths et al. 2002; Katra et al. 2009; Turner et al. 1984; Weaver 1981; Barrows pers. comm.).

The geographic scope of the cumulative effects analysis varied between the biological resources. Many of the analyses used the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) boundaries (BLM-CDD 2002). The NECO boundary closely approximates the boundaries of the Eastern and Northern Colorado Desert Tortoise Recovery Units; however, the recovery unit boundaries extend slightly to the north and west of the NECO boundary. For some resources, a different geographic scope was warranted, such as the use of watershed boundaries to analyze cumulative effects to desert washes, or the Chuckwalla Valley region of the I-10 corridor for populations or dune systems restricted to that geographic area.

Significant cumulative effects (including indirect effects) were identified in a number of biological resource areas where the Project contributes—at least incrementally—to the cumulative effect. These include:

Desert washes – Ford Watershed and the broader NECO planning area;

Desert tortoise habitat;

Golden eagle foraging habitat;

Mojave fringe-toed lizard and their habitat;

Habitat for American badger, desert kit fox, and burrowing owl;

LeConte's thrasher habitat;

Couch's spadefoot toad range;

Habitat for Harwood's milk-vetch and other dune/playa-dependent special-status plants;

Wildlife habitat and connectivity within the Palen-Ford WHMA (for Mojave fringe toed lizard, dunes, and playa);

Mojave and Sonoran creosote bush scrub; desert dry wash woodland (microphyll woodland); playa and sand drifts over playa, and dunes (active and stabilized)

Of particular concern are the cumulative effects of renewable energy projects within the geographic scope of the Chuckwalla Valley, which contains an isolated system of dunes and population of Mojave fringe-toed lizard. The direct loss of dune habitat and Mojave fringe-toed lizard is minor relative to the indirect downwind effects from obstructions within the active aeolian sand transport corridor, and the disruption of the fluvial processes that contribute sand to the system from the diversion of washes – approximately 63 miles of washes within the Ford watershed alone. Lessons learned

from decades of study at nearby Coachella Valley (a comparable and suitable reference site from which conclusions may be reasonably drawn about Chuckwalla Valley) suggest that these indirect effects are significant and adverse. In addition to the disruption of geomorphic processes, significant indirect effects that can be reasonably expected to occur in the Chuckwalla system from future projects include fragmentation and its effects on connectivity and gene flow; spread of invasive non-native plants; increase in avian predators, and; an increase in vehicle-related wildlife mortality.

Implementation of staff's proposed conditions of certification would reduce the Project's contribution to cumulative effects to a level that is not cumulatively considerable. There may be cumulative effects after mitigation is implemented by all projects, but due to the mitigation implemented by this proposed Project, this Project's contribution would be less than cumulatively considerable. These residual cumulative effects from all future projects could be addressed through a regional and coordinated planning effort aimed at preserving and enhancing large, intact expanses of wildlife habitat and linkages, including maintaining connections between wildlife management areas and other movement corridors.

Ongoing collaborative efforts by federal and state agencies to develop a Desert Renewable Energy Conservation Plan and BLM's Solar Energy Development Programmatic EIS offer an appropriate forum for such planning. Appendix B describes the Desert Wildlife Management Area management strategies that could achieve the goals of preservation and enhancement of wildlife connectivity in the NECO planning area. Staff supports these programmatic efforts and believes they represent an excellent means of integrating the State's and BLM's renewable resources goals and environmental protection goals.

C.2.9 COMPLIANCE WITH LORS

The proposed Project must comply with state and federal laws, ordinances, regulations, and standards that address state and federally listed species, as well as other sensitive species and their habitats.

C.2.9.1 STATE LORS

Under the Warren-Alquist Act (Public Resources Code § 25500) the Energy Commission's certificate for thermal power plants 50 MW and more is "in lieu of" other state, local, and regional permits (*ibid*.). Staff has incorporated all required terms and conditions that might otherwise be included in state permits into the Energy Commission's certification process. When conditions of certification are finalized they would satisfy the following state LORS and take the place of terms and conditions that, but for the Commission's exclusive authority, would have been included in the following state permits:

Incidental Take Permit: California Endangered Species Act (Fish and Game Code §§ 2050 et seq.) The California Endangered Species Act (CESA) prohibits the "take" (defined as "to hunt, pursue, catch, capture, or kill") of state-listed species except as otherwise provided in state law. Construction and operation of the proposed Project could result in the "take" of desert tortoise, listed as threatened

under CESA. Energy Commission staff's proposed Condition of Certification **BIO-12** specifies compensatory mitigation for desert tortoise habitat loss at a 1:1 ratio. Energy Commission staff have concluded that this funding and mitigation approach would ensure compliance with CESA.

Streambed Alteration Agreement: California Fish and Game Code §§ 1600 1607. Pursuant to these sections, CDFG typically regulates all changes to the natural flow, bed, or bank, of any river, stream, or lake that supports fish or wildlife resources. Construction and operation of the Project would result in direct impacts to 91 acres of waters of the state and 21 acres of indirect impacts. Staff's proposed Condition of Certification **BIO-22** would minimize and offset direct and indirect impacts to state waters and would assure compliance with CDFG codes that provide protection to these waters.

C.2.9.2 FEDERAL LORS

The Genesis Project is located on federal land under BLM's jurisdiction and is therefore subject to the provisions of BLM's California Desert Conservation Area (CDCA) Plan (BLM 1999). As an amendment to the CDCA Plan, BLM produced the Northern and Eastern Colorado Coordinated Management Plan (NECO) (BLM CDD 2002). The NECO Plan provides for conservation and management of special status species through a system of management areas including: Desert Wildlife Management Areas (DWMAs), multi-species Wildlife Habitat Management Areas (WHMAs), bighorn sheep WHMAs, Areas of Critical Environmental Concern (ACEC), and wilderness areas.

Desert Wildlife Management Areas (DWMA) are general areas recommended by the Desert Tortoise Recovery Plan (USFWS 1994) within which recovery efforts for the desert tortoise would be concentrated. DWMAs had no specific legal boundaries in the 1994 Recovery Plan. The BLM formalized the general DWMAs from the 1994 Recovery Plan through its planning process and administers them as Areas of Critical Environmental Concern (see below). The linear facilities south of I-10 pass through the Chuckwalla DWMA.

Area of Critical Environmental Concern (ACEC) are specific, legally defined, BLM designations where special management is needed to protect and prevent irreparable damage to important historical, cultural, scenic values, fish and wildlife, and natural resources or to protect life and safety from natural hazards. Besides the Chuckwalla DWMA/ ACEC, the Genesis Project is not included within a designated ACEC, but the Palen Dry Lake ACEC is located to the west.

Critical Habitat consists of specific areas defined by the USFWS as areas essential for the conservation of the listed species, which support physical and biological features essential for survival and that may require special management considerations or protection. Critical habitat for the desert tortoise was designated in 1994, largely based on proposed DWMAs in the draft Recovery Plan. The linear facilities overlap with 23 acres of the Chuckwalla Desert Tortoise Critical Habitat Unit.

Wildlife Habitat Management Areas address other special status species and habitat management in the NECO, and include two kinds: one for bighorn sheep,

one for all other special status species and habitats. Bighorn sheep WHMAs overlay the entire range of their occurrence and movement corridors. Multi-species WHMAs are complementary to existing restricted areas and DWMAs, which also cover other special status species and habitats. The plant site and portions of the linear facility routes are situated within the Palen-Ford Multi-Species WHMA.

Wilderness Area The Project is contiguous and south of the 259,000-acre Palen/McCoy Wilderness, which includes the Granite, McCoy, Palen, Little Maria and Arica Mountains, five distinct mountain ranges separated by broad sloping bajadas.

Potential take of the desert tortoise, listed as threatened by the USFWS, requires compliance with the federal Endangered Species Act (ESA) (16 USC §§ 1531 et seq.). "Take" of a federally-listed species is prohibited without an Incidental Take Permit, which would be obtained through a Section 7 consultation between BLM and the USFWS. The Applicant will submit a Draft Biological Assessment (BA) for the Project to BLM, and when BLM has reviewed and made appropriate revisions to the draft BA it will be submitted to the USFWS so that the formal Section 7 consultation process can be initiated.

C.2.10 NOTEWORTHY PUBLIC BENEFITS

The Genesis Project and the proposed alternative would result in significant impacts to sensitive biological resources, and would permanently diminish the extent and value of native plant and animal communities in the region. Staff has therefore concluded that the Genesis Project would not provide any noteworthy public benefits related to biological resources, despite the contributions the Project would make to meeting federal and state mandates for development of renewable energy resources.

C.2.11 CONCLUSIONS

Overview of Impacts to Biological Resources: The Genesis Solar Energy Project (Genesis Project or Project) would have significant impacts to biological resources, eliminating all of the Sonoran creosote bush scrub and other native plant and wildlife communities within the approximately 1,880-acre site. The Genesis Project would result in loss of an extensive network of desert washes comprising 91 acres of state jurisdictional waters, and would significantly alter the hydrology of the area by re-routing ephemeral drainages through engineered channels.

The Project site provides habitat for desert tortoise, a species listed as threatened under the federal and state endangered species acts. The Project would impact 1,786 acres of desert tortoise habitat, including 23 acres within the Chuckwalla Desert Critical Habitat Unit. Construction and operation of the Genesis Project would therefore require state and federal endangered species "take" authorization. In addition to direct loss of habitat the Project would fragment and degrade adjacent native plant and wildlife communities, and could promote the spread of invasive non-native plants and desert tortoise predators such as ravens.

The U.S. Bureau of Land Management (BLM) and California Energy Commission (Energy Commission) staffs (hereafter jointly referred to as staff unless otherwise noted) have concluded that without mitigation the Genesis Project would contribute to the cumulatively significant loss of biological resources within the Chuckwalla Valley and the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) area. Staff recommends compensatory mitigation to offset direct, indirect, and cumulative impacts to desert tortoise and other special-status species, and to assure compliance with state and federal laws such as the federal and state endangered species acts and regulations protecting waters of the state. With implementation of staff's proposed conditions of certification, Project impacts to biological resources would be reduced to less than significant levels.

Mitigation for Desert Tortoise: The measures in staff's proposed Conditions of Certification **BIO-9** through **BIO-11** would avoid and minimize potential take of desert tortoise during Project construction and operation. To offset the loss of 1,763 acres of desert tortoise habitat, staff's proposed Condition of Certification **BIO-12** recommends habitat compensation at a 1:1 ratio for desert tortoise (i.e., acquisition and preservation of one acre of compensation lands for every acre lost). For Project impacts to 23 acres of Chuckwalla Desert Critical Habitat Unit, the mitigation ratio would be 5:1. This compensatory mitigation is consistent with recommendations from the California Department of Fish and Game (CDFG), the U.S. Fish and Wildlife Service (USFWS), and BLM guidance in the NECO. Staff's proposed Condition of Certification **BIO-12** also requires that the land acquisitions be within the Colorado Desert Recovery Unit, and have potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise populations and designated critical habitat. These conditions satisfy the California Department of Fish and Game's requirements under Section 2081 of the California Fish and Game Code.

Staff's proposed Condition of Certification **BIO-13** requires implementation of a Raven Monitoring, Management and Control Plan to address Project-related increases in ravens, a desert tortoise predator.

Interim DRECP Process for Desert Tortoise Mitigation: Federal and state agencies are currently collaborating as the Renewable Energy Action Team (REAT) to establish joint policies and plans to expedite development of California's utility scale renewable energy projects. To accomplish this goal these agencies are developing a Desert Renewable Energy Conservation Plan (DRECP), a science-based process for reviewing, approving, and permitting renewable energy applications in California. Once the DRECP is complete, anticipated in late 2012, the plan will provide tools to expedite coordination of federal and state endangered species act permitting and a framework for implementing regionally coordinated land acquisition and mitigation.

Impacts to Mojave Fringe-toed Lizards: The Genesis Project would directly impact 66 acres of Mojave fringe-toed lizard habitat (including 28 acres of dunes and 38 acres of playa with sand drifts)and indirectly affect 453 acres of habitat downwind of the Project Disturbance Area. The indirect impact results from the Project solar arrays extending into sand transport corridors, diminishing the input of sand to downwind areas and reducing the active sand layer that is crucial to Mojave fringe-toed lizard habitat. The Mojave fringe-toed lizards in the Chuckwalla Valley are at the southernmost portion of

the species range, and the proposed Project could increase the risks of local extirpation of an already fragmented and isolated population. Staff's proposed Condition of Certification **BIO-20** recommends acquisition and protection of core populations of Mojave fringe-toed lizard habitat in the Chuckwalla Valley, which would reduce Project impacts to less than significant levels.

While the Project's impacts to sand dune habitat and Mojave fringe-toed lizards can be mitigated to less than significant levels, the cumulative impacts from all foreseeable projects in the Chuckwalla Valley and the NECO planning area remain significant. Development of proposed projects would result in the direct loss of over 16 percent of all Mojave fringe-toed lizard habitat in the NECO planning area, effects that are all the more significant when combined with the expected indirect effects to Mojave fringe-toed lizard habitat, including: interruption of wind sand transport processes; diversions of desert washes and interruption of fluvial transport of sand that contribute to the maintenance of habitat; an increase in predation from ravens and direct mortality from an increase of vehicles in previously undisturbed habitat, and the continuing spread of non-native, weedy species such as Sahara mustard and Russian thistle in the Chuckwalla Valley. Staff considers these cumulative direct and indirect effects of to the Chuckwalla Valley population of Mojave fringe-toed lizards and their habitat to be significant. The Project's contributions to significant impacts would be mitigated to less than significant levels with implementation of staff's proposed conditions of certification.

Ephemeral Drainages: The Project would directly impact 91 acres of state jurisdictional waters, including 16 acres of microphyllous riparian vegetation, eliminating the hydrological, biogeochemical, vegetation, and wildlife functions of this network of ephemeral drainages. As many as 21 acres of ephemeral drainages downstream of the Project area could also be indirectly impacted by changes in upstream hydrology. Staff considers the direct, indirect, and cumulative impacts to ephemeral drainages to be significant. The measures in staff's proposed Condition of Certification **BIO-22** would minimize and offset direct and indirect impacts to state waters to less than significant levels and would assure compliance with CDFG codes that provide protection to these state waters. These measures include acquisition and enhancement of 132 acres of ephemeral dry washes within the Chuckwalla Valley watershed, as well as avoidance and minimization measures to protect drainages near the Project site.

Special-Status Plants: No federal or state-listed plant species occur within the Project Disturbance Area, but four species of special-status plants were detected within the Study area during surveys including Harwood's milk-vetch, desert unicorn plant, Las Animas colubrina, and ribbed cryptantha. Harwood's milk-vetch (CNPS List 2.2) and desert unicorn plant (CNPS List 4.3) were identified in the Project Disturbance Area and ribbed cryptantha (CNPS List 4.3) and Las Animas colubrina (CNPS List 2) were identified in the buffer area and outside of the Project Disturbance Area. Four other species, Abram's spurge, flat-seeded spurge, lobed ground cherry, and glandular ditaxis, have the potential to occur within the Project site. They were not detected during spring 2009 botanical surveys, but these species are detectable only following late-summer, early-fall monsoonal rains, and no surveys were conducted at the appropriate time. Project construction and operation could result in direct and indirect impacts to all of these species, and impacts to even a small population of Abram's spurge, flat-seeded

spurge, lobed ground cherry, or glandular ditaxis would be significant. The California distribution of each of these species is currently documented at very few occurrences

The Applicant and staff have proposed spring and late-summer/early-fall season floristic surveys for these species. If Abram's spurge, flat-seeded spurge, lobed ground cherry, or glandular ditaxis are found, compensatory mitigation would be required as specified in staff's proposed Condition of Certification BIO-19 and would reduce impacts to less than significant levels. If results of surveys for Abram's spurge, flat-seeded spurge, lobed ground cherry, and glandular ditaxis are inconclusive due to low rainfall levels, then compensatory mitigation shall be required on the basis of habitat loss. Staff has determined that impacts to the other species besides Abram's spurge, flat-seeded spurge, lobed ground cherry, and glandular ditaxis would be less than significant and would not require compensatory mitigation. Staff's proposed Condition of Certification BIO-19 would prevent accidental impacts to special-status plants in close proximity to construction and reduce direct and indirect impacts to special-status plant species to less than significant levels.

Impacts to Groundwater Dependent Vegetation Communities: The proposed Project's groundwater pumping would have an impact on groundwater levels in the Chuckwalla Valley Groundwater Basin (see **Soil and Water** section), with potential adverse effects to groundwater dependent sensitive plant communities and to wildlife. Groundwater is also important to sustain vegetation for wildlife habitat in some areas where surface waters are not present. Groundwater-dependent vegetation is documented at Palen Lake, where near-surface groundwater has been observed. Phreatophytes also occur sporadically with smaller examples at Ford Dry Lake, where groundwater levels are deeper. The project has the potential to lower groundwater levels as a result of water production during both construction and operations. The lowering of groundwater levels could have a significant impact to biological resources in areas where deep-rooted phreatophytes occur. Considerable uncertainty remains as to the potential extent of Project impacts to groundwater (see **Soil and Water** section) and to groundwater dependent plant communities, but staff considers these impacts to be potentially significant.

Even modest drawdowns of 0.3 feet can adversely affect vegetation if groundwater drops below the effective rooting levels sustained over time (so that plants never have an opportunity to recover), or occurs not just in summer (when plants are dormant) but throughout early spring when plants need and utilize water most, and when they are least tolerant of drought.

To ensure that the Project's proposed use of groundwater does not lower groundwater levels in the basin so that biological resources are significantly and adversely affected, staff has proposed that the Applicant develop a vegetation monitoring program and identify what changes are occurring in basin water levels and in groundwater-dependent vegetation. Substantial changes to groundwater levels caused by the proposed Project and other pumping in the basin would be documented by the Groundwater Well Monitoring and Reporting program outlined in Condition of Certification **SOIL&WATER-5**. Substantial changes in the vigor of groundwater-dependent vegetation would be monitored and documented under the Vegetation Monitoring and Reporting Plan outlined in staff's proposed Condition of Certification **BIO-25**. Condition of Certification

BIO-26 specifies remedial action to be taken if adverse effects are detected. These measures would be sufficient to ensure that the groundwater pumping for the Project would not result in significant adverse impacts to groundwater-dependent ecosystems in the Chuckwalla Basin.

Migratory Birds/Burrowing Mammals: Sonoran creosote bush scrub and ephemeral drainages within the Project Area provide foraging, cover, and/or breeding habitat for migratory birds, including a number of special-status bird species potentially occurring at the site (including loggerhead shrike, western burrowing owl, and California horned lark). Migratory birds and their eggs and young are protected by the federal Migratory Bird Treaty Act and Fish and Game Code section 3503. Implementation of staff's proposed Conditions of Certification **BIO-8** (Impact Avoidance and Best Management Practices), **BIO-15** (Pre-Construction Nest Surveys), and **BIO-16** (Avian Protection Plan) would avoid these potentially significant impacts to nesting birds. Potential impacts to burrowing owls would be further mitigated by implementation of staff's proposed Condition of Certification **BIO-18**. This condition involves passive relocation of burrowing owls, as well as acquisition of off-site habitat suitable for burrowing owl.

American badgers and desert kit foxes occur throughout the Project area, and construction activities could crush or entomb these burrowing species. Staff's proposed Condition of Certification **BIO-17**, which requires preconstruction surveys and avoidance measures to protect badgers and kit foxes, would avoid these potential impacts.

Impacts and Mitigation for Golden Eagles: Although golden eagles were not detected during the avian surveys conducted for the Project, no focused survey for nest sites or breeding pairs was conducted, nor was an assessment made of the use of the Project site by wintering golden eagles. Surveys for golden eagles were conducted by the BLM in the late 1970s throughout the California desert and there are no known historic records for golden eagle nests within 14 miles from the Project site. While staff considers the direct and indirect impacts of the Genesis Project to be less than significant, information from golden eagle nest surveys in nearby mountains could change this conclusion.

On November 10, 2009 the USFWS introduced new rules (74 FR 46835) requiring a permit for all activities that might result in take of golden or bald eagles, including activities that might cause decreased productivity or nest abandonment. Staff is awaiting further guidance from USFWS to determine whether a federal Eagle Act take permit is warranted for the Palen Project. The USFWS may require higher resolution data from the Project vicinity to make that determination.

Project Closure and Decommissioning: Staff's proposed Condition of Certification **BIO-23** requires the Applicant to develop a Decommissioning and Closure Plan and a cost estimate that meets the requirements of BLM's 43 CFR 3809.550 et seq. This plan would need to include a conceptual approach for removing the engineered channels and other Project facilities, restoration of the site's topography and hydrology, and a revegetation plan for restoring the function and values of the vegetation communities and wildlife habitat. Condition of Certification **BIO-23** also requires a cost estimate of the funding required to undertake those activities.

Alternatives: Staff analyzed two alternatives to the Proposed Project other than the No Project Alternative, the Reduced Acreage Alternative and the Dry Cooling Alternative. The smaller Reduced Acreage Alternative would have smaller impacts on many of the biological resources within the Project area, and substantially less impact on Mojave fringe-toed lizard habitat. The Reduced Acreage Alternative would use approximately 50 percent less groundwater than the Proposed Project. Because the linear facilities for the Proposed Project and the Reduced Acreage Alternatives share the same route, impacts associated with this corridor remain very similar, such as impacts to Couch's spadefoot toad and microphyll woodland. In addition, although the Reduced Acreage Project does represent fewer acres of impacts, it is the same overall length as the Proposed Project, and therefore indirect impacts to desert washes that currently flow through the area would be similar.

The Dry Cooling Alternative is located entirely within the boundaries of the Proposed Project. Because this alternative would occupy the same footprint as the Proposed Project, the impacts remain the same between the two except for impacts to groundwater-dependent ecosystems. The Dry Cooling Alternative would use over 95 percent less groundwater than the Proposed Project.

Staff considers direct, indirect, and cumulative impacts from the Proposed Project and both alternatives to be similar (aside from differences in impact acreage) for most biological resources, including impacts to desert tortoise habitat, Couch's spadefoot toad, microphyll woodland, and migratory birds. While impacts from the Reduced Acreage Alternative are substantially less to Mojave fringe-toed lizard habitat and desert wash, these impacts would still be considered significant under this alternative as well as under the Proposed Project and Dry Cooling Alternative. Staff currently has insufficient information to fully assess the indirect and cumulative impacts to groundwater-dependent vegetation, but these impacts may be considered significant under the Proposed Project and the Reduced Acreage Alternative. Impacts from the Dry Cooling Alternative are identical to those from the Proposed Project, except that this alternative would eliminate any potential Project impacts to groundwater-dependent vegetation.

Proposed conditions of certification under the Reduced Acreages Alternative are identical to those for the Proposed Project, except that the compensatory mitigation acreages recommended for desert tortoise habitat (staff's proposed Condition of Certification **BIO-12**), western burrowing owl (staff's proposed Condition of Certification **BIO-18**), sand dunes (staff's proposed Condition of Certification **BIO-20**), Mojave fringe-toed lizards (staff's proposed Condition of Certification **BIO-20**), and state waters (staff's proposed Condition of Certification **BIO-22**) are adjusted to reflect the reduced areas of impacts. Proposed conditions of certification under the Dry Cooling Alternative are identical to those for the Proposed Project, except that proposed Condition of Certification **BIO-25** and **BIO-26** would not be required. Staff concludes that with implementation of these conditions, impacts from both alternatives would be less than significant.

Proposed 2010 Surveys: In addition to pre-construction surveys, staff and the Applicant have indicated that additional special-status species surveys need to be conducted in 2010. The absence of the 2010 survey data has not precluded staff from

coming to conclusions about the significance of potential impacts to biological resources or prevented development of appropriate mitigation; staff has incorporated avoidance, minimization, or compensation measures into proposed conditions of certification in a manner that accommodates the results of the surveys. The proposed 2010 surveys include the following:

Desert Tortoise. The Applicant proposes conducting protocol-level surveys for desert tortoise and special-status plant species within the northern portion of the transmission line route (north of I-10) that was not surveyed during 2009 field surveys (TTEC 2009c).

Plant Surveys. The following will be targeted for 2010 focused botanical surveys: glandular ditaxis (CEC 2009d), Abram's spurge, white-margined penstemon, Palmer's jackass clover, small-flowered androstephium, argus blazing star, bitter hymenoxys, spiny abrojo, winged cryptantha, lobed ground cherry, angel trumpets, flat-seeded spurge, pink velvet mallow, and desert portulaca (CEC 2009d).

Couch's Spadefoot Toad: Staff has concluded that a potential breeding pond for Couch's spadefoot toad occurs along the linear facilities corridor, and is requiring surveys for potential breeding habitat along other portions of the linear facilities.

Cumulative Effects: Construction and operation of the Genesis Project will have effects on a number of biological resources that are individually limited but cumulatively considerable. The cumulative effects analysis employed a quantitative, GIS-based analysis of direct impacts to habitat, and a qualitative analysis of indirect effects (e.g., increases in predators, noxious weeds, etc.). In many cases, the anticipated indirect effects are more significant, or adverse, than the direct loss of habitat, but are more difficult to quantify. Geographic scope varied between biological resources, but most analyses were based on the Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) boundaries (BLM-CDD 2002).

Significant cumulative effects (including indirect effects) were identified in a number of biological resource areas where the Project contributes—at least incrementally—to the cumulative effect. These include: desert washes in the Ford Watershed and the broader NECO planning area; desert tortoise habitat; golden eagle foraging habitat; Mojave fringe toed lizard and their habitat; habitat for American badger, desert kit fox, and burrowing owl; LeConte's thrasher habitat; Couch's spadefoot toad range; habitat for Harwood's milk-vetch and other dune/playa-dependent special-status plants; wildlife habitat and connectivity within the Palen-Ford WHMA (for Mojave fringe toed lizard, dunes, and playa); Mojave and Sonoran creosote bush scrub; desert dry wash woodland (microphyll woodland); playa and sand drifts over playa, and dunes (active and stabilized).

Of particular concern are the cumulative effects of renewable energy projects within the geographic scope of the Chuckwalla Valley, which contains an isolated system of dunes and population of Mojave fringe-toed lizard. The direct loss of dune habitat and Mojave fringe-toed lizard is minor relative to the indirect downwind effects from obstructions within the active aeolian sand transport corridor, and the disruption of the fluvial processes that contribute sand to the system from the diversion of washes--approximately 63 miles of washes within the Ford watershed alone. In addition to the

disruption of geomorphic processes, significant indirect effects that can be reasonably expected to occur in the Chuckwalla system from future projects include: fragmentation and its effects on connectivity and gene flow; spread of invasive non-native plants; increase in avian predators; and an increase in vehicle-related wildlife mortality.

Implementation of staff's proposed conditions of certification would reduce the Project's contribution to cumulative effects to a level that is not cumulatively considerable. There may be cumulative effects after mitigation is implemented by all projects, but due to the mitigation implemented by the Project, its contribution would be less than cumulatively considerable. These residual cumulative effects from all future projects could be addressed through a regional and coordinated planning effort aimed at preserving and enhancing large, intact expanses of wildlife habitat and linkages, including maintaining connections between wildlife management areas and other movement corridors.

Ongoing collaborative efforts by federal and state agencies to develop a Desert Renewable Energy Conservation Plan and BLM's Solar Energy Development Programmatic EIS offer an appropriate forum for such planning. Appendix B describes the Desert Wildlife Management Area management strategies that could achieve the goals of preservation and enhancement of wildlife connectivity in the NECO planning area. Staff supports these programmatic efforts and believes they represent an excellent means of integrating the State's and BLM's renewable resources goals and environmental protection goals.

C.2.12 PROPOSED CONDITIONS OF CERTIFICATION

The accelerated timing requirements described in these proposed conditions of certification reflect the need for the Genesis Solar Power Project to commence construction before the end of 2010 in order to receive American Recovery and Reinvestment Act of 2009 (ARRA) funding.

DESIGNATED BIOLOGIST SELECTION AND QUALIFICATIONS[6]

BIO-1 The Project owner shall assign at least one Designated Biologist to the Project. The Project owner shall submit the resume of the proposed Designated Biologist(s), with at least three references and contact information, to the Energy Commission Compliance Project Manager (CPM) and BLM's Authorized Officer for approval in consultation with CDFG and USFWS.

The Designated Biologist must meet the following minimum qualifications:

1. Bachelor's degree in biological sciences, zoology, botany, ecology, or a closely related field;

[6] USFWS <www.fws.gov/ventura/speciesinfo/protocols_guidelines/docs/dt> designates biologists who are approved to handle tortoises as "Authorized Biologists." Such biologists have demonstrated to the USFWS that they possess sufficient desert tortoise knowledge and experience to handle and move tortoises appropriately, and have received USFWS approval. Authorized Biologists are permitted to then approve specific monitors to handle tortoises, at their discretion. The California Department of Fish and Game (CDFG) must also approve such biologists, potentially including individual approvals for monitors approved by the Authorized Biologist. **Designated Biologists are the equivalent of Authorized Biologists.** Only Designated Biologists and certain Biological Monitors who have been approved by the Designated Biologist would be allowed to handle desert tortoises.

2. Three years of experience in field biology or current certification of a nationally recognized biological society, such as The Ecological Society of America or The Wildlife Society;

3. Have at least one year of field experience with biological resources found in or near the Project area;

4. Meet the current USFWS Authorized Biologist qualifications criteria (www.fws.gov/ventura/speciesinfo/protocols_guidelines), demonstrate familiarity with protocols and guidelines for the desert tortoise, and be approved by the USFWS; and

5. Possess a California ESA Memorandum of Understanding pursuant to Section 2081(a) for desert tortoise.

In lieu of the above requirements, the resume shall demonstrate to the satisfaction of BLM's Authorized Officer and the CPM, in consultation with CDFG and USFWS, that the proposed Designated Biologist or alternate has the appropriate training and background to effectively implement the conditions of certification.

Verification: No fewer than 30 days prior to construction-related ground disturbance, the Designated Biologists shall complete a USFWS Desert Tortoise Authorized Biologist Request Form (www.fws.gov/ventura/speciesinfo/protocols_guidelines) and submit it to the USFWS, BLM's Authorized Officer, and the CPM for review and final approval.

The Project owner shall submit the CPM and Authorized Officer-approved Designated Biologist within 7 days of receiving the Energy Commission Decision. No construction-related ground disturbance, grading, boring, or trenching shall commence until an approved Designated Biologist is available to be on site.

If a Designated Biologist needs to be replaced, the specified information of the proposed replacement must be submitted to BLM's Authorized Officer and the CPM at least 10 working days prior to the termination or release of the preceding Designated Biologist. In an emergency, the Project owner shall immediately notify the BLM's Authorized Officer and the CPM to discuss the qualifications and approval of a short-term replacement while a permanent Designated Biologist is proposed to BLM's Authorized Officer and the CPM and for consideration.

DESIGNATED BIOLOGIST DUTIES

BIO-2 The Project owner shall ensure that the Designated Biologist performs the activities described below during any site mobilization activities, construction-related ground disturbance, grading, boring or trenching activities. The Designated Biologist may be assisted by the approved Biological Monitor(s) but remains the contact for the Project owner, BLM's Authorized Officer and the CPM. The Designated Biologist Duties shall include the following:

1. Advise the Project owner's Construction and Operation Managers on the implementation of the biological resources conditions of certification;

2. Consult on the preparation of the Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP) to be submitted by the Project owner;

3. Be available to supervise, conduct and coordinate mitigation, monitoring, and other biological resources compliance efforts, particularly in areas requiring avoidance or containing sensitive biological resources, such as special-status species or their habitat;

4. Clearly mark sensitive biological resource areas and inspect these areas at appropriate intervals for compliance with regulatory terms and conditions;

5. Inspect active construction areas where animals may have become trapped prior to construction commencing each day. At the end of the day, inspect for the installation of structures that prevent entrapment or allow escape during periods of construction inactivity. Periodically inspect areas with high vehicle activity (e.g., parking lots) for animals in harm's way;

6. Notify the Project owner and BLM's Authorized Officer and the CPM of any non-compliance with any biological resources condition of certification;

7. Respond directly to inquiries of BLM's Authorized Officer and the CPM regarding biological resource issues;

8. Maintain written records of the tasks specified above and those included in the BRMIMP. Summaries of these records shall be submitted in the Monthly Compliance Report and the Annual Compliance Report;

9. Train the Biological Monitors as appropriate, and ensure their familiarity with the BRMIMP, Worker Environmental Awareness Program (WEAP) training, and USFWS guidelines on desert tortoise surveys and handling procedures <www.fws.gov/ventura/speciesinfo/protocols_guidelines>; and

10. Maintain the ability to be in regular, direct communication with representatives of CDFG, USFWS, BLM's Authorized Officer and the CPM, including notifying these agencies of dead or injured listed species and reporting special-status species observations to the California Natural Diversity Data Base.

Verification: The Designated Biologist shall provide copies of all written reports and summaries that document biological resources compliance activities in the Monthly

Compliance Reports submitted to BLM's Authorized Officer and the CPM. If actions may affect biological resources during operation a Designated Biologist shall be available for monitoring and reporting. During Project operation, the Designated Biologist shall submit record summaries in the Annual Compliance Report unless his or her duties cease, as approved by BLM's Authorized Officer and the CPM.

BIOLOGICAL MONITOR SELECTION AND QUALIFICATIONS

BIO-3 The Designated Biologist shall submit the resume, at least three references, and contact information of the proposed Biological Monitors to BLM's Authorized Officer and the CPM. The resume shall demonstrate, to the satisfaction of the CPM, the appropriate education and experience to accomplish the assigned biological resource tasks. The Biological Monitor is the equivalent of the USFWS designated Desert Tortoise Monitor (USFWS 2008).

Biological Monitor(s) training by the Designated Biologist shall include familiarity with the conditions of certification, BRMIMP, WEAP, and USFWS guidelines on desert tortoise surveys and handling procedures <www.fws.gov/ventura/speciesinfo/protocols_guidelines>.

Verification: The Project owner shall submit the specified information to the BLM's Authorized Officer and the CPM for approval at least 30 days prior to the start of any site mobilization or construction-related ground disturbance, grading, boring and trenching. The Designated Biologist shall submit a written statement to BLM's Authorized Officer and the CPM confirming that individual Biological Monitor(s) has been trained including the date when training was completed. If additional biological monitors are needed during construction the specified information shall be submitted to BLM's Authorized Officer and the CPM and for approval at least 10 days prior to their first day of monitoring activities.

BIOLOGICAL MONITOR DUTIES

BIO-4 The Biological Monitors shall assist the Designated Biologist in conducting surveys and in monitoring of site mobilization activities, construction-related ground disturbance, grading, boring or trenching. The Designated Biologist shall remain the contact for the Project owner, BLM's Authorized Officer and the CPM.

Verification: The Designated Biologist shall submit in the Monthly Compliance Report to BLM's Authorized Officer and the CPM copies of all written reports and summaries that document biological resources compliance activities, including those conducted by Biological Monitors. If actions may affect biological resources during operation a Biological Monitor, under the supervision of the Designated Biologist, shall be available for monitoring and reporting. During Project operation, the Designated Biologist shall submit record summaries in the Annual Compliance Report unless their duties cease, as approved by BLM's Authorized Officer and the CPM.

DESIGNATED BIOLOGIST AND BIOLOGICAL MONITOR AUTHORITY

BIO-5 The Project owner's construction/operation manager shall act on the advice of the Designated Biologist and Biological Monitor(s) to ensure

conformance with the biological resources conditions of certification. The Project owner shall provide Energy Commission and BLM staff with reasonable access to the Project site under the control of the Project owner and shall otherwise fully cooperate with the Energy Commission's and BLM's efforts to verify the Project owner's compliance with, or the effectiveness of, mitigation measures set forth in the conditions of certification. The Designated Biologist shall have the authority to immediately stop any activity that is not in compliance with these conditions and/or order any reasonable measure to avoid take of an individual of a listed species. If required by the Designated Biologist and Biological Monitor(s) the Project owner's construction/operation manager shall halt all site mobilization, ground disturbance, grading, boring, trenching and operation activities in areas specified by the Designated Biologist. The Designated Biologist shall:

1. Require a halt to all activities in any area when determined that there would be an unauthorized adverse impact to biological resources if the activities continued;

2. Inform the Project owner and the construction/operation manager when to resume activities; and

3. Notify BLM's Authorized Officer and the CPM if there is a halt of any activities and advise them of any corrective actions that have been taken or would be instituted as a result of the work stoppage.

If the Designated Biologist is unavailable for direct consultation, the Biological Monitor shall act on behalf of the Designated Biologist.

Verification: The Project owner shall ensure that the Designated Biologist or Biological Monitor notifies BLM's Authorized Officer and the CPM immediately (and no later than the morning following the incident, or Monday morning in the case of a weekend) of any non-compliance or a halt of any site mobilization, ground disturbance, grading, construction, or operation activities. The Project owner shall notify BLM's Authorized Officer and the CPM of the circumstances and actions being taken to resolve the problem.

Whenever corrective action is taken by the Project owner, a determination of success or failure will be made by BLM's Authorized Officer and the CPM within five working days after receipt of notice that corrective action is completed, or the Project owner would be notified by BLM's Authorized Officer and the CPM that coordination with other agencies would require additional time before a determination can be made.

WORKER ENVIRONMENTAL AWARENESS PROGRAM (WEAP)

BIO-6 The Project owner shall develop and implement a Project-specific Worker Environmental Awareness Program (WEAP) and shall secure approval for the WEAP from BLM's Authorized Officer and the CPM. The WEAP shall be administered to all onsite personnel including surveyors, construction engineers, employees, contractors, contractor's employees, supervisors, inspectors, subcontractors, and delivery personnel. The WEAP shall be

implemented during site preconstruction, construction, operation, and closure. The WEAP shall:

1. Be developed by or in consultation with the Designated Biologist and consist of an on-site or training center presentation in which supporting written material and electronic media, including photographs of protected species, is made available to all participants;

2. Discuss the locations and types of sensitive biological resources on the Project site and adjacent areas, and explain the reasons for protecting these resources; provide information to participants that no snakes, reptiles, or other wildlife shall be harmed;

3. Place special emphasis on desert tortoise, including information on physical characteristics, distribution, behavior, ecology, sensitivity to human activities, legal protection, penalties for violations, reporting requirements, and protection measures;

4. Include a discussion of fire prevention measures to be implemented by workers during Project activities; request workers dispose of cigarettes and cigars appropriately and not leave them on the ground or buried;

5. Describe the temporary and permanent habitat protection measures to be implemented at the Project site;

6. Identify whom to contact if there are further comments and questions about the material discussed in the program; and

7. Include a training acknowledgment form to be signed by each worker indicating that they received training and shall abide by the guidelines.

The specific program can be administered by a competent individual(s) acceptable to the Designated Biologist.

Verification: Within 7 days of docketing of the Energy Commission's Final Decision, or publication of the Record of Decision/ROW Issuance, whichever comes first, the Project owner shall provide to BLM's Authorized Officer and the CPM a copy of the final WEAP and all supporting written materials and electronic media prepared or reviewed by the Designated Biologist and a resume of the person(s) administering the program.

The Project owner shall provide in the Monthly Compliance Report the number of persons who have completed the training in the prior month and a running total of all persons who have completed the training to date. At least 10 days prior to construction-related ground disturbance activities the Project owner shall submit two copies of the BLM- and CPM-approved final WEAP.

Training acknowledgement forms signed during construction shall be kept on file by the Project owner for at least six months after the start of commercial operation.

Throughout the life of the Project, the WEAP shall be repeated annually for permanent employees, and shall be routinely administered within one week of arrival to any new

construction personnel, foremen, contractors, subcontractors, and other personnel potentially working within the Project area. Upon completion of the orientation, employees shall sign a form stating that they attended the program and understand all protection measures. These forms shall be maintained by the Project owner and shall be made available to BLM's Authorized Officer and the CPM and upon request. Workers shall receive and be required to visibly display a hardhat sticker or certificate that they have completed the training.

During Project operation, signed statements for operational personnel shall be kept on file for six months following the termination of an individual's employment.

BIOLOGICAL RESOURCES MITIGATION IMPLEMENTATION AND MONITORING PLAN

BIO-7 The Project owner shall develop a Biological Resources Mitigation Implementation and Monitoring Plan (BRMIMP), and shall submit two copies of the proposed BRMIMP to the BLM-Authorized Officer and the CPM for review and approval. The Project owner shall implement the measures identified in the approved BRMIMP. The BRMIMP shall incorporate avoidance and minimization measures described in final versions of the Desert Tortoise Relocation Translocation Plan, the Raven Management Plan, the Closure, Conceptual Restoration Plan, the Burrowing Owl Mitigation and Monitoring Plan, and the Weed Management Plan.

The BRMIMP shall be prepared in consultation with the Designated Biologist and shall include accurate and up-to-date maps depicting the location of sensitive biological resources that require temporary or permanent protection during construction and operation. The BRMIMP shall include complete and detailed descriptions of the following:

1. All biological resources mitigation, monitoring, and compliance measures proposed and agreed to by the Project owner;

2. All biological resources conditions of certification identified as necessary to avoid or mitigate impacts;

3. All biological resource mitigation, monitoring and compliance measures required in federal agency terms and conditions, such as those provided in the USFWS Biological Opinion;

4. All sensitive biological resources to be impacted, avoided, or mitigated by Project construction, operation, and closure;

5. All required mitigation measures for each sensitive biological resource;

6. All measures that shall be taken to avoid or mitigate temporary disturbances from construction activities;

7. Duration for each type of monitoring and a description of monitoring methodologies and frequency;

8. Performance standards to be used to help decide if/when proposed mitigation is or is not successful;

9. All performance standards and remedial measures to be implemented if performance standards are not met;

10. Biological resources-related facility closure measures including a description of funding mechanism(s);

11. A process for proposing plan modifications to BLM's Authorized Officer and the CPM and appropriate agencies for review and approval; and

12. A requirement to submit any sightings of any special-status species that are observed on or in proximity to the Project site, or during Project surveys, to the California Natural Diversity Data Base (CNDDB) per CDFG requirements.

Verification: The Project owner shall submit the final BRMIMP to BLM's Authorized Officer and the CPM at least 30 days prior to start of any preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching. The BRMIMP shall contain all of the required measures included in all biological Conditions of Certification. No construction-related ground disturbance, grading, boring or trenching may occur prior to approval of the final BRMIMP by BLM's Authorized Officer and the CPM.

If any permits have not yet been received when the BRMIMP is first submitted, these permits shall be submitted to BLM's Authorized Officer and the CPM within 5 days of their receipt, and the BRMIMP shall be revised or supplemented to reflect the permit condition within at least 10 days of their receipt by the Project owner. Ten days prior to site and related facilities mobilization the revised BRMIMP shall be resubmitted to BLM's Authorized Officer and the CPM.

To verify that the extent of construction disturbance does not exceed that described in this analysis, the Project owner shall submit aerial photographs, at an approved scale, taken before and after construction to the CPM and BLM's Authorized Officer. The first set of aerial photographs shall reflect site conditions prior to any preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching, and shall be submitted at least 60 days prior to initiation of such activities. The second set of aerial photographs shall be taken subsequent to completion of construction, and shall be submitted to the CPM and BLM's Authorized Officer no later than 90 days after completion of construction. The Project owner shall also provide a final accounting of the acreages of vegetation communities/cover types present before and after construction.

Any changes to the approved BRMIMP must be approved by BLM's Authorized Officer and the CPM and in consultation with CDFG and USFWS.

Implementation of BRMIMP measures (for example, construction activities that were monitored, species observed) shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of Project construction, the Project owner shall provide to BLM's Authorized Officer and the CPM, for review and approval, a written construction termination report identifying which items of the BRMIMP have been completed, a summary of all modifications to mitigation measures made during the Project's preconstruction site mobilization and construction-related ground disturbance, grading, boring, and trenching, and which mitigation and monitoring items are still outstanding.

IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-8 The Project owner shall undertake the following measures to manage the construction site and related facilities in a manner to avoid or minimize impacts to biological resources:

1. Limit Disturbance Areas. The boundaries of all areas to be disturbed (including staging areas, access roads, and sites for temporary placement of spoils) shall be delineated with stakes and flagging prior to construction activities in consultation with the Designated Biologist. Spoils and topsoil shall be stockpiled in disturbed areas lacking native vegetation and which do not provide habitat for special-status species. Parking areas, staging and disposal site locations shall similarly be located in areas without native vegetation or special-status species habitat. All disturbances, Project vehicles and equipment shall be confined to the flagged areas.

2. Minimize Road Impacts. New and existing roads that are planned for construction, widening, or other improvements shall not extend beyond the flagged impact area as described above. All vehicles passing or turning around would do so within the planned impact area or in previously disturbed areas. Where new access is required outside of existing roads or the construction zone, the route shall be clearly marked (i.e., flagged and/or staked) prior to the onset of construction.

3. Minimize Traffic Impacts. Vehicular traffic during Project construction and operation shall be confined to existing routes of travel to and from the Project site, and cross country vehicle and equipment use outside designated work areas shall be prohibited. The speed limit shall not exceed 25 miles per hour within the Project area, on maintenance roads for linear facilities, or on access roads to the Project site.

4. Monitor During Construction. In areas that have not been fenced with desert tortoise exclusion fencing and cleared, the Designated Biologist shall be present at the construction site during all Project activities that have potential to disturb soil, vegetation, and wildlife. The Designated Biologist or Biological Monitor shall walk immediately ahead of equipment during brushing and grading activities.

5. Minimize Impacts of Pipeline Alignments, Roads, Staging Areas. Staging areas for construction on the plant site shall be within the area that has been fenced with desert tortoise exclusion fencing and cleared. For construction activities outside of the plant site (transmission line, pipeline alignments) access roads, pulling sites, and storage and parking areas shall be designed, installed, and maintained with the goal of minimizing impacts to native plant communities and sensitive biological resources.

6. Implement APLIC Guidelines. Transmission lines and all electrical components shall be designed, installed, and maintained in accordance with the Avian Power Line Interaction Committee's (APLIC's) *Suggested Practices for Avian Protection on Power Lines* (APLIC 2006) and *Mitigating Bird Collisions with Power Lines* (APLIC 1994) to reduce the likelihood of large bird electrocutions and collisions.

7. Avoid Use of Toxic Substances. Soil bonding and weighting agents used on unpaved surfaces shall be non-toxic to wildlife and plants.

8. Minimize Lighting Impacts. Facility lighting shall be designed, installed, and maintained to prevent side casting of light towards wildlife habitat. Lighting shall be kept to the minimum level for safety and security needs by using motion or infrared light sensors and switches to keep lights off when not required, and shielding operational lights downward to minimize skyward illumination. No high intensity, steady burning, bright lights such as sodium vapor or spotlights shall be used. FAA visibility lighting shall employ only strobed, strobe-like or blinking incandescent lights, preferably with all lights illuminating simultaneously. Minimum intensity, maximum "off-phased" duel strobes are preferred, and no steady burning lights (e.g., L-810s) shall be used.

9. Minimize Noise Impacts. A continuous low-pressure technique shall be used for steam blows, to the extent possible, in order to reduce noise levels in sensitive habitat proximate to the Genesis Project. Loud construction activities (i.e., steam blowing, both low and high pressure, and pile driving) shall be avoided from February 15 to April 15, which is the height of the local bighorn sheep lambing and bird breeding season (see **BIO-15** for additional impact avoidance measures for breeding birds).

10. Avoid Vehicle Impacts to Desert Tortoise. Parking and storage shall occur within the area enclosed by desert tortoise exclusion fencing to the extent feasible. No vehicles or construction equipment parked outside the fenced area shall be moved prior to an inspection of the ground beneath the vehicle for the presence of desert tortoise. If a desert tortoise is observed, it shall be left to move on its own. If it does not move within 15 minutes, a Designated Biologist or Biological

Monitor under the Designated Biologist's direct supervision may remove and relocate the animal to a safe location if temperatures are within the range described in the USFWS' 2009 *Desert Tortoise Field Manual* (http://www.fws.gov/ventura/speciesinfo/protocols_guidelines.

11. Avoid Wildlife Pitfalls: To avoid trapping desert tortoise and other wildlife in trenches, pipes or culverts, the following measures shall be implemented:

    a. Backfill Trenches. At the end of each work day, the Designated Biologist shall ensure that all potential wildlife pitfalls (trenches, bores, and other excavations) outside the area fenced with desert tortoise exclusion fencing have been backfilled. If backfilling is not feasible, all trenches, bores, and other excavations shall be sloped at a 3:1 ratio at the ends to provide wildlife escape ramps, or covered completely to prevent wildlife access, or fully enclosed with desert tortoise-exclusion fencing. All trenches, bores, and other excavations outside the areas permanently fenced with desert tortoise exclusion fencing shall be inspected periodically throughout the day and at the end of each workday by the Designated Biologist or a Biological Monitor. Should a tortoise or other wildlife become trapped, the Designated Biologist or Biological Monitor shall remove and relocate the individual as described in the Desert Tortoise Relocation/Translocation Plan. Any wildlife encountered during the course of construction shall be allowed to leave the construction area unharmed.

    b. Avoid Entrapment of Desert Tortoise. Any construction pipe, culvert, or similar structure with a diameter greater than 3 inches, stored less than 8 inches aboveground and within desert tortoise habitat (i.e., outside the permanently fenced area) for one or more nights, shall be inspected for tortoises before the material is moved, buried or capped. As an alternative, all such structures may be capped before being stored outside the fenced area, or placed on pipe racks. These materials would not need to be inspected or capped if they are stored within the permanently fenced area after the clearance surveys have been completed.

12. Minimize Standing Water. Water applied to dirt roads and construction areas (trenches or spoil piles) for dust abatement shall use the minimal amount needed to meet safety and air quality standards in an effort to prevent the formation of puddles, which could attract desert tortoises and common ravens to construction sites. A Biological Monitor shall patrol these areas to ensure water does not puddle and shall take appropriate action to reduce water application where necessary.

13. Dispose of Road-killed Animals. Road killed animals or other carcasses detected on roads near the Project area shall be picked up

immediately and delivered to the Biological Monitor. For special-status species road-kill, the Biological Monitor shall contact CDFG and USFWS within 1 working day of receipt of the carcass for guidance on disposal or storage of the carcass. The Biological Monitor shall report the special-status species record as described in **BIO-11** below.

14. Minimize Spills of Hazardous Materials. All vehicles and equipment shall be maintained in proper working condition to minimize the potential for fugitive emissions of motor oil, antifreeze, hydraulic fluid, grease, or other hazardous materials. The Designated Biologist shall be informed of any hazardous spills immediately as directed in the Project Hazardous Materials Plan. Hazardous spills shall be immediately cleaned up and the contaminated soil properly disposed of at a licensed facility. Servicing of construction equipment shall take place only at a designated area. Service/maintenance vehicles shall carry a bucket and pads to absorb leaks or spills.

15. Worker Guidelines. During construction all trash and food-related waste shall be placed in self-closing containers and removed daily from the site. Workers shall not feed wildlife or bring pets to the Project site. Except for law enforcement personnel, no workers or visitors to the site shall bring firearms or weapons. Vehicular traffic shall be confined to existing routes of travel to and from the Project site, and cross country vehicle and equipment use outside designated work areas shall be prohibited. The speed limit when traveling on dirt access routes within desert tortoise habitat shall not exceed 25 miles per hour.

16. Implement Erosion Control Measures. Standard erosion control measures shall be implemented for all phases of construction and operation where sediment run-off from exposed slopes threatens to enter “Waters of the State”. Sediment and other flow-restricting materials shall be moved to a location where they shall not be washed back into the stream. All disturbed soils and roads within the Project site shall be stabilized to reduce erosion potential, both during and following construction. Areas of disturbed soils (access and staging areas) with slopes toward drainages shall be stabilized to reduce erosion potential.

17. Monitor Ground Disturbing Activities Prior to Pre-Construction Site Mobilization. If pre-construction site mobilization requires ground-disturbing activities such as for geotechnical borings or hazardous waste evaluations, a Designated Biologist or Biological Monitor shall be present to monitor any actions that could disturb soil, vegetation, or wildlife.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP and implemented. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of Project construction, the Project owner shall provide to BLM’s

Authorized Officer and the CPM, for review and approval, a written construction termination report identifying how measures have been completed.

DESERT TORTOISE CLEARANCE SURVEYS AND FENCING

BIO-9 The Project owner shall undertake appropriate measures to manage the construction site and related facilities in a manner to avoid or minimize impacts to desert tortoise. Methods for clearance surveys, fence specification and installation, tortoise handling, artificial burrow construction, egg handling and other procedures shall be consistent with those described in the USFWS' 2009 *Desert Tortoise Field Manual* <http://www.fws.gov/ventura/speciesinfo/protocols_guidelines> or more current guidance provided by CDFG and USFWS. The Project owner shall also implement all terms and conditions described in the Biological Opinion prepared by USFWS. These measures include, but are not limited to, the following:

1. Desert Tortoise Exclusion Fence Installation. To avoid impacts to desert tortoises, permanent desert tortoise exclusion fencing shall be installed along the permanent perimeter security fence and temporarily installed along the utility corridors. The proposed alignments for the permanent perimeter fence and utility rights-of-way fencing shall be flagged and surveyed within 24 hours prior to the initiation of fence construction. Clearance surveys of the perimeter fence and utility rights-of-way alignments shall be conducted by the Designated Biologist(s) using techniques outlined in the USFWS' 2009 *Desert Tortoise Field Manual*. and may be conducted in any season with USFWS and CDFG approval. Biological Monitors may assist the Designated Biologist under his or her supervision. These fence clearance surveys shall provide 100-percent coverage of all areas to be disturbed and an additional transect along both sides of the fence line. This fence line transect shall cover an area approximately 90 feet wide centered on the fence alignment. Transects shall be no greater than 15 feet apart. All desert tortoise burrows, and burrows constructed by other species that might be used by desert tortoises, shall be examined to assess occupancy of each burrow by desert tortoises and handled in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*. Any desert tortoise located during fence clearance surveys shall be handled by the Designated Biologist(s) in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*.

    a. Timing, Supervision of Fence Installation. The exclusion fencing shall be installed prior to the onset of site clearing and grubbing. The fence installation shall be supervised by the Designated Biologist and monitored by the Biological Monitors to ensure the safety of any tortoise present.

    b. Fence Material and Installation. The permanent tortoise exclusionary fencing shall be constructed in accordance with the

USFWS' 2009 *Desert Tortoise Field Manual* (Chapter 8 – Desert Tortoise Exclusion Fence).

c. Security Gates. Security gates shall be designed with minimal ground clearance to deter ingress by tortoises. The gates may be electronically activated to open and close immediately after the vehicle(s) have entered or exited to prevent the gates from being kept open for long periods of time. Cattle grating designed to safely exclude desert tortoise shall be installed at the gated entries to discourage tortoises from gaining entry

d. Fence Inspections. Following installation of the desert tortoise exclusion fencing for both the permanent site fencing and temporary fencing in the utility corridors, the fencing shall be regularly inspected. If tortoise were moved out of harm's way during fence construction, permanent and temporary fencing shall be inspected at least two times a day for the first 7 days to ensure a recently moved tortoise has not been trapped within the fence. Thereafter, permanent fencing shall be inspected monthly and during and within 24 hours following all major rainfall events. A major rainfall event is defined as one for which flow is detectable within the fenced drainage. Any damage to the fencing shall be temporarily repaired immediately to keep tortoises out of the site, and permanently repaired within 48 hours of observing damage. Inspections of permanent site fencing shall occur for the life of the project. Temporary fencing shall be inspected weekly and, where drainages intersect the fencing, during and within 24 hours following major rainfall events. All temporary fencing shall be repaired immediately upon discovery and, if the fence may have permitted tortoise entry while damaged, the Designated Biologist shall inspect the area for tortoise.

2. Desert Tortoise Clearance Surveys within the Plant Site. Following construction of the permanent perimeter security fence and the attached tortoise exclusion fence, the permanently fenced power plant site shall be cleared of tortoises by the Designated Biologist, who may be assisted by the Biological Monitors. Clearance surveys shall be conducted in accordance with the USFWS' 2009 *Desert Tortoise Field Manual* (Chapter 6 – Clearance Survey Protocol for the Desert Tortoise – Mojave Population) and shall consist of two surveys covering 100 percent of the project area by walking transects no more than 15-feet apart. If a desert tortoise is located on the second survey, a third survey shall be conducted. Each separate survey shall be walked in a different direction to allow opposing angles of observation. Clearance surveys of the power plant site may only be conducted when tortoises are most active (April through May or September through October). Surveys outside of these time periods require approval by USFWS and CDFG. Any tortoise located during clearance

surveys of the power plant site shall be relocated and monitored in accordance with the Desert Tortoise Relocation/Translocation Plan

a. Burrow Searches. During clearance surveys all desert tortoise burrows, and burrows constructed by other species that might be used by desert tortoises, shall be examined by the Designated Biologist, who may be assisted by the Biological Monitors, to assess occupancy of each burrow by desert tortoises and handled in accordance with the USFWS' 2009 *Desert Tortoise Field Manual*. To prevent reentry by a tortoise or other wildlife, all burrows shall be collapsed once absence has been determined. Tortoises taken from burrows and from elsewhere on the power plant site shall be relocated or translocated as described in the Desert Tortoise Relocation/Translocation Plan.

b. Burrow Excavation/Handling. All potential desert tortoise burrows located during clearance surveys shall be excavated by hand, tortoises removed, and collapsed or blocked to prevent occupation by desert tortoises. All desert tortoise handling and removal, and burrow excavations, including nests, shall be conducted by the Designated Biologist, who may be assisted by a Biological Monitor in accordance with the USFWS' 2009 *Desert Tortoise Field Manual.*

3. Monitoring Following Clearing. Following the desert tortoise clearance and removal from the power plant site and utility corridors, workers and heavy equipment shall be allowed to enter the Project site to perform clearing, grubbing, leveling, and trenching. A Designated Biologist shall monitor clearing and grading activities to find and move tortoises missed during the initial tortoise clearance survey. Should a tortoise be discovered, it shall be relocated or translocated as described in the Desert Tortoise Relocation/Translocation Plan.

4. Reporting. The Designated Biologist shall record the following information for any desert tortoises handled: a) the locations (narrative and maps) and dates of observation; b) general condition and health, including injuries, state of healing and whether desert tortoise voided their bladders; c) location moved from and location moved to (using GPS technology); d) gender, carapace length, and diagnostic markings (i.e., identification numbers or marked lateral scutes); e) ambient temperature when handled and released; and f) digital photograph of each handled desert tortoise. Desert tortoise moved from within Project areas shall be marked and monitored in accordance with the Desert Tortoise Translocation Plan.

Verification: All mitigation measures and their implementation methods shall be included in the BRMIMP and implemented. Implementation of the measures shall be reported in the Monthly Compliance Reports by the Designated Biologist. Within 30 days after completion of desert tortoise clearance surveys the Designated Biologist shall submit a report to BLM's Authorized Officer, the CPM, USFWS, and CDFG describing implementation of each of the mitigation measures listed above. The report shall include

the desert tortoise survey results, capture and release locations of any relocated desert tortoises, and any other information needed to demonstrate compliance with the measures described above.

DESERT TORTOISE RELOCATION/TRANSLOCATION PLAN

BIO-10 The Project owner shall develop and implement a final Desert Tortoise Relocation/Translocation Plan (Plan) that is consistent with current USFWS approved guidelines, and meets the approval of BLM's Authorized Officer and the CPM. The goals of the Desert Tortoise Relocation/Translocation Plan shall be to: relocate/translocate all desert tortoises from the project site to nearby suitable habitat; minimize impacts on resident desert tortoises outside the project site; minimize stress, disturbance, and injuries to relocated/translocated tortoises; and assess the success of the relocated/translocated effort through monitoring. The final Plan shall be based on the draft Desert Tortoise Relocation/Translocation Plan submitted by the Applicant (TTEC 2010a) and shall include all revisions deemed necessary by BLM, USFWS, CDFG and the Energy Commission staff.

Verification: Within 7 days of docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the Project owner shall provide BLM's Authorized Officer and the CPM with the final version of a Plan that has been reviewed and approved by BLM's Authorized Officer and the CPM in consultation with USFWS and CDFG. All modifications to the approved Plan shall be made only after approval by BLM's Authorized Officer and the CPM, in consultation with USFWS and CDFG.

Within 30 days after initiation of relocation and/or translocation activities, the Designated Biologist shall provide to BLM's Authorized Officer and the CPM for review and approval, a written report identifying which items of the Plan have been completed, and a summary of all modifications to measures made during implementation of the Plan.

DESERT TORTOISE COMPLIANCE VERIFICATION

BIO-11 The Project owner shall provide Energy Commission and BLM staff with reasonable access to the Project site and compensation lands under the control of the Project owner and shall otherwise fully cooperate with the Energy Commission's and BLM's efforts to verify the Project owner's compliance with, or the effectiveness of, mitigation measures set forth in the conditions of certification. The Project owner shall hold the Designated Biologist, the Energy Commission, and BLM harmless for any costs the Project owner incurs in complying with the management measures, including stop work orders issued by BLM's Authorized Officer, the CPM, or the Designated Biologist. The Designated Biologist shall do all of the following:

1. Notification. Notify BLM's Authorized Officer and the CPM and at least 14 calendar days before initiating construction-related ground disturbance activities; immediately notify BLM's Authorized Officer and the CPM in writing if the Project owner is not in compliance with any

conditions of certification, including but not limited to any actual or anticipated failure to implement mitigation measures within the time periods specified in the conditions of certification;

2. Monitoring During Grubbing and Grading. Remain onsite daily while vegetation salvage, grubbing, grading and other ground-disturbance construction activities are taking place to avoid or minimize take of listed species, to check for compliance with all impact avoidance and minimization measures, and to check all exclusion zones to ensure that signs, stakes, and fencing are intact and that human activities are restricted in these protective zones.

3. Monthly Compliance Inspections. Conduct compliance inspections at a minimum of once per month after clearing, grubbing, and grading are completed and submit a monthly compliance report to the CPM, BLM's Authorized Officer, USFWS and CDFG during construction.

4. Notification of Injured or Dead Listed Species. If an injured or dead listed species is detected within or near the Project Disturbance Area the CPM, BLM's Authorized Officer, CDFG, and USFWS shall be notified immediately by phone. Notification shall occur no later than noon on the business day following the event if it occurs outside normal business hours so that the agencies can determine if further actions are required to protect listed species. Written follow-up notification via FAX or electronic communication shall be submitted to these agencies within two calendar days of the incident and shall include the following information as relevant:

    a. Injured Desert Tortoise. If a desert tortoise is injured as a result of Project-related activities during construction, the Designated Biologist shall immediately take it to a CDFG-approved wildlife rehabilitation and/or veterinarian clinic. Any veterinarian bills for such injured animals shall be paid by the Project owner. Following phone notification as required above, the CPM, BLM's Authorized Officer, CDFG, and USFWS shall determine the final disposition of the injured animal, if it recovers. Written notification shall include, at a minimum, the date, time, location, circumstances of the incident, and the name of the facility where the animal was taken.

    b. Desert Tortoise Fatality. If a desert tortoise is killed by Project-related activities during construction or operation, a written report with the same information as an injury report shall be submitted to the CPM, BLM's Authorized Officer, CDFG, and USFWS. These desert tortoises shall be salvaged according to guidelines described in *Salvaging Injured, Recently Dead, Ill, and Dying Wild, Free-Roaming Desert Tortoise* (Berry 2001). The Project owner shall pay to have the desert tortoises transported and necropsied. The report shall include the date and time of the finding or incident.

5. Stop Work Order. The CPM and BLM's Authorized Officer may issue the Project owner a written stop work order to suspend any activity related to the construction or operation of the Project to prevent or remedy a violation of one or more conditions of certification (including but not limited to failure to comply with reporting, monitoring, or habitat acquisition obligations) or to prevent the illegal take of an endangered, threatened, or candidate species. The Project owner shall comply with the stop work order immediately upon receipt thereof.

Verification: No later than 2 days following the above required notification of a sighting, injury, kill, or relocation of a listed species, the Project owner shall deliver to BLM's Authorized Officer, the CPM, CDFG, and USFWS via FAX or electronic communication the written report from the Designated Biologist describing all reported incidents of injury, kill, or relocation of a listed species, identifying who was notified, and explaining when the incidents occurred. In the case of a sighting in an active construction area, the Project owner shall, at the same time, submit a map (e.g., using Geographic Information Systems) depicting both the limits of construction and sighting location to BLM's Authorized Officer, the CPM, CDFG and USFWS.

No later than 45 days after initiation of Project operation the Designated Biologist shall provide the BLM Authorized Officer and the CPM a Final Listed Species Mitigation Report that includes, at a minimum: 1) a copy of the table in the BRMIMP with notes showing when each of the mitigation measures was implemented; 2) all available information about Project-related incidental take of listed species; 3) information about other Project impacts on the listed species; 4) construction dates; 5) an assessment of the effectiveness of conditions of certification in minimizing and compensating for Project impacts; 6) recommendations on how mitigation measures might be changed to more effectively minimize and mitigate the impacts of future Projects on the listed species; and 7) any other pertinent information, including the level of take of the listed species associated with the Project.

DESERT TORTOISE COMPENSATORY MITIGATION

BIO-12 To fully mitigate for habitat loss and potential take of desert tortoise, the Project owner shall provide compensatory mitigation at a 1:1 ratio for impacts to 1,763 acres (or the final Project Disturbance Area), and at a 5:1 ratio for 23 acres (or the final Project Disturbance Area), within the

Chuckwalla Desert Tortoise Critical Habitat Unit. The requirements for acquisition of 1,878 acres of compensation lands (or 1,131 acres for the Reduced Acreage Alternative) shall include the following:

1. Selection Criteria for Compensation Lands. The compensation lands selected for acquisition shall:

    a. be within the Colorado Desert Recovery Unit, with potential to contribute to desert tortoise habitat connectivity and build linkages between desert tortoise designated critical habitat, known populations of desert tortoise, and/or other preserve lands;

    b. provide habitat for desert tortoise with capacity to regenerate naturally when disturbances are removed;

    c. be near larger blocks of lands that are either already protected or planned for protection, or which could feasibly be protected long-term by a public resource agency or a non-governmental organization dedicated to habitat preservation;

    d. be connected to lands currently occupied by desert tortoise, ideally with populations that are stable, recovering, or likely to recover;

    e. not have a history of intensive recreational use or other disturbance that might make habitat recovery and restoration infeasible;

    f. not be characterized by high densities of invasive species, either on or immediately adjacent to the parcels under consideration, that might jeopardize habitat recovery and restoration; and

    g. not contain hazardous wastes.

2. Review and Approval of Compensation Lands Prior to Acquisition. A minimum of three months prior to acquisition of the property, the Project owner shall submit a formal acquisition proposal to the CPM, BLM's Authorized Officer, CDFG, and USFWS describing the parcel(s) intended for purchase. This acquisition proposal shall discuss the suitability of the proposed parcel(s) as compensation lands for desert tortoise in relation to the criteria listed above. Approval from the CPM and CDFG, in consultation with BLM and the USFWS, shall be required for acquisition of all parcels comprising the 1,878 acres.

3. Mitigation Security: The Project owner shall provide financial assurances to the CPM and CDFG, with copies of the document(s) to BLM and the USFWS, to guarantee that an adequate level of funding is available to implement the mitigation measures described in this condition. These funds shall be used solely for implementation of the measures associated with the Project. Financial assurance can be provided to the CPM and BLM's Authorized Officer in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security") prior to initiating ground-disturbing Project

activities. Prior to submittal to the CPM, the Security shall be approved by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS, to ensure sufficient funding. As of the publication of the SA/DEIS, this amount is $4,281,840 ($2,578,680 if the Reduced Acreage Alternative were adopted). This Security amount may be revised based on land costs or the estimated costs of enhancement and endowment (see subsection C.2.4.2, Desert Tortoise, for a discussion of the assumptions used in calculating the Security, which are based on an estimate of $2,280 per acre to fund acquisition, enhancement, and long-term management). The final amount due will be determined by the PAR analysis conducted pursuant to this condition.

4. Compensation Lands Acquisition Conditions: The Project owner shall comply with the following conditions relating to acquisition of the compensation lands after the CPM and BLM's Authorized Officer, in consultation with CDFG and USFWS, have approved the proposed compensation lands and received Security as applicable and as described above.

    a. Preliminary Report: The Project owner, or approved third party, shall provide a recent preliminary title report, initial hazardous materials survey report, biological analysis, and other necessary documents for the proposed 1,878 acres. All documents conveying or conserving compensation lands and all conditions of title/easement are subject to a field review and approval by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS, California Department of General Services and, if applicable, the Fish and Game Commission and/or the Wildlife Conservation Board.

    b. Title/Conveyance: The Project owner shall transfer fee title or a conservation easement to the 1,878 acres of compensation lands to CDFG under terms approved by the CPM and CDFG. Alternatively, a non-profit organization qualified to manage compensation lands (pursuant to California Government Code section 65965) and approved by CDFG and the CPM may hold fee title or a conservation easement over the habitat mitigation lands. If the approved non-profit organization holds title, a conservation easement shall be recorded in favor of CDFG in a form approved by CDFG. If the approved non-profit holds a conservation easement, CDFG shall be named a third party beneficiary. If a Security is provided, the Project owner or an approved third party shall complete the proposed compensation lands acquisition within 18 months of the start of Project ground-disturbing activities.

    c. Initial Habitat Improvement Fund. The Project owner shall fund the initial protection and habitat improvement of the 1,878 acres. Alternatively, a non-profit organization may hold the habitat

improvement funds if they are qualified to manage the compensation lands (pursuant to California Government Code section 65965) and if they meet the approval of CDFG and the CPM. If CDFG takes fee title to the compensation lands, the habitat improvement fund must go to CDFG.

d. Conduct a Property Analysis Record. Upon identification of the mitigation lands the project owner shall conduct a Property Analysis Record (PAR) or PAR-like analysis to establish the appropriate endowment to fund the in-perpetuity management of the acquired mitigation lands.

e. Long-term Management Endowment Fund. Prior to ground-disturbing Project activities, the Project owner shall provide to CDFG a non-wasting capital endowment in the amount determined through the Property Analysis Record (PAR) or PAR-like analysis that would be conducted for the 1,878 acres. Alternatively, a non-profit organization may hold the endowment fees if they are qualified to manage the compensation lands (pursuant to California Government Code section 65965) and if they meet the approval of CDFG and the CPM. If CDFG takes fee title to the compensation lands, the endowment must go to CDFG, where it would be held in the special deposit fund established pursuant to California Government Code section 16370. If the special deposit fund is not used to manage the endowment, the California Wildlife Foundation or similarly approved entity identified by CDFG shall manage the endowment for CDFG and with CDFG supervision.

f. Interest, Principal, and Pooling of Funds. The Project owner, CDFG and the CPM shall ensure that an agreement is in place with the endowment holder/manager to ensure the following conditions:

   i. Interest. Interest generated from the initial capital endowment shall be available for reinvestment into the principal and for the long-term operation, management, and protection of the approved compensation lands, including reasonable administrative overhead, biological monitoring, improvements to carrying capacity, law enforcement measures, and any other action approved by CDFG designed to protect or improve the habitat values of the compensation lands.

   ii. Withdrawal of Principal. The endowment principal shall not be drawn upon unless such withdrawal is deemed necessary by the CDFG or the approved third-party endowment manager to ensure the continued viability of the species on the 1,878 acres. If CDFG takes fee title to the compensation lands, monies received by CDFG pursuant to this provision shall be deposited in a special deposit fund established pursuant to Government Code section 16370. If the special deposit fund is not used to

manage the endowment, the California Wildlife Foundation or similarly approved entity identified by CDFG would manage the endowment for CDFG with CDFG supervision.

iii. Pooling Endowment Funds. CDFG, or a CPM and CDFG approved non-profit organization qualified to hold endowments pursuant to California Government Code section 65965, may pool the endowment with other endowments for the operation, management, and protection of the 1,878 acres for local populations of desert tortoise. However, for reporting purposes, the endowment fund must be tracked and reported individually to the CDFG and CPM.

iv. Reimbursement Fund. The Project owner shall provide reimbursement to CDFG or an approved third party for reasonable expenses incurred during title, easement, and documentation review; expenses incurred from other state or state approved federal agency reviews; and overhead related to providing compensation lands.

The Project owner is responsible for all compensation lands acquisition/easement costs, including but not limited to, title and document review costs, as well as expenses incurred from other state agency reviews and overhead related to providing compensation lands to the department or approved third party; escrow fees or costs; environmental contaminants clearance; and other site cleanup measures.

Verification: No later than 30 days prior to beginning Project ground-disturbing activities, the Project owner shall provide written verification of Security in accordance with this condition of certification. The Project owner, or an approved third party, shall complete and provide written verification of the proposed compensation lands acquisition within 18 months of the start of Project ground-disturbing activities.

No less than 90 days prior to acquisition of the property, the Project owner shall submit for review and approval a formal acquisition proposal to BLM's Authorized Officer, the CPM, CDFG, and USFWS describing the parcels intended for purchase. At the same time the project owner shall submit a PAR or PAR-like analysis for the parcels for review and approval by the CPM, BLM's Authorized Officer, CDFG and USFWS.

The Project owner, or an approved third party, shall provide BLM's Authorized Officer, the CPM, CDFG and USFWS with a management plan for the compensation lands and associated funds within 180 days of the land or easement purchase, as determined by the date on the title. BLM's Authorized Officer and the CPM shall review and approve the management plan, in consultation with CDFG and the USFWS.
Within 90 days after completion of Project construction, the Project owner shall provide to the CPM and CDFG an analysis with the final accounting of the amount of habitat disturbed during Project construction.
The Project owner shall provide written verification to BLM's Authorized Officer, the CPM, USFWS and CDFG that the compensation lands or conservation easements have been acquired and recorded in favor of the approved recipient no later than 18 months

from docketing of the Final Energy Commission Decision for the Genesis Solar Energy Project.

RAVEN MANAGEMENT PLAN

BIO-1 The Project owner shall implement a raven monitoring and control plan that is consistent with the most current USFWS-approved raven management guidelines, and which meets the approval of BLM's Authorized Officer and the CMP, in consultation with USFWS and CDFG. The draft Common Raven Monitoring, Management, and Control Plan (Raven Plan) submitted by the Applicant (TTEC 2010r) shall provide the basis for the final plan, subject to review and revisions and approval from BLM's Authorized Officer, the CPM, CDFG and USFWS. The Raven Plan shall include but not be limited to a program to monitor increased raven presence in the Project vicinity and to implement raven control measures as needed based on that monitoring.

Verification: No less than 10 days prior to start of any Project-related ground disturbance activities, the Project owner shall provide BLM's Authorized Officer, the CPM, USFWS, and CDFG with the final version of a Raven Plan. All modifications to the approved Raven Plan shall be made only with approval of BLM's Authorized Officer and CPM in consultation with USFWS and CDFG.

Within 30 days after completion of Project construction, the Project owner shall provide to the CPM for review and approval, a written report identifying which items of the Raven Plan have been completed, a summary of all modifications to mitigation measures made during the Project's construction phase, and which items are still outstanding.

On January 31st of each year following construction the Designated Biologist shall provide a report to the CPM and BLM's Authorized Officer that includes: a summary of the results of raven management and control activities for the year; a discussion of whether raven control and management goals for the year were met; and recommendations for raven management activities for the upcoming year.

WEED MANAGEMENT PLAN

BIO-14 The Project owner shall implement a Weed Management Plan that meets the approval of BLM's Authorized Officer and the CPM. The Weed Management Plan shall prescribe methods to monitor for weeds, prevent weed introduction, and control the spread of weeds during construction and operation of the Project. The draft Weed Management Plan submitted by the Applicant (TTEC 2009g) shall provide the basis for the final plan, subject to review and revisions from BLM's Authorized Officer and the CPM.

Verification: No less than 10 days prior to start of any Project-related ground disturbance activities, the Project owner shall provide BLM's Authorized Officer and the CPM with the final version of a Weed Management Plan that has been reviewed and approved by BLM, and Energy Commission staff, USFWS, and CDFG. Modifications to

the approved Weed Control Plan shall be made only after consultation with the Energy Commission staff, BLM, USFWS, and CDFG.

Within 30 days after completion of Project construction, the Project owner shall provide to BLM's Authorized Officer and the CPM for review and approval, a written report identifying which items of the Weed Management Plan have been completed, a summary of all modifications to mitigation measures made during the Project's construction phase, and which items are still outstanding.

On January 31st of each year following construction the Designated Biologist shall provide a report to the CPM and BLM's Authorized Officer that includes: a summary of the results of noxious weeds surveys and management activities for the year; a discussion of whether weed management goals for the year were met; and recommendations for weed management activities for the upcoming year.

PRE-CONSTRUCTION NEST SURVEYS

BIO-15 Pre-construction nest surveys shall be conducted if construction activities would occur at any time during the period of February 1 through August 31. The Designated Biologist or Biological Monitor conducting the surveys shall be experienced bird surveyors familiar with standard nest-locating techniques and shall perform surveys in accordance with the following guidelines:

1. Surveys shall cover all potential nesting habitat in the Project site or within 500 feet of the boundaries of the site (including linear facilities);

2. At least two pre-construction surveys shall be conducted, separated by a minimum 10-day interval. One of the surveys shall be conducted within the 14-day period preceding initiation of construction activity. Additional follow-up surveys may be required if periods of construction inactivity exceed three weeks, an interval during which birds may establish a nesting territory and initiate egg laying and incubation;

3. If active nests are detected during the survey, a buffer zone (protected area surrounding the nest, the size of which is to be determined by the Designated Biologist in consultation with CDFG) and monitoring plan shall be developed. Nest locations shall be mapped and submitted, along with a report stating the survey results, to the CPM; and

4. The Designated Biologist shall monitor the nest until he or she determines that nestlings have fledged and dispersed; activities that might, in the opinion of the Designated Biologist, disturb nesting activities, shall be prohibited within the buffer zone until such a determination is made.

Verification: At least 10 days prior to the start of any Project-related ground disturbance activities, the Project owner shall provide the CPM a letter-report describing the findings of the pre-construction nest surveys, including the time, date, and duration of the survey; identity and qualifications of the surveyor (s); and a list of species observed. If active nests are detected during the survey, the report shall include a map

or aerial photo identifying the location of the nest and shall depict the boundaries of the no-disturbance buffer zone around the nest(s) that would be avoided during project construction.

AVIAN PROTECTION PLAN

BIO-16 The project owner shall prepare and implement an Avian Protection Plan to monitor death and injury of birds from collisions with facility features such as reflective mirror-like surfaces and from heat, and bright light from concentrating sunlight, and to implement adaptive management measures to minimize such impacts. The Avian Protection Plan shall be approved by BLM's Authorized Officer and the CPM in consultation with CDFG and USFWS, and shall be incorporated into the project's BRMIMP and implemented. The Avian Protection Plan shall include detailed specifications on data and carcass collection protocol and a rationale justifying the proposed schedule of carcass searches. The study shall also include seasonal trials to assess bias from carcass removal by scavengers as well as searcher bias.

Verification: No less than 10 days following docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the project owner shall submit to the CPM, BLM's Authorized Officer, USFWS and CDFG a final Avian Protection Plan. Modifications to the Avian Protection Plan shall be made only after approval from BLM's Authorized Officer and the CPM. For one year following the beginning of power plant operation the Designated Biologist shall submit quarterly reports to BLM's Authorized Officer, CPM, CDFG, and USFWS describing the dates, durations, and results of monitoring. The quarterly reports shall provide a detailed description of any Project-related bird or wildlife deaths or injuries detected during the monitoring study or at any other time. Following the completion of the fourth quarter of monitoring the Designated Biologist shall prepare an Annual Report that summarizes the year's data, analyzes any Project-related bird fatalities or injuries detected, and provides recommendations for future monitoring and any adaptive management actions needed.

No later than January 31st of every year the Annual Report shall be provided to the CPM, BLM's Authorized Officer, CDFG, and USFWS. Quarterly reporting shall continue until BLM's Authorized Officer and the CPM, in consultation with CDFG and USFWS determine whether more years of monitoring are needed, and whether mitigation and adaptive management measures are necessary. After two years of data collection the project owner or contractor shall prepare a report that describes the study design and monitoring results of the Avian Protection Plan to be submitted to a peer-reviewed scientific journal. Proof of submittal shall be provided to BLM's Authorized Officer and the CPM no later than the third year after onset of Project operation.

AMERICAN BADGER AND DESERT KIT FOX IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-17 To avoid direct impacts to American badgers and desert kit fox, pre-construction surveys shall be conducted for these species concurrent with the desert tortoise surveys. Surveys shall be conducted as described below:

Biological Monitors shall perform pre-construction surveys for badger and kit fox dens in the Project area, including areas within 250 feet of all Project facilities, utility corridors, and access roads. If dens are detected each den shall be classified as inactive, potentially active, or definitely active.

Inactive dens that would be directly impacted by construction activities shall be excavated by hand and backfilled to prevent reuse by badgers or kit fox. Potentially and definitely active dens that would be directly impacted by construction activities shall be monitored by the Biological Monitor for three consecutive nights using a tracking medium (such as diatomaceous earth or fire clay) and/or infrared camera stations at the entrance. If no tracks are observed in the tracking medium or no photos of the target species are captured after three nights, the den shall be excavated and backfilled by hand. If tracks are observed, the den shall be progressively blocked with natural materials (rocks, dirt, sticks, and vegetation piled in front of the entrance) for the next three to five nights to discourage the badger or kit fox from continued use. After verification that the den is unoccupied it shall then be excavated and backfilled by hand to ensure that no badgers or kit fox are trapped in the den. BLM approval may be required prior to release of badgers on public lands.

Verification: The Project owner shall submit a report to the CPM and CDFG within 30 days of completion of badger and kit fox surveys. The report shall describe survey methods, results, impact avoidance and minimization measures implemented, and the results of those measures.

BURROWING OWL IMPACT AVOIDANCE, MINIMIZATION, AND COMPENSATION MEASURES

BIO-18 The Project owner shall implement the following measures to avoid, minimize and offset impacts to burrowing owls:

1. Pre-Construction Surveys. The Designated Biologist or Biological Monitor shall conduct pre-construction surveys for burrowing owls in accordance with CDFG guidelines (California Burrowing Owl Consortium 1993). The survey area shall include the Project Disturbance Area and surrounding 500 foot survey buffer.

2. Implement Avoidance Measures. If an active burrowing owl burrow is detected within 500 feet from the Project Disturbance Area the following avoidance and minimization measures shall be implemented:

    a. Establish Non-Disturbance Buffer. Fencing shall be installed at a 250-foot radius from the occupied burrow to create a non-disturbance buffer around the burrow. The non-disturbance buffer and fence line may be reduced to 160 feet if all Project-related activities that might disturb burrowing owls would be conducted during the non-breeding season (September 1st through January 31st). Signs shall be posted in English and Spanish at the fence line

indicating no entry or disturbance is permitted within the fenced buffer.

b. Monitoring: If construction activities would occur within 500 feet of the occupied burrow during the nesting season (February 1 – August 31st) the Designated Biologist or Biological Monitor shall monitor to determine if these activities have potential to adversely affect nesting efforts, and shall implement measures to minimize or avoid such disturbance.

3. Implement Burrowing Owl Mitigation Plan. If pre-construction surveys indicate the presence of burrowing owls within the Project Disturbance Area, the project owner shall prepare and implement a Burrowing Owl Mitigation Plan, in addition to the avoidance measures described above. The final Burrowing Owl Mitigation Plan shall be approved by BLM's Authorized Officer and the CPM, in consultation with USFWS and CDFG, and shall:

   a. Identify and describe suitable relocation sites within 1 mile of the Project Disturbance Area, and describe measures to ensure that burrow installation or improvements would not affect sensitive species habitat or existing burrowing owl colonies in the relocation area;

   b. Provide guidelines for creation or enhancement of at least two natural or artificial burrows per relocated owl, including a discussion of timing of burrow improvements, specific location of burrow installation, and burrow design. Design of the artificial burrows shall be consistent with CDFG guidelines (CDFG 1995) and shall be approved by the CPM in consultation with CDFG;

   c. Provide detailed methods and guidance for passive relocation of burrowing owls occurring within the Project Disturbance Area; and

   d. Describe monitoring and management of the relocated burrowing owl site, and provide a reporting plan.

4. Acquire Compensatory Mitigation Lands for Burrowing Owls. The following measures for compensatory mitigation shall apply only if burrowing owls are detected within the Project Disturbance Area which need to be relocated. The Project owner shall acquire, in fee or in easement, 39 acres of land for each pair of nesting owls that is displaced by construction of the Project. The project owner shall provide funding for the enhancement and long-term management of these compensation lands. The acquisition and management of the compensation lands may be delegated by written agreement to CDFG or to a third party, such as a non-governmental organization dedicated to habitat conservation, subject to approval by the CPM, in consultation with CDFG and USFWS prior to land acquisition or management activities. Additional funds shall be based on the adjusted

market value of compensation lands at the time of construction to acquire and manage habitat.

a. Criteria for Burrowing Owl Mitigation Lands. The terms and conditions of this acquisition or easement shall be as described in **BIO-12** [Desert Tortoise Compensatory Mitigation], with the additional criteria to include: 1) the 39 acres of mitigation land must provide suitable habitat for burrowing owls, and 2) the acquisition lands must either currently support burrowing owls or be no farther than 5 miles from an active burrowing owl nesting territory. The 39 acres of burrowing owl mitigation lands may be included with the 1,878 acres of desert tortoise mitigation lands ONLY if these two burrowing owl criteria are met. If the 39 acres of burrowing owl mitigation land is separate from the 1,878 acres required for desert tortoise compensation lands, the Project owner shall fulfill the requirements described below in this condition.

b. Security. The Security measures described below is based on the assumption that one pair of owls would be impacted by construction of the Project, and would therefore require 39 acres of compensatory mitigation land. If the 3939 acres of burrowing owl mitigation land is separate from the acreage required for desert tortoise compensation lands the Project owner or an approved third party shall complete acquisition of the proposed compensation lands prior to initiating ground-disturbing Project activities. Alternatively, financial assurance can be provided by the Project owner to the CPM and CDFG with copies of the document(s) to BLM and the USFWS, to guarantee that an adequate level of funding is available to implement the mitigation measure described in this condition. These funds shall be used solely for implementation of the measures associated with the Project. Financial assurance can be provided to the CPM and the BLM's Authorized Officer in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security") prior to initiating ground-disturbing Project activities. Prior to submittal to the CPM, the Security shall be approved by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS to ensure funding. As of the publication of the SA/DEIS, this amount is $44,460 but this amount may change based on land costs or the estimated costs of enhancement and endowment (see subsection C.2.4.2, Desert Tortoise, for a discussion of the assumptions used in calculating the Security, which are based on an estimate of $2,280 per acre to fund acquisition, enhancement, and long-term management). The final amount due will be determined by the PAR analysis conducted pursuant to **BIO-12**.

Verification: If pre-construction surveys detect burrowing owls within 500 feet of proposed construction activities, the Designated Biologist shall provide to the CPM and BLM's Authorized Officer documentation indicating that non-disturbance buffer fencing has been installed at least 10 days prior to the start of any Project-related site disturbance activities. The Project owner shall report monthly to BLM's Authorized

Office, the CPM, CDFG and USFWS for the duration of construction on the implementation of burrowing owl avoidance and minimization measures. Within 30 days after completion of construction the Project owner shall provide to the CDFG and CPM a written construction termination report identifying how mitigation measures described in the plan have been completed.

If pre-construction surveys detect burrowing owls within the Project Disturbance Area and relocation of the owls is required, the Project owner shall do the following:

a. Within 30 days of completion of the burrowing owl pre-construction surveys, submit to BLM's Authorized Officer, the CPM, CDFG and USFWS a Burrowing Owl Mitigation Plan.

b. No less than 90 days prior to acquisition of the burrowing owl compensation lands, the Project owner, or an approved third party, shall submit a formal acquisition proposal to the CPM, BLM's Authorized Officer, CDFG, and USFWS describing the 39-acre parcel intended for purchase. At the same time the project owner shall submit a PAR or PAR-like analysis for the parcels for review and approval by the CPM, BLM's Authorized Officer, CDFG and USFWS.

c. Within 90 days of the land or easement purchase, as determined by the date on the title, the Project owner shall provide the CPM and BLM's Authorized Officer with a management plan for review and approval, in consultation with CDFG and USFWS, for the compensation lands and associated funds.

d. No later than 30 days prior to beginning Project ground-disturbing activities, the project owner shall provide written verification of Security in accordance with this condition of certification.

e. No later than 18 months from a Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the Project owner shall provide written verification to the BLM's Authorized Officer, the CPM and CDFG that the 39 acres of compensation lands or conservation easements have been acquired and recorded in favor of the approved recipient.

f. On January 31st of each year following construction for a period of five years, the Designated Biologist shall provide a report to the CPM, BLM's Authorized Officer, USFWS and CDFG that describes the results of monitoring and management of the burrowing owl relocation area.

SPECIAL-STATUS PLANT IMPACT AVOIDANCE AND MINIMIZATION PLAN

BIO-19 The Project owner shall prepare a Special-Status Plant Mitigation Plan ("Plan") that meets the approval of BLM's Authorized Officer and the CPM. The objective of the Plan is to:

1. Protect preserved plants near the Project Disturbance Area from direct and indirect effects of construction and operation,

2. Ensure that any special-status plants that may have been missed during the 2009 surveys are detected, and

3. Provide detailed specifications and performance standards to compensate for unavoidable impacts to special-status plants.

1. Preconstruction Surveys: The project owner shall retain a qualified botanist to conduct pre-construction surveys in 2010 within the Project site and a 100-foot buffer around the solar power plant site and linears. Spring 2010 surveys of the previously unsurveyed portions of the Project shall include the following species (in addition to those contained on the target list for the 2009 surveys [GSEP 2009a]): winged Cryptantha, angel trumpets, white-margined penstemon, Palmer's jackass clover, small-flowered Androstephium, argus blazing star, bitter Hymenoxys, spiny abrojo, pink velvet mallow, and desert portulaca.

   Additional summer-fall surveys shall be conducted of the entire Project Disturbance Area, and shall target the following late-season special-status plant species: glandular ditaxis, Abram's spurge, lobed ground cherry, angel trumpets, flat-seeded spurge, pink velvet mallow, and desert portulaca (CEC 2009d). The surveys should be timed to follow a 'significant' rain event of at least 12-18 mm (Andre pers comm). If results of surveys are inconclusive due to inadequate rainfall, then compensatory mitigation shall be required on the basis of habitat loss.

   A botanical survey report and map detailing the results of the spring and summer/fall 2010 surveys shall be submitted to the CPM and BLM's Authorized Officer no later than December 31, 2010. The map shall clearly depict the occurrences and the Project features and indicate which occurrences shall be preserved, and include a description of each occurrence (population size, associated species, any distinctive characteristics, reproduction, etc).

2. Avoidance and Minimization Measures: The Plan shall include avoidance and minimization measures for Harwood's milk-vetch, desert unicorn plant, ribbed cryptantha, and any other special-status plant species detected during the 2010 surveys. The Project Owner shall implement avoidance and minimization measures contained in the Data Request Responses – Set 1A (Pages BR-55-56) for all special-status plant occurrences to be preserved. These include:

   - Worker training;
   - Designating special-status plants to be avoided as Environmentally Sensitive Areas;
   - Designate spoil areas and storage areas at least 100 feet from any preserved occurrence;
   - Minimize ground-disturbing activities;
   - Use existing roads wherever possible;
   - Enforce vehicle speed limits;
   - Construction monitoring and reporting;
   - Weed management and control of chemical drift;
   - Dust control;
   - Spill containment kits;

- Locating wash areas a minimum of 100 feet away from preserved occurrences.

Additionally, the Project Owner shall revise the layout of the discharge points of the engineered channel to ensure that any special-status plants occurring downstream are adequately protected.

3. Preserve and Manage Compensatory Habitat and Criteria for Abram's spurge, glandular ditaxis, flat-seeded spurge, and lobed ground cherry:

   To compensate for potential impacts to Abram's spurge, glandular ditaxis, flat-seeded spurge, and lobed ground cherry, the project owner shall acquire compensatory mitigation land as follows:

   - Abram's spurge: playa (38 acres); dunes (28 acres); desert washes (91 acres).
   - Glandular ditaxis: desert washes (91 acres).
   - Flat-seeded spurge: playa (38 acres); dunes (28 acres).
   - Lobed ground cherry: playa (38 acres).

   The criteria need to be met on a species by species bases; the acreages totals for these special-status species are 114 acres of playa and sand drift over playa habitat, 56 acres of dune habitat, and 182 acres of desert wash habitat (including at least 16 acres of microphyll woodland – see BIO-22 in this subsections for more details). Habitat acquisition for these species may also be integrated with habitat compensation for other species if the criteria listed below are met.
   The compensatory lands acquired for each of these species must meet at least one of the following criteria:

   a. Contain occupied habitat for an occurrence anywhere in the species' range in California;

   b. Contain unoccupied habitat that is in the immediate watershed of an extant occurrence in California and considered to have a high potential for occurrence, or;

   c. Provide watershed protection to extant and protected occurrences on federal land regardless of the habitat the acquired lands support.

4. The compensatory lands shall meet the following additional criteria 1) provide habitat for the special-status plant species that is of similar or better quality than that impacted; 2) contain OR abut land that contains occurrences that are stable, recovering, or likely to recover; and 3) be adequately sized and buffered to support self-sustaining special-status plant populations. These mitigation lands may be included with the desert tortoise mitigation lands, dunes/Mojave fringe-toed lizard mitigation lands, and desert wash mitigation lands ONLY if the above criteria are met.

   The compensatory mitigation would not be required if 2010 botanical surveys definitively rule out potential presence of these species (i.e., surveys were conducted at the appropriate time of year and under appropriate environmental

conditions). Habitat acquisition for special status plants may also be integrated with compensatory mitigation described in Conditions of Certification BIO-12, BIO-20, and BIO-22 if the criteria listed above are met.

5. Security. The Project owner shall provide financial assurances to the CPM and BLM to guarantee that an adequate level of funding is available to implement the mitigation measures described in this condition. These funds shall be used solely for implementation of the measures associated with the Project. Financial assurance can be provided to the CPM and BLM's Authorized Officer in the form of an irrevocable letter of credit, a pledged savings account or another form of security ("Security") prior to initiating ground-disturbing Project activities. Prior to submittal to the CPM, the Security shall be approved by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS, to ensure sufficient funding. As of the publication of the SA/DEIS, this amount is $802,560. This amount may change based on land costs or the estimated costs of enhancement and endowment (see subsection C.2.4.2, Desert Tortoise, for a discussion of the assumptions used in calculating the Security, which are based on an estimate of $2,280 per acre to fund acquisition, enhancement and long-term management).

Verification: Within 10 days of publication of the Energy Commission License Decision or the Record of Decision/ROW Issuance, whichever comes first, the Project owner shall submit to BLM's Authorized Officer, the CPM and CDFG, an agency-approved final Special-status Plant Impact Avoidance and Minimization Plan.

A botanical survey report and map detailing the results of the spring and summer/fall 2010 surveys shall be submitted to the CPM and BLM's Authorized Officer no later than December 31, 2010. The map shall clearly depict the occurrences and the Project features and indicate which occurrences shall be preserved, and include a description of each occurrence (population size, associated species, any distinctive characteristics, reproduction, etc).

A qualified botanist shall delineate the boundaries of these special-status plant occurrences at least 30 days prior to the initiation of ground disturbing activities.

Within 30 days after completion of Project construction, the Project owner shall provide to BLM's Authorized Officer and the CPM for review and approval, a written report identifying which items of the Special-Status Plant Species Avoidance and Mitigation Plan have been completed, a summary of all modifications to mitigation measures made during the Project's construction phase, and which items are still outstanding.

No later than 30 days prior to beginning Project ground-disturbing activities, the Project owner shall provide written verification of Security in accordance with this condition of certification for compensatory is provided, the Project owner, or an approved third party, shall complete and provide written verification of the proposed compensation lands acquisition within 18 months of the start of Project ground-disturbing activities.

No less than 90 days prior to acquisition of the property, the Project owner shall submit a formal acquisition proposal to BLM's Authorized Officer, the CPM and CDFG describing the parcels intended for purchase. The Project owner, or an approved third party, shall provide BLM's Authorized Officer, the CPM and CDFG with a management

plan for the compensation lands and associated funds within 180 days of the land or easement purchase, as determined by the date on the title. BLM's Authorized Officer and the CPM shall review and approve the management plan, in consultation with CDFG.

On January 31st of each year following construction for a period of five years, the Designated Biologist shall provide a report to the CPM, BLM's Authorized Officer and CDFG that describes the results of monitoring and management of the habitat compensation lands for Abram's spurge, glandular ditaxis, flat-seeded spurge, and lobed ground cherry.

SAND DUNES/MOJAVE FRINGE-TOED LIZARD MITIGATION

BIO-20 The project owner shall mitigate for direct and indirect impacts to stabilized and partially stabilized sand dunes and other Mojave fringe-toed lizard habitat by acquisition of 424 acres of Mojave fringe-toed lizard habitat, at least 84 acres of which shall be stabilized or partially stabilized desert dune. The project owner shall provide funding for the acquisition, initial habitat improvements and long-term management endowment of the compensation lands.

1. Criteria for Compensation Lands: The compensation lands selected for acquisition shall:

    a. Provide suitable habitat for Mojave fringe-toed lizards, and may include stabilized and partially stabilized desert dunes or sand drifts over playas or Sonoran creosote bush scrub;

    b. Be within the Chuckwalla Valley with potential to contribute to Mojave fringe-toed lizard habitat connectivity and build linkages between known populations of Mojave fringe-toed lizards and preserve lands with suitable habitat;

    c. Be connected to lands currently occupied by Mojave fringe-toed lizard;

    d. Be near larger blocks of lands that are either already protected or planned for protection, or which could feasibly be protected long-term by a public resource agency or a non-governmental organization dedicated to habitat preservation;

    e. Not have a history of intensive recreational use or other disturbance that might make habitat recovery and restoration infeasible;

    f. Not be characterized by high densities of invasive species, either on or immediately adjacent to the parcels under consideration, that might jeopardize habitat recovery and restoration;

    g. Not contain hazardous wastes;

h. Not be subject to property constraints (i.e. mineral leases, cultural resources); and

i. Be on land for which long-term management is feasible.

2. Security for Implementation of Mitigation: The project owner shall provide financial assurances to the CPM and BLM's Authorized Officer to guarantee that an adequate level of funding is available to implement the acquisitions and enhancement of Mojave fringe-toed lizard habitat as described in this condition. These funds shall be used solely for implementation of the measures associated with the Project. Financial assurance can be provided to the CPM and BLM's Authorized Officer in the form of an irrevocable letter of credit, a pledged savings account or Security prior to initiating ground-disturbing project activities. PThe Security shall be approved by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS, to ensure sufficient funding. As of the publication of the SA/DEIS, this amount is $966,720 ($310,080 If the Reduced Acreage Alternative were adopted). This amount may change based on land costs or the estimated costs of enhancement and endowment (see subsection C.2.4.2, Desert Tortoise, for a discussion of the assumptions used in calculating the Security, which are based on an estimate of $2,280 per acre to fund acquisition, enhancement and long-term management).
3. Preparation of Management Plan: The project owner shall submit to the CPM, BLM's Authorized Officer, CDFG and USFWS a draft Management Plan that reflects site-specific enhancement measures for the Mojave fringe-toed lizard habitat on the acquired compensation lands. The objective of the Management Plan shall be to enhance the value of the compensation lands for Mojave fringe-toed lizards, and may include enhancement actions such as weed control, fencing to exclude livestock, erosion control, or protection of sand sources or sand transport corridors.

Verification: No later than 30 days prior to beginning Project ground-disturbing activities, the Project owner shall provide written verification of Security in accordance with this condition of certification. The Project owner, or an approved third party, shall complete and provide written verification of the proposed compensation lands acquisition within 18 months of the start of Project ground-disturbing activities.

No less than 90 days prior to acquisition of the property, the Project owner shall submit a formal acquisition proposal to BLM's Authorized Officer, the CPM, CDFG, and USFWS describing the parcels intended for purchase. At the same time the project owner shall submit a PAR or PAR-like analysis for the parcels for review and approval by the CPM, BLM's Authorized Officer, CDFG and USFWS.

The Project owner, or an approved third party, shall provide BLM's Authorized Officer, the CPM, CDFG and USFWS with a management plan for the compensation lands and associated funds within 180 days of the land or easement purchase, as determined by the date on the title. BLM's Authorized Officer and the CPM shall review and approve the management plan, in consultation with CDFG and the USFWS.

Within 90 days after completion of Project construction, the Project owner shall provide to the CPM and CDFG an analysis with the final accounting of the amount of Mojave fringe-toed lizard habitat disturbed during Project construction.
The Project owner shall provide written verification to BLM's Authorized Officer, the CPM, USFWS and CDFG that the compensation lands or conservation easements have been acquired and recorded in favor of the approved recipient no later than 18 months from docketing of the Final Energy Commission Decision for the Genesis Solar Energy Project.

EVAPORATION POND NETTING AND MONITORING

BIO-21 The Project owner shall cover the evaporation ponds prior to any discharge with 1.5-inch mesh netting designed to exclude birds and other wildlife from drinking or landing on the water of the ponds. Netting with mesh sizes other than 1.5-inches may be installed if approved by the CPM in consultation with CDFG and USFWS. The netted ponds shall be monitored regularly to verify that the netting remains intact, is fulfilling its function in excluding birds and other wildlife from the ponds, and does not pose an entanglement threat to birds and other wildlife. The ponds shall include a visual deterrent in addition to the netting, and the pond shall be designed such that the netting shall never contact the water. Monitoring of the evaporation ponds shall include the following:

1. Monthly Monitoring. The Designated Biologist or Biological Monitor shall regularly survey the ponds at least once per month starting with the first month of operation of the evaporation ponds. The purpose of the surveys shall be to determine if the netted ponds are effective in excluding birds, if the nets pose an entrapment hazard to birds and wildlife, and to assess the structural integrity of the nets. Surveys shall be of sufficient duration and intensity to provide an accurate assessment of bird and wildlife use of the ponds during all seasons. Surveyors shall be experienced with bird identification and survey techniques. Operations staff at the Project site shall also report finding any dead birds or other wildlife at the evaporation ponds to the Designated Biologist within one day of the detection of the carcass. The Designated Biologists shall report any bird or other wildlife deaths or entanglements within two days of the discovery to the CPM, CDFG, and USFWS.

2. Dead or Entangled Birds. If dead or entangled birds are detected, the Designated Biologist shall take immediate action to correct the source of mortality or entanglement. The Designated Biologist shall make immediate efforts to contact and consult the CPM, CDFG, and USFWS by phone and electronic communications prior to taking remedial action upon detection of the problem, but the inability to reach these parties shall not delay taking action that would, in the judgment of the Designated Biologist, prevent further mortality of birds or other wildlife at the evaporation ponds.

3. Quarterly Monitoring. If after 12 consecutive monthly site visits no bird or wildlife deaths or entanglements are detected by or reported to the Designated Biologist, monitoring can be reduced to quarterly visits.

4. Biannual Monitoring. If after 12 consecutive quarterly site visits no bird or wildlife deaths or entanglements are detected by or reported to the Designated Biologist, and with approval from the CPM, USFWS and CDFG, future surveys may be reduced to two surveys per years, during the spring nesting season and during fall migration. If approved by the CPM, USFWS and CDFG, monitoring outside the nesting season may be conducted by the Environmental Compliance Manager.

5. Modification of Monitoring Program. Without respect to the above requirements the project owner, CDFG or USFWS may submit to the CPM a request for modifications to the evaporation pond monitoring program based on information acquired during monitoring, and may also suggest adaptive management measures to remedy any problems that are detected during monitoring or modifications if bird impacts are not observed. Modifications to the evaporation pond monitoring described above and implementation of adaptive management measures shall be made only after approval from the CPM, in consultation with USFWS and CDFG.

Verification: No less than 30 days prior to operation of the evaporation ponds the project owner shall provide to the CPM as-built drawings and photographs of the ponds indicating that the bird exclusion netting has been installed. For the first year of operation the Designated Biologist shall submit quarterly reports to the CPM, CDFG, and USFWS describing the dates, durations and results of site visits conducted at the evaporation ponds. Thereafter the Designated Biologist shall submit annual monitoring reports with this information. The quarterly and annual reports shall fully describe any bird or wildlife death or entanglements detected during the site visits or at any other time, and shall describe actions taken to remedy these problems. The annual report shall be submitted to the CPM, CDFG, and USFWS no later than January 31st of every year for the life of the project.

MITIGATION FOR IMPACTS TO STATE WATERS

BIO-22 The Project owner shall implement the following measures to avoid, minimize and mitigate for direct and indirect impacts to waters of the state and to satisfy requirements of California Fish and Game Code sections 1600 and 1607.

1. Acquire Off-Site State Waters: The project owner shall acquire, in fee or in easement, a parcel or parcels of land that includes at least 132 acres of state jurisdictional waters. The parcel or parcels comprising the 132 acres of ephemeral washes shall include at least 48 acres of microphyll woodland. If the Reduced Acreage Alternative were constructed the mitigation requirements for impacts to state waters would be a minimum of 109 acres that included at least 48 acres of microphyll woodland. The terms and conditions of this acquisition or easement shall be as described in Condition of Certification **BIO-12**.

Mitigation for impacts to state waters shall occur within the Chuckwalla-Palen or surrounding watersheds, as close to the Project site as possible.

2. Security for Implementation of Mitigation: The project owner shall provide financial assurances to the CPM and CDFG to guarantee that an adequate level of funding is available to implement the acquisitions and enhancement of state waters as described in this condition. These funds shall be used solely for implementation of the measures associated with the project. Financial assurance can be provided to the CPM and CDFG in the form of an irrevocable letter of credit, a pledged savings account or Security prior to initiating ground-disturbing project activities. Prior to submittal to the CPM, the Security shall be approved by the CPM and BLM's Authorized Officer, in consultation with CDFG and the USFWS, to ensure sufficient funding. As of the publication of the SA/DEIS, this amount is $300,960 ($248,520 if the Reduced Acreage Alternative were adopted). These amounts may change based on changes in land costs or the estimated costs of enhancement and endowment (see subsection C.2.4.2, Desert Tortoise, for a discussion of the assumptions used in calculating the Security, which are based on an estimate of $2,280 per acre to fund acquisition, enhancement and long-term management). The final amount due shall be determined by the PAR analysis conducted pursuant to **BIO-12**.

3. Preparation of Management Plan: The project owner shall submit to the CPM and CDFG a draft Management Plan that reflects site-specific enhancement measures for the drainages on the acquired compensation lands. The objective of the Management Plan shall be to enhance the wildlife value of the drainages, and may include enhancement actions such as weed control, fencing to exclude livestock, or erosion control.

4. Code of Regulations: The Project owner shall provide a copy of this condition (Condition of Certification **BIO-22)** from the Energy Commission Final Decision to all contractors, subcontractors, and other on-site personnel. Copies shall be readily available at work sites at all times during periods of active work and must be presented to any CDFG personnel upon demand. The CPM reserves the right to issue a stop work order or allow CDFG to issue a stop work order after giving notice to the Project owner, the CPM, if the CPM in consultation with CDFG, determines that the Project owner has breached any of the terms or conditions or for other reasons, including but not limited to the following:

    a. The information provided by the Applicant regarding impacts to waters of the state is incomplete or inaccurate;
    b. New information becomes available that was not known to staff in preparing the terms and conditions; or

c. The Project or Project activities as described in the Staff Assessment have changed.

5. Best Management Practices: The Project owner shall also comply with the following conditions to protect drainages near the Project Disturbance Area:

   a. The Project owner shall minimize road building, construction activities and vegetation clearing within ephemeral drainages to the extent feasible.

   b. The Project owner shall not allow water containing mud, silt, or other pollutants from grading, aggregate washing, or other activities to enter ephemeral drainages or be placed in locations that may be subjected to high storm flows.

   c. The Project owner shall comply with all litter and pollution laws. All contractors, subcontractors, and employees shall also obey these laws, and it shall be the responsibility of the Project owner to ensure compliance.

   d. Spoil sites shall be located at least 30 feet from the boundaries and drainages or in locations that may be subjected to high storm flows, where spoils might be washed back into drainages.

   e. Raw cement/concrete or washings thereof, asphalt, paint or other coating material, oil or other petroleum products, or any other substances that could be hazardous to vegetation or wildlife resources, resulting from Project-related activities, shall be prevented from contaminating the soil and/or entering waters of the state. These materials, placed within or where they may enter a drainage, shall be removed immediately.

   f. No broken concrete, debris, soil, silt, sand, bark, slash, sawdust, rubbish, cement or concrete or washings thereof, oil or petroleum products or other organic or earthen material from any construction or associated activity of whatever nature shall be allowed to enter into, or placed where it may be washed by rainfall or runoff into waters of the state.

   g. When operations are completed, any excess materials or debris shall be removed from the work area.

   h. No equipment maintenance shall occur within 150 feet of any ephemeral drainage where petroleum products or other pollutants from the equipment may enter these areas under any flow.

Verification: No less than 30 days prior to the start of construction-related ground disturbance activities potentially affecting waters of the state, the Project owner shall provide written verification (i.e., through incorporation into the BRMIMP) to the CPM that the above best management practices shall be implemented. The project owner shall

also provide a discussion of work in waters of the state in Compliance Reports for the duration of the Project.

No less than 30 days prior to beginning Project ground-disturbing activities, the Project owner shall provide written verification of Security in accordance with this condition of certification. The Project owner, or an approved third party, shall complete and provide written verification of the proposed compensation lands acquisition within 18 months of the start of Project ground-disturbing activities.

The Project owner, or an approved third party, shall provide BLM's Authorized Officer, the CPM, CDFG and USFWS with a management plan for the compensation lands and associated funds within 180 days of the land or easement purchase, as determined by the date on the title. The CPM and BLM's Authorized Officer shall review and approve the management plan, in consultation with CDFG.

Within 90 days after completion of Project construction, the Project owner shall provide to the CPM and CDFG an analysis with the final accounting of the amount of jurisdictional state waters disturbed during Project construction.

The Project owner shall provide written verification to BLM's Authorized Officer, the CPM, USFWS and CDFG that the compensation lands or conservation easements have been acquired and recorded in favor of the approved recipient no later than 18 months from docketing of the Final Energy Commission Decision for the Genesis Solar Energy Project).

The Project owner shall notify the CPM and CDFG, in writing, at least five days prior to initiation of Project activities in jurisdictional state waters and at least five days prior to completion of Project activities in jurisdictional areas. The Project owner shall notify the CPM and CDFG of any change of conditions to the Project, impacts to state waters, or the mitigation efforts. The notifying report shall be provided to the CPM and CDFG no later than seven days after the change of conditions is identified. As used here, change of condition refers to the process, procedures, and methods of operation of a Project; the biological and physical characteristics of a Project area; or the laws or regulations pertinent to the Project as defined below. A copy of the notifying change of conditions report shall be included in the annual reports or until it is deemed unnecessary by the CPM and CDFG.

Biological Conditions: a change in biological conditions includes, but is not limited to, the following: 1) the presence of biological resources within or adjacent to the Project area, whether native or non-native, not previously known to occur in the area; or 2) the presence of biological resources within or adjacent to the Project area, whether native or non-native, the status of which has changed to endangered, rare, or threatened, as defined in section 15380 of Title 14 of the California Code of Regulations.

Physical Conditions: a change in physical conditions includes, but is not limited to, the following: 1) a change in the morphology of a river, stream, or lake, such as the lowering of a bed or scouring of a bank, or substantial changes in stream form and configuration caused by storm events; 2) the movement of a river or stream channel

to a different location; 3) a reduction of or other change in vegetation on the bed, channel, or bank of a drainage, or 4) changes to the hydrologic regime such as fluctuations in the timing or volume of water flows in a river or stream.

Legal Conditions: a change in legal conditions includes, but is not limited to, a change in Regulations, Statutory Law, a Judicial or Court decision, or the listing of a species, the status of which has changed to endangered, rare, or threatened, as defined in section 15380 of Title 14 of the California Code of Regulations.

DECOMMISSIONING AND CLOSURE PLAN

BIO-23 Upon Project closure the Project owner shall implement a final Decommissioning and Closure Plan to remove the engineered diversion channels from the Project site. The goal of the plan shall be to restore the site's topography and hydrology to a relatively natural condition and to establish native plant communities within the Project Disturbance Area. The Decommissioning and Closure Plan shall include a cost estimate for implementing the proposed decommissioning and reclamation activities, and shall be consistent with the guidelines in BLM's 43 CFR 3809.550 et seq., subject to review and revisions from BLM's Authorized Officer and the CPM in consultation with USFWS and CDFG.

Verification: No less than 30 days from docketing of the Energy Commission Final Decision for the Genesis Solar Energy Project or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the Project owner shall provide to BLM's Authorized Officer and the CPM an agency-approved final Decommissioning and Closure Plan. Modifications to the approved Decommissioning and Closure Plan shall be made only after approval from BLM's Authorized Officer and the CPM, in consultation with USFWS, and CDFG.

No less than 10 days prior to initiating Project-related ground disturbance activities the Project owner shall provide financial assurances to BLM's Authorized Officer and the CPM to guarantee that an adequate level of funding would be available to implement measures described in the Decommissioning and Closure Plan.

REVEGETATION OF TEMPORARILY DISTURBED AREAS

BIO-24 The Project owner shall prepare and implement a Revegetation Plan to restore all areas subject to temporary disturbance. The final Revegetation Plan shall be based on the draft Revegetation Plan submitted by the Applicant (TTEC 2010i) and shall include all revisions deemed necessary by BLM, USFWS, CDFG and the Energy Commission staff. The objectives of the Revegetation Plan shall be to stabilize disturbed soils, minimize erosion and sedimentation impacts to soil and water resources, prevent colonization by noxious weeds and other non-native plants, salvage native plantings and seed from Project Disturbance Areas, and to achieve restoration of disturbed areas to functioning, established early-successional native plant communities. Target performance standards at the end of the monitoring period shall be as follows:

a. total absolute cover of all plants shall equal at least 30 percent;

b. survivorship of salvaged and transplanted cacti and other native plantings shall equal 30% percent

c. at least 90 percent (relative cover) of the species observed within the temporarily disturbed areas shall be locally native species that naturally occur in the adjacent desert scrub habitats; and

d. relative cover of perennial plant species shall equal at least 60 percent of the total vegetative cover.

Verification: No less than 30 days following the docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the project owner shall submit to the CPM and BLM's Authorized Officer a final agency-approved Revegetation Plan that has been reviewed and approved by BLM's Authorized Officer and the CPM. All modifications to the Revegetation Plan shall be made only after approval from BLM's Authorized Officer and the CPM.

Within 30 days after completion of project construction, the project owner shall provide to the CPM for review and approval a report identifying which items of the Revegetation Plan have been completed, a summary of all modifications to revegetation measures made during the project's construction phase, and which items are still outstanding.

On January 31st of each year following construction until the completion of the revegetation monitoring specified in the Revegetation Plan, the Designated Biologist shall provide a report to the CPM and BLM's Authorized Officer that includes: a summary of revegetation activities for the year, a discussion of whether revegetation performance standards for the year were met; and recommendations for revegetation remedial action, if warranted, planned for the upcoming year.

GROUNDWATER DEPENDENT VEGETATION MONITORING

BIO-25 The Applicant shall prepare and implement a Draft Groundwater-Dependent Vegetation Monitoring Plan (Vegetation Monitoring Plan). The objectives of the Vegetation Monitoring Plan shall be to monitor the Project effects of groundwater pumping on groundwater-dependent vegetation (phreatophytes) and, in conjunction with **BIO-26**, to ensure that the Project has a less than significant effect on groundwater-dependent ecosystems. The Vegetation Monitoring Plan shall be consistent with guidance for designing vegetation monitoring plans and conducting statistical analysis in *Measuring and Monitoring Plant Populations* (Elzinga et al. 1998). Monitoring shall focus on areas containing obligate or facultative phreatophytes (mesquite, ironwood, bush seep-weed, palo verde, cat's claw, smoke tree, and tamarisk) in areas that clearly are not influenced by surface water. Monitoring sites shall include:

1. Reference Monitoring Sites: sites outside of the zone of Project influence that can be compared to sites influenced by Project pumping and used to distinguish Project effects from the effects of climate change or normal drought cycles.

2. Project Monitoring Sites: sites within the predicted worst-case scenario drawdown cone around the Project pumping well (Figure 3 of the Groundwater Resources Cumulative Impacts Analysis [Worley-Parsons 2009]), an area within a radius of approximately 10 miles from the Project pumping well. Ford Dry Lake is included within this zone.

3. Distant Monitoring Sites: sites located around Palen Dry Lake where near-surface groundwater has been detected and where plant communities dominated by phreatophytes occur.

Baseline data shall be collected at all sites prior to the start of pumping, and annual monitoring for the life of the Project shall be required at Project, Distant, and Reference Monitoring sites. A statistician shall be retained to use the first year of baseline data to conduct a "prior power analysis" and evaluate the adequacy of the sampling design.

The Vegetation Monitoring Plan shall:

1. Be prepared by a qualified plant ecologist with a demonstrated understanding of desert plant ecology and physiology. The plant ecologist overseeing the monitoring and preparing the annual reports shall be approved by the CPM and BLM's Authorized Officer.

2. Identify Project Monitoring Sites within the zone of potential Project effect depicted in Figure 3 of the Groundwater Resources Cumulative Impacts Analysis (Worley-Parsons 2009). Monitoring shall focus on areas containing obligate or facultative phreatophytes in areas that are clearly not influenced by surface water (e.g., around Ford Dry Lake and not along defined channels, or across the bajada between channels).

3. Identify Distant Monitoring sites around Palen Dry Lake where near-surface groundwater and plant communities dominated by phreatophytes occur, including mesquite stands, bush seepweed-dominant sink scrubs, and dune scrubs in areas of near-surface groundwater.

4. Identify Reference Monitoring Sites within the Sonoran or Colorado desert regions of California that contain examples of the target groundwater-dependent plant communities represented at the Project and Distant Monitoring Sites. Reference sites shall be characterized by surface and groundwater hydrology unaltered by anthropogenic influences such as groundwater pumping or other diversions

5. Provide a detailed description of sampling protocol for collecting a minimum of three years of baseline data from the Reference, Project, and Distant Monitoring Sites. The sampling protocol shall include a requirement that monitoring data be collected from all three monitoring sites at the same time of year at the start of the growing season (for example, March 15).

6. Provide a detailed description of the long-term data collection approach including: sampling objectives (target/threshold, change/trend-based) attributes measured, field techniques, minimum standards for monitoring personnel, data management,

statistical analysis, monitoring schedule, reporting requirements, and responsible parties.

7. Include appropriate field techniques for measuring drought response, including (at a minimum): percent dieback; live crown density; percent cover of live (versus dead or residual) vegetation, and any other vigor indicators that detect subtle changes over time; percent cover/frequency of associated species, changes over time in percent composition of native versus non-native species, and facultative wetland plants present. A detailed description of monitoring protocol shall also be included (for example, photo monitoring at permanent photo stations, among other monitoring techniques).

8. Include a description of the biological and ecological characteristics of groundwater-dependent species and natural communities, such as whether species are obligate vs. facultative; root growth and water acquisition; morphological adaptations to the desert environment; reproduction and germination; general and micro-habitat preferences; salt tolerance; role in the morphology of dunes; wildlife uses, etc.

9. Describe annual reporting requirements, which shall include (at a minimum): summaries of the results of the Groundwater Well Monitoring **(Soil&Water-5)** and a comparison of predicted versus actual water table declines during the early spring monitoring period, summary of the Vegetation Monitoring data, sampling and monitoring techniques used, field measurements employed, names and contact information for the monitoring personnel and responsible parties, description of data management, statistical analysis, photos, and conclusions.

If shallow water table declines or adverse effects to groundwater-dependent vegetation are detected, the project owner shall implement remedial action as described in **BIO-26.**

Verification: No less than 30 days following the docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the project owner shall submit to the CPM and BLM's Authorized Officer a final Vegetation Monitoring Plan that has been reviewed and approved by BLM's Authorized Officer and the CPM. All modifications to the Vegetation Monitoring Plan shall be made only after approval from BLM's Authorized Officer and the CPM.

Monitoring shall begin no later than April 1st following docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first.

The results of the first year baseline data, prior power analysis, and recommended changes shall be submitted for approval to the CPM and BLM's Authorized Officer by January 31st of the first baseline year.

On January 31st of each year following construction, the Designated Biologist shall provide a report prepared by the qualified botanist to the CPM and BLM's Authorized Officer that describes monitoring activities and results, including recommendations for remedial action. If monitoring reveals adverse effects that reach the threshold triggering remedial action, as described above, the Designated Biologist shall prepare submit a report describing the recommended remedial action within 30 days of completion of that

monitoring. If shallow water table declines or adverse effects to groundwater-dependent vegetation attributable to the project are detected, the project owner hall implement remedial action as described in BIO-26.

REMEDIAL ACTION FOR ADVERSE EFFECTS TO GROUNDWATER-DEPENDENT BIOLOGICAL RESOURCES

BIO-26 The project owner shall implement remedial action if the monitoring described in **BIO-25** detects declining spring water tables—in any amount greater than the normal year-to-year variability—combined with a decline in plant vigor in groundwater dependent vegetation at the Project Monitoring Sites compared to the Reference Monitoring Sites. The baseline spring water table depth, as measured in groundwater monitoring conducted pursuant to **Soil & Water-4 and 5**, shall be established based on the normal range of variability in area shallow water tables in spring (March 15-April 1). The Applicant shall submit a detailed proposal for remedial action to be approved by the CPM and BLM's Authorized Officer. The proposal shall clearly demonstrate how the proposed remedial action would restore the spring groundwater tables to a level necessary to sustain healthy ecological functioning in the affected plant communities, as defined by the trigger described above, and informed by data on Project water usage. The Applicant may choose the most feasible method of restoring healthy ecological functioning providing it meets the criterion above.

Verification: Within 30 days of detection of an adverse effect to groundwater dependent vegetation, as defined in **BIO-25**, the project owner shall submit to the CPM and BLM's Authorized Officer a report describing the adverse effect and a draft conceptual plan for remedial action. The report shall summarize the data and observations describing the adverse effect, including all calculations and assumptions made in development of the report data and interpretations.

Within 60 days of detection of an adverse effect, the project owner shall submit to the CPM and BLM's Authorized Officer for review and approval a remedial action plan for avoiding the adverse effects of the Project groundwater pumping on groundwater dependent vegetation.

No later than one year following approval of the remedial action plan, the Project owner shall provide to the CPM and BLM's Authorized Officer for review and approval, documentation of completed remedial action.

If, after review of the annual monitoring data described in **BIO-25** and in **Soil & Water-5**, the CPM and BLM's Authorized Officer agree, monitoring measurements and frequencies may be revised or eliminated.

COUCH'S SPADEFOOT TOAD IMPACT AVOIDANCE AND MINIMIZATION MEASURES

BIO-27 The project owner shall prepare and implement a Couch's Spadefoot Toad Protection and Mitigation Plan (Protection and Mitigation Plan) to avoid, minimize or mitigate impacts to Couch's spadefoot toads and their

breeding habitat during construction and operation of the Project. The Protection and Mitigation Plan shall be approved by BLM's Authorized Officer and the CPM in consultation with CDFG, and shall be incorporated into the Project's BRMIMP and implemented. It is expected that, as currently proposed, the Project could avoid the known breeding pond south of I-10 near Wiley Well Road and minimize impacts to the surrounding upland buffer. The Protection and Mitigation Plan shall address methods to achieve this avoidance and minimization, and shall include avoidance, minimization, and mitigation measures that would be required if additional habitat is found during habitat surveys. The Protection and Mitigation Plan shall include, at a minimum:

1. Habitat Survey Results:
    a. Survey methodology;
    b. Survey results, including a detailed discussion of potential breeding sites, and a description of areas determined not to include breeding habitat; and
    c. Figures showing the areas surveyed and the location of potential breeding habitat in relation to proposed Project features.
2. Impacts Assessment from:
    a. Habitat disturbance from construction;
    b. Noise from construction, operations, and potential ORV traffic;
    c. Increased access for vehicles from road construction or improvements;
    d. Changes in breeding habitat due to changes in flow levels and flow patterns to breeding ponds;
    e. Increased traffic from construction and operations;
    f. Increased risk of predation.
3. Avoidance and Minimization Measures:
    a. Description of measures that would be implemented to avoid impacts to potential breeding ponds, such as design strategies; protective fencing or other barriers, worker's education, minimizing construction traffic within the vicinity of breeding ponds, and biological monitoring;
    b. Designation of a Management Area around breeding ponds that includes an appropriate upland buffer, and a description of measures used to minimize impacts t within this buffer.
4. Mitigation: If complete avoidance of the pond south of I-10 or other breeding sites identified during surveys is not possible, the plan shall

include plans to create additional breeding habitats (ephemeral pond) at least equal in area to the acreage of ponds being impacted.

Verification: No less than 10 days following docketing of the Energy Commission Final Decision or publication of BLM's Record of Decision/ROW Issuance, whichever comes first, the project owner shall submit to the CPM, BLM's Authorized Officer, and CDFG a final Protection and Mitigation Plan. Modifications to the Protection and Mitigation Plan shall be made only after approval from BLM's Authorized Officer and the CPM, in consultation with CDFG.

BIOLOGICAL RESOURCES APPENDIX A

1.0 INTRODUCTION

Genesis Solar, LLC is proposing to construct, own, and operate a concentrated solar electric generating facility named Genesis Solar Energy Project (Proposed Project). The Proposed Project will utilize solar parabolic trough technology to generate electricity and consists of two independent solar electric generating facilities with a nominal net electrical output of 125 megawatts (MW) each, for a total net electrical output of 250 MW. Electrical power would be produced using steam turbine generators fed from solar steam generators. The solar steam generators receive heated transfer fluid from solar thermal equipment comprised of arrays of parabolic mirrors that collect energy from the sun.

The Proposed Project would use a wet cooling tower for power plant cooling. Water for cooling tower makeup, process water makeup, and other industrial uses such as mirror washing would be supplied from on-site groundwater wells. Project cooling water blowdown will be piped to lined, on-site evaporation ponds. A transmission line, access road, and natural gas pipeline will be co-located in one linear corridor to serve the main Project facility.

The Proposed Project site is located in eastern Riverside County, California, approximately 25 miles west of the City of Blythe, California. The Proposed Project right-of-way (ROW), for which an ROW grant has been sought from the Bureau of Land Management (BLM), will extend across approximately 4,640 acres of BLM land, with an eastern and western portion. Once constructed, the Project would permanently occupy approximately 1,800 acres within the eastern portion (the Project footprint), plus approximately 90 acres of linear facilities. The remainder of the acreage in the ROW application is not anticipated to be needed for the Project. Analyses contained within this report are based on the Proposed Project footprint.

HELIX Environmental Planning, Inc. (HELIX) conducted a biological reconnaissance for four alternative sites for the Proposed Project: the Reduced Acreage Alternative, Western Lands Alternative #1, Western Lands Alternative #2, and the Gabrych Alternative. The purpose of the reconnaissance was to assess the alternative sites in order to compare the potential impacts to biological resources on the Proposed Project site to the potential impacts to biological resources on the alternative sites. The first three alternative sites listed are on site reconfigurations of the Proposed Project site. The Gabrych Alternative is an off-site alternative. The Reduced Acreage Alternative site consists of 924 acres of the proposed 1,800-acre Project footprint. The Western Lands Alternative #1 site consists of approximately 888 acres located in the western portion of the Proposed Project ROW. The Western Lands Alternative #2 site consists of approximately 887 acres located partially in the western portion of the Proposed Project ROW, as well as to the south of this area. The Gabrych Alternative site consists of 2,137 acres located in northern Imperial County, approximately 13

miles south of Blythe, and 2.5 miles east of Palo Verde, California, adjacent to the Colorado River. It is comprised primarily of private agricultural land.

2.0 ENVIRONMENTAL SETTING

The Proposed Project site and all alternative sites are located in the Colorado Desert bioregion, encompassing all of Imperial County, the southeastern portion of Riverside County, the eastern end of San Bernardino County, and the eastern portion of San Diego County. This agriculturally rich bioregion is semi-arid and heavily irrigated (California Environmental Resources Evaluation System [CERES] 2010). The Proposed Project site, Reduced Acreage Alternative, and Western Alternatives are located in the Chuckwalla Valley, immediately north of Ford Dry Lake. The Gabrych Alternative is located in the Palo Verde Valley, east of the Palo Verde Mesa and the City of Palo Verde, immediately north and west of the Colorado River.

The Colorado Desert is the western extension of the Sonoran desert, which covers southern Arizona and northwestern Mexico. Much of the Colorado Desert lies below 1,000 feet in elevation. Mountain peaks rarely exceed 3,000 feet. Common habitats include sandy desert, scrub, palm oasis, and desert wash. Summers are hot and dry, and winters are cool and moist (CERES 2010).

The Colorado Desert supports a diverse array of plant and animal species including the Yuma antelope ground squirrel (*Ammospermophilus harrisii*), white-winged dove (*Zenaida asiatica*), muskrat (*Ondatra zibethicus*), southern mule deer (*Odocoileus hemionus fuliginata*), coyote (*Canis latrans*), bobcat (*Lynx rufus*), and raccoon (*Procyon lotor*). Rare animals include desert pupfish (*Cyprinodon macularius*), flat-tailed horned lizard (*Phrynosoma mcallii*), Andrew's dune scarab beetle (*Pseudocotalpa andrewsi*), Coachella Valley fringe-toed lizard (*Uma inornata*),
Le Conte's thrasher (*Toxostoma lecontei*), and California leaf-nosed bat (*Macrotus californicus*). Rare plants include Orcutt's woody aster (*Xylorhiza orcuttii*), Orocopia sage (*Salvia greatae*), foxtail cactus (*Coryphantha alversonii*), Coachella Valley milk-vetch (*Astragalus lentiginosus* var. *coachellae*), and crown of thorns (*Euphorbia* sp.; CERES 2010).

3.0 METHODS AND LIMITATIONS

As preparation for the field reconnaissance, HELIX reviewed these documents, references, and databases: Genesis Solar Energy Project Application for Certification (Tetra Tech and WorleyParsons 2009) and associated Data Requests and Responses, Genesis Solar Energy Project Biological Resources Technical Report (Tetra Tech 2009a), Survey for Jurisdictional Waters and Wetlands at the Genesis Solar Energy Project (Tetra Tech 2009b), STATSGO soils data (Soil Survey Staff, Natural Resources Conservation Service, U.S. Department of Agriculture [Soil Survey Staff] 2009), critical habitat mapping from the U.S. Fish and Wildlife Service, and California Natural Diversity Database (CNDDB; California Department of Fish and Game [CDFG] 2009) records.

HELIX biologists Stacy Nigro, Deborah Leonard, Dale Ritenour, and Kimberly Davis conducted a field reconnaissance of the Proposed Project site and Western Land Alternative sites on 7 January 2010. On 8 January 2010, Deborah Leonard and Kimberly Davis conducted additional field work at the Western Alternative sites, as well as a field reconnaissance on the Reduced Acreage Alternative. Also on 8 January 2010, Stacy Nigro and Dale Ritenour conducted a field reconnaissance of the off-site Gabrych Alternative. The purpose of the reconnaissance field work was to make site-specific comparisons between the biological resources on the Proposed Project site and those that HELIX observed on the alternative sites, or that HELIX interpreted from aerial photography where access was restricted. Access was restricted to roads for the Gabrych Alternative because it is privately held.

The reconnaissance included comparing and photographing representative samples of vegetation communities throughout the Proposed Project footprint and the alternative sites by driving roads within and/or adjacent to the vegetation communities, as well as conducting brief habitat assessments on foot for parcels with public access. Vegetation community types and plant and animal species observed were noted, as well as potential U.S. Army Corps of Engineers (ACOE) and/or CDFG jurisdictional features.

The potential for special status species to occur on the alternative sites was determined using a habitat-based analysis, by referring to the special status species observed or with potential to occur on the Proposed Project site, and by consulting the CNDDB. Detailed vegetation mapping, delineation of potential ACOE/CDFG jurisdictional features, and focused surveys for special status plant and animal species were outside the scope of services provided by HELIX.

While detailed vegetation mapping was not conducted for the Gabrych Alternative site, vegetation polygons were sketched based on what could be seen from public access points in the field as well as aerial photograph interpretation. These polygons were then digitized using a Geographic Information System (GIS), thereby providing a rough estimate of the total acreage for each vegetation community on the Gabrych Alternative site. This mapping and the acreages derived from it are extremely preliminary (reconnaissance level) and should be used only to provide a generalized understanding of the amount and types of vegetation present. A full vegetation mapping effort would be required to provide more accurate maps and figures.

The remaining alternatives (Reduced Acreage, Western Lands Alternative #1, and Western Lands Alternative #2) occur within the survey area for the Proposed Project site, and GIS data for the vegetation in these areas is available. Therefore, HELIX used this GIS data to calculate the acreages for the vegetation within the Reduced Acreage and Western Lands alternatives.

4.0 RESULTS

4.1 LAND USE, ELEVATION, TOPOGRAPHY, AND SOILS

4.1.1 Off-site Alternative

Gabrych Alternative. This alternative site consists mainly of active agricultural fields and active sheep grazing. Neighbors Boulevard traverses the central portion of the site from north to south, and several unnamed dirt roads cross the site between agricultural fields. Five named irrigation canals cross the site: C Canal, D-23-1 Canal, D-23-1-3 Canal, D-23-1-4 Canal, and D-23-1-5 Canal. Several residences occur in a concentrated area at the southern end of Neighbors Boulevard, adjacent to the river. A small sand/gravel mining operation occurs just west of the residential area. Approximately 160 acres of the site support native vegetation communities; these parcels occur primarily in the southwest corner of the site. Surrounding lands include the Colorado River to the east and south, and active agriculture to the west and north. Cibola National Wildlife Refuge is located approximately three miles south of the site, in Arizona. Topography on site is relatively flat, with elevation ranging from approximately 235 to 245 feet above mean sea level (AMSL). There are nine soil series mapped for this alternative: Cibola, Gilman, Glenbar, Holtville, Imperial, Indio, Meloland, Ripley, and Rositas, much of which prime farmland (Soil Survey Staff 2009).

4.1.2 Reconfigured Alternatives (On Site)

Reduced Acreage Alternative. The Reduced Acreage Alternative consists of 924 acres of land comprising the western half of the 1,793-acre Proposed Project footprint. It consists of undeveloped lands managed by the BLM. Surrounding lands include the Palen/McCoy Wilderness Area to the north, Ford Dry Lake to the south, and other BLM lands to the east and west. Topography on site is relatively flat, with elevation ranging from approximately 371 to 394 feet AMSL. Soils mapped for this alternative are comprised of one soil series, Cherioni, which is a gravelly sandy loam (Soil Survey Staff 2009).

Western Lands Alternative #1. The Western Lands Alternative #1 consists of 888 acres of land comprising part of the western portion of the 4,640-acre ROW. It consists of undeveloped lands managed by the BLM. Surrounding lands include the Palen/McCoy Wilderness Area to the north, Ford Dry Lake to the south, and other BLM lands to the east and west. Topography on site is relatively flat, with elevation ranging from approximately 377 to 410 feet AMSL. Soils mapped for this alternative are comprised of two soil series, Cherioni and Gunsight, both of which are gravelly sandy loams (Soil Survey Staff 2009).

Western Lands Alternative #2. The Western Lands Alternative #2 consists of 887 acres of land comprising part of the western portion of the 4,640-acre ROW and lands to the south. It consists of undeveloped lands managed by the BLM. Surrounding lands include the Palen/McCoy Wilderness Area to the north, Ford Dry Lake to the south, and other BLM lands to the east and west. Topography on site is relatively flat,

with elevation ranging from approximately 377 to 410 feet AMSL. Soils mapped for this alternative are comprised of two soil series, Cherioni and Gunsight, both of which are gravelly sandy loams (Soil Survey Staff 2009).

4.2 JURISDICTIONAL AREAS

4.2.1 Off-site Alternative

Gabrych Alternative. Approximately 7 acres of the Colorado River occur within the southern portion of the site, and is jurisdictional to the ACOE and CDFG. A small stand of riparian scrub occurring along the D-23-1-3 Canal in the northeast portion of the site, as well as more extensive riparian habitat occurring along the C Canal in the southwestern portion of the site and along the Colorado River in the southern portion of the site would be considered waters of the state under the jurisdiction of the CDFG and may be considered waters of the U.S. under the jurisdiction of the ACOE. Areas of arrowweed scrub occurring in the southwestern corner of the site also would be considered waters of the state under the jurisdiction of the CDFG and may be considered waters of the U.S. under the jurisdiction of the ACOE. The named on-site canals may be considered connected to the Colorado River and as such are potentially jurisdictional to the ACOE and CDFG. A jurisdictional delineation and coordination with the ACOE and CDFG would be necessary to formally determine the jurisdictional areas on site.

4.2.2 Reconfigured Alternatives (On Site)

Reduced Acreage Alternative. A large wash, approximately ten feet wide (Tetra Tech 2009b), passes through the southwestern corner of the alternative site. No other jurisdictional features were documented by Tetra Tech or observed during HELIX's field reconnaissance. Species present in the wash include creosote bush, white bursage (*Ambrosia dumosa*), galleta grass (*Pleuraphis rigida*), ironwood (*Olneya tesota*), and catclaw acacia (*Acacia greggii*). This wash is likely considered isolated and not under jurisdiction of the ACOE, though it would be considered waters of the State under jurisdiction of the CDFG.

Western Lands Alternative #1. One wash was observed in the southwest corner of this alternative, and other washes may be present. A formal delineation was outside the scope of HELIX's services; however, based on aerial interpretation it appears that other ephemeral washes may occur on the alternative site. Rather than washes, these areas also may be shallow rivulets that convey sheet flow across the site from the mountains to the north. Any ephemeral washes on site would be considered waters of the State by the CDFG. Although the ACOE may take jurisdiction over these features, it does appear that they are isolated from other waters of the U.S and would not fall under ACOE jurisdiction.

Western Lands Alternative #2. Two washes were observed in this alternative, one in the southwest portion of the site and the other in the south central portion of the site; however, other washes may be present. A formal delineation was outside the scope of

HELIX's services; however, based on aerial interpretation it appears that other ephemeral washes may occur on the alternative site. Rather than washes, these areas also may be shallow rivulets that convey sheet flow across the site from the mountains to the north. Any ephemeral washes on site would be considered waters of the State by the CDFG. Although the ACOE may take jurisdiction over these features, it does appear that they are isolated from other waters of the U.S and would not fall under ACOE jurisdiction.

4.3 WILDLIFE USE

4.3.1 Off-site Alternative

Gabrych Alternative. Undeveloped portions of the site (the southwest corner) are used by a variety of common animal species such as coyote (*Canis latrans*), black-tailed jackrabbit (*Lepus californicus*), desert cottontail (*Sylvilagus bachmani*), raccoon (*Procyon lotor*), and various resident and migratory bird species such as American kestrel (*Falco sparverius*), Gambel's quail (*Callipepla gambelii*), white-crowned sparrow (*Zonotrichia leucophrys*), sage sparrow (*Amphispiza belli*), Say's phoebe (*Sayornis saya*), and black phoebe (*Sayornis nigricans*), as well as the desert kangaroo rat (*Dipodomys deserti*). Agricultural areas on site support foraging habitat for red-tailed hawk (*Buteo jamaicensis*), northern harrier (*Circus cyaneus*), turkey vulture (*Cathartes aura*), American kestrel, and phoebes. The canals carrying water support potential foraging habitat for species such as the belted kingfisher (*Ceryle alcyon*) and white-faced ibis (*Plegadis chihi*).

Although the site itself does not function as a movement corridor for wildlife, the adjacent Colorado River and contiguous undeveloped lands (where present) do provide corridor functions for several species.

4.3.2 Reconfigured Alternatives (On Site)

Reduced Acreage Alternative. The alternative site is used by a variety of common animal species such as coyote, black-tailed jackrabbit, desert cottontail, desert kangaroo rat, desert kit fox, and greater roadrunner (*Geococcyx californianus*).

The alternative site is part of a larger area of BLM land that supports numerous wildlife species, although no particular portion of the site is considered a wildlife corridor.

Western Lands Alternative #1. The alternative site is used by a variety of common animal species such as coyote, black-tailed jackrabbit, desert cottontail, wild burro (*Equus asinus*), desert kangaroo rat, desert kit fox, side-blotched lizard (*Uta stansburiana*), and harvester ants (*Pogonomyrmex* sp.). Numerous rodent and lizard burrows occur on site.

The alternative site is part of a larger area of BLM land that supports numerous wildlife species, although no particular portion of the site is considered a wildlife corridor.

Western Lands Alternative #2. The alternative site is used by a variety of common animal species such as coyote, black-tailed jackrabbit, desert cottontail, wild burro (*Equus asinus*), desert kangaroo rat, desert kit fox, side-blotched lizard (*Uta stansburiana*), and harvester ants (*Pogonomyrmex* sp.). Numerous rodent and lizard burrows occur on site.

The alternative site is part of a larger area of BLM land that supports numerous wildlife species, although no particular portion of the site is considered a wildlife corridor.

4.4 VEGETATION COMMUNITIES

4.4.1 Off-site Alternative

Gabrych Alternative. Active agriculture, riparian scrub, arrowweed scrub, desert saltbush scrub (including disturbed), disturbed habitat, and developed land are the six primary vegetation communities on the alternative site. The acreages presented below are rough estimates, as detailed vegetation mapping was not conducted.

Active agriculture (including crops and sheep grazing) occurs on approximately 1,817 acres (approximately 85 percent) of this alternative site. The edges of the fields consist of low dirt berms supporting sparse non-native plant cover, including crabgrass (*Digitaria* sp.), London rocket (*Sisymbrium irio*), and nettleleaf goosefoot (*Chenopodium murale*).

Riparian scrub occurs on approximately 38 acres, almost all of which is adjacent to the river in the southern portion of the site and along the C Canal where it traverses disturbed saltbush scrub in the southwest corner of the site. This habitat is comprised of a mix of black willow (*Salix gooddingii*), arrowweed (*Pluchea sericea*), and tamarisk (*Tamarix* sp.), along with presence of cattails (*Typha* sp.) in the wetter areas, and occasional horsetail (*Equisetum* sp.).

Arrowweed scrub occurs on approximately 82 acres in the south and southwestern portions of the site. This habitat consists primarily of arrowweed, with some areas supporting a mix of arrowweed, tamarisk, four-wing saltbush (*Atriplex canescens*), and other saltbush species (*Atriplex* spp.).

Desert saltbush scrub occurs on approximately 35 acres, consisting of approximately nine acres of undisturbed desert saltbush scrub and 26 acres of disturbed desert saltbush scrub located in the southwestern corner of the site. Undisturbed desert saltbush scrub consists of habitat with moderate to dense coverage by saltbush (*Atriplex* spp.), while disturbed saltbush scrub consists primarily of old alluvial deposits that appear to have been cleared of vegetation in the past and are still recovering. Shrub cover in these disturbed areas is approximately five to ten percent, comprised of various species of saltbush, as well as occasional creosote bush (*Larrea tridentata*) and arrowweed, while herbaceous cover is approximately 35 to 45 percent, consisting primarily of Mediterranean grass (*Schismus barbatus*) with occasional plicate coldenia (*Tiquilia plicata*) and Russian thistle (*Salsola tragus*).

Disturbed habitat comprises approximately 126 acres of land in the southwestern corner of the site that has been cleared of vegetation and supports sparse coverage by non-native species, as well as areas west of the residential area, including areas formerly used for camping and illegal dumping.

Developed land comprises approximately 34 acres at the southern terminus of Neighbors Boulevard, comprising approximately 26 acres of residential development and eight acres of ongoing sand/gravel mining along the north side of the river.

In comparison to the Gabrych Alternative site, the Proposed Project footprint consists of approximately 1,793 acres of native vegetation communities, of which the vast majority is Sonoran creosote bush scrub, along with smaller areas of stabilized and partially stabilized sand dunes and playa and sand drifts over playa (Tetra Tech 2009a), whereas the Gabrych Alternative supports approximately 1,817 acres of active agricultural lands, 160 acres of disturbed habitat/developed lands, and 160 acres of native vegetation communities.

Table 1

TOTAL	**1,793**	**924**	**888**	**887**	**2,137**

*Acreages for the Proposed Project disturbance area have been rounded. Acreages are approximate for the alternatives (see Section 3.0, *Methods and Limitations* in this report). It is assumed herein that all of the vegetation for the alternatives would be impacted.
**Includes direct impacts for the Proposed Project footprint and does not include impacts from the transmission line (see Section 6.0, *Construction Impacts,* in this report).

4.4.2 Reconfigured Alternatives (On Site)

Reduced Acreage Alternative. Sonoran creosote bush scrub and playa and sand drifts over playa are the two primary vegetation communities on the Reduced Acreage Alternative site.

Sonoran creosote bush scrub covers approximately 911 acres of the site and primarily supports sparse cover of creosote bush, white bursage, and galleta grass, as well as other scattered perennial and annual plant species such as plantain (*Plantago ovata*), cryptantha (*Cryptantha* sp.), and rush milkweed (*Asclepias subulata*).

Playa and sand drifts over playa occupy approximately 13 acres in the southwestern corner of the alternative site. Creosote bush and white bursage are the dominant species present.

In comparison to the Reduced Acreage Alternative site, the Proposed Project footprint is nearly double in size, consisting of 1,793 acres. Approximately 1,751 acres are covered by Sonoran creosote bush scrub, 28 acres by stabilized and partially stabilized sand dunes, and 14 acres by playa and sand drifts over playa.

Western Lands Alternative #1. Sonoran creosote bush scrub is the only vegetation community occurring on site. It supports sparse to moderate cover of creosote bush, white bursage, galleta grass, and Parry dalea (*Marina parryi*), as well as other scattered perennial and annual plant species such as plantain (*Plantago ovata*), cryptantha (*Cryptantha* sp.), Saharan mustard (*Brassica tournefortii*), prostrate spurge (*Chamaecyse polycarpa*), cholla (*Cylindropuntia echinocarpa*), and devil's spineflower (*Chorizanthe rigida*).

In comparison to the Western Lands Alternative #1 site, the Proposed Project footprint is over double in size, consisting of 1,793 acres. Approximately 1,751 acres are covered by Sonoran creosote bush scrub, 28 acres by stabilized and partially stabilized sand dunes, and 14 acres by playa and sand drifts over playa.

Western Lands Alternative #2. Two vegetation communities occur on site: Sonoran creosote bush scrub and stabilized and partially stabilized sand dunes. Sonoran creosote bush scrub covers approximately 839 acres of the site (95 percent) and stabilized and partially stabilized sand dunes cover approximately 48 acres in the southwestern corner.

Sonoran creosote bush scrub on the Western Lands Alternative #2 site supports widely spaced creosote bush and white bursage, with plantain comprising the primary ground cover. Vegetative coverage is denser in the southern portion of the site. Other species observed include galleta grass, Parry dalea, white rhatany (*Krameria grayi*), cryptantha, Saharan mustard, prostrate spurge, blue paloverde (*Cercidium floridum*), and devil's spineflower. Several areas of desert pavement are interspersed throughout this habitat.

Stabilized and partially stabilized sand dunes in the southwestern corner are vegetated more densely than other areas of the site. Typical species include creosote bush, white bursage, and galleta grass.

In comparison to the Western Lands Alternative #2 site, the Proposed Project footprint is more than double in size, consisting of 1,793 acres. Approximately 1,751 acres are covered by Sonoran creosote bush scrub, 28 acres by stabilized and partially stabilized sand dunes, and
14 acres by playa and sand drifts over playa.

4.5 SPECIAL STATUS SPECIES

4.5.1 Off-site Alternative

Gabrych Alternative. Special status species observations have been reported to the CNDDB within five miles of the alternative site (Table 2). These CNDDB records include two non-listed, special status plant species, bitter hymenoxys (*Hymenoxys odorata*) and Wiggins cholla (*Cylindropuntia wigginsii*), three listed animal species, federally and state listed endangered razorback sucker (*Xyrauchen texanus*), federally endangered and state threatened Yuma clapper rail (*Rallus longirostris yumanensis*), and federal candidate and state endangered western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), as well as eight non-listed special status animal species, Couch's spadefoot (*Scaphiopus couchii*), vermillion flycatcher (*Pyrocephalus rubinus*), Yuma myotis (*Myotis yumanensis*), Townsend's big-eared bat (*Corynorhinus townsendii*), pallid bat (*Antrozous pallidus*), American badger (*Taxidea taxus*), and Colorado River cotton rat (*Sigmodon arizonae plenus*).

Table 2
CALIFORNIA NATURAL DIVERSITY DATABASE RECORDS FOR SPECIAL STATUS SPECIES WITHIN FIVE MILES OF THE GABRYCH ALTERNATIVE SITE

Common Name ***Scientific Name***	**Status State/Fed/CNPS/BLM**	**Occurrence Within 5 Miles of Gabrych Alternative Site**
Bitter hymenoxys (*Hymenoxys odorata*)	--/--/List 2/--	Reported approximately 2.5 miles west of the site.
Wiggins cholla (*Cylindropuntia wigginsii*)	--/--/List 3.3/--	Reported approximately 2.5 miles west of the site.
Razorback sucker (*Xyrauchen texanus*)	SE/FE/--/--	Reported approximately 1 mile southwest of the site and 2.5 miles west of the site.
Couch's spadefoot (*Scaphiopus couchii*)	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
Yuma clapper rail (*Rallus longirostris yumanensis*)	ST/FE/--/--	Reported approximately 2 miles southwest of the site in a natural meander of the Colorado River, west of the

Table 2
CALIFORNIA NATURAL DIVERSITY DATABASE RECORDS FOR SPECIAL STATUS SPECIES WITHIN FIVE MILES OF THE GABRYCH ALTERNATIVE SITE

Common Name ***Scientific Name***	**Status State/Fed/CNPS/BLM**	**Occurrence Within 5 Miles of Gabrych Alternative Site**
		channelized river.
Western yellow-billed cuckoo (*Coccyzus americanus occidentalis*)	SE/FC/--/--	Reported along the eastern edge of the site, in riparian habitat associated with the river.
Vermillion flycatcher (*Pyrocephalus rubinus*),	SSC/--/--/--	Reported approximately 2.5 miles west of the site.
Yuma myotis (*Myotis yumanensis*)	--/--/--/S	Reported along the southern boundary of the site, where Neighbors Boulevard crosses the river.
Townsend's big-eared bat (*Corynorhinus townsendii*),	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
Pallid bat (*Antrozous pallidus*),	SSC/--/--/S	Reported approximately 2.5 miles west of the site.
American badger (*Taxidea taxus*)	SSC/--/--/--	Reported approximately 2.5 miles west of the site.
Colorado River cotton rat (*Sigmodon arizonae plenus*)	SSC/--/--/--	Reported approximately 2.5 miles west of the site.

Status Codes:
Federal FE - Federally listed endangered: species in danger of extinction throughout a significant portion of its range
FT - Federally listed threatened: species likely to become endangered within the foreseeable future
FC – Candidate for listing

Status Codes (cont.):
State SE - State listed endangered
ST = State listed threatened
SSC = Species of special concern
California Native Plant Society
List 1B - Rare, threatened, or endangered in California and elsewhere
List 2 - Rare, threatened, or endangered in California but more common elsewhere
List 3 - Plants which need more information
List 4 - Limited distribution – a watch list
0.1 - Seriously threatened in California (high degree/immediacy of threat)
0.2 - Fairly threatened in California (moderate degree/immediacy of threat)
0.3 - Not very threatened in California (low degree/immediacy of threats or no current threats known)
BLM S = Sensitive
BLM Manual § 6840 defines sensitive species as "…those species that are (1) under status review by the FWS/NMFS; or (2) whose numbers are declining so rapidly that federal listing may become necessary, or (3) with typically small and widely dispersed populations; or (4) those inhabiting ecological refugia or other specialized or unique habitats." <www.blm.gov/ca/pdfs/pa_pdfs/biology_pdfs/SensitiveAnimals.pdf>

In addition to the species reported to the CNDDB within five miles of the alternative site, there are other special status species that have been observed on the Proposed Project site or have been reported to the CNDDB within five miles of the Proposed Project site that have potential to occur on the Gabrych Alternative site. A list of all species with

their potential to occur (or presence) on the Proposed Project site and the alternative sites is provided as Appendix A. Northern harrier was the only special status species observed on the alternative site during the field reconnaissance.

In comparison to this alternative site, the Proposed Project footprint supports three non-listed, special status plant species (Harwood's milk-vetch [*Astragalus insularis* var. *harwoodii*], desert unicorn plant [*Proboscidea althaeifolia*], and Wiggins' cholla [*Cylindropuntia wigginsii*]), evidence of one listed animal species (desert tortoise [*Gopherus agassizii*) – bone fragments only), and two non-listed special status animal species (burrowing owl [*Athene cunicularia*] – pellets and inactive burrows, and numerous desert kit fox [*Vulpes macrotis arsipus*] burrows; Tetra Tech 2009a). CNDDB records also report two non-listed special status plant species (Abrams spurge [*Chamaesyce abramsiana*] and dwarf germander [*Teucrium cubense depressum*]) and one non-listed special status animal species (Crissal thrasher [*Toxostoma crissale*]) within five miles of the Proposed Project facility site.

Except for Wiggins' cholla, there are no CNDDB records for any of the above-listed species within five miles of the alternative site; however, there is low potential for Harwood's milk-vetch, desert unicorn plant, Abrams spurge, and dwarf germander to occur in the sandy areas comprising the southwestern corner of the alternative site, as well as moderate potential for burrowing owl to forage in the agricultural fields and Crissal thrasher to occupy riparian scrub along the river. The remaining species require habitats that are not present on the alternative site.
There are other special status plant and animal species with potential to occur on the alternative site (Appendix A), but the primary species of concern are the desert tortoise and burrowing owl. The desert tortoise is unlikely to occur on the alternative site as native habitat is limited and is isolated from other potential habitat areas. Special status species most likely to use the site are species associated with foraging in agricultural fields (e.g., burrowing owl), and bird species associated with riparian habitat along the river. There is moderate potential for burrowing owl to use the site for foraging; owls also may inhabit burrows in berms constructed along irrigation canals, though no burrows were observed during the field reconnaissance.

4.5.2 Reconfigured Alternatives (On Site)

Reduced Acreage Alternative. Special status species observations have been reported to the CNDDB within five miles of the alternative site (Table 3) and include two non-listed special status plant species (Abrams spurge and dwarf germander) and one non-listed special status animal species (Crissal thrasher).

Table 3
CALIFORNIA NATURAL DIVERSITY DATABASE RECORDS FOR SPECIAL STATUS SPECIES WITHIN FIVE MILES OF THE REDUCED ACREAGE ALTERNATIVE SITE

Common Name ***Scientific Name***	**Status State/Fed/CNPS/BLM***	**Occurrence Within 5 Miles of Reduced Acreage Alternative Site**
Abrams spurge *Chamaecyse abramsiana*	--/--/List 2.2/--	Reported approximately 4 miles south of the site.
Dwarf germander *Teucrium cubense depressum*	--/--/List 2.2/--	Reported approximately 4 miles southeast of the site.
Crissal thrasher *Toxostoma crissale*	--/SSC/--/--	Reported approximately 5 miles southeast of the site.

*See following Table 2 for an explanation of status codes used in Table 3. Refer to Appendix A for a complete listing of species with potential to occur.

In addition to the species reported to the CNDDB within five miles of the alternative site, there are other special status species that have been observed on the Proposed Project site or have been reported to the CNDDB within five miles of the Proposed Project site that would have equal likelihood to occur on the Reduced Acreage Alternative site. A list of all species with their potential to occur (or presence) on the Proposed Project site and the alternative site is provided as Appendix A.

The Proposed Project footprint and the Reduced Acreage Alternative site support the same special status species, as the two sites overlap. No special status species were observed during the field reconnaissance, however, the following three non-listed plant species have been documented on the Proposed Project footprint and Reduced Acreage Alternative (Tetra Tech 2009a): Harwood's milk-vetch, Wiggins' cholla, and desert unicorn plant. In addition, bone fragments from the state and federally listed threatened desert tortoise were observed, as well as evidence of two non-listed special status animal species: burrowing owl and desert kit fox.

Western Lands Alternative #1. No special status species observations have been reported to the CNDDB within five miles of the alternative site. However, there are other special status species that have been observed on the Proposed Project site or have been reported to the CNDDB within five miles of the Proposed Project site that have potential to occur on the Western Lands Alternative #1 site. A list of all species with their potential to occur (or presence) on the Proposed Project site and the alternative site is provided as Appendix A.

No special status species were observed on the alternative site during the field reconnaissance; however, results of field surveys conducted by Tetra Tech (2009a) indicate that Wiggins' cholla, loggerhead shrike (*Lanius ludovicianus*), American badger, desert kit fox, short-eared owl (*Asio flammeus*), northern harrier, desert tortoise, and burrowing owl all occur on the alternative site. A burrowing owl was observed in the southwest corner and an active burrow along the southern boundary, with numerous

inactive burrows also noted. Three active desert tortoise burrows also were observed in the western portion of the site.

Western Lands Alternative #2. Special status species observations have been reported to the CNDDB within five miles of the alternative site and include one listed special status animal species (desert tortoise). The record for this species occurs approximately 4.5 miles south of the alternative site.

In addition to the species reported to the CNDDB within five miles of the alternative site, there are other special status species that have been observed on the Proposed Project site or have been reported to the CNDDB within five miles of the Proposed Project site that have potential to occur on the Western Lands Alternative #2 site. A list of all species with their potential to occur
(or presence) on the Proposed Project site and the alternative sites is provided as Appendix A.

California horned lark (*Eremophila alpestris*), a CDFG Watch List (WL) species, was the only special status species observed on the alternative site during the field reconnaissance. However, results of field surveys conducted by Tetra Tech (2009a) indicate that desert kit fox, short-eared owl, northern harrier, desert tortoise, and burrowing owl all occur on the alternative site. A burrowing owl was observed in the southwest corner and numerous inactive burrows also were noted. In addition, three active desert tortoise burrows were observed in the central and northwestern portions of the site.

4.6 NECO HABITAT MANAGEMENT AREAS, LANDFORMS, AND CRITICAL HABITAT

4.6.1 Off-site Alternative (Gabrych)

NECO Habitat Management Areas. The Gabrych Alternative occurs just outside of the NECO planning area and does not occur within or adjacent to any NECO Wildlife Habitat Management Area (WHMA; BLM and CDFG 2002).

Landforms. The Gabrych Alternative is located just southeast of the NECO planning area. The nearest NECO landforms are cultivated lands, as shown on Map 3-4 of the NECO (BLM and CDFG 2002).

Critical Habitat. No critical habitat for special status plant or animal species occurs on or adjacent to the Gabrych Alternative. The site is located just southeast of the NECO planning area; the NECO Desert Tortoise Habitat Model (BLM and CDFG 2002) shows low quality desert tortoise habitat (potential value of 0) adjacent to the site.

4.6.2 On-site Alternatives (Reduced Acreage, Western Lands #1 and #2)

NECO Habitat Management Areas. The Reduced Acreage Alternative, Western Lands Alternative #1, and Western Lands Alternative #2 sites, as well as the Proposed Project

site, all occur completely or nearly completely within a NECO Multiple Species Wildlife Habitat Management Area (WHMA; BLM and CDFG 2002). Only a sliver of land along the northeastern edges of the Proposed Project footprint and Reduced Acreage Alternative site occur outside of the WHMA. NECO Multiple Species WHMAs have been designated to protect habitats assumed to be suitable for many species and, therefore, to preserve biodiversity.

Landforms. Landforms on the Proposed Project site include fans and sand covered fans, landforms on the Reduced Acreage Alternative include only fans, and landforms on both of the Western Lands Alternatives include fans and dissected fans, as shown on Map 3-4 of the NECO (BLM and CDFG 2002).

Sand covered fans are landforms with potential to support the Mojave fringe-toed lizard; this landform is mapped in the southeastern corner of the Proposed Project site.

Critical Habitat. No critical habitat for special status plant or animal species occurs on or adjacent to the Proposed Project site or on site alternatives. The nearest critical habitat is for desert tortoise, located approximately 2.6 miles south of the Proposed Project site. The NECO Desert Tortoise Habitat Model (BLM and CDFG 2002) shows low quality desert tortoise habitat (potential value of 0, 0.1, and 0.2) throughout the Proposed Project site and on site alternatives.

5.0 ALTERNATIVE COMPARISON SUMMARY

Table 4 provides a summarized comparison of the biological resources on the Proposed Project site and the alternative sites.

Table 4
ALTERNATIVES COMPARISON FOR BIOLOGICAL RESOURCES

BIOLOGICAL RESOURCE	PROPOSED PROJECT FOOTPRINT (1,793 ACRES)	ON-SITE RECONFIGURED ALTERNATIVES			OFF-SITE ALTERNATIVE
		Reduced Acreage Alternative (924 acres)	Western Lands Alternative # 1 (888 acres)	Western Lands Alternative # 2 (887 acres)	Gabrych Alternative (2,137 acres)
Vegetation Communities	Vegetative cover is 100 percent native, consisting of Sonoran creosote bush scrub; stabilized and partially stabilized sand dunes, playa, and sand drifts over playa.	Vegetative cover is 100 percent native, consisting of Sonoran creosote bush scrub and playa and sand drifts over playa.	Vegetative cover is 100 percent native, consisting of Sonoran creosote bush scrub	Vegetative cover is 100 percent native, consisting of Sonoran creosote bush scrub	Vegetative cover is approximately 9 percent native. Native vegetations communities consist of riparian scrub, arrowweed scrub, and desert saltbush scrub (including disturbed). Other communities present include active agriculture, disturbed habitat, and developed land.
Jurisdictional Areas	Waters of the State: eleven ephemeral washes occur on site. It is anticipated that the ACOE will not assert jurisdiction over these areas.	Waters of the State: one ephemeral wash occurs on site. It is anticipated that the ACOE will not assert jurisdiction over these areas.	Waters of the State: one ephemeral wash was observed on site and others may be present. It is anticipated that the ACOE will not assert jurisdiction over ephemeral washes on site.	Waters of the State: two ephemeral washes were observed on site and others may be present. It is anticipated that the ACOE will not assert jurisdiction over ephemeral washes on site.	Colorado River is Waters of the U.S. and Waters of the State. Five named irrigation canals may be considered waters of the State and waters of the U.S. Riparian habitat, including riparian scrub and arrowweed scrub in the southwestern corner of the site

					would likely be considered Waters of the State and also may be Waters of the U.S.

*See following Table 2 for an explanation of status codes. Refer to Appendix A for a complete listing of species with potential to occur.

6.0 CONSTRUCTION IMPACTS

Proposed Project Site. According to the Genesis Solar Energy Project Biological Resources Technical Report (BRTR; Tetra Tech 2009a), the Proposed Project would directly impact Sonoran creosote bush scrub and stabilized and partially stabilized sand dune communities.

No state or federally listed plant species occur on the Proposed Project footprint, so there would be no impacts to these types of species. Three non-listed, special status plant species,
21 Harwood's milk-vetch individuals, 109 Wiggins' cholla individuals, and one desert unicorn plant individual would be directly impacted.

The Proposed Project footprint site would permanently impact approximately 1,793 acres of low quality desert tortoise habitat that does not support active desert tortoise burrows or recent sign of tortoise. Impacts are expected to be negligible due to lack of current occupation (Tetra Tech 2009a). The nearest active tortoise burrow observed during surveys was approximately four miles west of the site, although tracks were documented approximately 0.5 mile north of the site.

The Proposed Project also would directly impact non-listed, special status animal species including the burrowing owl (loss of potential nesting and foraging habitat) and Mojave fringe-toed lizard (loss of potential habitat – not observed on site but adjacent areas are occupied), and desert kit fox through the loss of burrows and foraging habitat.

OFF-SITE ALTERNATIVE

Gabrych Alternative Site. It is expected that the facility could be sited on the least sensitive 1,800 acres of the 2,137-acre Gabrych Alternative site. This would result in impacts to active agricultural lands and disturbed habitat and/or developed land. All riparian areas and native vegetation communities in the southwestern corner of the site could be avoided. Potential impacts may still occur to canals, depending on the site design, which may result in impacts to waters of the State and/or waters of the U.S.

It is unlikely that any special status plant species occur on site, and if so, they could be avoided by constructing the facility outside of the native vegetation areas in the southwestern corner of the alternative. Few impacts to special status animal species would be expected because the alternative site is largely active agricultural land and native habitat along the river and in the southwestern corner could be avoided while still having the minimum 1,800 acres needed for facility construction. However, a northern harrier was observed foraging on site, and burrowing owl, which is known to use agricultural land for foraging, also may be affected if it is present.

Two special status species documented in CNDDB records could be affected if riparian habitat along the river and in the southwestern corner is impacted. These include western yellow-billed cuckoo and Colorado River cotton rat. Impacts to razorback sucker are not anticipated as this species inhabits the Colorado River and is not expected to occur on site. Several species of bats may forage along the river, but are not anticipated to be affected by facility construction. There is also some potential for special status plant species to occur in the native habitat areas in the southwestern corner. These include Harwood's milk-vetch, desert unicorn plant, Abrams spurge, and dwarf germander.

Wildlife movement across the site would be impeded by project development but would not affect overall wildlife movement in the area, as movement is likely to be concentrated along the river corridor.

Additional impacts to vegetation communities, and possibly special status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the alternative site. Information regarding these linear facilities is not available, and estimating the types or extent of the potential impacts from such facilities is outside the scope of services provided by HELIX.

RECONFIGURED ALTERNATIVES (ON SITE)

Reduced Acreage Alternative Site. It is expected that the Reduced Acreage Alternative site and all of the vegetation communities on it (i.e., Sonoran creosote bush scrub and playa and sand drifts over playa) as well as any jurisdictional areas (e.g., ephemeral wash) would be permanently lost as a result of vegetation clearing, grading, and construction of the solar facilities.

Pursuant to site surveys and CNDDB records, construction also would affect two special status plant species (Wiggins' cholla and desert unicorn plant), as well as affect the desert kit fox and potentially affect desert tortoise and burrowing owl (only inactive owl burrows were observed and tortoise bone fragments). Several other special status plant and animal species have been observed off site but in the project vicinity, including Harwood's milk-vetch, Harwood's phlox, Las Animas colubrina, loggerhead shrike, northern harrier, short-eared owl, American badger, and Mojave and/or Colorado fringe-toed lizard. Any of these species could occur on the alternative site, though potential habitat for the fringe-toed lizard is restricted to the sand drift areas.

Wildlife movement across the site would be impeded by project development but would not affect overall wildlife movement in the area, as undeveloped BLM lands occur to all sides, and no portion of the alternative site is an identified wildlife corridor.

Additional impacts to vegetation communities, and possibly special status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the alternative site. Pursuant to mapping conducted by Tetra Tech (2009a), impacts from linear facilities leading to the Proposed Project footprint (and also to the Reduced Acreage Alternative) could affect stabilized and partially stabilized sand dunes, in addition to creosote bush scrub and playa/sand drifts over playa, as well as affecting ephemeral washes, and any of the special status species listed above, but particularly Mojave and/or Colorado fringe-toed lizard. The linear facility impacts would likely be the same as those for the Proposed Project footprint, though overall project impacts would be less as this alternative is a reduced acreage configuration of the Proposed Project footprint.

Western Lands Alternative Site #1. It is expected that the Western Lands Alternative #1 site and all of the vegetation communities on it (i.e., Sonoran creosote bush scrub) as well as any jurisdictional areas (e.g., ephemeral washes) would be permanently lost as a result of vegetation clearing, grading, and construction of the solar facilities.

Pursuant to site surveys and CNDDB records, construction also would affect one special status plant species (Wiggins' cholla), as well as affect seven special status animal species, including loggerhead shrike, American badger, desert kit fox, short-eared owl, northern harrier, desert tortoise, and burrowing owl. A burrowing owl was observed in the southwest corner and an active burrow along the southern boundary, with numerous inactive burrows also noted. Three active desert tortoise burrows also were observed in the western portion of the site.

Four other special status plant species have been observed off site but in the project vicinity, including Harwood's milk-vetch, Harwood's phlox, Las Animas colubrina, and desert unicorn plant. The only special status animal species that has been documented in the overall vicinity is the Mojave and/or Colorado fringe-toed lizard, which is not expected to occur on the site since suitable habitat is not present.

Wildlife movement across the site would be impeded by project development but would not affect overall wildlife movement in the area, as undeveloped BLM lands occur to all sides, and no portion of the alternative site is an identified wildlife corridor.

Additional impacts to vegetation communities, and possibly special status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the alternative site. Information regarding these linear facilities is not available, and estimating the types or extent of the potential impacts from such facilities is outside the scope of services provided by HELIX.

Compared to the Proposed Project footprint, overall project impacts from this alternative would be less to vegetation communities, jurisdictional areas, and special status plant

species. However, impacts to special status animal species would be equal, or in some cases greater, than for the Proposed Project footprint, due to the presence of active burrowing owl and desert tortoise burrows that were not documented on the Proposed Project footprint.

Western Lands Alternative Site #2. It is expected that the Western Lands Alternative #2 site and all of the vegetation communities on it (i.e., Sonoran creosote bush scrub and stabilized and partially stabilized sand dunes) as well as any jurisdictional areas (e.g., ephemeral washes) would be permanently lost as a result of vegetation clearing, grading, and construction of the solar facilities.

Pursuant to site surveys and CNDDB records, construction would not affect any special status plant species, although five plant species documented in the project vicinity could potentially occur on site, including Wiggins' cholla, Harwood's milk-vetch, Harwood's phlox, Las Animas colubrina, and desert unicorn plant. The project also would affect five special status animal species documented on site: desert kit fox, short-eared owl, northern harrier, desert tortoise, and burrowing owl. A burrowing owl was observed in the southwest corner and numerous inactive burrows also were noted. In addition, three active desert tortoise burrows were observed in the central and northwestern portions of the site.

Other special status animal species documented in the project vicinity include loggerhead shrike, American badger, and Mojave and/or Colorado fringe-toed lizard. Potential habitat for the shrike and badger occurs throughout the site, though suitable habitat for the fringed-toed lizards occurs only in the southwestern corner.

Wildlife movement across the site would be impeded by project development but would not affect overall wildlife movement in the area, as undeveloped BLM lands occur to all sides, and no portion of the alternative site is an identified wildlife corridor.

Additional impacts to vegetation communities, and possibly special status species, would occur due to the construction of linear facilities (e.g., transmission lines) associated with a solar project on the alternative site. Information regarding these linear facilities is not available, and estimating the types or extent of the potential impacts from such facilities is outside the scope of services provided by HELIX.

Compared to the Proposed Project footprint, overall project impacts from this alternative would be less to vegetation communities, jurisdictional areas, and special status plant species. However impacts to special status animal species would be equal, or in some cases greater, than for the Proposed Project footprint, due to the presence of active burrowing owl and desert tortoise burrows that were not documented on the Proposed Project footprint.

General Construction Impacts to Wildlife. Any wildlife residing on the Proposed Project or alternative sites would potentially be displaced, injured, or killed during project construction activities. Animal species in the project area could fall into construction trenches, be crushed by construction vehicles or equipment, or be harmed by project

personnel. In addition, construction activities may attract predators or crush animal burrows or nests.

Migratory/Special Status Bird Species Impacts. The Proposed Project and alternative sites provide foraging, cover, and/or breeding habitat for migratory birds, including special status bird species such as the northern harrier. Project construction could impact nesting birds in violation of the Migratory Bird Treaty Act.

Spread of Noxious Weeds. Construction of a solar project at the Proposed Project or alternative sites could result in the introduction and/or dispersal of invasive or exotic weeds. The permanent and temporary earth disturbance adjacent to native habitats increases the potential for exotic, invasive plant species to establish and disperse into native plant communities, which leads to community and habitat degradation.

Excessive Noise. Noise from construction activities on the Proposed Project and alternative sites could temporarily discourage wildlife from foraging and nesting immediately adjacent to the project area. Many bird species rely on vocalization during the breeding season to attract a mate within their territory. Noise levels from certain construction activities could reduce the reproductive success of nesting birds.

7.0 OPERATIONAL IMPACTS

Operation of transmission lines associated with a solar project on the Proposed Project or on the alternative sites could result in increased avian mortality due to collision with the new transmission lines.

8.0 CONCLUSION

Definitive conclusions about the amount of potential adverse impacts to biological resources in the absence of site-specific survey and project design information for the alternative sites cannot be made. However, provided that riparian and other native habitat areas on the Gabrych Alternative site could be avoided, development of a solar project at the Gabrych Alternative site would impact fewer biological resources compared to the Proposed Project footprint because development of the alternative site would occur primarily on agricultural land, whereas development of the Proposed Project site would occur primarily on land supporting native vegetation communities.

Furthermore, while a number of special status plant and animal species have been reported to the CNDDB within five miles of the Gabrych Alternative site, these are primarily associated with the Colorado River as well as riparian areas east of the City of Palo Verde. Burrowing owl, loggerhead shrike, and northern harrier are the special status species most likely to be affected if the agricultural lands were developed. The Proposed Project footprint also may support these same species, in addition to supporting special status plant species (Wiggins' cholla, Harwood's milk-vetch, and desert unicorn plant) and other special status animal species (desert tortoise and kit fox). Due to its location within a larger expanse of native habitat, which also connects to the Palen/McCoy Wilderness Area, the Proposed Project site has greater potential to

support a variety of special status species, such as the American badger and wild burro, which are not expected to occur on the Gabrych Alternative site. If riparian and native habitats were avoided, development of a solar project on the Gabrych Alternative site would have fewer impacts to biological resources than development of a solar project on the Proposed Project site.

If the Gabrych Alternative site is not feasible, selection of one of the reconfigured alternative sites (Reduced Acreage or Western Lands #1 or #2) would result in fewer impacts to biological resources than would occur with the Proposed Project footprint, as less impact would occur to native vegetation communities.

Selection of any of the reconfigured alternatives would result in fewer impacts to jurisdictional areas, though the actual extent of jurisdictional impacts on the Western Lands Alternatives is unknown since a jurisdictional delineation has not been conducted on these two sites.

The Reduced Acreage Alternative would result in impacts to three non-listed special status plant species (Wiggins' cholla, Harwood's milk-vetch, and desert unicorn plant), while the Western Lands Alternative #1 would impact only one special status plant species (Wiggins' cholla), and the Western Lands Alternative #2 would not impact any special status plant species.

The Reduced Acreage Alternative would result in impacts to one listed and two non-listed special status animal species (desert tortoise, burrowing owl, and desert kit fox), while the Western Lands Alternative #1 would impact one listed and six non-listed special status animal species (desert tortoise, loggerhead shrike, American badger, desert kit fox, short-eared owl, northern harrier, and burrowing owl), and the Western Lands Alternative #2 would impact one listed and four non-listed special status animal species (desert tortoise, desert kit fox, short-eared owl, northern harrier, and burrowing owl.

Three active desert tortoise burrows were recorded on the two western lands alternative sites and inactive burrows and old bone fragments were recorded on all three reconfigured sites, though overall use of the three reconfigured alternatives by desert tortoise is expected to be low since little current activity was noted during focused surveys and habitat quality is low. Burrowing owl has equal likelihood of occurring on any of the three sites, though it was documented only on the two western alternatives, and an active burrow was recorded on the Western Alternative #1 site.

Development of a solar project on any of the three reconfigured alternative sites would have fewer biological impacts than development on the larger Proposed Project footprint. However, the amount of biological impacts associated with any of the three reconfigured alternatives are similar, with the Reduced Acreage Alternative possibly resulting in slightly less biological impacts since the one active burrowing owl burrow and three active desert tortoise burrows occurring on the western alternatives would not be impacted.

Appendix A
SENSITIVE SPECIES POTENTIALLY OCCURRING IN THE VICINITY OF THE GENESIS SOLAR PROJECT AND POTENTIAL ALTERNATIVES

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants							
Angel trumpets *(Acleisanthes longiflora)*	Federal – None State – None CNPS List 2.2	Sonoran Desert Scrub generally on limestone, mountains or base of mountains at elevations of 0-2500 m. Blooms April through May.	None – no limestone or rocky habitat; not observed. Two occurrences in CA from 1906 and 1970 at same location at base of Big Maria Mts, north of Blythe; to TX and northern MX.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
Chaparral sand verbena (*Abronia villosa* var. *aurita*)	Federal – None State – None CNPS – 1B.1	Found in chaparral, coastal sage scrub, and desert dunes, loose to aeolian sands at elevations of 80-1600m. Blooms January through September.	Highly unlikely/Not observed	Low. Very little suitable habitat exists on site.	Very low. No suitable habitat exists on site.	Low. Very little suitable habitat exists on site.	Low. Very little suitable habitat exists on site.
Desert sand-parsley (*Ammoselinum giganteum*)	Federal – None State – None CNPS List 2.3	Sonoran Desert, in creosote bush scrub, desert mesa and valley bottoms in open to heavy soils under shrubs 396 m. Herbaceous annual that blooms March through April.	Highly unlikely, but possible. Not observed. Known from one site, near Hayfield Dry Lake at 366 m.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.

SENSITIVE SPECIES POTENTIALLY OCCURRING IN THE VICINITY OF THE GENESIS SOLAR PROJECT AND POTENTIAL ALTERNATIVES

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Small-flowered androstephium (*Androstephium breviflorum*)	Federal – None State – None CNPS List 2.2	Perennial herb, primarily found in open sandy flats and bajadas, often stabilized blowsand, at low to moderate elevations (between 270 and 640m). Blooms in March possiblly through May. Relatively short period of active growth, distribution in California poorly documented.	Would not be expected – all known locations well to north and generally higher; not observed.	Low. Suitable habitat on site, however site elevation likely to low.	Low. Suitable habitat on site, however site elevation likely to low.	Low. Suitable habitat on site, however site elevation likely to low.	Low. Suitable habitat on site, however site elevation likely to low.
Harwood's milkvetch (*Astragalus insularis* var. *harwoodii*)	Federal – None State – None CNPS List 2.2	Sonoran Desert, sandy to gravelly areas 0 to 366 m. Annual that blooms January through May	Observed during surveys	Moderate to high. Suitable habitat exists on site but species was not observed during rare plant surveys.	High. Suitable habitat exists on site.	High. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Coachella Valley milkvetch (*Astragalus lentiginosus* var. *coachellae*)	Federal – Endangered State – None CNPS List 1B.2	Sonoran Desert, in sandy areas growing at elevations of 0 to 350m. Annual or perennial herb that flowers February through May.	Highly unlikely; no known nearby populations (population in Chuckwalla Valley misidentified)/Not observed	Low. No known nearby populations.	Low. No known nearby populations.	Low. No known nearby populations.	Very low. Suitable habitat does not exist on site.

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Ayenia (*Ayenia compacta*)	Federal – None State – None CNPS List 2.3	Sandy and gravelly washes and canyons in desert scrubs, 150 – 1095m. Blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site, but site is just below the low end of the species' elevation range.	Moderate. Suitable habitat exists on site, but site is just below the low end of the species' elevation range.	Moderate. Suitable habitat exists on site, but site is just below the low end of the species' elevation range.	Very low. Suitable habitat does not exist on site.
Pink fairyduster (*Calliandra eriophylla*)	Federal – None State – None CNPS List 2.3	Sonoran Desert, sandy washes, slopes, and mesas typically found at ± 1500m. Shrub <1 foot in height; blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Sand evening primrose (*Camissonia arenaria*)	Federal – None State – None CNPS List 2.2	Sandy washes and rocky slopes below 900 m. Blooms November through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Crucifixion thorn (*Castela emoryi*)	Federal – None State – None CNPS List 2.3	Mojavean and Sonoran desert scrub on dry, gravelly washes, slopes, plains ±650m Shrub <10 feet in height; blooms April through May.	Unlikely/Not observed	Low. Habitat is suitable but site elevation is too low.	Low. Habitat is suitable but site elevation is too low.	Low. Habitat is suitable but site elevation is too low.	Very low. Suitable habitat does not exist on site.

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Abram's spurge (*Chamaesyce abramsiana*)	Federal – None State – None CNPS List 2.2	Sandy sites in Mojavean and Sonoran Desert Scrubs in eastern California; 0 – 915m. Blooms September through November.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Arizona spurge (*Chamaesyce arizonica*)	Federal – None State – None CNPS List 2.3	Sandy flats in Sonoran Desert Scrub below ~ 300m. Blooms March through April.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Flat-seeded spurge (*Chamaesyce platysperma*)	Federal – None State – None CNPS List 2	Sandy flats in Sonoran Desert Scrub below ~ 100m. Blooms February through September.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Las Animas colubrine (*Colubrina californica*)	Federal – None State – None CNPS List 2.3	Sonoran Desert creosote bush scrub <1100m in deeper, well incised washes. Plants are generally <1 m in height; blooms June through July.	Observed north of project area in Zone of Influence surveys	Moderate. Some suitable habitat occurs on site.	Moderate. Some suitable habitat occurs on site.	Moderate. Some suitable habitat occurs on site.	Very low. Suitable habitat does not exist on site.

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Spiny abrojo (*Condalia globosa* var. *pubescens*)	Federal – None State – None CNPS List 4.2	Sonoran Creosote Bush Scrub, 150 to 1000m. Blooms March through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Foxtail cactus (*Coryphantha alversonii*)	Federal – None State – None CNPS List 4.3	Primarily rocky substrates between 75 and 1200m in Creosote Bush Scrub.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Winged cryptantha *(Cryptantha holoptera)*	Federal – None State – None CNPS List 4.3	CNPS: 100-1690 m, Moj. And Son. D. scrubs; Jepson: 100-1200 m in eastern Moj. And Son. D.; sandy to rocky soils; creosote bush scrub San Diego to Inyo Cos., including Los Angeles, San Bernardino, Riverside, and Imperial Cos., toAZ, NV, and Sonora, MX.	Possible, but not observed. CalFlora has 11 Riverside Co. records, 9 Imperial Co. records, and 7 San Bernardino Co. records, none within miles of the Genesis Project. (Note: The NECO Plan stated that there were no records in the NECO Planning Area and there are no nearby records in the CNDDB data base. However, there is a 1992 location near McCoy Spring.)	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Low. Little suitable habitat occurs on site.
Wiggins' cholla (*Cylindropuntia wigginsii*)	Federal – None State – None CNPS List 3.3	Sonoran Creosote Bush Scrub; 30 – 900m. Blooms in March.	Possibly observed during surveys.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.

SENSITIVE SPECIES POTENTIALLY OCCURRING IN THE VICINITY OF THE GENESIS SOLAR PROJECT AND POTENTIAL ALTERNATIVES

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Glandular ditaxis (*Ditaxis claryana*)	Federal – None State – None CNPS List 2.2	Sonoran Desert at elevations <465m in sandy soils in creosote bush scrub Annual or perennial herb; blooms from December through May.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
California ditaxis (*Ditaxis serrata* var. *californica*)	Federal – None State – None CNPS List 3.2	Sonoran creosote bush scrub from 30 – 1000 m. Blooms March through December.	Possible/Not observed	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Harwood's phlox (*Eriastrum harwoodii*)	Federal – None State – None CNPS List 1B.2	Desert slopes below 2200m, eastern Riverside and San Bernardino Counties.	Possibly observed during Zone of Influence surveys; however, now flower to positively ID	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Moderate. Suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Bitter hymenoxys *(Hymenoxys odorata)*	Federal – None State – None CNPS List 2	Sandy flats near the Colorado River. An annual herb producing a branching stem to a maximum height near 60 centimeters. Blooms February to November.	Highly unlikely – known only from the Colorado River alluvial plain; not observed	Very low. Known only from the Colorado River alluvial plain.	Very low. Known only from the Colorado River alluvial plain.	Very low. Known only from the Colorado River alluvial plain.	Moderate. Site is adjacent to the Colorado River and supports some potentially suitable habitat. CNDDB records for this species occur 2.5 miles west, near Palo Verde.

Plants (cont.)							
Pink velvet-mallow (*Horsfordia alata*)	Federal – None State – None CNPS List 4.3	Perennial subshrub, Sonoran Desert at elevations of 100–500 m. in rocky canyons, creosote-bush scrub, washes. Blooms from Mar–Apr, Nov–Dec	None – no rocky habitat on project; not observed	Low to moderate. Suitable habitat (creosote bush scrub) occurs on site, though species was not observed during surveys.	Low to moderate. Suitable habitat (creosote bush scrub) occurs on site.	Low to moderate. Suitable habitat (creosote bush scrub) occurs on site.	Very low. Suitable habitat does not exist on site.
Spearleaf (*Matelea parvifolia*)	Federal – None State – None CNPS List 2.3	Rocky ledges and slopes, 440 to 1095m, in Mojave and Sonoran Desert Scrubs. Blooms March through May.	Unlikely; no habitat/Not observed	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.	Very low. Suitable habitat does not exist on site.
Argus blazing star (*Mentzelia puberla*)	Federal – None State – None CNPS List 2	Perennial herb found on rocky or gravelly sites in creosote bush scrub below 760m. Ord/Chocolate Mountains to AZ and northern Mexico. Blooms from March – May.	Highly unlikely based on habitat and range; not observed.	Low. Outside of known range.	Low. Outside of known range.	Low. Outside of known range.	Very low. Suitable habitat does not exist on site.

SENSITIVE SPECIES POTENTIALLY OCCURRING IN THE VICINITY OF THE GENESIS SOLAR PROJECT AND POTENTIAL ALTERNATIVES

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Slender woolly-heads (*Nemacaulis denudate* var. *gracilis*)	Federal – None State – None CNPS List 2.2	Dunes in coastal and Sonoran Desert scrubs, primarily in the Coachella Valley; below 400m. Blooms April-May.	Possible/Not observed	Low to moderate. A small amount of suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.	Low to moderate. A small amount of suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Lobed ground-cherry (*Physalis lobata*)	Federal – None State – None CNPS List 2.3	Mojave desert scrub (decomposed granite) and playas at elevations of 500-800 m. Blooms September-January.	None – all known locations well to north and at higher elevations than project.	Low. Outside of known elevation and geographic range.	Low. Outside of known elevation and geographic range.	Low. Outside of known elevation and geographic range.	Very low. Suitable habitat does not exist on site and site is outside of known range.
Desert portulaca (*Portulaca halimoides*)	Federal – None State – None CNPS List 4.2	Sandy washes and flats in desert mountains at 1000-1200 m. Blooms in September.	None – No habitat and project elevations too low.	Low. Suitable habitat on site, however elevations likely too low.	Low. Suitable habitat on site, however elevations likely too low.	Low. Suitable habitat on site, however elevations likely too low.	Very low. Suitable habitat does not exist on site and site is outside of known elevation range.
Desert unicorn plant (*Proboscidea althaeifolia*)	Federal – None State – None CNPS - None	Sandy areas in Sonoran Desert Scrub throughout southeastern California, below 1000m. Blooms May-August.	Observed during surveys.	Present on site.	High. Suitable habitat on site.	High. Suitable habitat on site.	Low. Some suitable habitat on site.

Appendix A (cont.)

SPECIES	SENSITIVITY STATUS	HABITAT	POTENTIAL TO OCCUR/ STATUS ON SITE				
			Proposed Project Site*	**Reduced Acreage Alternative**	**Western Lands Alternative #1**	**Western Lands Alternative #2**	**Gabrych Alternative**
Plants (cont.)							
Orocopia sage (*Salvia greatae*)	Federal – None State – None CNPS List 1B.3 BLM	Mojavean and Sonoran Desert Scrub; gravelly/rocky bajadas, mostly near washes; below 825m. Blooms March-April.	Unlikely/Not observed	Low to moderate. Some suitable habitat exists on site.	Low to moderate. Some suitable habitat exists on site.	Low to moderate. Some suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Coves' cassia (*Senna covesii*)	Federal – None State – None CNPS List 2.2	Dry, sandy desert washes, slopes of the Sonoran Desert between 305 to 1070m. Small perennial shrub to 2 feet tall; blooms March-June.	Possible, but elevations may be too low/Not observed	Low. Suitable habitat on site, however elevations likely too low.	Low. Suitable habitat on site, however elevations likely too low.	Low. Suitable habitat on site, however elevations likely too low.	Very low. Suitable habitat does not exist on site.
Mesquite neststraw (*Stylocline sonorensis*)	Federal – None State – None CNPS List 1A	Open sandy drainages; known from one site near Hayfield Spring at 425 m. Blooms in April.	Highly unlikely; not observed	Low to moderate. Some suitable habitat exists on site.	Low to moderate. Some suitable habitat exists on site.	Low to moderate. Some suitable habitat exists on site.	Very low. Suitable habitat does not exist on site.
Dwarf germander (*Teucrium cubense* ssp. *depressum*)	Federal – None State – None CNPS List 2.2	Sandy soils, washes, and fields in the Sonoran Desert below 366m. Annual plants up to 6 inches tall; blooms from March through May	Possible/Not observed	Moderate. Suitable habitat exists on site and CNDDB records for this species occur approximately 4 miles to the southeast.	Moderate. Suitable habitat exists on site and CNDDB records for this species occur approximately 9 miles to the southeast.	Moderate. Suitable habitat exists on site and CNDDB records for this species occur approximately 10 miles to the southeast.	Low. Little suitable habitat occurs on site.

BIOLOGICAL RESOURCES APPENDIX B

Northern and Eastern Colorado Desert Coordinated Management Plan NECO Land Use Plan Amendments

Except for the No Action Alternative, the following proposed Northern and Eastern Colorado Desert Coordinated Management Plan (NECO) amendments would apply to all alternatives.

1. Pinto Basin-Chuckwalla DWMA Tortoise Linkage Area

Approximately 16,135 acres of BLM land surrounding the unused portions of the First Solar Right of Way (ROW) would be designated specifically as the Pinto Basin-Chuckwalla DWMA Tortoise Linkage Area. This area has been identified as an essential linkage between the Chuckwalla and Chemehuevi critical habitat units and would be managed to maintain connectivity for tortoises between the Chuckwalla Desert Wildlife Management Area and the Pinto Basin in Joshua Tree National Park. The eastern portion of this area has been identified as an essential sand transport corridor between the Pinto Basin to the Palen –Ford dry lake/ dune system. Protection of this corridor is critical for the maintenance of the Palen-Ford dune system, which contains habitat for the BLM sensitive Mojave fringe-toed lizard, and other dune dependent species. The Pinto Basin- Chuckwalla DWMA Tortoise Linkage Area would be managed as a right-of-way (ROW) exclusion area with the exception of the existing transmission corridor.

Impact: Designation of the Pinto Basin- Chuckwalla DWMA Tortoise Linkage Area would ensure that the most valuable connectivity habitat for the desert tortoise would be preserved, and that an essential sand transport corridor into the Palen-Ford dune system is maintained. This action would not adversely affect any of the 18 currently proposed solar developments that exist within the NECO land use planning area. With the exception of the transmission corridor, this designation would preclude further development from all major ground disturbing activities. Casual use of the area would be allowed. This area would provide critical long term habitat connectivity between the northern portions of the Chuckwalla DWMA and Joshua Tree National Park with high value tortoise habitat south of Interstate 10.

Protection of this area would have additional significant benefits by offsetting impacts associated with solar development that are currently proposed along Interstate 10 corridor east of Desert Center.

A wide variety of use would still be expected to occur within this area. On a case by case basis, BLM would continue to consider opportunities for casual use activities that may be received from the public requesting permits or other land use authorizations that are non-surface disturbing.

This area contains no private lands and is completely federally owned (BLM).

2. Palen Dunes Solar Exclusion Area

Approximately 33,053 acres of BLM land would be designated as the Palen Dunes Solar Exclusion Area. The area would be managed specifically for maintaining the most essential portion of the Palen Dune system, habitat for the BLM sensitive Mojave fringe-toed lizard and other dune dependent species. This area was originally designated in the NECO Plan as the Palen-Ford Wildlife Habitat Management Area to protect the dunes and playas, which are listed as BLM sensitive habitat types. It would be managed as a ROW exclusion area for solar energy only.

Impact: Approximately 33,053 acres of high value Mojave fringe-toed lizard habitat would be protected within the Palen Dunes Solar Exclusion Area by limiting major surface disturbing activities.

Protection of this area would have additional significant benefits by offsetting impacts associated with solar development that are currently proposed along the Interstate 10 corridor east Desert Center in other Mojave fringe-toed lizard habitat.

A wide variety of use would still be expected to occur within this area. On a case by case basis, BLM would continue to consider opportunities for casual use activities that may be received from the public requesting permits or other land use authorizations that are non-surface disturbing.

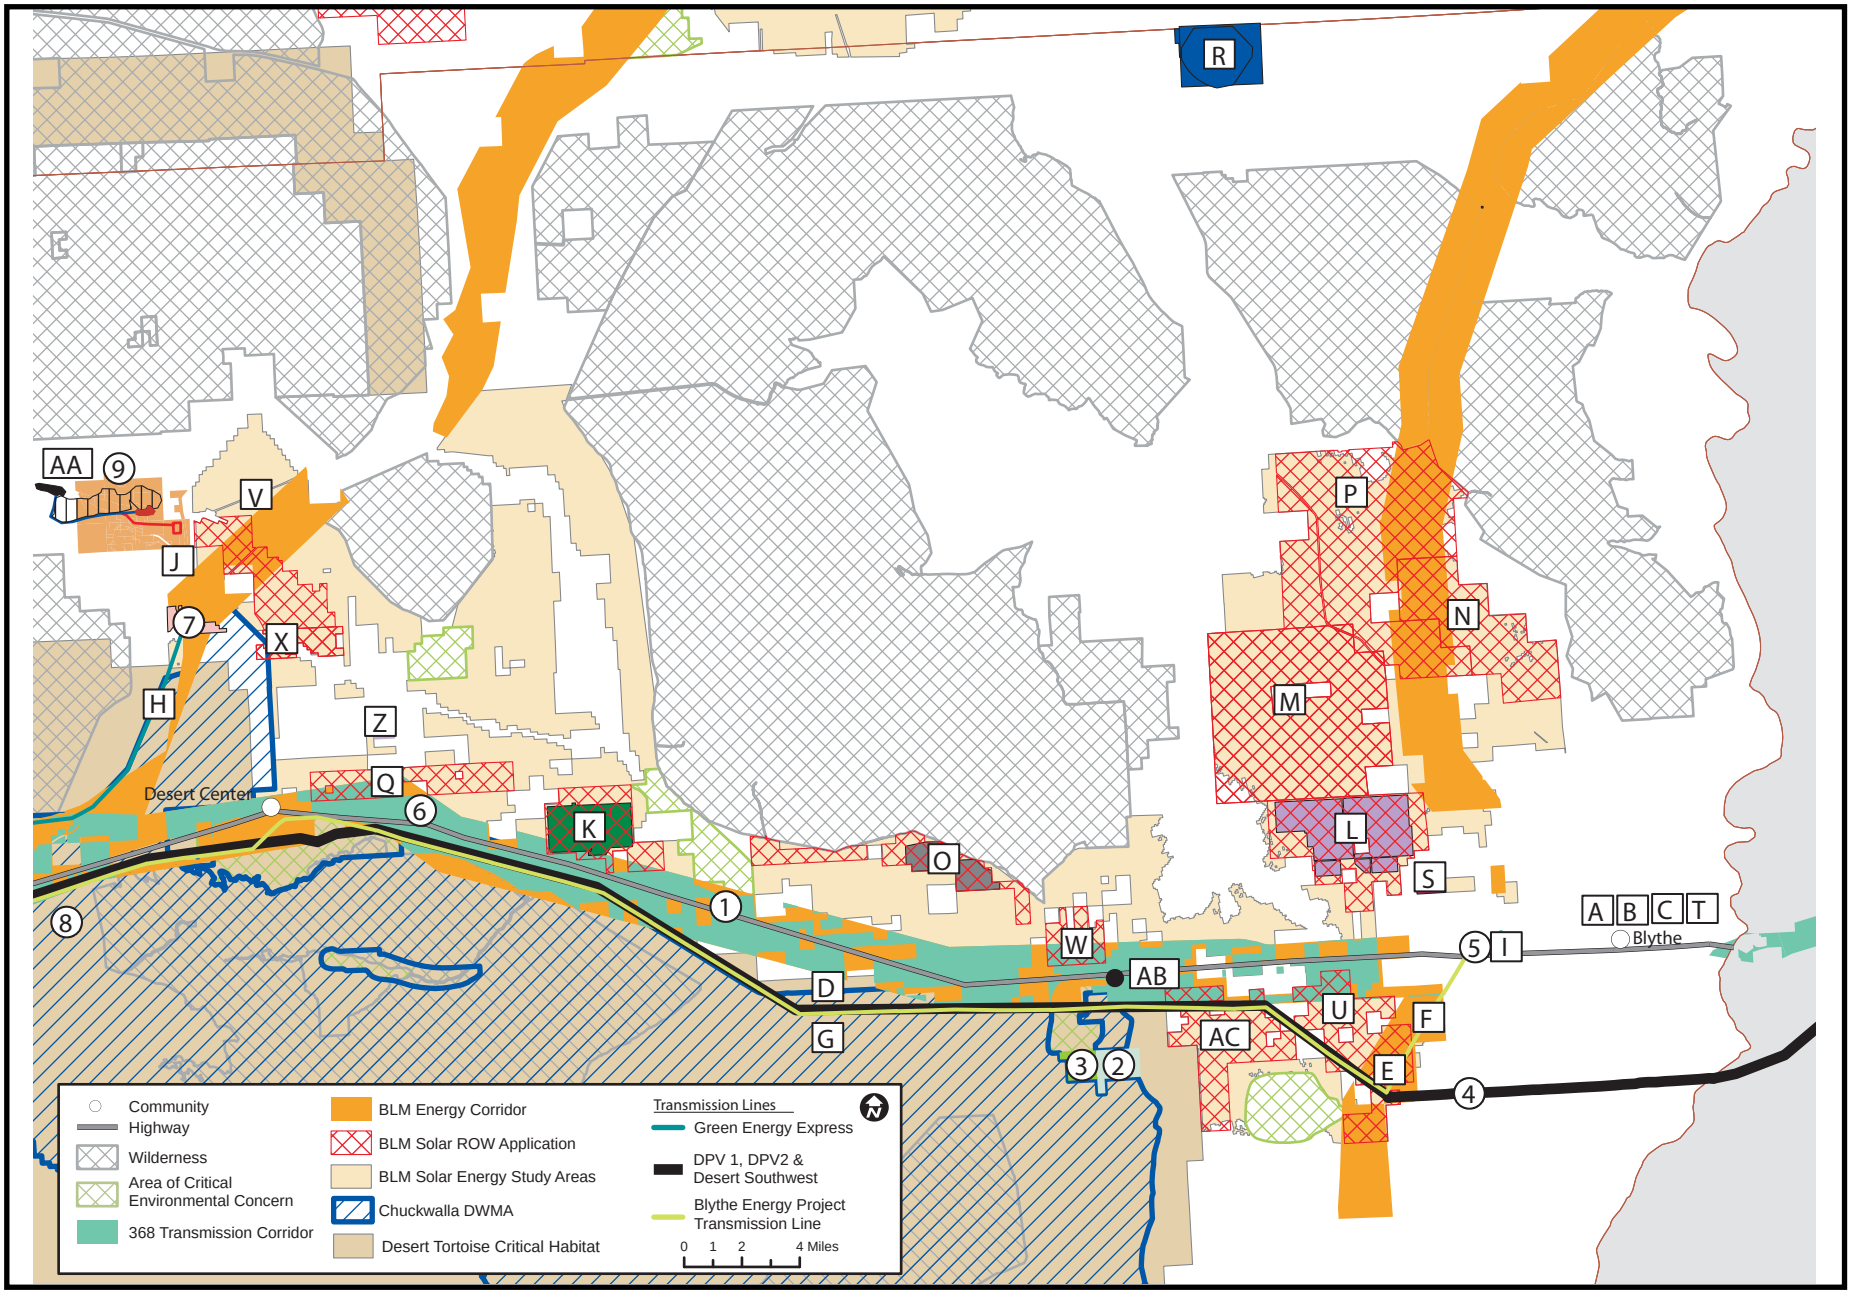
The development, use and enjoyment of private lands would not be affected by this proposed land use planning decision.

3. Palen Wilderness- Chuckwalla DWMA Wildlife Linkage Area

Approximately 16,135 acres of BLM land would be designated as the Palen Wilderness-Chuckwalla DWMA Wildlife Linkage Area. The area would be managed specifically for maintaining wildlife connectivity between the Palen-McCoy Wilderness Area and the Chuckwalla DWMA. This area would be a ROW Exclusion Area for major ground disturbing activities, particularly for solar energy. It encompasses the area between the proposed Solar Millennium Palen and Genesis Ford Dry Lake solar projects, and provides the shortest wildlife linkage between two protected areas (Palen-McCoy Wilderness and Chuckwalla DWMA) along the I-10 corridor east of Desert Center. This area includes the most significant portion of the DWMA Connectivity WHMA designated in the NECO Plan at the suggestion of the US Fish and Wildlife Service to provide connectivity between the Chuckwalla and Chemehuevi desert tortoise critical habitat units. It is the narrowest width of sand dunes in the Palen-Ford dry lake/ sand dune system, presumably to the benefit of movement of the desert tortoise. This area would also protect a significant portion of the Palen-Ford dune system, cultural sites, and

includes the existing 3,621-acre Palen Dry Lake Area of Critical Environmental Concern (ACEC).

Impact: This action would not adversely affect any of the 18 currently proposed solar developments that exist within the NECO land use planning area. Protection of this area would have additional significant benefits by offsetting impacts associated with solar development that are currently proposed along the Interstate 10 corridor east Desert Center in other Mojave fringe-toed lizard habitat and desert tortoise connectivity habitat.



A wide variety of use would still be expected to occur within this area. On a case by case basis, BLM would continue to consider opportunities for casual use activities that may be received from the public requesting permits or other land use authorizations that are non-surface disturbing.

The development, use and enjoyment of private lands would not be affected by this proposed land use planning decision.

Cumulatively, the above planning decisions would provide significant offsets to ongoing solar development along the I-10 corridor. All of the above decisions are in accordance with BLM Land Use Planning Handbook-1601, Resource Management Planning, Appendix C-Program Specific and Resource Decision Guidance, Part II, E. Land and Realty. This part mandates that BLM is required to designate public lands as 10 open to Rights of Way, subject to standard terms and conditions, 2) Right of Way Avoidance Areas, subject to specific land use prescriptions, and 3) Right of Way Exclusion Areas, no further ROW development.

C.3 - CULTURAL RESOURCES AND NATIVE AMERICAN VALUES

Testimony of Elizabeth A. Bagwell and George E. Kline[1]

C.3.1 SUMMARY OF CONCLUSIONS

Staff[2] concludes that the proposed Genesis Solar Energy Project (GSEP) would have a significant direct impact on 14 historically significant archaeological resources and a potential significant indirect impact on 1 ethnographic resource. These resources include eight prehistoric-to-historic-period Native American archaeological sites, two of which are potential contributing elements to the prehistoric cultural landscape herein referred to as the Prehistoric Trails Network (PTN) Cultural Landscape; six sites that are potential contributing elements to a historic-period cultural landscape (historic district), herein referred to as the World War II Desert Training Center California-Arizona Maneuver Area (DTC/C-AMA) Cultural Landscape; and the ethnographic resource referred to herein as McCoy Spring National Register District (McCoy Spring).

The Reduced Acreage Alternative would have a significant direct impact on 7 of the 14 historically significant archaeological resources listed above and a potential significant indirect impact on 1 ethnographic resource. These resources include five prehistoric to historic-period Native American archaeological sites, two of which are potential contributing elements to the PTN Cultural Landscape; two historic sites that are potential contributing elements to the DTC/C-AMA Cultural Landscape; and McCoy Spring National Register District.

The Dry-Cooling Alternative would have significant direct and indirect impacts on the same 15 cultural resources listed above. However, potential indirect impacts on McCoy Spring National Register District may be greater as a result of the increased height of the dry cooling tower.

The three variations of the No Project/No Action Alternative would not impact any cultural resources. However, No Project/No Action Alternative #3, where the Bureau of Land Management (BLM) would make the proposed site unavailable for future solar development, also would ensure that there would be no future impacts to cultural resources.

Staff concludes that the alternative that has the least impact on cultural resources is a No Project/No Action Alternative followed by the Reduced Acreage Alternative. The proposed project and the Dry-Cooling Alternative have nearly identical impacts to cultural resources. However, the impacts to McCoy Spring National Register District have not yet been assessed by local Native American community members (see below).

[1] With contributions by Dwight Simons and Sarah Allred.

[2] "Staff" means BLM and Energy Commission staff, unless otherwise distinguished.

The present analysis seeks to resolve the potentially significant effects of the proposed and alternative actions on cultural resources through the development of measures that satisfy the common conceptual threads of effects resolution in the California Environmental Quality Act (CEQA), National Environmental Policy Act (NEPA), and Section 106 of the National Historic Preservation Act (NHPA). Energy Commission staff here proposes that the Energy Commission fulfill the bulk of its obligations under CEQA to mitigate any potentially significant effects that the proposed or alternative actions may have on cultural resources by making a condition of certification (CUL-1) the applicant's compliance with the terms of a programmatic agreement (PA) under Section 106. The BLM here proposes to use the present cultural resources analysis and its consultation efforts under Section 106, which includes the negotiation and drafting of the PA, to demonstrate its compliance with NEPA. Energy Commission staff also expects to propose additional mitigation measures to provide for the appropriate treatment of cultural resources discovered during construction. The applicant's implementation of the terms of the PA and of the additional conditions of certification would ensure compliance with applicable LORS, as well as CEQA, NEPA, and Section 106.

If the PA is properly implemented, the proposed, the GSEP would result in a less-than-significant impact on known and newly found archaeological resources.

However, the impacts to possible Traditional Cultural Property (TCP)[3] McCoy Spring National Register District have not yet been determined. Staff expects these impacts to be minor as McCoy Spring is relatively distant from the GSEP site. However, these impacts may cause damage that can only be determined by an expert in the behavior, beliefs, and knowledge germane to understanding the property's cultural significance. Only members of the community that value the resource culturally and/or spiritually can determine impacts and suggest possible mitigation. During the consultation with Native Americans that is part of the development process for the GSEP Programmatic Agreement, possible impacts to McCoy Spring would be considered from the perspective of Native Americans, and mitigation measures for these impacts could possibly be devised, based on recommendations by Native Americans. But significant unavoidable impacts that cannot be fully mitigated may be possible. A final determination on this issue would be in the Programmatic Agreement, included in the Staff Supplemental Assessment/Final Environmental Impact Statement (SSA/FEIS), along with mitigation measures, if any.

C.3.2 INTRODUCTION

This cultural resources assessment identifies the potential impacts of the NextEra Genesis Solar Energy Project (GSEP) on cultural resources. Cultural resources are categorized as buildings, sites, structures, objects, and districts under both federal law [for the purposes of the National Environmental Policy Act (NEPA) and the National Historic Preservation Act (NHPA), § 106] and under California state law [for the purposes of the California Environmental Quality Act (CEQA)]. Three kinds of cultural

[3] A Traditional Cultural Property, as described in the regulations for Section 106 of the NHPA, can be a site, structure, district, landscape, or natural feature that has traditional cultural significance, that is, significance based in the role the property plays in a community's historically rooted beliefs, customs, and practices.

resources, classified by their origins, are considered in this assessment: prehistoric, ethnographic, and historic.

Prehistoric archaeological resources are associated with the human occupation and use of California prior to prolonged European contact. These resources may include sites and deposits, structures, artifacts, rock art, trails, and other traces of Native American human behavior. In California, the prehistoric period began over 12,000 years ago and extended through the eighteenth century until 1769, when the first Europeans settled in California.

Ethnographic resources represent the heritage of a particular ethnic or cultural group, such as Native Americans or African, European, Latino, or Asian immigrants. They may include traditional resource-collecting areas, ceremonial sites, value-imbued landscape features, cemeteries, shrines, or ethnic neighborhoods and structures.

Historic-period resources, both archaeological and architectural, are associated with Euro-American exploration and settlement of an area and the beginning of a written historical record. They may include archaeological deposits, sites, structures, traveled ways, artifacts, or other evidence of human activity. Groupings of historic-period resources are also recognized as historic districts and as historic vernacular landscapes. Under federal and state historic preservation law, cultural resources must be at least 50 years old to have sufficient historical importance to merit consideration of eligibility for listing in the National Register of Historic Places (NRHP) or in the California Register of Historical Resources (CRHR). A resource less than 50 years of age must be of exceptional historical importance to be considered for listing.

For the GSEP staff provides an overview of the environmental setting and history of the project vicinity, an inventory of the cultural resources identified in the project vicinity, an analysis of the project's potential impacts to significant cultural resources, and recommendations of measures by which the project's adverse impacts to significant cultural resources may be resolved or mitigated.

C.3.3 GSEP CULTURAL RESOURCES LAWS, ORDINANCES, REGULATIONS, STANDARDS, AND EXECUTIVE ORDERS

Projects licensed by the Energy Commission are reviewed to ensure compliance with all applicable laws. Although the Energy Commission has pre-emptive authority over local laws, it typically ensures compliance with local laws, ordinances, regulations, standards, plans, and policies. For this project, proposed for construction on federally managed public lands, the Energy Commission must assess the project's conformance with federal laws, ordinances, regulations, standards, and executive orders as well.

CULTURAL RESOURCES Table 1
Laws, Ordinances, Regulations, and Standards to Which the GSEP is Subject

Applicable Law	**Description**
Federal	
Antiquities Act of 1906 16 United States Code (USC) 431–433	Establishes criminal penalties for unauthorized destruction or appropriation of "any historic or prehistoric ruin or monument, or any object of antiquity" on federal land; empowers the President to establish historical monuments and landmarks.
Archaeological Resources Protection Act of 1979 (ARPA) 16 USC 470aa et seq.	Protects archaeological resources from vandalism and unauthorized collecting on public and Indian lands.
Native American Graves Protection and Repatriation Act of 1990 (NAGPRA) 25 USC 3001–3013	Provides for the protection of Native American graves, funerary objects, and "objects of cultural patrimony" on federal land; Establishes the procedures for determining ownership for Native American human remains, funerary objects, and other sacred objects under federal jurisdiction.
State	
Public Resources Code (PRC), Section 5097.98(b) and (e)	Requires a landowner on whose property Native American human remains are found to limit further development activity in the vicinity until he/she confers with the Native American Heritage Commission-identified Most Likely Descendents (MLDs) to consider treatment options. In the absence of MLDs or of a treatment acceptable to all parties, the landowner is required to re-inter the remains elsewhere on the property in a location not subject to further disturbance.
PRC, Sections 5097.99 and 5097.991	5097.99 establishes as a felony the acquisition, possession, sale, or dissection with malice or wantonness Native American remains or funerary artifacts. 5097.991 establishes as state policy the repatriation of Native American remains and funerary artifacts.
Health and Safety Code (HSC), Section 7050.5	Makes it a misdemeanor to mutilate, disinter, wantonly disturb, or willfully remove human remains found outside a cemetery; Requires a project owner to halt construction if human remains are discovered and to contact the county coroner.

Applicable Law	Description
Local	
Riverside County General Plan, Multipurpose Open Space Element (Chapter 5), Open Space Policies OS 19.2–19.4	OS 19.2 requires the review of all proposed development for archaeological sensitivity; OS 19.3 Employs procedures to protect the confidentiality and prevent inappropriate public exposure of sensitive archaeological resources when soliciting the assistance of public and volunteer organizations. OS 19.4 Require a Native American Statement as part of the environmental review process on development projects with identified cultural resources.
Riverside County General Plan, Multipurpose Open Space Element (Chapter 5), Open Space Policies OS 19.5–19.7	OS 19.5 allows the History Division of the Riverside County Regional Park and Open-Space District to evaluate large project proposals for their potential preservation or destruction of historic sites; requires projects to provide feasible mitigation for impacts to historic sites prior to county approval. OS 19.6 enforces the California State Historic Building Code so that historic buildings can be preserved and used without posing a hazard to public safety. OS 19.7 endorses the allocation of resources and/or tax credits to prioritize retrofit of historic structures.
Riverside County General Plan, Exhibit A, CEQA Findings of Fact and Statement of Overriding Considerations, Mitigation Monitoring Program, Measures 4.7.1A, 4.7.1B, and 4.7.1C	Outlines mitigation measures for cultural resources monitoring programs.

C.3.4 METHODOLOGY AND THRESHOLDS FOR DETERMINING ENVIRONMENTAL CONSEQUENCES

The purpose of the present cultural resources analysis is to provide evidence of the ongoing public process by which the Energy Commission and the Bureau of Land Management (BLM) are jointly complying with local, state, and federal regulations to which each agency is variously subject. The Energy Commission, pursuant to section 25519, subsection (c) of the Warren-Alquist Act of 1974 (Act), is the lead agency for the

purpose of complying with CEQA in relation to the certification of the proposed facility and the site on which the facility would operate, and is further responsible, pursuant to section 25525 of the Act, for ensuring that the facility would conform with applicable State, local, or regional standards, ordinances, or laws. The BLM is the lead agency for the purpose of complying with NEPA, as the federal government considers the environmental implications of the proposed action, and has further obligations to comply with Section 106 of the National Historic Preservation Act of 1966, as amended (16 USC 470(f)) (NHPA), and other federal historic preservation programs.

The structure of the cultural resources analysis for the proposed action accommodates both the primary need of the Energy Commission to demonstrate under CEQA a consideration of the potential for the proposed project to affect cultural resources and the primary need of the BLM to conduct similar analyses under NEPA and Section 106. (Each of these three regulatory programs uses slightly different terminology to refer to the proposed action. Clarifications on the use of “proposed action,” “proposed project,” and “undertaking” may be found in the “Cultural Resources Glossary” subsection, below.)

The present analysis strives to fulfill the similar goals of CEQA, NEPA, and Section 106 through the implementation of one variant of the basic process that the Energy Commission and the BLM would, under normal circumstances, have chosen to coordinate state and federal cultural resources regulatory compliance. The variant of the basic regulatory process that the Energy Commission and the BLM use for the present analysis is referred to herein as “Approach 3” (see “Alternate Approaches to Coordinated State and Federal Regulatory Compliance” subsection, below). The basic regulatory process is set out in detail below to provide a context for the derivation and use of Approach 3. The basic coordinated regulatory process for cultural resources would normally proceed through five basic analytic phases. These five phases include

1. The determination of the appropriate geographic extent of the analysis for the proposed action and for each alternative action under consideration;

2. The production of a cultural resources inventory for each such geographic area;

3. The development of determinations on the historical significance of the cultural resources in the inventory for each geographic area, unless the construction, operation and maintenance, and decommissioning and closure of the proposed or alternative actions will avoid particular resources;

4. The assessment of the character and the severity of the effects of the proposed or alternative actions on the historically significant cultural resources in each respective inventory that cannot be avoided; and

5. The development of measures that would resolve those effects that are found to be significant.

Further details of each of these phases follow below and help provide the parameters of the present analysis.

C.3.4.1 The Project Area of Analysis and the Area of Potential Effects

A useful precursor to a cultural resources analysis under CEQA and NEPA and a requisite part of the Section 106 process (36 CFR Part 800) is to define the appropriate geographic limits for an analysis. The area that Energy Commission staff typically considers when identifying and assessing impacts to cultural resources under CEQA is referred to here as the "project area of analysis." Energy Commission staff defines the project area of analysis as the area of and surrounding a project site and ancillary linear facility corridors. The area reflects, although does not necessarily equate with, the minimum standards set out in the Energy Commission Power Plant Site Certification Regulations (Cal. Code Regs., tit. 20, § 1701 et seq., app. B, subd. (g)(2)) and is sufficiently large and comprehensive in geographic area to facilitate and encompass considerations of archaeological, ethnographic, and built-environment resources. The project area of analysis is a composite, though not necessarily contiguous, geographic area that accommodates the analysis of each of these resource types:

- For archaeological resources, the project area of analysis is minimally defined as the project site footprint, plus a buffer of 200 feet, and the project linear facilities routes, plus a buffer of 50 feet to either side of the rights-of way for these routes.
- For ethnographic resources, the project area of analysis is expanded to take into account traditional use areas and traditional cultural properties which may be far-ranging, including views that contribute to the significance of the property. These resources are often identified in consultation with Native Americans and other ethnic groups, and issues that are raised by these groups may define the area of analysis.
- For built-environment resources, the project area of analysis is confined to one parcel deep from the project site footprint in urban areas, but in rural areas is expanded to include a half-mile buffer from the project site and above-ground linear facilities to encompass resources whose setting could be adversely affected by industrial development.
- For a historic district or a cultural landscape, staff defines the project area of analysis based on the particulars of each siting case (i.e. specific to that project).

The BLM concludes here that the project area of analysis concept provides an appropriate areal scope for the consideration of cultural resources under NEPA and is consistent with the definition of the area of potential effects (APE) in the Section 106 process (36 CFR § 800.16(d)). The project area of analysis will, therefore, be equivalent to the APE for the purpose of the present discussion and the present analysis.

C.3.4.2 Inventory of Cultural Resources in the Project Area of Analysis

A cultural resources inventory specific to each proposed or alternative action under consideration is a necessary step in any staff effort to determine whether each such action may cause, under CEQA, a substantial adverse change in the significance of any cultural resources that are on or would qualify for the California Register of Historical Resources (CRHR), may, under NEPA, significantly affect important historic and cultural aspects of our national heritage, or may, under Section 106, adversely affect any

cultural resources that are on or would qualify for the National Register of Historic Places (NRHP).

The development of a cultural resources inventory entails working through a sequence of investigatory phases to establish the universe of cultural resources that will be the focus of the analyses of each proposed or alternative action. Generally the research process proceeds from the known to the unknown. These phases typically involve doing background research to identify known cultural resources, conducting fieldwork to collect requisite primary data on not-yet-identified cultural resources in the vicinity of an action, and assessing the results of any geotechnical studies or environmental assessments completed for a project site. The results of this research then support, in part, the development of determinations of historical significance for the cultural resources that are found.

C.3.4.3. Determining the Historical Significance of Cultural Resources

A key part of any cultural resources analysis under CEQA, NEPA, or Section 106 is to determine which of the cultural resources that a proposed or alternative action may affect, are important or historically significant (each of these three regulatory programs uses slightly different terminology to refer to historically significant cultural resources; clarifications on the use of the terms “historical resource,” “important historic and cultural aspects of our national heritage,” and “historic property” may be found in the “Cultural Resources Glossary” subsection, of this report). Subsequent effects assessments are only made for those cultural resources that are determined to be historically significant. Cultural resources that can be avoided by construction may remain unevaluated. Unevaluated cultural resources that cannot be avoided are treated as eligible when determining effects. The criteria for evaluation and the requisite thresholds of resource integrity that are, taken together, the measures of historical significance, vary among the three regulatory programs.

C.3.4.3.1. Evaluation of Historical Significance Under CEQA

CEQA requires the Energy Commission, as a lead agency, to evaluate the historical significance of cultural resources by determining whether they meet certain criteria. Under CEQA, the definition of a historically significant cultural resource is that it is eligible for listing in the CRHR, and such a cultural resource is referred to as a “historical resource,” which is a “resource listed in, or determined to be eligible by the State Historical Resources Commission, for listing in the CRHR”, or “a resource listed in a local register of historical resources or identified as significant in a historical resource survey meeting the requirements of section 5024.1(g) of the Public Resources Code,” or “any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California, provided the agency’s determination is supported by substantial evidence in light of the whole record” (Cal. Code Regs., tit. 14, § 15064.5(a)). The term, “historical resource,” therefore, indicates a cultural resource that is historically significant and eligible for listing in the CRHR.

Consequently, under the CEQA Guidelines, to be historically significant, a cultural resource must meet the criteria for listing in the CRHR. These criteria are essentially the same as the eligibility criteria for the NRHP. In addition to being at least 50 years old, a resource must meet at least one (and may meet more than one) of the following four criteria (Pub. Resources Code, § 5024.1):

- Criterion 1, is associated with events that have made a significant contribution to the broad patterns of our history;
- Criterion 2, is associated with the lives of persons significant in our past;
- Criterion 3, embodies the distinctive characteristics of a type, period, or method of construction, or represents the work of a master, or possesses high artistic values; or
- Criterion 4, has yielded, or may be likely to yield, information important to history or prehistory.

In addition, historical resources must also possess integrity of location, design, setting, materials, workmanship, feeling, and association (Cal. Code Regs., tit. 14, § 4852(c)).

Additionally, cultural resources listed in or formally determined eligible for the National Register of Historical Places (NRHP) and California Registered Historical Landmarks numbered No. 770 and up are automatically listed in the CRHR and are therefore also historical resources (Pub. Resources Code, § 5024.1(d)). Even if a cultural resource is not listed or determined to be eligible for listing in the CRHR, CEQA allows a lead agency to make a determination as to whether it is a historical resource (Pub. Resources Code, § 21084.1).

C.3.4.3.2. Evaluation of Historical Significance Under NEPA

NEPA establishes national policy for the protection and enhancement of the environment. Part of the function of the federal government in protecting the environment is to “preserve important historic, cultural, and natural aspects of our national heritage.” Cultural resources need not be determined eligible for the NRHP, as in the Section 106 process, to receive consideration under NEPA. NEPA is implemented by the regulations of the Council on Environmental Quality, 40 CFR 1500-1508. NEPA provides for public participation in the consideration of cultural resources issues, among other issues, during agency decisionmaking.

C.3.4.3.3. Evaluation of Historical Significance Under Section 106

The federal government has developed laws and regulations designed to protect cultural resources that may be affected by actions undertaken, regulated, or funded by federal agencies. Cultural resources are considered during federal undertakings chiefly under Section 106 of the NHPA through its implementing regulations, 36 CFR Part 800). Properties of traditional, religious, and cultural importance to Native Americans are considered under Section 101(d)(6)(A) of the NHPA.

The Section 106 process requires federal agencies to consider the effects of their undertakings on any district, site, building, structure, or object that is included in or eligible for inclusion in the NRHP and to afford the Advisory Council on Historic

Preservation (ACHP) a reasonable opportunity to comment on such undertakings (36 CFR § 800.1). Significant cultural resources (historic properties) are those resources, districts, sites, buildings, structures, or objects, that are listed in or are eligible for listing on the NRHP per the criteria listed at 36 CFR § 60.4 and presented below.

Per National Park Service (NPS) regulations, 36 CFR § 60.4, and guidance published by the NPS, National Register Bulletin, Number 15, *How to Apply the National Register Criteria for Evaluation*, different types of values embodied in districts, sites, buildings, structures, and objects are recognized. These values fall into the following categories:

- Associate Value (Criteria A and B): Properties significant for their association with or linkage to events (Criterion A) or persons (Criterion B) important in our past.
- Design or Construction Value (Criterion C): Properties significant as representatives of the man-made expression of culture or technology.
- Information Value (Criterion D): Properties significant for their ability to yield important information about prehistory or history.

The quality of significance in American history, architecture, archaeology, engineering and culture is present in districts, sites, buildings, structures, and objects that possess integrity of location, design, setting, materials, workmanship, feeling and association. Cultural resources that are determined eligible for listing in the NRHP, along with SHPO concurrence, are termed “historic properties” under Section 106, and are afforded the same protection as sites listed in the NRHP.

C.3.4.4. Assessing Action Effects

The core of a cultural resources analysis under CEQA, NEPA, or Section 106 is the assessment of the character of the effects that a proposed or alternative action may have on historically significant cultural resources. The analysis takes into account three primary types of potential effects which each of the three above regulatory programs defines and handles in slightly different ways. The three types of potential effects include direct, indirect, and cumulative effects. Once the character of each potential effect of a proposed or alternative action has been assessed, a further assessment is made as to whether each such effect is significant, relative to specific regulatory criteria under CEQA, NEPA, and Section 106.

C.3.4.4.1. Direct and Indirect Effects

Direct and indirect effects are those that are more clearly and immediately attributable to the implementation of proposed or alternative actions. Direct and indirect effects are conceptually similar under CEQA and NEPA. The uses of the concepts vary under Section 106 relative to their uses under CEQA and NEPA.

C.3.4.4.1.1. Direct and Indirect Impacts Under CEQA

In the abstract, direct impacts to cultural resources are those associated with project development, construction, and co-existence. Construction usually entails surface and subsurface disturbance of the ground, and direct impacts to archaeological resources may result from the immediate disturbance of the deposits, whether from vegetation removal, vehicle travel over the surface, earth-moving activities, excavation, or

demolition of overlying structures. Construction can have direct impacts on historic built-environment resources when those structures must be removed to make way for new structures or when the vibrations of construction impair the stability of historic structures nearby. New structures can have direct impacts on historic structures when the new structures are stylistically incompatible with their neighbors and the setting, and when the new structures produce something harmful to the materials or structural integrity of the historic structures, such as emissions or vibrations.

Generally speaking, indirect impacts to archaeological resources are those which may result from increased erosion due to site clearance and preparation, or from inadvertent damage or outright vandalism to exposed resource components due to improved accessibility. Similarly, historic structures can suffer indirect impacts when project construction creates improved accessibility and vandalism or greater weather exposure becomes possible.

Ground disturbance accompanying construction at a proposed plant site, along proposed linear facilities, and at a proposed laydown area has the potential to directly impact archaeological resources, unidentified at this time. The potential direct, physical impacts of the proposed construction on unknown archaeological resources are commensurate with the extent of ground disturbance entailed in the particular mode of construction. This varies with each component of the proposed project. Placing the proposed plant into this particular setting could have a direct impact on the integrity of association, setting, and feeling of nearby standing historic structures.

C.3.4.4.1.2. Direct and Indirect Effects Under NEPA

The concepts of direct and indirect effects under NEPA are almost equivalent to those under CEQA. Direct effects under NEPA are those “which are caused by the [proposed or alternative] action and [which] occur at the same time and place” (40 CFR § 1508.8(a)). Indirect effects are those “which are caused by the [proposed or alternative] action and are later in time or farther removed in distance, but are still reasonably foreseeable” (40 CFR § 1508.8(b)).

C.3.4.4.1.3. Direct and Indirect Effects Under Section 106

The Section 106 regulation narrows the range of direct effects and broadens the range of indirect effects relative to the definitions of the same terms under CEQA and NEPA. The regulatory definition of “effect,” pursuant to 36 CFR § 800.16(i), is that the term “means alteration to the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.” In practice, a “direct effect” under Section 106 is limited to the direct physical disturbance of a historic property. Effects that are immediate but not physical in character, such as visual intrusion, and reasonably foreseeable effects that may occur at some point subsequent to the implementation of the proposed undertaking are referred to in the Section 106 process as “indirect effects.”

C.3.4.4.2. Cumulative Impacts

Cumulative Impacts are slightly different concepts under CEQA and NEPA, and are, under Section 106, undifferentiated as an aspect of the potential effects of an undertaking, of a proposed or alternative action. The consideration of cumulative

impacts reaches beyond the project area of analysis or the area of potential effects. It is a consideration of how the effects of a proposed or alternative action in those areas contributes or does not contribute to the degradation of a resource group or groups that is or are common to the project area of analysis and the surrounding area or vicinity.

C.3.4.4.2.1. Cumulative Impacts Under CEQA

A cumulative impact under CEQA refers to a proposed project's incremental effects considered over time and taken together with those of other, nearby, past, present, and reasonably foreseeable future projects whose impacts may compound or increase the incremental effect of the proposed project (Pub. Resources Code sec. 21083; Cal. Code Regs., tit. 14, secs. 15064(h), 15065(a)(3), 15130, and 15355). Cumulative impacts to cultural resources in a project vicinity could occur if any other existing or proposed projects, in conjunction with the proposed project, had or would have impacts on cultural resources that, considered together, would be significant. The previous ground disturbance from prior projects and the ground disturbance related to the future construction of a proposed project and other proposed projects in the vicinity could have a cumulatively considerable effect on archaeological deposits, both prehistoric and historic. The alteration of the natural or cultural setting which could be caused by the construction and operation of a proposed project and other proposed projects in the vicinity could be cumulatively considerable, but may or may not be a significant impact to cultural resources.

C.3.4.4.2.2. Cumulative Impacts Under NEPA

Under NEPA, a cumulative is the “impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or non-federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time” (40 CFR § 1508.7). Cumulatively significant impacts are taken into consideration as an aspect of the intensity of a significant effect (40 CFR § 1508.27(b)(7).

C.3.4.4.2.3. Cumulative Effects Under Section 106

The Section 106 regulation makes explicit reference to cumulative effects only in the context of a discussion of the criteria of adverse effect (36 CFR § 800.5(a)(1)). Cumulative effects are largely undifferentiated as an aspect of the potential effects of an undertaking. Such effects are enumerated and resolved in conjunction with the consideration of direct and indirect effects.

C.3.4.5. Assessing the Significance of Action Effects

Once the character of the effects that proposed or alternative actions may have on historically significant cultural resources has been determined, the severity of those effects needs to be assessed. CEQA, NEPA, and Section 106 each have different definitions and tests that factor into decisions about how severe, how significant the effects of particular actions may be.

C.3.4.5.1. Significant Impacts Under CEQA

Under CEQA, “a project that may cause a substantial adverse change in the significance of an historical resource is a project that may have a significant effect on the environment” (Pub. Resourced Code, § 21084.1). Thus, staff analyzes whether a proposed project would cause a substantial adverse change in the significance, that is, the CRHR eligibility, of the subset of the historical resources in the cultural resources inventory for a project area that the proposed project demonstrably has the potential to effect. The degree of significance of an impact depends on:

- The cultural resource impacted;
- The nature of the resource’s historical significance;
- How the resource’s historical significance is manifested physically and perceptually;
- Appraisals of those aspects of the resource’s integrity that figure importantly in the manifestation of the resource’s historical significance; and how much the impact will change those integrity appraisals.

C.3.4.5.2. Significant Effects Under NEPA

Significant effects under NEPA require considerations of both context and intensity (40 CFR § 1508.27). These considerations are:

a. Context. This means that the significance of an action must be analyzed in several contexts such as society as a whole (human, national), the affected region, the affected interests, and the locality. Significance varies with the setting of the proposed action. For instance, in the case of a site-specific action, significance would usually depend upon the effects in the locale rather than in the world as a whole. Both short- and long-term effects are relevant.

b. Intensity. This refers to the severity of impact. Responsible officials must bear in mind that more than one agency may make decisions about partial aspects of a major action. The following should be considered in evaluating intensity:

    1. Impacts that may be both beneficial and adverse. A significant effect may exist even if the federal agency believes that on balance the effect will be beneficial.

    2. Unique characteristics of the geographic area such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas.

    3. The degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration.

    4. Whether the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.

5. The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural, or historical resources.

6. Whether the action threatens a violation of federal, state, or local law or requirements imposed for the protection of the environment.

C.3.4.5.3. Adverse Effects Under Section 106

In accordance with 36 CFR § 800.5 of the ACHP's implementing regulations, which describes criteria for adverse effects, impacts on cultural resources are considered significant if one or more of the following conditions would result from implementation of the proposed action:

a. An undertaking has an effect on a historic property when the undertaking may alter characteristics of the property that may qualify the property for inclusion in the NRHP. For the purpose of determining the type of effect, alteration to features of a property's location, setting, or use may be relevant, depending on the property's significant characteristics, and should be considered.

b. An undertaking is considered to have an adverse effect when the effect on a historic property may diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Adverse effects on historic properties include, but are not limited to:

   1. Physical destruction, damage, or alteration of all or part of the property

   2. Isolation of the property from or alteration of the character of the property's setting when that character contributes to the property's qualification for the NRHP

   3. Introduction of visual, audible, or atmospheric elements that are out of character with the property or that alter its setting

   4. Neglect of the property, resulting in its deterioration or destruction

   5. Transfer, lease, or sale of the property

Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative. A formal effect finding under Section 106 relates to the proposed or alternative action as a whole rather than relating to individual resources.

C.3.4.6. Resolving Significant Effects

The concluding phase in a cultural resources analysis, whether under CEQA, NEPA, or Section 106, is to resolve those effects of a proposed or alternative action that have

been found to be significant or adverse. The terminology used to describe the process of effects resolution differs among the three regulatory programs. The resolution of significant effects under CEQA involves the development of mitigation measures the implementation of which would minimize any such effects (14 CCR § 15126.4). Mitigation under NEPA includes proposals that avoid or minimize any potential significant effects of a proposed or alternative action on the quality of the human environment (40 CFR § 1502.4). The definition of mitigation in the NEPA regulation includes the development of measures that would avoid, minimize, or rectify significant effects, progressively reduce or eliminate such effects over time, or provide compensation for such effects (40 CFR § 1508.20). The Section 106 process directs the resolution of adverse effects through the development of proposals to avoid, minimize, or otherwise mitigate such effects (36 CFR § 800.6(a)).

The present analysis seeks to resolve the potentially significant effects of proposed and alternative actions on significant cultural resources (i.e. historical resources/historic properties) through the development of measures that satisfy the common conceptual threads of effects resolution in CEQA, NEPA, and Section 106. Energy Commission staff here proposes that the Energy Commission fulfill the bulk of its obligation under CEQA to resolve any potentially significant effects that the proposed or alternative actions may have on cultural resources by making the applicant's compliance with the terms of the BLM's programmatic agreement (PA) under Section 106 a condition of certification (CUL-1). The BLM here proposes to use the present cultural resources analysis and its consultation efforts under Section 106, which includes the negotiation and drafting of the PA, to evidence its compliance with NEPA. The applicant's implementation of the terms of the PA would ensure compliance with applicable laws, ordinances, regulations, and standards (LORS), in addition to compliance with CEQA, NEPA, and Section 106.

C.3.4.7. Alternate Approaches to Coordinated State and Federal Regulatory Compliance

State and federal agencies have the latitude to develop any number of alternate approaches to the above basic coordinated regulatory process for cultural resources compliance. Energy Commission staff, in consultation with BLM staff, proposed three alternate approaches to cultural resources regulatory compliance for the proposed and alternative actions (Approaches 1–3), and asked the applicant to choose which of the three approaches the applicant would like to implement. The applicant chose Approach 3. Each of the three approaches is described below. The use of both Approaches 2 and 3 require a further consultation process to develop and execute a Section 106 agreement document. That process is described subsequent to the descriptions of the three approaches.

C.3.4.7.1. Approach 1

Approach 1 would typically cover solar thermal projects that encompass a modest number (< 75) of cultural resources. Under this approach, the Energy Commission and the BLM would normally try to conclude all investigations necessary to identify, evaluate the historical significance of, and assess the reasonably foreseeable and particular effects to the cultural resources in a project area of analysis prior to the Energy Commission's or the BLM's respective decisions on such projects. Where historically

significant cultural resources are affected, the conclusion of these investigations prior to agency decisions facilitates the development of more refined measures to reduce significant project effects, which, in turn, reduces post-decision delays to construction start-up, reduces redirection or stoppage of work during construction, and can substantially reduce the overall cost of cultural resources compliance. federal agency responsibility under Section 106 of the NHPA to reduce any significant project effects is typically accomplished through the execution of a memorandum of agreement (MOA) that is the result of consultation among the California State Historic Preservation Officer (SHPO), the ACHP, and other consulting parties.

C.3.4.7.2. Approach 2

Approach 2 accommodates solar thermal power projects that encompass a large number (> 75) of cultural resources. Energy Commission and BLM staff, under this approach, draft the joint NEPA and CEQA analysis for cultural resources on the basis of a relatively large (≥ 25%) and reliable sample of the cultural resources inventory in a project area of analysis, and ensure the thorough consideration and treatment of all of the resources in that inventory through the negotiation and execution of a programmatic agreement (PA) pursuant to the Section 106 regulatory process. Staff subsequently incorporates the PA into the joint analysis by reference. The implementation of a PA under the Section 106 process facilitates cultural resources compliance under both NEPA and CEQA for large and complex projects by helping to reduce the effort, time, and cost to gather information prior to a decision. The use of a PA allows for modifications in the scheduling of efforts to identify and evaluate the historical significance of the total complement of cultural resources in a project area of analysis. Such modifications in schedule can substantially reduce the scope of the effort and the time necessary to gather cultural resources information prior to a decision and, consequently, the pre-decision cost of cultural resources compliance. The major drawback to the second approach is that it may result in significant post-decision delays in construction start-up as most of the cultural resources investigations that, under the first approach, would have been done prior to the decision would, instead, be done after the decision. The overall cost of cultural resources compliance under either the first or second approach, on the basis of cost per cultural resource, is approximately the same, and the applicant may also enjoy comparable reductions in construction monitoring obligations.

C.3.4.7.3. Approach 3

Approach 3 handles cultural resources that are known prior to construction differently from those that are discovered during construction. Prior to construction, the Approach 3 would streamline the time necessary to produce the joint cultural resources analyses under NEPA and CEQA by foregoing potentially lengthy investigations to evaluate the historical significance of the cultural resources found on the surface of a project area of analysis, and, instead, addressing those cultural resources that are demonstrably subject to project effects, as though they were historically significant. Energy Commission and BLM staff would, prior to any decision, study the results of the cultural resources pedestrian survey, identify those cultural resources on the surface of the project area of analysis that would be subject to project effects, assume that all surface cultural resources are historically significant, and then develop measures to reduce project effects to those surface resources to less than significant through the use of a

phased treatment plan. Staff would ensure the thorough consideration and treatment of all of the surface resources through the negotiation and execution of a PA pursuant to the section 106 regulatory process, which staff would subsequently incorporate, by reference, into the joint analysis. The primary benefit of the proposed approach is that, depending on the nature of the cultural resources and the potential character of resulting project effects, it has the potential to substantively reduce both the amount of time necessary to gather information for the cultural resources analysis and the amount of time necessary to draft the actual analysis. This approach, however, has the real potential to result in post-decision delays in construction start-up, increases in requisite construction monitoring, and cost. Contrary to the regulatory review process under either Approaches 1 or 2, every cultural resource in a project area of analysis known prior to the onset of construction, many of which may have otherwise been found not to be historically significant, would, under Approach 3, be subject to potentially costly post-decision and pre-construction data recovery investigation. The only exceptions would be those cultural resources that staff could demonstrate that the proposed project would not affect or those resources which staff could determine were not historically significant on the basis of extant information.

Due to the absence of the finer resolution data that Approaches 1 and 2 provide, Energy Commission and BLM staff would be unable, under Approach 3, to tailor a unique construction monitoring protocol for the proposed or alternative actions. As a consequence, construction monitoring could become requisite across the entirety of the ultimate project area, and each discovery of a new archaeological deposit, during construction, would have to be dealt with on an individual basis. Each new construction discovery would be subject to an evaluation of historical significance and resources thought to be historically significant would then be subject to data recovery investigation as construction progressed. Potential increases in the overall number of requisite data recovery investigations, both for surface cultural resources known prior to construction and for new resources found during construction, in the extent and duration of construction monitoring, and in construction discovery events may cause greater construction delays and result in higher overall costs for cultural resources compliance.

C.3.4.7.4. Programmatic Agreement (PA)

The use of Approaches 2 and 3 require the development and execution of a PA under Section 106. In accordance with 36 CFR § 800.14(b), PAs are used for the resolution of adverse effects for complex project situations and when effects on historic properties, resources eligible for or listed in the NRHP, cannot be fully determined prior to approval of an undertaking. The BLM will prepare a PA in consultation with the ACHP, the SHPO, the Energy Commission, interested Native American groups, and the public at large (including tribal governments as part of government to government consultation). The PA will govern the conclusion of the identification and evaluation of historic properties (eligible for the NRHP) and historical resources (eligible for the CRHR), as well as the resolution of any significant effects that may result from the proposed or alternative actions. Historic properties and historical resources are significant prehistoric and historic cultural resources as determined by Energy Commission and BLM staff.

As a result of the anticipated significant effects of the proposed action on cultural resources and the large geographic area in the APE, a PA with the BLM, other federal

agencies, the Energy Commission, the SHPO, interested Native American tribes (government to government consultation), and the public at large is necessary. Treatment plans regarding historic properties and historical resources that cannot be avoided by project construction will be developed in consultation with stakeholders, as stipulated in the PA. When the PA is executed and fully implemented, the project will have fulfilled the requirements of CEQA, NEPA, and Section 106 of the NHPA.

The BLM is presently in the process of initiating formal consultation with the ACHP, the SHPO, Energy Commission staff, Native American groups, and the public at large on the development of a PA for the proposed action. BLM and Energy Commission staff anticipates that the draft PA would be available for public comment concurrent with the publication of the supplemental staff assessment and final environmental impact statement, presently anticipated to occur in July, 2010. Comments on the draft PA would be incorporated into the final version of the document which would be executed no later than the BLM's signature of the Record of Decision for the Right-of-Way grant for the action.

C.3.5. PROPOSED PROJECT

C.3.5.1. Setting and Existing Conditions

Information provided regarding the setting of the proposed project places it in its geographical and geological context and specifies the technical description of the project. Additionally, the prehistoric, ethnographic, and historical background provides the context for the evaluation of the NRHP and CRHR eligibility of any identified cultural resources within staff's area of analysis for this project.

C.3.5.1.1. Regional Setting

The proposed GSEP site is located in eastern Riverside County within the central Chuckwalla Valley, an east-southeast-trending valley in California's Mojave Desert Geomorphic Province. This province is characterized by east-west-trending ranges separated by desert valleys with enclosed drainages and dry lakes. The project area of analysis is surrounded by the Palen Mountains to the north, the McCoy Mountains to the northeast, the Little Chuckwalla Mountains to the south, and the Chuckwalla Mountains to the west. The Chuckwalla Valley is a relatively stable tectonic region located between the seismically active Salton Trough to the west and southwest, and the Garlock Fault to the north. The nearest active seismic features, the San Andreas Fault and the Brawley Seismic Zone, are located approximately 47 miles to the southwest (GSEP 2009a, p. 5.5-2). The elevation of Chuckwalla Valley ranges from under 400 feet at its lowest point to approximately 1,800 feet along the valley flanks. The surrounding mountains reach between 3,000 and 5,000 feet in elevation (GSEP 2009a, p. 5.4-1). The project region is relatively flat and generally slopes from north to south with elevations of approximately 400 to 370 feet (GSEP 2009a, p. 3-3).

Physiographically, the project vicinity lies near the toe of alluvial fans which emanate from the Palen Mountains to the north and the McCoy Mountains to the east. The eastern portion of the project site footprint is underlain by a broad, valley-axial drainage that extends southward between these mountains and drains to the Ford Dry Lake playa about one mile south of the project site footprint (GSEP 2009a, p. 3-3). This area

receives an average of 5 inches of rain per year. Rather than forming major drainages, rains create sheet wash which eventually reaches the lake bed, but more commonly is absorbed into the ground water (GSEP 2009a, 5.4-3).The site is located near the transition between the Mojave and Colorado Deserts. The dryer Mojave Desert is characterized by Joshua Tree woodland interspersed with creosote bush and white bursage. The more summer-wet climate of the Colorado Desert is also characterized by creosote bush and white bursage but in addition can support such trees as palo verde, ironwood, and ocotillo (West et al. 2007, p. 30). The project vicinity has two main vegetation types: Sonoran creosote bush scrub and stabilized and partially stabilized sand dunes (GSEP 2009a, p. 5.3-1).

The desert environment supports a variety of animals depending on the amount and source of water available. Small mammals, birds and reptiles are the most common in the proposed project vicinity. Some of the mammals in the region include rodents especially rabbits, ground squirrels, gophers, mice, and Kangaroo Rats. Larger mammals are not as common but might include mule deer, Bighorn sheep, and Pronghorn antelope. Among the carnivores, Coyote, Kit Fox, American Badger, Bobcat, and Mountain Lions have been noted. Common reptiles noted in the area include snakes, chuckwalla, Desert Iguana, Mojave Fringe-toed lizard, and the Desert Tortoise. Among the birds hawks, quail, doves, burrowing owls, songbirds, and migrating waterfowl are relatively common.

The project site footprint and linear facilities corridor land is owned and managed by the Bureau of Land Management (BLM) as part of the Big Maria Colorado Desert Planning Unit. Other units include: Imperial, Santa Rosa, Orocopia, Twenty-nine Palms, Bristol/Cadiz, Palen, Turtle Mountain Whipple Mountain, Big Maria and Picacho. The Big Maria Unit is managed as part of an amendment to the 25-million-acre California Desert Conservation Area (CDCA)—the Northern and Eastern Colorado Desert Coordinated Management (NECO) Plan—which encompasses 5.5 million acres in the southeastern California Desert (GSEP 2009a, p. 5.3-1). Under BLM's Multiple Use Classification system, the project site footprint and linear facilities corridor lies in Class M (Moderate Use) lands. These lands are managed to provide a variety of uses such as mining, livestock grazing, recreation, utilities, and energy development. Nearby BLM-managed lands with more sensitive classifications include the Palen-McCoy Wilderness, immediately to the north of the project site footprint and the Palen Dry Lake Area of Critical Environmental Concern (ACEC), designated to protect prehistoric cultural resources, adjacent to the southwest corner of the project site footprint.

The Chuckwalla Valley is primarily undeveloped. Historically, its main role has been as an important trade and transportation route between the Pacific coast and the Colorado River. Other uses of the valley include mining, ranching, military training, and recreation. The project site footprint itself has recently been used for off-road vehicle races and sheep grazing, but neither activity currently takes place.

C.3.5.1.2. Project, Site, and Vicinity Description

The proposed facility would be located approximately two miles to the north of Interstate 10 (I-10) between the communities of Blythe, California (21 miles to the east) and Desert Center, California (32 miles to the west). Other nearby landmarks include

Ironwood and Chuckwalla State Prisons 6 miles to the south, the Blythe airport 13 miles to the east, and Joshua Tree National Park 61 miles to the west. The facility would be accessed from I-10.

The proposed GSEP consists of two independent, concentrated solar electric-generating facilities. Each facility would have a nominal electrical output of 125 megawatts (MW), for a total of 250 MW. The proposed power blocks and solar arrays would occupy approximately 1,360 acres while the evaporation ponds, access road, administration buildings, and other support facilities would occupy 440 acres. In all, the facility would occupy a total of 1,800 acres, with an additional 90 acres for a natural gas pipeline and a transmission line through which the proposed project would connect to California's electrical grid system (GSEP 2009a, p. 3-1).

The proposed project would entail the construction of two 125-MW solar collector fields, six 8-acre evaporation ponds, a 10-acre bioremediation land treatment unit, a 230-kV on-site switchyard, a new 6.5-mile, 230-kV transmission line, natural gas pipelines, access roads, a septic system, an on-site leach field, and two power blocks. Existing ground water wells would supply project water. The size and location of the septic system and associated leach field are unspecified. Each proposed power block would include: solar steam generator heat exchangers; a steam turbine generator and condensers; two wet-cooling towers; two natural-gas fired auxiliary boilers; surge volume tanks; fire suppression pumps and pump house; diesel generators; and water storage tanks (GSEP 2009a, p. 3-4). Foundation excavation for the above project components would reach between 2 and 30 feet below the present ground surface (TTEC 2010c).

Extensive earthwork would be required to grade the site to achieve an average slope of one to three percent. Grading cuts would reach approximately two feet below the present ground surface. The final expected elevation across the project site footprint is unspecified. The proposed drainage realignment would also involve extensive earthwork. In the event of an intense rain storm, the project facilities would need to be protected from storm runoff. As discussed in the Drainage Erosion and Sediment Control Plan, three off-site water diversion channels would be constructed, one passing on either side of the facility and the third through the center. The east and west storm diversion facilities would include the use of swales, ditches, and detention ponds with proposed volumes of 49 acre-feet and 66 acre-feet respectively (GSEP 2009a, p. 3-23). The exact size and location of these drainage facilities are still being determined by the applicant's engineers.

Overall, the total soil volume to be moved to level the site, including drainage diversion channels, evaporation and retention pond excavation, and berm fill placement, would be approximately 712,000 cubic yards of cut and 1,000,000 cubic yards of fill (GSEP 2009a, p. 3-25). However, since the applicant's engineers are still in the process of designing some of the project components, these figures may change.

The proposed project places one 125-MW facility on the east side of the project site footprint with a second 125 MW facility immediately adjacent to the southeast. In order to tie into the proposed Southern California Edison 500–230-kV Colorado River Substation, the applicant proposes that a transmission line from the facility would travel

in a southeast direction until it crosses the existing Imperial Irrigation District Blythe-to-Eagle Mountain 162-kV transmission line and then I-10. The line would eventually connect with the Blythe Energy Project Transmission Line (BEPTL). From that intersection, or generation-tie, the line would travel east sharing a series of transmission poles with the BEPTL until it terminates at the Colorado River Substation (GSEP 2009a, p. 3-25; TTEC 2010j).

C.3.5.1.3 Environmental Setting

Identifying the kinds and distribution of resources necessary to sustain human life in an environment, and the changes in that environment over time is central to understanding whether and how an area was used during prehistory and history. During the time that humans have lived in California, the region in which the proposed project is located, the Mojave Desert, has undergone several climatic shifts. These shifts have resulted in variable availability of vital resources, and that variability has influenced the scope and scale of human use of the vicinity of the project site. Consequently, it is important to consider the historical character of local climate change, or the paleoclimate, and the effects of the paleoclimate on the physical development of the area and its ecology.

C.3.5.1.3.1. Paleoclimate and Paleoecology

Over the last 20 years studies of pack-rat middens and lake-level studies have provided a picture of the paleoclimate and paleoecology of the Mojave and Colorado Deserts. During prehistoric times, this region fluctuated between cool-and-moist and warm-and-dry periods. These fluctuations in temperature and moisture were crucial to the human occupation of the region. Environmental changes also had important implications for the project vicinity specifically, because of the proximity of Dry Ford Lake. During cool, wet times the regional lakes filled and the necessary resources for human occupation were available. During warm, dry times the lakes dried and the region became a difficult place to live and traverse.

Recent environmental studies suggest that during the Late Pleistocene (18,000 to 8000 cal BC[4]), when humans first occupied North America, conditions in the Mojave Desert were cool and wet (West et al. 2007). Vegetation in the region was dominated by juniper and pinyon woodland, and the freshwater lakes of the region were permanent. This period was followed by the Early Holocene (8000 to 6000 cal BC), which was relatively wet and characterized by regular lake-refilling episodes. This wet environment continued to support the woodland. In contrast, the Middle Holocene (6000 to 4500 cal BC) was significantly dryer with shallow, rapidly oscillating lake levels. During this period the vegetation began to transition to desert scrub. The drying trend continued between 4500 and 1900 cal BC, resulting in persistently dry lake beds and the complete transition to the creosote biotic communities of the modern Mojave and Colorado Deserts, by approximately 4900 cal BC. From 1900 cal BC to the present, the dry

[4] There are two kinds of radiocarbon (C14) dates: uncalibrated and calibrated dates. Uncalibrated dates are not identical to calendar dates because the level of atmospheric radiocarbon (C14) has not been constant over time. Uncalibrated ages can be converted to calendar dates by means of calibration curves based on comparison of raw radiocarbon dates of samples independently dated by other methods, such as tree ring dating and stratigraphy. Such calibrated dates are expressed as cal AD or BC, where "cal" indicates "calendar years" or "calibrated years."

pattern has been dominant, with lakes filling periodically for short periods (Sutton et al., 2007, pp. 231–233).

C.3.5.1.3.2. Geology

The Mojave Desert has undergone a complex geologic history that includes sedimentation, volcanic activity, folding, faulting, uplift, and erosion. The project site footprint and linear facilities corridor is underlain by Quaternary[5] alluvial fill. This fill includes Holocene to Pleistocene alluvial fan and stream deposits, as well as lake (lacustrine) and ephemeral lake (playa) deposits. These sediments consist of gravel, sand, silt, and clay, with the coarser deposits located near the valley edges and the finer deposits near the center of the basin. The Quaternary deposits are underlain by the Pliocene Bouse Formation. This formation includes ocean and estuary deposits from an arm of the proto-Gulf of California, or alternatively, a closed brackish basin. No descriptions of this formation come from the Chuckwalla Valley, but in other locations it is a basal limestone (marl) overlain by interbedded clay, silt, sand, and tufa. The Bouse Formation is irregularly underlain by pebbles cemented in a sandy matrix, representing composite alluvial fans (called a fanglomerate). It is likely Miocene-age, but may also be Pliocene-age. Bedrock beneath the GSEP site consists of metamorphic and igneous intrusive rocks of greater than 63 million years of age (GSEP 2009a, p. 5.5-2).

C.3.5.1.3.2.1. Geomorphology

Geomorphology is the scientific study of landforms and the processes that shape them. Geomorphologists seek to understand why landscapes look the way they do, to understand landform history and dynamics, and to predict future changes through a combination of field observation, physical experiment, and modeling. Archaeologists use geomorphology to understand how archaeological sites were formed and to predict where sites of various types can be found. Over time, objects, sites and other man-made objects are moved, buried, or exposed by wind, water, plant growth, animal activity, and other natural processes. Geomorphology is a technique that helps archaeologists interpret physical clues in order to understand the specific nature of the changes that have taken place over time. In the case of the current project, geomorphology can be used to predict the location of buried sites, to estimate their current condition, and to estimate the relative age of various geological or archaeological features.

C.3.5.1.3.2.1.1. Present Process Geomorphology

Two geomorphological investigations were completed by the applicant for the proposed project vicinity (Farmer et al. 2009, app. C; TTEC 2010e). Both investigations included a review of existing literature and a site visit to ground-check information from the documentary sources. Kenney (TTEC 2010e) also conducted shallow test excavations (1.5 feet in depth), drew cross-sections of the existing stratigraphy, and estimated the age of the local geologic units.

[5] The Quaternary period is the youngest period of the Cenozoic era in the geologic time scale, spanning 2.588 +/- 0.005 million years ago to the present. It includes two geologic epochs: the Pleistocene (1.8 million–10,000 years ago) and the Holocene (the current epoch, 10,000 years ago to the present).

Kenney (TTEC 2010e) determined the minimum age of the site geologic units in both numerical and relative terms. Relative ages were assigned by stratigraphic position of the sedimentary layers. Numerical ages for sedimentary units were assigned by careful examination of the soil profiles. Desert soils are typically dated utilizing the Soil Development Index (SDI) method. With an SDI value, a soil in question may be compared to other regional soils evaluated with the same method and dated with absolute techniques such as carbon^{14}. For this study, numerical ages for sediments were arrived at by correlating site soil profiles with known dated soils in the Coachella Valley (TTEC 2010e, p. 2).

One of the geomorphic hallmarks of the Basin and Range Geomorphic Province is that streams terminate in local or regional valley sinks and not the Pacific Ocean or Sea of Cortez. A central feature of the proposed project vicinity is one of these sinks, Dry Ford Lake. Two kinds of lakes form in these kinds of conditions: pluvial and playa lakes. Pluvial or perennial lakes formed during Pleistocene glacial maximums that existed for thousands of years. Playa lakes, formed during the Holocene, are quite ephemeral, with life cycles of one to a few tens of years. Each type of lake would have supported different kinds of plants and animals, and as such, would have been attractive to humans in different ways. The sediments of these two types of lakes are also distinct. Pluvial lakes deposit sediments are: green, yellow, or olive-brown in color; consist of sand and clay; form thin, distinct layers; contain aquatic fossils; and lack saline layers. Playa lakes deposit sediments are: orange or brown in color; consist of silt and sand; do not form distinct layers; do not contain aquatic fossils; and contain saline layers. Geological bore samples from Ford Dry Lake show that it contains playa lake deposits to depths of approximately160 meters (TTEC 2010e, p. 3).

Field mapping within the GSEP vicinity yielded a local stratigraphy of only six units. These included stream deposits, both active and dormant sand deposits, alluvial deposits, and lake deposits. These six units, their distribution across the project site footprint, their estimated age and approximate depths, are described in detail below (TTEC 2010e).

Qw:

These sediments are active stream wash deposits composed of loose very fine to very coarse light brown to yellowish brown sand with small gravel. This unit is confined within the active washes and is typically 1 to 6 inches thick, but may be greater than 2 feet thick in some of the larger washes. This unit was identified but not recorded in this study.

Qs:

Qs deposits are active, dormant, and relict aeolian sand deposits. They consist of fine, yellowish brown sand sheets up to 1 foot thick. These deposits are scattered across the project site footprint on the modern ground surface of Dry Ford Lake.

Qal:

These sediments consist of Quaternary alluvium composed of fine to coarse brown sand mixed with small gravels averaging 1 foot thick. Gravel surfaces similar to desert pavement can form. This alluvium is present across most of the project site footprint and linear facilities corridor, usually overlaying older alluvium above elevation 374 feet, lake

deposits below elevation 374 feet (approximate elevation of latest Pleistocene shoreline). This sediment can be divided into two soil types, the upper which ranges in age from 1,000 to 3,000 years old, and the lower which ranges in age from 7,000 to 8,000 years old. Unit Qsr typically overlays this alluvium.

Qsr:

This unit consists of a relict sand sheet and highly degraded small coppice dune deposits. These sediments were deposited within wind transport and depositional areas during the Holocene that are no longer active. Deposits consist of fine brown sand ranging between 4 and 8 inches thick. Coarse sand and gravel surfaces similar to desert pavement can form. Soil horizons in the upper 2 to 6 inches of this unit range in age from 1,000 to 7,000 years old. Unit Qsr is the most common unit exposed on the surface and typically overlies unit Qal.

Qoaf:

This unit consists of older alluvial fan deposits likely created by Pleistocene glaciers. It is composed of yellowish red fine to coarse silty sand with small to medium gravels. These deposits are ubiquitous across the site near to the surface except for below elevation 374 feet (old shore line) where it may exist below several layers of lake deposits (Ql). This sediment can be divided into multiple soils, the youngest of which is 12,000 to 20,000 years old. The average depth of this unit was not determined, but extended beyond the bottom of most of the test units (deeper than 1.5 feet).

Ql:

Ql sediments are lake deposits associated with the ancient playa Dry Ford Lake. They consist of light yellowish brown fine to medium sandy silt with iron oxide staining. No fossils were noted. Multiple layers of this unit were noted at distinct elevations. Deposits between 377 and 380 feet were found beneath unit Qoaf indicating they were formed during the Pleistocene at least 12,000 years ago but more likely between 15,000 and 20,000 years ago. All other Ql deposits were above Qoaf indicating that they were formed during the Holocene, at least 12,000 years ago. Deposits between 373 and 374 feet are estimated to 12,000 years old, those between 367 and 370 feet in elevation to be between 8,000 and 12,000 years old, and those at 364 feet in elevation to be between 5,000 and 12,000 years old. The most recent shoreline is located at 360 feet in elevation and appears to have been created during the late Holocene. Ql sediments tend to be overlain by Qal alluvium or Qs sand dunes. These deposits are located mainly in the southwest edges of the project site footprint.

C.3.5.1.3.3. Prehistoric Background[6]

Human populations have occupied the California desert for at least 10,000 years (Moratto 1984). Stratified sites that would aid in providing temporal controls and help establish a cultural chronology are virtually unknown in the study area. The earliest explorations of the Mojave and Colorado Deserts took place in the 1930s and 1940s (Campbell 1931, 1936; Campbell and Campbell 1935; Campbell et al. 1937; Rogers 1939, 1945). During this time a basic cultural-historical outline was established, which

[6] This subsection was written by Dwight Simons and Kim Tremaine of Tremaine and Associates.

has formed the foundation for subsequent efforts (Arnold et al. 2002, pp. 46–48; Love and Dahdul 2002; Schaefer 1994; Warren 1984). However, these early attempts were based on surface scatters and inference rather than large-scale data recovery projects or regional surveys.

Numerous cultural resource management projects have resulted in dramatic increases in our understanding of the prehistory of the region. Two of the most notable synthetic works include the BLM's large-scale cultural resources inventory of the Central Mojave and Colorado Desert Regions (Gallegos et al. 1980) and Crabtree's (1980) overview. It was not until the late 1990s that any archaeological site was excavated and reported in the literature within 100 kilometers of the GSEP APEs. Jones and Klar's (2007) recent review of California archaeology builds from where these earlier authors left off, including the results of recent data recovery projects (Schaefer and Laylander 2007; Sutton et al. 2007). The following discussion and culture-historical sequence primarily follows the sources listed above.

C.3.5.1.3.3.1. Paleo-Indian Period (about 10,000–8000 BC)

The Paleoindian Period occurs during the first half of the Early Holocene. Isolated fluted projectile points, assignable to the Western Clovis Tradition have been recovered from the Pinto Basin, Ocotillo Wells, Cuyamaca Pass, and the Yuha Desert (Dillon 2002, p. 113; Moratto 1984, pp. 77, fig. 3.1, 87; Rondeau et al. 2007, pp. 64–65, fig. 5.1, table 5.1). All are surface finds, and have no associations with extinct fauna.

C.3.5.1.3.3.2. Lake Mojave Complex (8000–6000 BC)

The Lake Mojave complex, also known as the Western Pluvial Lakes/Western Stemmed Tradition (Beck and Jones 1997; Erlandson et al. 2007; papers in Graf and Schmitt 2007; Schaefer 1994, pp. 63–64; Sutton et al. 2007; papers in Willig et al. 1988), occurs during the second half of the Early Holocene. It is characterized by Great Basin Stemmed Series projectile points (Lake Mojave and Silver Lake types), abundant bifaces, steep-edged unifaces, crescents, and occasional cobble tools and ground stone tools. These artifacts often occur in undated surface contexts. Assemblage composition and site structure suggest highly mobile foragers, often traveling considerable distances. Little reliance upon vegetal resources is evidenced. The value of wetland habitats remains unclear. Lake Mojave lifeways may result from relatively rapidly changing climate and habitats during the Early Holocene. This would have produced unpredictability in resource distribution and abundance, producing a high degree of residential mobility.

C.3.5.1.3.3.3. Deadman Lake Complex (7500–5200 BC)

Currently, the Deadman Lake complex appears confined to the Twentynine Palms area. Sites usually are surficial and located on old alluvial pediments. Artifacts include small-to-medium-size contracting stemmed or lozenge-shaped points, large concentrations of battered cobbles and core tools, and abundant bifaces, simple flake tools, and ground stone tools. The abundance of cobble tools suggests an emphasis upon plant processing. The Deadman Lake and Pinto complexes may represent two different human populations practicing different seasonal/annual rounds, or Deadman Lake may represent a component of the overall Pinto complex adaptation.

C.3.5.1.3.3.4. Pinto Complex (8000–3000 BC)

The Pinto complex spans portions of the Early and Middle Holocene. Toolstone use, based on sites attributed to this complex, focus upon materials other than obsidian and cryptocrystalline silicate (CCS). Pinto Series points are stemmed with indented bases, and display high levels of reworking. Bifacial and unifacial cores/tools are common. Ground stone tools are moderately to very abundant, indicating greatly increased use of plant resources. Pinto sites occur in a broad range of topographic and environmental settings, especially within remnant pluvial lake basins. Moderate to large numbers of people, practicing a collector subsistence strategy, occupied large residential base camps for prolonged periods. Logistical forays into surrounding resource patches probably were made from these sites.

C.3.5.1.3.3.5. Possible Abandonment (3000–2000 BC)

Beginning roughly at this time, conditions in the Mojave Desert were warmer and drier. Few archaeological sites date to this period. This suggests population densities were very low. It is possible some areas were largely abandoned. This period corresponds in part to the latter part of the proposed “Altithermal Abandonment,” recognized by some prehistorians as characterizing portions of the Great Basin (see Kelly 1997, pp. 8–9).

C.3.5.1.3.3.6.Gypsum Complex (2000 BC–200 AD)

The Gypsum complex, spanning most of the Early Late Holocene, is characterized by the presence of corner-notched Elko Series points, concave-base Humboldt Series points, and well-shouldered contracting-stemmed Gypsum Series points. Numerous bifaces also occur. Manos and metates are relatively common. During the early portion of the Gypsum complex, settlement-subsistence appears focused near streams. At this time, increased trade and social complexity apparently occurred. Gypsum components are smaller, more abundant, and occur over a more diverse suite of settings than those dating previously. Evidence for ritual activities include quartz crystals, paint, split-twig animal figurines, and rock art. Gypsum sites are uncommon in the southern and eastern Mojave Desert.

C.3.5.1.3.3.7. Rose Spring Complex (200 AD–1000 AD)

Cultural systems profoundly changed in the southern California deserts during Late Late Holocene with the introduction of the bow and arrow, represented by Rosegate Series points. During this time, a major increase in population is thought to have occurred, possibly resulting from a more productive environment and a more efficient hunting technology. Sites often are located near springs, along washes, and sometimes along lakeshores. Intensive occupation is indicated by the presence of wickiups, pit houses, and other types of structures. Well-developed middens have yielded artifact assemblages containing knives, drills, pipes, bone awls, various ground stone tools, marine shell ornaments, and large amounts of obsidian. Obsidian procurement and processing apparently significantly structured settlement-subsistence.

During the middle of this period, a drought referred to as the Medieval Climatic Anomaly occurred, resulting in hypothesized resource shortages.

C.3.5.1.3.3.8 Late Prehistoric Period (1000 AD–1700 AD)

During the Late Prehistoric period, horticultural practices and pottery were introduced (most likely from the Hohokam area in southern Arizona or from northern Mexico), having its greatest impact along the Lower Colorado River (McGuire and Schiffer 1982; Schaefer 1994, pp. 65–74; Schaefer and Laylander 2007, pp. 253–254). Ceramic artifacts began to appear in the Colorado Desert approximately 1000 AD, assigned to the Lowland Patayan (Lower Colorado Buff Ware) and Tizon Brown Ware traditions (Lyneis 1988; Waters 1982a, 1982b).

A complex cultural landscape composed of rock art, trails, and geoglyphs[7] developed during the Late Prehistoric period. Trade and exchange were elaborated, with an emphasis on links between coastal southern California and the Southwest. In addition to pottery, artifact assemblages include Desert Series projectile points, shell and steatite beads, and a variety of milling tools. Obsidian use declines significantly, with CCS becoming the dominant toolstone.

C.3.5.1.3.4. Prehistory of the Chuckwalla Valley

Singer (1984) presents a lithic quarry-oriented prehistoric settlement model for the Chuckwalla Valley and environs. Over 200 prehistoric sites occur in the region. Past peoples inhabiting the area appear to have been very mobile, especially during late prehistoric and early historic times. During early historic times, native peoples inhabited towns/hamlets located along the Colorado River, within the Coachella Valley, and at major desert springs/oases.

The Chuckwalla Valley was a relatively closed resource exploitation zone. It served as an east-west oriented trade route/corridor between the Pacific Ocean and the Colorado River/greater Southwest. An extensive network of trails is present within the Chuckwalla Valley. Given its orientation and location, the valley may have been neutral territory (i.e., a buffer zone), unclaimed by neighboring native peoples. Quarry sites probably were "owned" by tribal groups. The distribution of particular types of toolstones may have corresponded to a group's territorial boundaries, and a toolstone type may not have occurred beyond the limits of a group's specific territory.

Within the Chuckwalla Valley, prehistoric sites are clustered around springs, wells, and other obvious important features/resources. Sites include villages with cemeteries, occupation sites with and without pottery, large and small concentrations of ceramic sherds and flaked stone tools, rock art sites, rock shelters with perishable items, rock rings/stone circles, geoglyphs, and cleared areas, a vast network of trails, markers and shrines, and quarry sites. Possible village locations are present at Dry Ford Lake, McCoy Spring, Palen Lake, Granite Well, and Hayfield Canyon.

A cluster of temporary habitation and special activity (task) sites occurs around a quarry workshop in the Chuckwalla Valley. The Chuckwalla Valley aplite quarry workshop

[7] Geoglyphs, also known as intaglios, were created on desert pavements by rearranging and/or clearing pebbles and rocks to form alignments, clearings, and/or figures. Rock alignments are present throughout this region, while representational figures only occur close to the Lower Colorado River. It is assumed that they played some role in sacred or ritual activities.

complex probably was used throughout the Holocene. During this period, Chuckwalla Valley most likely was occupied, abandoned, and reoccupied by a succession of ethnic groups. In the Early Holocene (i.e., Lake Mohave complex times), the area may have been relatively densely inhabited. During the Middle Holocene (i.e., Pinto and Gypsum complexes period) it may only have been sporadically visited. The subsequent Late Holocene Rose Spring and Late Prehistoric periods probably witnessed reoccupation of the valley by Yuman and Numic-speaking peoples.

C.3.5.1.3.5. Research Topics

Research topics commonly appearing in the Colorado Desert archaeological literature include toolstone procurement, ceramic traditions, horticulture, trade and exchange, and cultural landscapes.

C.3.5.1.3.5.1. Toolstone Procurement

C.3.5.1.3.5.1.1. Obsidian and Other Toolstone Materials

The geology of the Colorado Desert provided prehistoric peoples with a variety of lithic materials for artifact production (Schaefer and Laylander 2007, pp. 252–253). These included obsidian, cryptocrystalline silicates (chert), crystalline volcanics (basalt, rhyolite), quartz, and plutonic, metamorphic, and sedimentary rocks.

Coso obsidian was the dominant source of obsidian used by Colorado Desert peoples prior to 1000 AD. Other obsidian sources, from the southern Mojave Desert, include Bristol Mountains and Devil Peak (Shackley 1994). Approximately a dozen sources located in Baja California, extreme northwest Sonora, and western Arizona may also have been used (Shackley 1988, 1995, 2005). During the last thousand years, however, Obsidian Butte was the principal obsidian used in the Colorado Desert and coastal southern California (Hughes 1986; Hughes and True 1983; Laylander and Christenson 1988; Schaefer and Laylander 2007, p. 251). Obsidian Butte, located near the southern edge of the Salton Sea, was inaccessible when Lake Cahuilla rose to inundate it (130 feet above sea level).

C.3.5.1.3.5.1.2. Procurement Strategies

Several topics relating to prehistoric quarrying and tool manufacturing/use have been identified, including: distinction between formal versus the expedient procurement of toolstone (Wilke and Schroth 1989); lithic reduction strategies and transport of toolstone (Bamforth 1990, 1992); scales of production at ground stone tool quarries (Schneider et al. 1995); and differences in tools/toolstones by gender (Walsh 2000).

Bamforth (1990, 1992) considers Holocene settlement, raw material, and lithic procurement at several quarry sites in the central Mojave Desert. He suggests that quarry use was conditioned upon mobility strategies, regional quality and abundance of toolstone, as well as quarry location. Bamforth suggests that an emphasis on transporting prepared cores during the period 2000 BC–500 AD may have resulted from the formation of relatively large and stable communities in areas with concentrated plant resources.

C.3.5.1.3.5.1.3. Local Aplite Quarrying

Singer (1984) studied two quarry workshop sites located in Chuckwalla Valley. Core production and reduction from locally available aplite was emphasized. This yielded flakes and bifaces, which appear to have been exported from the quarries for final reduction at other sites. Few formed tools were observed. Those that were present were choppers and scrapers, possibly used to manufacture wooden digging or prying sticks and shafts. The quarry sites appeared to have experienced long-term occupation and use.

Manufacturing efforts appear to have been directed towards production of expedient, rapidly discarded cutting/scraping/pounding/milling tools from locally available toolstone(s) (Ludwig 2005; Schaefer and Laylander 2007, pp. 252–252; Singer 1984). Specialized tool manufacturing included production of sandstone metates along the western side of the Colorado Desert, projectile point (arrow) workshops at seasonal task sites situated around playas, and large quarries at volcanic outcrops within the Lower Colorado and Gila River Valleys, where mortars and pestles were made (Schaefer and Laylander 2007, p. 252).

C.3.5.1.3.5.2. Ceramic Traditions

Schaefer and Laylander (2007, pp. 252–253) note that buffware pottery occurring within the Colorado Desert was initially assigned to the Hakataya ceramic series (Schroeder 1958, 1979). Subsequent studies (Waters 1982a, 1982b, 1982c) place it within the Lowland Patayan Ceramic Tradition. Both typologies are based on surface collections of sherds, with little data resulting from stratigraphic excavations, or associated radiocarbon dates. Schroeder focuses upon details of temper, inclusions, and surface treatment, while Waters emphasize rim form. Both attempt to define geographic limits of production for each type. Difficulties in applying either typology and problems with stratigraphic integrity, archaeological contexts, and anomalous associated radiocarbon dates, have allowed only gross chronological estimates and have limited identification of manufacturing regions.

In the Salton Basin, some sites dating between about 350 and 1200 AD contain pottery (Love and Dahdul 2002). This evidence suggests pottery was not introduced or rarely used prior to about 1000 AD. Earlier dates from the preceding 200 years suggest Lake Cahuilla may have attracted Colorado River peoples (and their pottery). Early ceramic dates from the Colorado Desert correspond closely with the inception of widespread use of Tizon Brownware pottery in the Peninsular Ranges and along the Pacific Coast (Lyneis 1988; Griset 1996), although some dates suggest initial introduction of ceramics by 1200 BC, if not before.

Viewed regionally, pottery use within the Late Prehistoric of the Colorado Desert can be divided into three periods (Arnold et al. 2002, pp. 46–47; Love and Dahdul 2002, pp. 72–73; Waters 1982a, 1982b, 1982c). Patayan I times, about 1200–950 BC, witnessed the inception of several ceramic traditions. During Patayan II times, 950–500 BC, increased local manufacture and use of pottery occurred. Patayan III, 500–240 BC, saw the introduction of “Colorado Buff” pottery, and the westerly spread of ceramics to coastal southern California.

With respect to social and cultural factors governing pottery adoption and use within the Colorado Desert, recent analyses of pottery from the Mojave Desert and surrounding areas provide models focused on behavioral implications regarding its manufacture and function. One concern has been with determining if ceramic vessels were locally made (Eerkens 2001; Eerkens et al. 1999, 2002a; Griset 1996). Neutron activation analysis and petrographic studies have been used to identify chemical and material signatures (Eerkens et al. 2002b). Pottery manufacture does not appear to have been organized at a higher regional level. Instead, pots generally appear to have been locally produced and used, with limited exchange of pots between different groups. Production appears to have been organized at an individual or family level, emphasizing production of largely utilitarian wares.

Pottery from sites in the northern Mojave is characterized by a relatively high number of elemental signatures suggesting higher levels of mobility (Eerkens et al. 2002b). In addition to a higher degree of residential mobility, Eerkens (2003b) suggests people inhabiting the northern Mojave Desert produced a fairly large numbers of pots. The combination of high mobility and a fairly high level of pottery production is seen as leading to caching pots near lowland wetlands, which were fixed in the landscape, development of pottery attributes promoting fuel consumption, and a high degree of standardization of largely utilitarian ceramics.

Sedentism in the Owens Valley, northeast of the Project Area, appears to have developed concurrently with, or immediately prior to, an emphasis on resource storage, at approximately 500 AD. Small seed intensification appears to have occurred about 700–600 BC, at the time brownware pottery became widely used. He concludes that social models, such as those suggesting the activities of aggrandizers or the stabilization of long-distance exchange networks, do not explain these developments. The role played by decrease(s) in population-to-resource balance(s), resulting from increased population pressure, remains unclear.

Eerkens (2003c; 2004) suggests the significant increase in small seed use and the advent of brownware pottery around 700–600 BC are linked. People focused upon seeds because they could easily be privatized. That is, they could be individually owned and thus would not be subject to unrestricted sharing. Pots were a critical component of small seed intensification, because they generally were individually made and owned and could be used within houses, allowing food preparation and consumption to occur in private. Privatization of small seeds may have resulted from increased population size yielding more potential “freeloaders,” new community kinship structures, and the creation of resource surplus.

C.3.5.1.3.5.3. Horticulture

At the time of initial Euroamerican contact, 240 years ago, native peoples living along the Lower Colorado River and the Colorado Delta were growing a wide variety of domesticates and wild grasses, which provided 30–50 percent of their subsistence economy (Bean and Lawton 1993; Castetter and Bell 1951; Schaefer and Laylander 2007, pp. 253–254). Annual flooding of the floodplains along the Colorado rejuvenated the soil and provided enough moisture to sustain crops. Lower Colorado River agriculture is presumed to have begun around 700 AD. It probably spread either from

the Hokokam area (to the east), or from northern Mexico (to the southeast) (McGuire and Schiffer 1982).

Horticulture subsequently appears to have spread west from the Colorado River. Desert Tipai peoples practiced floodplain agriculture along the New and Alamo Rivers. They also constructed small dams and ditches along washes to direct irrigation water onto adjacent terraces. Agricultural elements probably reached the Imperial Valley around 300 BC Seed caches and mythological references to cultigens possibly indicate very late prehistoric adoption of agriculture. However, the caches contained both native and Old World cultigens. Thus it is unclear if agriculture penetrated west of the Peninsular Ranges in southern California before Euroamerican contact and the sustained influence that came with the establishment of Spanish missions.

Native cultigens may have reached the western Colorado Desert through trade instead of by local production (Schaefer and Laylander 2007, p. 254). Within the Colorado Desert, several archaeological sites have ceramic jars or rock-lined cache pits containing food remains of native or Old World plants (cf., Bayman et al. 1996; Swenson 1984; Wilke 1978; Wilke and McDonald 1989; Wilke et al. 1977). Pumpkin seeds occur in human coprolites (fossilized feces) from the Myoma Dunes at the north end of Lake Cahuilla, and also in a ceramic jar from the west shore of Lake Cahuilla, north of the Fish Creek Mountains. The latter dated to 580–340 BC (Wilke 1978; Wilke et al. 1977).

Early-to mid-nineteenth-century Cahuilla archaeological sites contain glass beads, flaked glass, domestic animal bones, carbonized maize and tepary beans, and uncarbonized gourds. Abundant evidence exists indicating the Cahuilla practiced irrigated agriculture during the early- and mid-nineteenth century. The paucity of macro- and micro-fossil cultigen remains from prehistoric archaeological deposits in Cahuilla territory strongly suggests agriculture did not play a significant role in the Cahuilla economy until the early nineteenth century. Early historic intensification of agriculture may have resulted from final desiccation of Lake Cahuilla, regional population growth, decreased mobility, and acculturation, including introduction of Euroamerican irrigation techniques.

In the Mojave Desert and environs, in the approximate period from 2000 to 800 BC, agriculture first was practiced in southern Nevada and environs as a consequence of the Anasazi Intrusion (Warren 1984, p. 421, fig 8.25). Maize, squash, beans, grain amaranth, and sunflowers were grown. Agriculture was practiced along with foraging for wild plants and animals. Fields probably were irrigated in some manner. Agriculture appears to have intensified over time.

The Owens Valley Paiute were Great Basin Numic-speaking horticulturalists (Lawton et al. 1976; Liljeblad and Fowler 1986, pp. 417–418; Steward 1930, 1933, 1938, 1941, 1970). Ditch and surface irrigation of blue dicks (*Brodiaea capitata*), yellow nut grass (*Cyperus esculentus*), and spikerush (*Eleocharis* sp.), was practiced. This most likely developed during late prehistoric times, possibly triggered by increased population pressure resulting from climatic change and/or immigration (Bouey 1979).

Yohe (1997) notes aboriginal cultigens, such as melons, squash, and beans, were present at two rockshelters dating to the late nineteenth or early twentieth century in Death Valley. Fowler (1995, pp. 110–112; 1996, pp. 91–98) details garden horticulture among the Southern Paiute and Panamint and Timbisha Shoshone. Stream-irrigated gardens were cultivated, in which corn, beans, squash, sunflowers, and amaranth were grown. These groups also planted gardens near springs, had communal fields with irrigation ditches, and unirrigated stream-bank garden plots. Various land management practices were employed, including intentional burning, clearing, pruning, and coppicing, transplanting and cultivation, and cleaning of water sources.

Winter and Hogan (1986, pp. 125–127, table 1) note that during protohistoric times, agriculture was practiced by the southern California/Nevada Chemehuevi and Ash Meadows, Pahrump, Las Vegas, and Moapa Southern Paiute bands. Among the crops grown were corn, beans, squash, and sunflowers. Forms of plant husbandry directed towards non-domesticates included burning to encourage growth of new plants, broadcast seed sowing, and irrigation of wild stands of bulb and seed plants (Winter and Hogan 1986, pp. 128–129, table 2). These practices are thought to have begun prehistorically, continuing and possibly expanding during early historic times. Wallace(1980) suggests Native American agriculture in the Mojave region was exclusively a historic-period phenomenon.

C.3.5.1.3.5.4. Trade and Exchange

As Schaefer and Laylander (2007, pp. 254–256) note, prehistoric and ethnohistoric Colorado Desert peoples had a highly developed network of connections linking locations within and beyond the region. High mobility produced considerable cross-cultural interaction and integration in spite of frequent open aggression and warfare between different groups. This integration and interaction occurred between mobile hunter-gatherers and sedentary horticultural peoples. They are archaeologically manifested by the spatial distribution of site types, rock art, artifacts (especially ceramics and shell ornaments), and toolstones (especially obsidian).

Archaeologists monitor the dynamics of prehistoric trade in the Colorado Desert by analysis of the distributions of artifacts made from various toolstones, shell beads and ornaments, and ceramic types and composition (Schaefer and Laylander 2007, pp. 255–256). As previously stated, with respect to toolstones, obsidian from Obsidian Butte is fairly commonly represented in sites located within montane and coastal southern California (Hughes 1986; Hughes and True 1982; Laylander and Christensen 1988). Obsidian from sources in northern Baja California may have been routed via the Colorado Desert to coastal southern California sites (McFarland 2000). Wonderstone from the Rainbow Rock source is present in western San Diego County and the northern Coachella Valley (Bean et al. 1995; Pigniolo 1995). Material for steatite artifacts found in Colorado Desert sites probably comes from sources in the Peninsular Ranges. Material for argillite artifacts may be from a central Arizona source.

Artifacts made from shellfish species inhabiting the northern Sea of Cortez occur in coastal southern California and the Great Basin (Bennyhoff and Hughes 1987; Fitzgerald et al., 2005) and may have been traded through the Colorado Desert (Schaefer and Laylander 2007, p. 255). Shells from southern California coastal species

have been found at a number of Colorado Desert sites and those in the Southwest (Ford 1983). These artifacts may have resulted from direct procurement of shells, or exchange. At the Elmore site, associated with the protohistoric recession of Lake Cahuilla, shell debitage indicates local manufacture of shell beads and ornaments (Rosen 1995). In the Coachella Valley, shell artifacts may reflect close ties to peoples living along the Santa Barbara Channel.

A cache of Lower Colorado Buffware (i.e., Patayan) anthropomorphic figures found in an Orange County site indicates interregional connections (Koerper and Hedges 1996). These also are suggested by the frequency of Lower Colorado Buffware (i.e., Patayan/Hakataya) pottery throughout the Colorado Desert (Bean et al. 1995; Cordell 1997; McGuire 1982; Schaefer and Laylander 2007, p. 255; Schroeder 1979; Shaul and Hill 1998; Waters 1982a, 1982b, 1982c). However, its use occurred among a number of prehistoric peoples practicing divergent settlement and subsistence patterns. Consequently little effort has been made to refine or apply the Patayan tradition as an integrative model.

On a local level, Plymale-Schneeberger (1993) examined pottery from three sites in Riverside County. Petrographic and geochemical analyses allowed quantitative distinction between Tizon Brown Ware and Lower Colorado Buff Ware. The study concluded that Brown Ware was locally produced while Buff Ware was imported. Seymour and Warren (2004) examined proportions of Tizon Brown Ware and Lower Colorado Buff Ware present at sites in Joshua Tree National Park and noted correspondence of pottery types with approximate boundaries of territories occupied by ethnohistorically known native peoples (that is, Cahuilla, Serrano, Chemehuevi).

Davis (1961) and Sample (1950) note that a considerable degree of historic-period trade between Native Americans occurred within and across the Colorado Desert. Trade networks across the Colorado Desert extended to the Yokuts and Chumash. Native peoples living along the Colorado River received and reciprocated goods from many groups living to the west.

C.3.5.1.3.5.5. Cultural Landscapes

In the Colorado Desert, trails, cairns, geoglyphs, cleared circles, rock rings, other desert pavement features, rock art sites, and artifact scatters appear to be elements of prehistoric-ethnohistoric cultural landscapes[8] (Schaefer and Laylander 2007, pp. 254–255; Cleland and Apple 2003). Specific localities include the Pilot Knob Complex, the rock art complex at Palo Verde Point, the Ripley Locality, and the Quien Sabe-Big Maria complex. Lower Colorado River geoglyph and rock art sites may represent prehistoric ceremonial centers, located along a route extending between sacred places, representing the cosmology and iconography of Yuman peoples (Altschul and Ezzo 1995; Cleland 2005; Ezzo and Altschul 1993; Gregory 2005; Hedges 2005; Johnson 1985, 2004; Woods et al. 1985).

[8] "Ethnohistoric" refers to the period during which Euroamerican accounts of Native Americans augment the archaeological record and Native American oral traditions as sources of information on Native Americans. Cultural landscapes, when related to specific ethnic groups, are referred to as "ethnographic landscapes" (Hardesty 2000).

C.3.5.1.3.5.5.1. Trails

During late prehistoric and ethnohistoric times, an extensive network of Native American trails was present in the Colorado Desert and environs (Heizer 1978; Cleland 2007; Sample 1950, p. 23; Apple 2005; Earle 2005; McCarthy 1993; Melmed and Apple 2009; Von Werlhof 1986). Segments of many trails are still visible, connecting various important natural and cultural elements of landscape, for example, these trails are often marked by votive stone piles (cairns) and ceramic sherd scatters (pot drops).

A late prehistoric-early historic Native American trail has been reported traversing roughly east/west through the Chuckwalla Valley (Johnson and Johnstone 1957, map 1). Johnson (1980, p.89-93, fig. 1) identifies this route as part of the Halchedhoma Trail (recorded as CA-Riv-53T) running from San Bernardino through San Gorgonio Pass to the Colorado River at present day Palo Verde Valley. In the vicinity of the Chuckwalla Valley, the trail proceeded roughly east-northeast from Hayfield Dry Lake past the future site of Desert Center to Gruendike Well. From there it went east, south of Palen Dry Lake to Sidewinder Well, then turned east, north of Ford Lake to McCoy Spring. It then headed south, around the south end of the McCoy Mountains, before going northeast towards the Colorado River. Work by McCarthy (1993, Fig. 10) suggests that offshoots of this trail may have crossed the GSEP site footprint leading to Dry Ford Lake and points to the south and west.

C.3.5.1.3.5.5.2. Geoglyphs

Geoglyphs were constructed on desert pavements by rearranging and/or clearing pebbles and rocks to form alignments, clearings, and/or figures (Arnold et al. 2002; Gilreath 2007, pp. 288–289; Solari and Johnson 1982). These rock alignments (Harner 1953) occur throughout the deserts of southeast California and adjacent portions of southern Nevada and western Arizona. Rock alignments are present throughout this region, including two recorded along the western foot of the McCoy Mountains (McCarthy 1993). Representational figures have only been noted in close proximity to the Lower Colorado River.

In the Mojave Desert, large rock alignments are found in Panamint Valley, Death Valley, Eureka Valley, and the Owens River Valley (Davis and Winslow 1965; Gilreath 2007, pp. 288–289; von Werlhof 1987). They have been interpreted as resulting from group ritual(s) (von Werlhof 1987). Many appear characterized by multiple-use episodes, with portions added through the years as part of ongoing rituals/ceremonies.

Colorado River geoglyphs include the Top Rock Maze (Rogers 1929) and a few dozen giant ground figures (Harner 1953; Setzler and Marshall 1952), often first observed from the air. During historic times, the Top Rock Maze was used by Yuman peoples for spiritual cleansing.

Johnson (1985, 2003), von Werlhof (2004), and Whitley (2000) relate the geoglyphs to Yuman cosmology, origin myths, and religion. Cation ratio dating[9] of desert varnish has

[9] Cation ratios between weathered rock varnish and unweathered rock are used as a relative dating technique to roughly determine the age of prehistoric rock carvings (petroglyphs). The quantity of positively-charged ions within the varnish (a chemically-changed layer built up of calcium and potassium

provided estimated ages of approximately 1200–1000 BC for the Colorado geoglyphs (Dorn et al. 1992; Schaefer 1994, p. 63; von Werlhof 1995), although use of the technique remains controversial (Gilreath 2007, p. 289).

Von Werlhof (1995, 2004) relates these sites to the Yuman creation story. They also may have functioned as focal points for shamanistic activities, vision quests, curing, and group rituals/ceremonies. Symbolic activities also were represented by intentional pot drop distributions along trails near water sources. The importance to Native Americans of water sources for survival during long-distance trips and seasonal rounds is obvious. Water sources also manifested significant spiritual values and often were associated with major rock art complexes (McCarthy 1993; Schaefer 1992).

C.3.5.1.3.6. Ethnographic Background[10]

Currently, it is unclear which historic Native American group or groups occupied or used the region in which the proposed project site is located, but the Chemehuevi, Serrano, Cahuilla, Mojave, Quechan, Maricopa, and Halchidhoma are the most likely.

Singer (1984, pp. 36–38) concluded the Chuckwalla Valley was not clearly assigned to any Native American group on maps depicting group territories. Following Johnson and Johnstone (1957), he observed that the west end of the Chuckwalla Valley was near the intersecting boundaries of Cahuilla-Serrano-Chemehuevi territory. Possibly before 800 BC, the Chemehuevi may have expanded into Serrano territory, occupying the Chuckwalla Valley. No evidence suggested that the Cahuilla occupied the area. Given its east-west orientation and location, however, the Chuckwalla Valley may have been neutral territory, occupied by no Native American group in particular, which served as an east-west trade and travel route.

C.3.5.1.3.6.1. The Cahuilla

A wealth of information exists regarding traditional and historic Cahuilla society and culture (see Bean and Lawton 1967 for a comprehensive bibliography of sources). Primary sources for the Cahuilla include Bean (1972; 1978), Bean and Saubel (1972), Drucker (1937), Gifford (1918), Hooper (1920), James (1960), Kroeber (1908; 1925, pp. 692–708), and Strong (1929, pp. 36–182). The Cahuilla language, divided into Desert, Pass, and Mountain dialects, has been assigned to the Cupan subfamily of the Takic branch of the Uto-Aztecan linguistic family (Golla 2007; Moratto 1984; Shipley 1978; Munro 1990, p. 218).

Territory traditionally claimed by the Cahuilla was topographically complex, including mountain ranges, passes, canyons, valleys, and desert. Bean (1978:375) described it as, "…from the summit of the San Bernardino Mountains in the north to Borrego Springs and the Chocolate Mountains in the south, a portion of the Colorado Desert west of Orocopia Mountain to the east, and the San Jacinto Plain near Riverside and the eastern slopes of Palomar Mountain to the west." The natural boundaries of the desert, mountains, hills, and plains separated the Cahuilla from surrounding Native American

leachate over time) is compared to those within the unweathered rock beneath the varnish.

[10] This subsection was written by Dwight Simons of Tremaine and Associates and Sarah Allred of the California Energy Commission.

groups. The Cahuilla interacted with surrounding peoples via intermarriage, ritual, trade, and war. The Cahuilla, Gabrielino, Serrano, and Luiseño shared common cultural traditions, with the Cahuilla having especially close ties to the two former groups.

Cahuilla villages usually were located in canyons or on alluvial fans near water and food patches. The area immediately around a village was owned in common by a lineage. Other lands were divided into tracts owned by clans, families, and individuals. Numerous sacred sites with rock art were associated with each village. Villages were connected by trail networks used for hunting, trading, and social visiting. Trading was a prevalent economic activity. Some Cahuilla were trading specialists. The Cahuilla went as far west as the Channel Islands and east to the Gila River to trade.

Hunting and meat processing were done by men. Game included deer, mountain sheep, pronghorn, rabbits, rodents, and birds. These were pursued by individuals and communal hunting groups. Blinds, pits, bows and arrows, throwing sticks, nets, snares, and traps were used to procure game. Communal hunts with fire drives sometimes occurred.

The Cahuilla had access to an immense variety of plant resources present within a diverse suite of habitats (Barrows 1900; Bean and Saubel 1972). Several hundred plant species were used for food, manufacture, and medicine. Acorns, mesquite and screw beans, pinyon nuts, and cactus fruits were the most important plant foods. They were supplemented by a host of seeds, tubers, roots, bulbs, fruits and berries, and greens. Corn, beans, squash, and melons were cultivated. Over 200 species of plants were used as medicines.

Structures varied in size from brush structures to dome-shaped or rectangular houses, 15–20 feet long, and ceremonial houses. The chief's house usually was the largest. Used for many social, ceremonial, and religious functions, it was located near a good water source. It generally was next to the ceremonial house, which was used for rituals, curing, and recreational activities. Other structures included a communal men's sweathouse and granaries.

Mortars and pestles, manos and metates, pottery, and baskets were used to process and prepare plant and animal foods. Cahuilla material culture included a variety of decorated and plain baskets; painted/incised pottery; bows, arrows, and other hunting-related equipment; clothing, sandals, and blankets; ceremonial and ritual costumes and regalia; and cordage, rope, and mats. Games and music were important social and ritual activities for the Cahuilla.

The Cahuilla had named clans, composed of 3–10 lineages, with distinct dialects, common genitors, and a founding lineage. Each lineage owned particular lands, stories, songs, and anecdotes. Each lineage occupied a village and controlled specific resource areas. Clan territory was jointly owned by all clan members. Territory ownership was established by marked boundaries (rock art, geographic features), and oral tradition. Most of a clan's territory was open to all Cahuilla. Kinship rules determined rights to assets and responsibilities within a lineage. Each lineage cooperated in defense, large-scale subsistence activities, and ritual performance. The founding lineage within a clan often owned the office of ceremonial leader, the ceremonial house, and sacred bundle.

Artifacts and equipment used in rituals and subsistence was owned by individuals and could be sold or loaned.

The office of lineage leader usually passed from father to eldest son. He was responsible for correct performance of rituals, care of the sacred bundle, and maintenance of the ceremonial house. The lineage leader also determined when and where people could gather and hunt, administered first-fruits rites, and stored food and goods. He knew boundaries and ownership rights, resolving conflict with binding decisions. The lineage leader met with other lineage leaders concerning various issues. He was assisted in his duties by a hereditary official responsible for arranging details for performance of rituals. Other functionaries included song leaders/ceremonialists, assisted by singers and dancers.

Laws were enforced by ritual, stories, anecdotes, and direct action. Supernatural and direct sanctions were used. Tradition provided authority. The past was the referent for the present and future. Old age provided access to privilege, power, and honor. Reciprocity was a significant expectation. Doing things slowly, deliberatively, and thoughtfully was stressed. Integrity and dependability in personal relations were valued. Secrecy and caution were exercised in dealing with knowledge.

Disputes between Cahuilla villages usually arose over access to resources. Other causes included sorcery, personal insults, kidnapping of women, nonpayment of bride price, and theft. Armed conflict occurred after all other efforts to resolve things had failed. A lineage leader and/or skillful warrior lead a temporary war party. Community rituals were held before and after a fight, which usually involved ambush.

Ritual and ceremony were a constant factor in Cahuilla society. Some ceremonies were scheduled and routine, while others were sporadic and situational. The most important ceremonies were the annual mourning ceremony, the eagle ceremony, rites of passage (especially those associated with birth, naming, puberty, marriage), status changes of adults, and rituals directed towards subsistence resources. The main focus was upon performance of cosmologically-oriented song cycles, which placed the Cahuilla universe in perspective, reaffirming the relationship(s) of the Cahuilla to the sacred past, present, to one another, and to all things.

C.3.5.1.3.6.2. The Serrano

Sources for the Serrano include Bean and Smith (1978), Benedict (1924,1929), Drucker (1937), Gifford (1918), Johnson (1965), Kroeber (1925, pp. 615–619), and Strong (1929, pp. 5–35). The Serrano Cahuilla shared many traits and artifacts with the Cahuilla, discussed above. The Serrano spoke a language belonging to the Serean Group of the Takic subfamily of the Uto-Aztecan family (Golla 2007; Moratto 1984; Shipley 1978).

It is nearly impossible to assign definite boundaries to Serrano territory. Territory traditionally claimed by the Serrano included the San Bernardino Mountains east of Cajon Pass, lands in the desert near Victorville, and territory extending east in the desert to Twenty-nine Palms and south to, and including, the Yucaipa Valley.

The Serrano occupied small village-hamlets located mainly in the foothills near water sources. Others were at higher elevations in coniferous forest, or in the desert. The availability of water was a critical determinant of the nature, duration, and distribution of Serrano settlements.

Women gathered, and men hunted and occasionally fished. Topography, elevations, and biota present within the Serrano territory varied greatly. Primary plant foods varied with locality. In the foothills, they included acorns and pinyon nuts. In the desert, honey mesquite, pinyon, yucca roots, and cactus fruits were staples. In both areas they were supplemented by a variety of roots, bulbs, shoots, and seeds, especially chia. Among primary game animals were deer, mountain sheep, pronghorn, rabbits, rodents, and quail. Large game was hunted with bows and arrows. Small game was taken with throwing sticks, traps, snares, and deadfalls. Meat was cooked in earth ovens. Meat and plant foods were parched or boiled in baskets. Plant foods were ground, pounded, or pulverized in mortars and pestles or with manos and metates. Processed meat and plant foods were dried and stored. Occasional communal deer and rabbit hunts were held. Communal acorn, pine nut, and mesquite gathering expeditions took place. These communal activities involved several lineages under a lineage leader's authority.

Serrano houses were circular, domed, individual family dwellings, with willow frames and tule thatching. They were occupied by a husband and wife along with their children, and often other kin. Houses were mainly used for sleeping and storage. Most daily activities occurred outside, often in the shade of a ramada (a flat-roofed, open-sided shade structure) or other sun cover.

Settlements usually had a large ceremonial house where the lineage leader and his family lived. It was the social and religious center for each lineage/lineage set. The latter was two or more lineages linked by marriage, economic reciprocity, and ritual participation. Other structures included semi-subterranean, earth-covered sweathouses located near water, and granaries.

Serrano material culture was very similar to that of the Cahuilla. Stone, wood, bone, plant fibers, and shell were used to make a variety of artifacts. These included highly decorated baskets, pottery, rabbit skin blankets, bone awls, bows and arrows, arrowshaft straighteners, fire drills, stone pipes, musical instruments, feathered costumes, mats, bags, storage pouches, cordage, and nets.

The clan was the largest autonomous landholding and political unit. No pan-tribal union between clans existed. Clans were aligned through economic, marital, and ceremonial reciprocity. Serrano clans often were allied with Cahuilla clans and Chemehuevi groups. The core of a clan was the linage. A lineage included all men recognizing descent from a common ancestor, their wives, and their descendants. Serrano lineages were autonomous and localized, each occupying and using defined, favored territories. A lineage rarely claimed territory at a distance from its home base.

The head of a clan was a ceremonial and religious leader. He also determined where and when people could hunt and gather. Clan leadership was passed down from father to son. The clan leader was assisted by a hereditary ceremonial official, from a different

clan. This official held ceremonial paraphernalia (the sacred bundle), notified people about ceremonies, and handled ceremonial logistics.

Serrano shamans were primarily healers who acquired their powers through dreaming. A shaman cured illness by sucking it out of the sick person and by the administration of herbal medicines. Various phases of an individual's' life cycle were occasions for ceremonies. After a woman gave birth, the mother and baby were "roasted," and a feast held. Differing puberty ceremonies were held for boys (*datura* ingestion used in a structured ceremonial vision quest) and girls ("pit roasting," ingestion of bitter herbs, dietary restrictions, instruction on how to be good wives). The dead were cremated, and a memorial service was held. During the annual seven-day mourning ceremony, the sacred bundle was displayed, the eagle-killing ceremony took place, a naming ceremony for all those born during the preceding year was held, images were made and burned of those who had died in the previous year, and the eagle dance was performed.

C.3.5.1.3.6.3. The Chemehuevi

Sources for the Chemehuevi include Drucker (1937), Kelly (1934; 1936), Kelly and Fowler (1986), Kroeber (1925, pp. 593–600), Miller and Miller (1967), and Roth (1976; 1977). Carobeth Laird married a Chemehuevi and collected a large corpus of data, primarily on ritual, religion, and myth (Laird 1974a; 1974b; 1975a; 1975b; 1976; 1977a; 1977b; 1977c; 1978a; 1978b; 1984). The Chemehuevi spoke a language belonging to the Southern Group of the Numic subfamily of the Uto-Aztecan family (Golla 2007; Moratto 1984; Shipley 1978). Many traits characterizing Chemehuevi culture are very similar or identical to those of the Mohave, discussed below. Several probable Quechan traits also were noted for the Chemehuevi.

For the territory traditionally claimed by the Chemehuevi, the Colorado River formed the eastern boundary south to the Palo Verde Mountains. The boundary then ran northwest, passing east of the Ironwood Mountains, crossing the Maria Mountains, paralleling the Iron Mountains, and then running between Old Woman Mountain and Cadiz Dry Lake (Kelly 1934; Kelly and Fowler 1986, p. 369, fig. 1). Mohave territory lay to the northeast, and that of the Las Vegas group of Southern Paiute to the north-northwest.

The Chemehuevi lacked any form of overall "tribal" organization. Anthropologists refer to territorial subdivisions among the Chemehuevi as "bands." Each band was composed of a small number of camps/communities/villages. Bands most likely correspond to economic clusters (Kelly 1964). Each group was a geographic unit, associated with a definite territory. In general, each band was economically self-sufficient.

In general, Chemehuevi settlement was mobile and scattered, with residence recurring within a fixed area. Houses were closely grouped. Their occupants usually were related by blood or marriage. Settlement size ranged from 1–2 households to 10–20. Springs often were inherited private property. Married siblings often camped at the same spring.

The Chemehuevi traveled widely. They had amicable contact with the Serrano, Cahuilla, Quechan/Yumans, and other Native American groups. The Chemehuevi sometimes joined with the Mohave/Quechan to fight the Cocopa/Halchidhoma. The Chemehuevi often crossed the Colorado River and hunted deer in Quechan, Yavapai,

and Western Walapai territory. They also traded, intermarried, and competed in games with the Yavapai. To the west, the Chemehuevi hunted in the Tehachapi area and went to the Pacific Coast along the Santa Barbara Channel to get abalone shell. Sometimes, a party of 8–10 Chemehuevi men joined men from neighboring groups to make a two-month journey to the Hopi villages (in what is now New Mexico) to trade.

The Chemehuevi apparently did not eat fish, but bighorn sheep, deer, pronghorn antelope, and desert tortoise were among the animal food resources they used (Kelly and Fowler 1986, p. 369). Plant foods in this region included pinyon nuts and mescal. Men inherited rights to hunt large game within certain tracts, defined in songs using geographic references. Women gathered a great variety of plant foods, which were more important in the Chemehuevi diet than game. In addition to pinyon nuts and mescal, agave and seeds were staples. Along the Colorado River, the Chemehuevi practiced floodplain agriculture. They grew corn, squash, gourds, beans, sunflowers, amaranth, winter wheat, grasses, and devil's claw using techniques similar to Mohave agricultural practices (see below).

Chemehuevi winter houses were conical/subconical structures. They also built earth-covered houses without a front wall, similar to those constructed by the Mohave. During the summer, many Chemehuevi lived outside, often building and occupying armadas and windbreaks.

With respect to material culture, Chemehuevi baskets and cradles were made from plant fibers. Plant fibers also provided materials for rope, string, and cordage nets. Pottery, which followed Mohave patterns and styles, included cooking pots, water jars, seed germination and storage pots, spoons/scoops, and large pots for ferrying children across the Colorado River. Watercraft included log rafts and reed balsas. Clothing consisted of double skin or fiber aprons and sandals for men and women. The Chemehuevi commonly had pierced ears and wore body paint.

Monogamy was the commonest form of marriage among the Chemehuevi, but some men had more than one wife. Women gave birth in a special enclosure, followed by a 30-day period of seclusion for mother, father, and child. Puberty rites for boys and girls were held, with the former focused on acquisition of hunting skills. Cremation of the dead was traditional, replaced by in-ground burial in the historic period.

In general, no central political control existed. Territorial boundaries were not rigid, and some bands were named, while others were not. The basic social and economic unit was the nuclear family and could include other close kin. Groups of individual households moved together on hunting and gathering trips, returning to the same spring or agricultural site. Most large bands had a headman whose leadership was more advisory than authoritative. He was usually succeeded by his eldest son.

The principal role of Chemehuevi shamans was curing illness. They acquired their healing powers through dreams rather than through the use of *datura* or a trance. Chemehuevi families held a mourning ceremony ("cry"), with which several speeches and songs were associated, within the year after the death of a relative. The "cry" was sponsored by the family and included the ceremonial burning of material goods.

The Chemehuevi had deer and mountain sheep song-dances, held for entertainment and hunting success. The Chemehuevi had other songs, as well: bird, salt, quail, and funeral songs. During winter evenings, men narrated a rich body of traditional stories and myths. These performances often included mimicry, song, and audience participation. Oral tradition related people to social norms, their territories, and to the subsistence resources present within them.

C.3.5.1.3.6.4. The Mohave

Information regarding the traditional lifeways of the Mohave has mainly been drawn from the accounts of early explorers and/or fur trappers who were among the first to encounter native groups, as well as from the later ethnographic accounts of anthropologists, usually well after the influences of Euro-American contact had begun to alter traditional ways of life. The following summary derives mainly from Kroeber (1925) and Stewart (1983a, 1983b).

The name Mohave is a variation on the name Hamakhava, which is what the tribal people called themselves (Kroeber 1925, p. 727). The Mohave language is classified into the Yuman subfamily of the Hokan language family. The Mohave were the northernmost and largest tribe of the River and Delta Yumans, who comprised a series of agricultural tribes that occupied the lower Colorado and Gila Rivers. The traditional ethnographic territory attributed to the Mohave includes the Mojave, Chemehuevi, and Colorado River Valleys along the lower Colorado River at the intersection of the borders of Arizona, Nevada, and California. In pre-contact times, Mohave tribal settlement is reported to have centered in the Mohave Valley where their population densities were observed to be the greatest (Stewart 1983b, p. 55).

The Colorado River served as something of an oasis in the otherwise harsh, dry environment that surrounded the river valleys. The spring overflow of the river, which spread gently over the bottomlands, left behind a rich silt deposit in its recession. It is within these bottomlands that the Mohave cultivated crops, which served as the foundation of their subsistence economy. Their agricultural methods were relatively simple, consisting of planting seeds on the richly silted floodplains and allowing their crops to mature with a minimum of maintenance or effort. Corn was the primary crop, but several varieties of tepary beans, pumpkins, melons, and other plants were also grown. Once harvested, the portions of the harvest that were not immediately consumed were dried in the sun and stored in large basketry granaries. The Mohave supplemented their diet mainly by gathering wild plants and by fishing, which served as their principle source of flesh non-plant food. Hunting played a minor role in the Mohave subsistence economy (Stewart 1983b, pp. 56–59).

Technology of the Mohave was relatively simple, and tools were reported to have been crafted to meet only the minimum requirements of utility (Stewart 1983b, p. 59). According to Kroeber (1925, p. 736), the farming implements consisted of only two items: a heavy wooden staff or digging stick for planting and a spatulate wooden hoe-like implement, whose square edge was pushed flat over the ground to control weeds. Metates, consisting of a rectangular block of stone, were used for grinding corn, wheat, and beans, and both stone and wooden pestles, as well as stone mortars, were also used for food processing (Kroeber 1925, pp. 736–737). Fish were commonly taken with

seines, large basketry scoops, sieves, dip nets, and weirs. The bow and arrow and cactus-spine fish hooks were also used for fishing. Mojave basketry was crudely woven, and their pottery was basic and utilitarian (Stewart 1983b, p. 59). Since hunting was of relatively little significance to the Mohave, hunting devices and techniques were not well developed, consisting mainly of snares, nets, bow and arrow, or curved throwing sticks (Stewart 1983b, pp. 59–61).

Mohave political and social organization was very informal, and no one individual or group had significant authority over another. Despite the Mohave's loose division into bands or local groups that were spread out over great distances, their cohesion as a tribe was very strong, and they considered themselves as one people occupying a nation with a well-defined territory (Stewart 1983a, 1983b).

The nuclear family was the basic unit of economic and social cooperation, although the extended family constituted the core of a settlement. Rather than large centralized villages, Mohave settlements were widely distributed along the riverbanks in close proximity to arable lands. Houses were situated on low rises above the floodplain and often separated by as much as a mile or two (Stewart 1983b, p. 57). During most of the year, the Mohave slept under ramadas; however, during the colder season, they occupied more substantial, semi-subterranean, rectangular earth-covered houses.

Warfare was a dominant strain in River Yuman culture, and the Mohave's strong tribal unity served them well in times of warfare. They apparently traveled great distances to do battle, and their principle weapons were bows and arrows and hard wood clubs. According to Kroeber (1925, p. 727), their main motivation was sheer curiosity, as they liked to see other lands and were eager to know the manners of other peoples, but were not heavily interested in trade.

The Mohave were culturally similar to the other River and Delta Yumans: the Quechan, Halichidhoma, Maricopa, and Cocopa. During ethnographic times, the Quechan were considered friends and allies of the Mohave, while the Halchidhoma, Maricopa, and Cocopa were considered to be enemies with whom the Mohave engaged in warfare (Stewart 1983b, p. 56). The Mohave were also friendly with the Upland Yuman tribes of the Yavapai and Walapai of western Arizona, although relations with the Walapai were somewhat mixed.

One of the most important rituals observed by the Mohave centered on death, namely the funeral and subsequent commemorative mourning ceremony. As soon as possible after death, the deceased was cremated upon a funeral pyre along with all of his or her possessions. The house and granary of the deceased were also burned. It was believed that by burning, these things would be transmitted to the land of the dead along with the soul of the deceased (Stewart 1983b, pp. 65–67).

Due to their relatively remote location inland, the Mohave maintained their independence throughout the Spanish period of the sixteenth and seventeenth centuries and were only rarely visited by explorers during that time. The few Spanish accounts of encounters with the Mohave provided similar descriptions of Mohave lifeways as those reported later by ethnographers. It is believed that the ancestors of

the Mojave resided in the area for at least 1000 years and the mode of life in prehistoric times is thought to be similar to that observed historically (Stewart 1983b, p. 56).

C.3.5.1.3.6.5. The Quechan/Yuma

The following summary of the Quechan or Yuma is derived mainly from Bee (1983), Kroeber (1925), and Stewart (1983a).

Quechan is a variation on the names Kwichyan or Kuchiana, which are the names the tribe called themselves, but this group is also commonly known as the Yuma. The Quechan are among the Yuman-speaking tribes who occupied the lower Colorado River where it forms the boundary between California and Arizona. According to Kroeber (1925, p. 782), the Quechan and their neighbors to the north, the Mohave, appear to be virtually identical in terms of their agriculture, manufactures, clothing, hair styles, houses, warfare, and sense of tribal unity.

The ethnographic territory traditionally associated with the Quechan, now divided between the states of California and Arizona, is centered around the confluence of the Colorado and the Gila Rivers, extending several miles north and south along the Colorado and east along the Gila. Quechan legend tells of a southward migration of their ancestors from a sacred mountain; however, it is not known when the ancestors of the Quechan first settled near the confluence (Bee 1983, p. 86). No group of this name was mentioned in the account of Hernando de Alarcón when he passed through the area during an expedition in 1540, and the first reference to this group did not appear in Spanish documents until the late seventeenth century, at which time they were settled around the river confluence area (Bee 1983, p. 86).

In an environment otherwise surrounded by dry desert terrain, the subsistence economy of the Quechan focused on riverine agriculture, which was one of the main sources of food for the tribe. Crops were cultivated in the richly silted river bottomlands following the recession of the spring floods and provided a relatively high yield in exchange for relatively low labor output (Bee 1983, pp. 86–87). The main cultivated crops included corn, tepary beans, pumpkins, and gourds. In post-contact times, watermelons, black-eyed peas, muskmelons, and wheat were introduced by Europeans and brought into cultivation by the Quechan, as well. The Quechan also relied on the gathering of wild foods, the most important of which were mesquite and screw-bean pods, although a variety of other wild plants were also collected (Bee 1983, p. 87; Castetter and Bell 1951, pp. 187–188). Fishing was of minor importance, as there were few species in the lower Colorado River suitable for eating. Among the fish sought were the humpback, white salmon, and boneytail, which were sometimes caught with unfeathered arrows or cactus-spine hooks, but more often taken with traps and nets during floods (Forde 1931, pp. 107–120). Given the low incidence of game available in the area, hunting played a minor role in the overall subsistence economy (Bee 1983, p. 86).

Like the Mohave, Quechan tribal settlements, or rancherias, consisted of extended family groups that were widely dispersed along the riverbanks. Settlements shifted throughout the year, dispersing into smaller groups along the bottomlands during the spring and summer farming seasons and reconvening into larger groups on higher ground, away from the river, during the winter and spring flood periods (Bee 1983, pp.

87–88). The geographic dispersion of the households within the rancheria groups was closely correlated with the condition of the rivers and the technology of riverine agriculture (Bee 1983, p. 89). The warm climate and scant precipitation made substantial housing unnecessary for most of the year, so most people made use of ramadas or dome-shaped arrowweed shelters. Each rancheria typically had one or two large, earth-covered shelters for the rancheria leaders' families, but these shelters also accommodated small crowds during colder weather (Forde 1931, p. 122).

Much like the Mohave, Quechan technology lacked technical or decorative elaboration beyond the demands of minimal utility (Bee 1983, p. 89). Quechan bows did not feature "backed" construction and so lacked power, and their arrows were frequently untipped, so the bow and arrow's range was short and the penetrating power weak. Sharpened staffs served as digging sticks or, when cut in longer lengths, as weapons (Bee 1983, p. 89).

In terms of property, there were no marked gradations in wealth, and social pressure favored the sharing of one's abundance with others who were less fortunate. Land ownership was informal, and people did not show much interest in the accumulation of material goods beyond the immediate needs of the family group or the surplus maintained by local leaders for redistribution to needy families within their rancheria (Bee 1983, p. 89). Lands were not inherited by family members upon the death of an individual; rather, the lands of the deceased were abandoned, and replacement plots were sought by the family members.

Despite the wide distribution of settlements, the Quechan had a strong sense of tribal unity. As with their neighbors and allies, the Mohave, warfare played a major role in Quechan culture, and it was during times of warfare that tribal unity was most prevalent among the individual settlements (Bee 1983, p. 92). Their major enemies were the Cocopa and the Maricopa, and they often allied themselves with the Mohave in strikes against common enemies (Bee 1983, p. 93). Bee (1983, p. 93) suggests that warfare among the riverine peoples may have increased in scale and intensity during the eighteenth and early nineteenth centuries due to new economic incentives, such as the opportunity to trade captives to the Spaniards or to other tribes for horses or goods.

Quechan social and political organization, like that of the Mohave, appears to have been very informal, with no one individual or group having significant authority over others. Two types of tribal leadership have been reported for the Quechan, one for civil affairs and the other for war, but it is questionable how influential these leadership roles may have been. Each rancheria had one or more headmen, but their authority was contingent upon public support and continued demonstration of competence. According to Bee (1983, p. 92), important matters at either the tribal or the rancheria level were always decided by consensus, sometimes after long debates dominated by the better and more forceful speaker.

Another important aspect of Quechan society that was shared with the Mohave concerns the commemoration of the dead, which was an elaborate ceremony involving wailing and the destruction of property and ritual paraphernalia. All possessions of the deceased, including the family home, were destroyed or given away (Bee 1983, pp. 89, 93–94).

C.3.5.1.3.6.6. The Maricopa and the Halchidhoma

Ethnographic information for the Maricopa and Halchidhoma is meager in comparison to the Mohave and the Quechan. The following brief summary is derived from Harwell and Kelly (1983) and Stewart (1983a).

The Halchidhoma first entered written history in the early seventeenth century with the account of Juan de Oñate, who encountered the “Alebdoma” or “Halchedoma” during a Spanish expedition on the lower Colorado River, below its junction with the Gila River. When later encountered by missionary-explorer Eusebio Francisco Kino in the early eighteenth century, the Halchidhoma (or “Alchedoma,” as they were referred to by Kino) had moved farther north up the Colorado beyond the Gila. The traditional territory attributed to the Halchidhoma lay along the lower Colorado between the Mohave and the Quechan territories. They were later driven from that area under pressure from their hostile Mohave and Quechan neighbors and moved to the middle Gila River area, where some merged with the Maricopa (Stewart 1983a).

The term Maricopa refers to the Yuman-speaking groups who in the early nineteenth century occupied the area along or near the Gila River and its tributaries (in what is now southern Arizona), but who earlier had occupied the lower Colorado River area. The Maricopa language is closely related to Quechan and Mohave, all three of which are classified as members of the River branch of the Yuman language family (Harwell and Kelly 1983, p. 71). The Maricopa call themselves *pi•pa•s*, “the people.” The name Maricopa is an English abbreviation of the name Cocomaricopa, first used by Eusebio Kino in the late seventeenth century (Harwell and Kelly 1983, p. 83).

The Maricopa, who by the early nineteenth century included remnant tribes of the Halyikwamai, Kahwan, Halchidhoma, and Kavelchadom, share common origins and are culturally similar to both the Quechan and the Mohave, the most prominent traits of which included floodwater agriculture and cremation of the dead. Their material culture was also essentially the same (Harwell and Kelly 1983, p. 71). The Colorado River Maricopa lived in low, rectangular, earth-covered houses, but the Maricopa of the Gila River had adopted the round houses of their Piman neighbors. Technology was of little interest to the River Yumans and remained at a low level of development (Stewart 1983a).

C.3.5.1.3.7. Historical Background[11]

The Mojave Desert area, in which the GSEP is located, has remained one of the more sparsely populated regions of the American West. The harsh arid environment and paucity of natural water supply has presented a challenge to the development of trans-desert routes for the movement of people and goods, to the exploitation of resources in the area, and to the establishment of permanent settlement. The major historical themes for the Mojave Desert region and GSEP vicinity, in particular, are centered on the establishment of transportation routes, water access, mineral exploitation, and military uses. The following brief historical background of the Mojave Desert area in eastern Riverside County is derived from the following sources: Bischoff (2000); Castillo

[11] This subsection was written by Sarah Allred of the California Energy Commission.

(1978); Farmer, et al. (2009); GSEP (2009); von Till Warren (1980); and WESTEC (1982).

The earliest recorded history of the lower Colorado River region began with the expeditions of Spanish explorers, who were lured by rumors of a rich northern Indian civilization. However, due to the Spaniards' failure to find the fabled northern treasures and the remoteness of the region, the Mojave Desert was seldom visited during the Spanish and Mexican periods.

The desert region has produced a variety of mineral deposits, including gold, silver, fluorite, manganese, copper, gypsum, and uranium. The 1880s and 1890s were years of relative prosperity for mining regions of eastern Riverside County, and intermittent mining activity has occurred in the area since that time. Early mining activities played a significant role in stimulating early occupation and travel across the arid desert. Following the end of the Mexican period in 1848 and the onset of the California Gold Rush in 1849, a flood of gold-seeking emigrants began to pour into California, many of whom were unprepared and suffered extreme hardships during the overland trek through the desert.

One of the earliest major trans-desert trail/wagon routes established in the vicinity of the GSEP was known as Frink's Route. Frink's Route was established in the mid nineteenth century (prior to 1856), connecting southern California supply points with mines and outposts along the Colorado River. Frink's route appears to have passed south of the GSEP site footprint. Another important stage route was the Bradshaw Trail, an overland stage route pioneered by William Bradshaw in 1862. It began in San Bernardino and passed through San Gorgonio Pass, Palm Springs, and the north shore of the Salton Sea before reaching the Colorado River near Blythe. This route followed traditional Indian trails and was used between 1862 and 1877 to haul miners and other passengers to the gold fields at La Paz, Arizona (now Ehrenberg). Wiley's Well Road, which intersects the GSEP linear facilities corridor, was an offshoot of the Bradshaw Trail. The construction and expansion of the Southern Pacific Railroad between Phoenix and Los Angeles by way of Yuma in the late 1870s also brought travelers and supplies to more remote areas, enabling further development of mines and irrigation.

Around the turn of the last century gypsum was found in the McCoy Mountains. A mining town, Midland, was established here. From 1925 to the 1960s, Midland was a company town owned by the U.S. Gypsum Co. The company had harvested vast amounts of gypsum found in the area. At its peak, the town had a population of approximately 1,000. The Arizona and California Railway, built between 1903 and 1907, was a 50 mile spur rail route connecting Blythe and Midland to the main Santa Fe Railway line at the town of Rice. There were daily trains along this line until the late 1930s. Midland was a thriving mining town until the 1960s when it was entirely abandoned.

Automobile travel across and within the Colorado Desert area first developed using existing wagon roads. By the early twentieth century, the automobile became the preferred means of transportation, and in 1916, Congress approved an Act to identify safe travel routes and ensure protection of available water within the least documented regions of the desert (Brown 1920). The Mecca-Blythe-Ehrenberg route, which

approximates the current Interstate 10, is one such route identified under the Act and is located near the southern GSE project boundary. Travelers along these routes relied on natural water sources such as McCoy Spring and wells excavated by wagon road users. Most of the wells in eastern Riverside County were excavated by early prospectors and/or landowners and were often named for the men who dug them. Among the early known wells near the GSEP site footprint and linear facilities corridor include the Hopkins Well, Wiley's Well, and the Ford Well, which appear on the 1920 USGS Water Supply Paper Map, south of the GSEP limits. Portions of Wiley's Well Road, where it passes near McCoy Spring, may have been improved in the 1940s and 1950s to provide access to Midland after rail service ceased.

The GSEP site footprint and linear facilities corridor falls within the limits of Gen. Patton's World War II Desert Training Center/California-Arizona Maneuver Area (DTC/C-AMA), which was in operation from 1942-1944. The area was chosen by Gen. George S. Patton, Jr. to prepare troops for the harsh conditions and environment of combat for the North Africa Campaign. At 12,000,000 acres, the DTC/C-AMA was the largest-ever military training center, stretching from west of Pomona, California, to Yuma, Arizona, and north into Nevada. The valley bordered by the Palen, Little Maria, and McCoy Mountains is considered one of the most extensive maneuver areas in the DTC/C-AMA. After two years in operation and the training of one million troops, the DTC/C-AMA was closed in 1944 as a result of the allied victory in North Africa and the need for trained troops elsewhere. Following the closure of the DTC/C-AMA dismantling and salvage efforts began and the land was ultimately returned to private and government holdings. The remains of the DTC/C-AMA areas consist of rock features, faint roads, structural features, concertina wire, tank tracks, footprints of runway and landing strips, foxholes and bivouacs, concrete defensive positions, refuse, and trails.

C.3.5.1.3.8. Cultural Resources Inventory

A project-specific cultural resources inventory is a necessary step in staff's effort to determine whether the proposed project may cause significant impacts to historically significant cultural resources and would therefore have an adverse effect on the environment.

The development of a cultural resources inventory entails working through a sequence of investigatory phases. Generally the research process proceeds from the known to the unknown. These phases typically involve doing background research to identify known cultural resources, conducting fieldwork to collect requisite primary data on not-yet-identified cultural resources within and near the proposed project, assessing the results of any geoarchaeological studies or environmental assessments completed for the proposed project site, and compiling recommendations or determinations of historical significance for any cultural resources that are identified.

This subsection describes the research methods used by the applicant and Energy Commission staff for each phase and provides the results of the research, including literature and records searches (California Historical Resources Information System (CHRIS) and local records, archival research, Native American consultation, and field investigations.

This subsection also provides a brief description of each cultural resource identified by the applicant. For this project, staff has used the analytic process of “approach 3” (defined above under “Methodology and Thresholds for Determining Environmental Consequences”), so the inventory consists of the body of resources the applicant identified in the AFC, and the descriptions are limited to what the applicant provided, either with the AFC or in response to staff’s data requests.

Staff’s assessments of the project’s impacts on known cultural resources, potential impacts on previously unidentified, buried archaeological resources, and proposed mitigation measures for the project’s impacts are presented in a separate subsection below.

C.3.5.1.3.8.1. Area of Potential Effects (APE) and Project Area of Analysis

The concept and general definition of the APE (and the approximately equivalent CEQA project area of analysis) are discussed above under “Methodology and Thresholds for Determining Environmental Consequences.” For this project, staff has defined the following APEs.

For archaeological resources, the APE is defined at the proposed project site footprint, plus a buffer of 200 feet, the project linear facilities routes plus 50 feet to either side of the route and the maximum depth that would be reached by all foundation excavations and by all pipeline installation trenches. This definition serves to address both direct and indirect impacts on resources whose dimensions may well extend below the surface and beyond the project site.

For ethnographic resources, the APE is expanded to take into account traditional use areas and traditional cultural places which may be further afield than the project site footprint or the project vicinity. The areas of analysis for ethnographic resources may include viewscapes that contribute to the historical integrity of a subject resource. Ethnographic resources are often identified in consultation with Native Americans as well as other ethnic or cultural communities, and issues that are raised by these communities may define the APE. For this project the ethnographic APE is the geographic area around and including the proposed project where the project has the potential to physically or visually degrade ethnographic resources.

For built-environment resources in the rural context of the proposed project, the APE is defined as the project site and any above-ground linear facilities, plus a half-mile buffer. As this project is located in an undeveloped area, the APE was reduced to include only the above-ground linear facilities and a half-mile buffer.

C.3.5.1.3.8.2. Background Inventory Research

Various repositories in California hold compilations of information on the locations and descriptions of cultural resources older than 45 years that have been identified and recorded in past cultural resources surveys. Applicants acquire information specific to the vicinity of their project from certain repositories and to provide it to staff as part of the AFC submitted to the Energy Commission. Additionally, to acquire further information on potential cultural resources in the vicinity of a proposed project, the applicant is required to make inquiries of knowledgeable individuals in local agencies

and organizations and to consult Native Americans who have expressed an interest in being informed about development projects in areas to which they have traditional ties.

The archaeologists for the applicant reviewed a number of resources during their background inventory research. This research of the GSEP site footprint and vicinity identified 30 previous cultural resources projects, 85 previously-identified sites, 117 previously-identified cultural isolates, 1 ethnographic resource, and no built-environment resources (Farmer et al. 2009).

C.3.5.1.3.8.2.1. CHRIS Records Search

The California Historical Resources Information System, or CHRIS, is a federation of 11 independent cultural resources data repositories overseen by the California State Office of Historic Preservation. These centers are located around the state, and each holds information about the cultural resources of several surrounding counties. Qualified cultural resources specialists obtain data on known resources from these centers and in turn submit new data from their ongoing research to the centers.

Under BLM's protocol for inventory-level cultural resources investigations on lands for which a Right-of-Way (ROW) grant has been requested, the applicant undertakes a Class I survey. This is a preliminary gathering of data for known sites and other resources from published and unpublished documents, records, files, registers, and other sources, and is intended to produce an analysis and synthesis of all reasonably available data. A Class I survey encompasses prehistoric, historic, and ethnological/sociological elements and essentially chronicles past land uses (BLM 2004, sec. 8110.21).

The Class I survey of the proposed GSEP was intended to compile information on known cultural resources and previously conducted cultural resources studies pertinent to the location of the proposed project location. These records include individual site forms for known archaeological sites and built-environment resources as well as survey and excavation reports from previous investigations. The primary source for the current project is the Eastern Information Center (EIC) of the CHRIS, at the Department of Anthropology, University of California, Riverside. TetraTech asked the staff of the EIC to conduct a literature and records search of the GSEP site footprint and vicinity (Farmer et al. 2009, p. 46). The search covered the areas proposed for the main project components and the linear facilities corridor with a 1.5-mile buffer. In addition, the EIC staff searched the following resources:

- National Register of Historic Places (NHRP);
- California Register of Historical Resources (CRHR);
- California State Historical Landmarks;
- California Points of Historical Interest;
- California Inventory of Historic Resources; and
- BLM cultural Areas of Critical Environmental Concern (ACEC).

C.3.5.1.3.8.2.1.1. CHRIS Results

The CHRIS literature and records search identified 30 previous cultural resources investigations within the search area (Cultural Resources Table 2). This included 22 surveys, 6 literature reviews, 1 set of miscellaneous field notes from the region, and 1 project whose nature is undefined. In their review, EIC staff found that 11 of these overlapped with the GSEP archaeological and built-environment APEs. Parts of three investigations took place on the project site. The first investigation (IC Report No. RI-220) was an intensive linear survey that cut a 123-meter corridor from southeast to northwest through much of the project site. The second investigation (IC Report No. RI-1249) was a sample survey sponsored by the BLM that covered approximately 64 acres or 4 percent of the 1,800-acre project site. The third survey was part of an earlier stage of the GSEP (Farmer et al. 2009). This BLM Class II survey covered a 20 percent random sample of 1,896 acres, including 520 acres within the proposed project site footprint and linear facilities corridor. After these three projects, approximately 68 percent of the project site remained unsurveyed prior to the preparation for the current proposed project. Seven additional surveys, associated with fiber optic lines, geothermal resources, transmission lines, highway improvements, and gas line installation (IC Report Nos. RI-01664, RI-02210, RI-03227, RI-04347, RI-07192, RI-1279, RI-00221), crossed the proposed APE for the GSEP linear alignment. These surveys covered roughly 25 percent of the 90-acre proposed linear facilities corridor (Farmer et al. 2009).

The most extensive previous research in the region was conducted by McCarthy (1993a). He and his volunteers recorded 227 sites along the western flank of the McCoy Mountains. Many of these sites and trails were directly associated with McCoy Spring, an arid-land oasis and major focus of prehistoric use in the region for several millennia. Only two of these sites (trail segments) were included in the CHRIS literature and records search, probably because they are located outside of the GSEP APEs.

In general the previous research in the Chuckwalla Valley suggests that prehistoric archaeological sites are typically located near water (specifically, near springs), on terraces near the shore of the dry lake bed, and in areas where natural resources were utilized. Prehistoric site types in the GSEP site footprint and vicinity include rock shelters, petroglyphs, special use sites, lithic scatters, temporary camps, gathering areas, sacred areas, trails, and isolated finds. Historical archaeological sites in the region are primarily associated with transportation, military maneuvers related to the DTC/C-AMA and Desert Strike, mining, and ranching. Historical archaeological site types for the area include road segments, wells, refuse scatters with domestic and/or military discards, tank tracks, and other isolates.

A total of 85 previously recorded archaeological sites and 117 isolated finds are known for the CHRIS literature and records search area (Cultural Resources Table 2). These figures include the results of the Class II survey. Sixty-eight of these sites were prehistoric sites and 14 were historic-period sites. Site types include:

34 prehistoric small artifact scatters;
31 prehistoric temporary camps;
2 prehistoric trail segments;

1 group of prehistoric rock rings;
11 historic-period refuse scatters;
1 possible historic-period military mound;
1 historic-period well;
1 two-track road;
1 historic-period refuse deposit/lithic scatter;
1 historic-period refuse deposit/temporary camp; and
1 unknown site type

Five of the sites fell within or near the boundary the GSEP APEs, including three sparse lithic scatters and two temporary camps. These sites were identified during the Class II survey. Ninety-three prehistoric isolates were identified including 78 lithics, 5 ceramics, 7 ground stone, 2 isolates with both lithics and ceramics, and 1 unspecified prehistoric artifact. Twenty-four historic-period isolates were identified during the literature search. They included 12 glass isolates, 8 cans, and 4 pieces of metal related to military activity. As is common practice in cultural resources management, staff has eliminated the isolated finds from consideration.

Additional important locations in the region include:

- McCoy Spring National Register District (approximately 5 miles north of the proposed linear facilties corridor at Wiley's Rest Area);
- Palen Dry Lake, BLM cultural Area of Critical Environmental Concern (adjacent);
- Alligator Rock, BLM cultural Area of Critical Environmental Concern (25 miles);
- Camp Young-Desert Training Center, BLM cultural Area of Critical Environmental Concern and State Historical Landmark Riv-985, (marker in Desert Center);
- Colorado River Aqueduct Contractor's General Hospital, State Historical Landmark Riv-922, marker in Desert Center); and
- 1877 Thomas Blythe Canal Intake, State Historical Landmark Riv-948, (marker in Blythe).

C.3.5.1.3.6.2.2. Archival and Library Research

Detailed resource-specific information needed by staff may entail primary and secondary research in various archives and libraries, holding such sources as historic aerial photography, historic maps, city directories, and assessors' records. The applicant may include archival information as part of the information provided to staff in the AFC or may undertake such research to respond to staff's data requests. Staff may also undertake such research to supplement information provided by the applicant.

C.3.5.1.3.6.2.2.1.Archival and Library Research Results

The archaeologists for the applicant conducted additional archival research on the history of the GSEP site footprint and vicinity at the BLM State Office Public Records Room where they obtained copies of General Land Office (GLO) maps and surveyor

field notes (Farmer et al. 2009, p. 46). The results of this research were primarily data for the historical background subsection of the cultural resources section of the AFC. Additional sources of information consulted for the built-environment section (Farmer et al. 2009, app. F, p. 3-1) of the AFC include:

- County of Riverside Transportation Department and Land Management Agency;
- Caltrans Bridge Inventory;
- San Francisco Public Library;
- Los Angeles Public Library;
- BLM Palm Springs/South Coast Field Office;
- American Automobile Association of Southern California's Archives, Los Angeles; and
- On-line maps.

C.3.5.1.3.6.2.3. Local Agency and Organization Consultation

California counties and cities may recognize particular cultural resources as locally historically important by ordinance, in general plans, or by maintaining specific lists. To facilitate the environmental review of their projects, applicants acquire information on locally recognized cultural resources specific to the vicinity of their project by consulting local planning agencies and local historical and archaeological societies.

C.3.5.1.3.6.2.3.1. Results of Inquiries to Local Agencies and Organizations

In order to identify the presence of any locally important cultural resources the archaeologists for the applicant contacted the following organizations by mail or email:

- City of Blythe Planning Department;
- Riverside County Planning Department;
- Coachella Valley Historical Society;
- Coachella Valley Archaeological Society;
- Colorado Desert Archaeology Society;
- George S. Patton Memorial Museum;
- Imperial County Historical Society Pioneers Museum;
- Imperial Valley College Desert Museum;
- Indio Chamber of Commerce;
- Pioneer Historical Society of Riverside;
- Twenty-nine Palms Historical Society; and
- Palo Verde Historical Society and Museum.

The majority of these groups did not respond. The City of Blythe, Coachella Valley Archaeological Society, the Riverside County Planning Department, and the Twenty-

nine Palms Historical Society all reported a lack of important cultural resources within or near the GSEP site footprint and linear facilities corridor and/or a lack of relevant information (Farmer et al. 2009, p. 46). Thus, no additional information on known cultural resources was obtained from these sources.

C.3.5.1.3.6.2.4. Native American Consultation

The Native American Heritage Commission (NAHC) maintains two databases to assist cultural resources specialists in identifying cultural resources of concern to California Native Americans, referred to by staff as Native American ethnographic resources. The NAHC Sacred Lands database has records for places and objects that Native Americans consider sacred or otherwise important, such as cemeteries and gathering places for traditional foods and materials. The NAHC Contacts database has the names and contact information for individuals, representing a group or themselves, who have expressed an interest in being contacted about development projects in specified areas. Both applicants and staff request information from the NAHC on the presence of sacred lands in the vicinity of a proposed project and also request a list of Native Americans to whom inquiries will be made to identify both additional cultural resources and any concerns the Native Americans may have about a proposed project. While the BLM must formally consult, government-to-government, with the federally recognized Native American tribes that have traditional cultural ties to the area in which the project is located, the Energy Commission provides information and sends notices of all public events regarding the project to all Native American groups and individuals whom the NAHC identifies as having an interest in development in the area, whether federally recognized or not.

C.3.5.1.3.6.2.4.1. Results of Native American Consultation

The applicant contacted the NAHC by email on October 17, 2007, in order to obtain information on known cultural resources and traditional cultural properties, and to learn of any concerns Native Americans may have about the GSEP. In addition, they requested a list of Native Americans who have heritage ties to Riverside County and who want to be informed about new development projects there (Farmer et al. 2009, app. E). The NAHC responded on October 19, 2007, with the information that the Sacred Lands File (SLF) database failed to indicate the presence of Native American cultural resources in the immediate GSEP vicinity. The NAHC also forwarded a list of Native American groups or individuals interested in development projects in Riverside County.

On November 26, 2007, the Palm Springs-South Coast Field Office of the BLM sent letters to 28 Native American groups, including those identified by the NAHC, initiating government-to-government consultation for the proposed project. In addition the letter invited comments or concerns regarding potential impacts to cultural resources or areas of traditional cultural importance within the vicinity of the proposed project. On November 23, 2009, an additional letter was sent to the Agua Caliente Band of Indians and informational copies to 12 groups listed in Cultural Resources Table 3, noting the Federal Register publication of the NOI for the proposed project. The letter urged any concerned groups to utilize the Section 106 process to provide comments or specific concerns.

CULTURAL RESOURCES Table 3
Dates of Inquiries Made to Native American Groups and their Replies

Native American Group	Contact Person	Dates of Contact with BLM
Agua Caliente Band of Cahuilla Indians	Richard Milanovitch, Chairman Richard Begay and Patty Tuck, Tribal Historic Preservation Officers	11/26/07 NAHC letter from BLM 01/29/08 Reply from Ms. Tuck 05/20/09 Meeting with BLM 06/05/09 Meeting with BLM 11/23/09 NOI letter from BLM
Ak-Chin Indian Community	Terry Enos, Chairman	11/23/09 Copy of NOI letter
Anza Cahuilla	Contact person unknown	05/20/09 Meeting with BLM 11/05/09 Meeting with BLM
Augustine Band of Cahuilla Mission Indians	Mary Ann Green, Chairperson	11/26/07 NAHC letter from BLM 11/23/09 Copy of NOI letter
Cabazon Band of Mission Indians	John A. James, Chairperson Judy Sapp, Cultural Resources Coordinator	11/26/07 NAHC letter from BLM 12/21/07 Reply from Ms. Sapp 05/20/09 Meeting with BLM 11/05/09 Meeting with BLM 11/23/09 Copy of NOI letter
Cahuilla Band of Indians	Anthony Madrigal, Jr., Chairperson	11/26/07 NAHC letter from BLM 11/23/09 Copy of NOI letter
Chemehuevi Reservation	Charles Wood, Chairperson	11/26/07 NAHC letter from BLM 11/23/09 Copy of NOI letter 12/09/09 Reply
Cocopah Tribal Council	Sherry Cordova, Chairwoman	11/23/09 Copy of NOI letter

Yavapai-Prescott Indian Tribe	Ernie Jones, Sr., President	11/23/09 Copy of NOI letter

Tetra Tech reports that no responses to the initial 2007 BLM letter were received by the time the final draft of the cultural resources technical report was included in the AFC in November 2009 (Farmer et al. 2009, app. E). However the BLM reports a number of contacts and meetings between November, 2007, and December, 2009. The details of these contacts are listed in Cultural Resources Tables 4 and 5. A number of tribes—Agua Caliente Band of Cahuilla Indians, Morongo Band of Mission Indians, Cabazon Band of Mission Indians, Torres-Martinez Desert Cahuilla Indians, Pechanga Band of Luiseño Indians, Anza Cahuilla, Ramona Band of Mission Indians, Twentynine Palms

Band of Mission Indians, and San Mañuel Band of Mission Indians—attended meetings with BLM staff about various solar energy and transmission line projects in the region. In general the tribes expressed concern over possible damage to cultural resources, cultural landscapes, and traditional cultural properties. In addition they expressed interest in receiving copies of archaeological reports after cultural resources surveys of the GSEP footprint and linear facilities corridors were complete and being informed about the amount of damage to these resources expected to take place. It is unclear which of these groups is specifically interested in GSEP, other than the three tribes discussed below.

Four tribes—the Quechan Tribe, the Agua Caliente Band of Cahuilla Indians, the Cabazon Band of Mission Indians, and the Chemehuevi Reservation—responded to BLM letters about GSEP. The Agua Caliente Band of Cahuilla Indians are not interested in consulting about GSEP as it is outside of tribal traditional use areas. The Cabazon Band of Mission Indians and the Chemehuevi Reservation expressed general concerns about the potential destruction of cultural resources and traditional cultural properties.

The Quechan Tribe has expressed the most interest in GSEP, and has contacted BLM multiple times. Their concerns have been summarized in a formal letter written in response to the proposed Programmatic Environmental Impact Statement for Solar Energy Development for the six southwestern states. In this letter they consider the area around Blythe, presumably including the GSEP site footprint and linear facilities corridor, to be part of the Quechan Tribe's traditional land. To alleviate potential impacts to cultural resources, spiritual landscapes, or traditional cultural properties (TCPs) they request to be consulted at the inception of the project, prior to any plans being finalized. They further request that the clustering of these large several thousand-acre projects be prohibited, that traditional areas rich in cultural resources be avoided, that projects be placed on land that has already been disturbed, and that existing buildings be favored over undisturbed land for the placement of solar panels. Finally, they emphasize their concern over indirect as well as direct impacts to cultural resources. They request that BLM not "focus exclusively on archaeological site impacts, while failing to fully address impacts to resources such as cultural landscapes and TCPs" (Jackson 2009, p. 3). An additional letter from the Quechan Tribe was sent on February 16, 2010. In this letter President Jackson expresses doubt that the appropriate Section 106 consultation process can be completed within the "fast-track" timeframe that requires a final record-of-decision by September 2010. He further comments that the Tribe does not believe that the "fast-track" projects meet the regulatory criteria for the use of a programmatic agreement.

CAlifornians for Renewable Energy (CARE) members favor a "no action" alternative. Among their concerns are several related to cultural resources. Alfredo Acosta Figueroa, a CARE member and member of the La Cuna de Aztlan Sacred Sites Protection Circle notes that the proposed project will "despoil a portion of the desert wilderness" (CARE 2009a, p. 2), which is sacred to the Uto-Aztecan language speakers. Further, he mentions that solar energy projects in general are "antithetical to the sacred sites purpose and appear to be intended to essentially trap the Creator Quetzalcoatl as the deity descends at sun down" (CARE 2009a, p. 2). In particular CARE is concerned about damage to sacred petroglyph sites—one in the Palen Mountains and another at McCoy Spring National Register District—and the ancient

trails that run between them. Knowledge of these sites is part of local traditional knowledge and has also been documented by archaeologists including Johnson and Johnstone (1957). According to the descriptions provided by Mr. Figueroa and by the archaeological maps, portions of several prehistoric trails potentially associated with McCoy Spring National Register District appear to pass near to or through the GSEP site footprint and linear facility corridor (McCarthy 1993, Fig. 10).

CULTURAL RESOURCES Table 4
Details of Communication between BLM and Native American Groups

Date	Group	Communication Details
12/18/07	Quechan Tribe	Bridget Nash replied: Expressed concerns for the potential impacts affiliated with the Tribe. Requests a copy of the cultural report once it is completed.
12/21/07	Cabazon Band of Mission Indians	Judy Sapp replied: If there are substantial impacts, the Tribe will request an in-person meeting with Morongo Tribal Historian and BLM staff. She requested additional cultural resource information and for the BLM to provide a report when it becomes available.
01/29/08	Agua Caliente Band of Cahuilla Indians	Patty Tuck replied: The project is beyond both the Reservation lands and traditional use areas of the Tribe. Suggests contacting the Augustine Band of Cahuilla Indians, the Cabazon Band of Mission Indians, the Twentynine Palms Band of Mission Indians, and the Torres-Martinez Desert Cahuilla Indians.
06/23/08	Quechan Tribe	Bridget Nash requests archaeological reports.
04/29/09	Quechan Tribe	A telephone and e-mail conversation between Bridget Nash (Quechan Tribe) and Wanda Raschkow (BLM); Ms. Nash sends requested reports and Ms. Raschkow sends e-mail regarding project status.
05/20/09	Multiple Tribes	A meeting was held to discuss various solar energy projects and transmission lines in the Chuckwalla and Coachella Valleys. Attendees included BLM staff C. Dalu, R. Queen, and J. Kalish and representatives from the Agua Caliente Band of Cahuilla Indians, Morongo Band of Mission Indians, Cabazon Band of Mission Indians, Torres-Martinez Desert Cahuilla Indians, Pechanga Band of Luiseno Indians, Anza Cahuilla, Ramona Band of Mission Indians, Twentynine Palms Band of Mission Indians, and San Manuel Band of Mission Indians.
05/21/09	Quechan Tribe	A letter was posted to Ms. Nash (Quechan Tribe) from BLM Palm Springs Field Office providing requested reports. C. Dalu sent Tetra Tech's archaeology reports.
05/29/09	Quechan Tribe	A package was posted to Ms. Nash (Quechan Tribe) from BLM Palm Springs Field Office providing requested reports.

Date	Group	Communication Details
06/05/09	Agua Caliente Band of Cahuilla Indians	Meeting with BLM and representatives of the Agua Caliente Band of Cahuilla Indians to discuss various solar projects.
06/09/09	Quechan Tribe	A telephone conversation between Bridget Nash (Quechan Tribe) and Wanda Raschkow (BLM); Ms. Raschkow reports status of project. Ms. Nash requests report. Ms. Raschkow indicates that a data sharing agreement will be necessary before providing archaeological reports and other sensitive data.
11/05/09	Multiple Tribes	Meeting with BLM to discuss various solar projects. Attendees included BLM staff and representatives from the Agua Caliente Band of Cahuilla Indians, Morongo Band of Mission Indians, Cabazon Band of Mission Indians, Torres-Martinez Desert Cahuilla Indians, Pechanga Band of Luiseno Indians, Anza Cahuilla, Ramona Band of Mission Indians, Twentynine Palms Band of Mission Indians, and San Manuel Band of Mission Indians. Tribes request a monthly report regarding all projects. The Agua Caliente Band of Cahuilla Indians requests a site visit.
09/03/09	Quechan Tribe	BLM receives a letter from President Mike Jackson, Sr. commenting on the Programmatic Environmental Impact Statement regarding solar development being developed for the six southwestern states. Concerns expressed over cultural resources and traditional cultural properties.
12/09/09	Chemehuevi Reservation	A telephone conversation between C. Dalu and a representative of the Chemehuevi Reservation expressing concern about the effect of Genesis, Palen, and Blythe solar projects on cultural resources and traditional cultural properties.
12/23/09	La Cuna de Aztlan Sacred Sites Protection Circle	This is a group composed of members from multiple tribes dedicated to the protection of sacred sites in traditional territories in the Colorado and Mojave Deserts. Their comments were included in a formal letter from the CAlifornians for Renewable Energy (CARE) in response to the BLM/CEC request for comments on the GSEP NOI. Concerned about damage to cultural resources such as trails and springs, in particular McCoy Spring.
02/16/10	Quechan Tribe	BLM receives a letter from President Mike Jackson, Sr. commenting on the regulatory approval schedule for the solar “fast-track” projects including Genesis. Concerns expressed about the ability of BLM to consult appropriately with the Tribe in the time frame envisioned. Also suggests that a Section 106 PA is inappropriate for these projects.

C.3.5.1.3.6.3. Field Inventory Investigations

To facilitate the environmental review of their projects, applicants conduct surveys to identify previously unrecorded cultural resources in or near the GSEP site footprint and linear facilities corridor. These surveys include a pedestrian archaeological survey and a built-environment windshield survey. The applicant includes the acquired new survey information as part of the information provided to staff in the AFC and may undertake additional field research, including geoarchaeological studies and site testing, to respond to staff's data requests. Staff may also undertake additional field research to supplement information provided by the applicant.

BLM's Class I survey, mentioned above, is an archival exercise. Under BLM's protocol for inventory-level cultural resources investigations on lands for which a Right-of-Way grant has been requested, after the Class I survey, the applicant generally undertakes field research, sequentially, at two increasing levels of intensity. A Class II survey, sometimes referred to as a "reconnaissance survey," is a statistically based sample survey designed to help characterize the probable density, diversity, and distribution of archaeological sites in a large area by interpreting the results of surveying (walking across and examining the ground surface) limited and discontinuous portions of the target area. A Class III survey is a continuous, intensive survey of an entire target area, aimed at locating and recording all archaeological properties that have surface indications, by walking close-interval parallel transects until the area has been thoroughly examined (BLM 2004, sec. 8110.21).

In summary, the archaeologists for the applicant employed six phases of fieldwork to inventory the cultural resources in the GSEP site footprint and linear facilities corridor: 2 geoarchaeological studies, 3 intensive pedestrian surveys, and 1 built-environment survey (Cultural Resources Table 2). This fieldwork identified 110 new cultural resources. The present cumulative cultural resources inventory for the GSEP site footprint and linear facilities corridor includes 33 archaeological resources, 75 archaeological isolate resources, 1 possible ethnographic resource, and 2 linear built-environment resources. These totals do not include the Class II survey.

C.3.5.1.3.6.3.1. Results of Pedestrian Archaeological Survey

The archaeologists for the applicant (Tetra Tech) undertook three distinct intensive pedestrian archaeological surveys of the proposed GSEP site footprint and linear facilities corridor and shortly will undertake a fourth.

The initial survey was a BLM Class II Sampling Field Inventory, which was conducted to facilitate decision-making regarding the placement of the project footprint. The results of this survey were included in the "CHRIS Results" subsection because this information helped inform the boundaries of the Class III survey area. During the Class II survey 20 percent of the original GSEP site footprint (9,480 acres) was surveyed. To identify locations to survey, this area was divided into 40-acre parcels along eighth-section lines. Forty-eight 40-acre parcels were then randomly selected from a total sample universe of 237 using a random numbers table. In total, 1,896 acres were surveyed. The field work was conducted between November, 2007, and January, 2008.

The second survey was an intensive BLM Class III survey of the 2,494-acre proposed project facility plus a perimeter buffer of 200 feet. The field work was conducted between March and April, 2009. Sites that had been recorded in this area during the initial Class II survey were briefly revisited during the Class III survey and updated if necessary.

The third pedestrian survey was an intensive BLM Class III survey of the proposed linear facilities corridor. Survey coverage included the proposed linear alignment, plus 75 feet to either side of the center line of the routes. A total of 449.5 acres were surveyed. The fieldwork was conducted in June of 2009.

The fourth pedestrian survey will be an intensive BLM Class III survey of a second proposed linear facilities corridor. Survey coverage will include the proposed linear facilities corridor, plus 75 feet to either side of the center line of the routes. The number of acres included in this survey is undetermined at this time, but is expected to be similar in size to the previous linear survey (approximately 450 acres). The field work will be completed in February of 2010.

The three completed surveys used identical methods and encountered similar working conditions. The survey methods entailed two-to ten-person survey teams walking at 15-meter intervals looking for archaeological remains. The survey team sought to relocate previously recorded sites and assess their current condition. For new resources, they defined three or more artifacts and/or features as a site and two or fewer as an isolate. They used an arbitrary distance of 50 meters (m) between artifacts and features to separate deposits into individual sites. They used handheld GPS units to plot the locations of features, sites, and isolated artifacts. All sites and architectural resources over 45 years of age with the data required by Department of Parks and Recreation (DPR) series 523 forms. They photographed site overviews and diagnostic artifacts, drew site sketch maps, compiled artifact and feature descriptions, and made observations on the terrain and ecology. Once a site was recorded the team removed all flagging tape. Overall visibility with all of the surveyed areas was good, and work days were sunny and clear with occasional days with extremely high winds. Tetra Tech undertook no subsurface testing and collected no artifacts (Farmer et al. 2009, pp. 58–59).

During the second and third intensive pedestrian archaeological surveys, 33 new archaeological sites and 75 archaeological isolates were found (Farmer et al. 2009). This total only includes sites found in the proposed project facility and linear facilities corridor areas. Sites found in the original, larger, 9,480-acre site footprint, are discussed in the “CHRIS Results” subsection above. When the fourth survey is complete, the results will be added to the above total. The new archaeological sites consisted of 23 prehistoric, 8 historic-period, and 2 multi-component archaeological sites. The archaeological isolates consisted of 53 prehistoric items, primarily lithics, and some ground stone. Twenty-two historic-period isolates were identified, mainly glass and metal. The prehistoric archaeological site types include lithic scatters of stone tool manufacturing and maintenance debris and potential temporary campsites. The historical archaeological site types consist of debris and refuse scatters. Many appear to be temporary camps associated with Desert Training Center California-Arizona Maneuver Area (DTC/C-AMA) maneuvers. The isolate types include prehistoric lithics

and ceramics as well as historic-period refuse. Cultural Resources Table 5 summarizes the previously known and newly identified archaeological sites. In many cases, however, for the newly identified sites, site function and the time periods represented were unspecified, despite the presence of artifacts that could provide the relevant information. This was particularly the case for the historical archaeological sites. These issues were not resolved by Data Requests.

C.3.5.1.3.6.3.2. Results of Geoarchaeological Investigations

The consultant for the applicant provided two geomorphological reports that summarize the geomorphology of the GSEP site footprint and linear facilities corridor on the basis of the extant geologic and soil science data for the region (Farmer et al. 2009, app. C) as well as field explorations (TTEC 2010e). As discussed in the "Geomorphology" subsection, above, six sedimentary units were identified during these investigations. The preliminary assessment for archaeological sensitivity of each of these units is presented below.

Qw:

These active stream wash deposits have a moderate potential for containing buried archaeological artifacts. However, the moderate-to-high-energy movement of water through these sediments would not be conducive to the preservation of archaeological materials and the spatial associations among them.

Qs:

These late Holocene-age, wind-deposited sand sheets are most commonly found to the south of the proposed GSEP site footprint often overlaying lake deposits (Ql). Staff considers this stratigraphic unit to have a moderate-to-high potential for containing buried archaeological deposits associated with human utilization of resources associated with Dry Ford Lake. Relatively low-energy alluvial and aeolian movement of sediments would be conducive to the preservation of archaeological materials and the spatial associations among them. Poorer preservation of these spatial associations is expected in sites located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash.

Qal:

This alluvium was deposited across most of the GSEP site footprint between 1,000 and 8,000 years ago, well within the human occupation of the region. This approximately 1-foot-thick layer was laid down by low-to-moderate-energy sheet wash and flood events. It is often covered by sand sheets 4 to 8 inches thick (Qsr). Staff considers this stratigraphic unit to have a moderate –to-high potential for containing buried deposits. The potential for buried deposits is expected to increase with proximity to the lake. Deposits formed by low- and moderate-energy sheet wash would be conducive to the preservation of archaeological materials and the spatial associations among them. Poorer preservation of these spatial associations is expected in sites located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash.

Qsr:

These ancient sand sheets were deposited between 1,000 to 7,000 years ago, within the human occupation of the region. This stratigraphic unit is common on the surface of the site footprint overlaying unit Qal in a layer 4 to 8 inches thick. Staff considers this stratigraphic unit to have a moderate-to-high potential for containing buried deposits. The potential for buried deposits is expected to increase with proximity to the lake. Relatively low-energy alluvial and aeolian movement of sediments would be conducive to the preservation of archaeological materials and the spatial associations among them. Poorer preservation of these spatial associations is expected in sites located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash.

Qoaf:

These distinctly red Pleistocene alluvial fan deposits were created between 12,000 and 20,000 years ago. They are present within 1 to 2 feet of the modern ground surface across most of the proposed GSEP site footprint. Staff considers this stratigraphic unit to have a low to moderate potential for archaeological materials on its upper surface. Because these deposits were formed prior to the human occupation of the region, the potential for containing buried cultural materials is considered low. The low-to-moderate-energy sheet wash and flood events on the surface of this stratigraphic unit would be moderately conducive to the preservation of archaeological materials and the spatial associations among them. Poorer preservation of these spatial associations is expected in sites located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash.

Ql:

This stratigraphic unit can be divided into two distinct groups, those deposited above the Qoaf alluvium and those deposited below the Qoaf alluvium. The lake deposits below the Qoaf alluvium were formed more than 12,000 years ago, prior to the human occupation of the area. As a result staff does not expect these lake sediments to contain cultural materials. Lake deposits above the Qoaf alluvium were formed during the human occupation of the area (Holocene period) and may contain cultural materials on the surface or buried by other lake deposits, Qal alluvium, or Qs sand dunes. Relatively low-energy alluvial movement of sediments would be conducive to the preservation of archaeological materials and the spatial associations among them. Poorer preservation of these spatial associations is expected in sites located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash. Preservation may also be poor due to high-energy wave action along eastern shoreline as a result of strong winds from the west.

Several of the ancient shorelines have been associated with estimated dates, potentially giving clues to the ages of the sites that cluster along their edges. One of the latest Holocene shorelines is located at 373 and 374 feet in elevation and is estimated to be 12,000 years old. The shoreline between 367 and 370 feet in elevation appears to be between 8000 and 12,000 years old, and the shoreline at 364 feet is estimated to be between 5000 and 12,000 years old. The most recent shoreline is located at 360 feet and appears to have been created during the past few thousand years.

Overall, the majority of the proposed site footprint is covered in deposits of Holocene age. Staff considers these deposits to have a moderate-to-high potential to contain well-preserved, buried cultural materials. However, these materials would be expected within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. The highest density of sites is expected in association with ancient lakeshores reflecting human utilization of plant and animal resources flourishing near this desert water source. These sites are also expected to be the best preserved since the gentle slope would result in low-energy sheet wash. The exception is those sites located in the McCoy-Palen Mountain valley, where moderate-energy sheet wash may have caused disturbance and potentially more deeply buried sites. Some of these sites may be dated by their association with particular shorelines. These patterns indicate that the areas of highest archaeological sensitivity are located in the southeastern part of the GSEP site footprint.

C.3.5.1.3.6.3.3. Results of Windshield Survey for Built-Environment Resources

The applicant also sought to identify standing structures that would be 45 years of age or older in 2010 (Farmer et al. 2009, app. F). The built-environment inventory covered the APE of the linear facilities and a 0.5-mile survey buffer. In consultation with Energy Commission staff, it was determined that a built-environment survey was not required for the plant facility APE since no historical architectural resources were identified within several miles of the site footprint. Fieldwork was conducted in July of 2009, resulting in the identification of two linear built-environment resources along the proposed linear facilities corridor. The historian for the applicant identified and recorded portions of the Blythe-Eagle Mountain Transmission Line and Wiley's Well Road within the built-environment study area, but did not evaluate them for their eligibility to be listed on the NRHP or CRHR.

C.3.5.1.3.6.4. Summary of Identified Cultural Resources in the APEs and Vicinity

Overall, previous projects and the cultural resources surveys of the applicant have identified a total of 313 cultural resources within the APEs and in the near vicinity (Cultural Resources Table 5). These resources include 118 archaeological sites, 192 archaeological isolates, 1 possible ethnographic resource, and 2 linear built-environment resources. One of these sites is of an unspecified type and from an unspecified time period and is therefore not included in the following discussion.

The prehistoric resources include 91 archaeological sites, with 4 additional multi-component sites containing prehistoric components, and 146 isolated artifacts. These sites primarily consist of sparse artifact scatters and possible temporary campsites. The sparse artifact scatters are primarily prehistoric flakes and cores. These tend to blend into the prehistoric isolates, which are also predominantly lithics, forming a landscape with regular but diffuse evidence of prehistoric human activities. These activities appear to be related to stone tool manufacturing and maintenance, possibly tied to the collection of wild resources. Ethnographic sources suggest that portions of the Mojave Desert distant from water sources were primarily used for travel and ritual activities rather than for the collection of resources (Cleland 2005).

Interestingly, travel-related sites were not present in the proposed site footprint and linear facilities corridor, and are rare in the project vicinity. Ethnographic sources and other archaeological projects in the region mention prehistoric trails leading to McCoy Spring National Historic District, at least four other natural “tanks” within the McCoy Mountains, and along the I-10 corridor (Johnson and Johnstone 1957; McCarthy 1993). Road construction in this corridor may well have destroyed evidence of the prehistoric trail that preceded the modern transportation routes and associated natural gas and electric lines. McCarthy’s (1993) work at McCoy Spring suggests that prehistoric trails potentially crossed the proposed site footprint and linear facilities corridor. However, these trails are easiest to see on landforms with desert pavement, which are rare in the GSEP site footprint. Linear alignments of deliberate “pot drops” (isolated scatters of sherds from a single pot, possibly associated with sacred activity) (Sutton et al. 2007) and artifact scatters consisting of only ceramics (McCarthy 1993) are both indications of nearby trails. Clear evidence of trails was not identified in the GSEP site footprint, its linear facilities corridor, or its vicinity. However, secondary indications, such as pot drops, were found during archaeological survey, and multiple recorded trails run in the direction of the GSEP site footprint (McCarthy 1993, Fig. 10).

Through its analysis, staff believes the trails and trail-associated sites described above contribute to the Prehistoric Trails Network (PTN) Cultural Landscape, a potentially NRHP- and CRHR-eligible cultural landscape whose boundaries have yet to be determined but which includes McCoy Spring, Ford Dry Lake, and the trails leading between them and other important destinations, such as the Colorado River.

Sites with features and the densest concentrations of artifacts appear to be located around the edges of Ford Dry Lake. Most archaeologists have referred to these as temporary camps. Clearly this would have been an attractive place to camp when traveling, an excellent place to collect resources when water was temporarily present, and a possible permanent village location when water was present for long periods. The lack of midden on the surface of any of the recorded sites suggests that these sites had short-term, resource-gathering, resource-processing, and residential functions. As many of these sites have ground stone, the temporary camps appear to date after the Paleo-Indian period. Further, most of the sites also have ceramics, suggesting that they have components from the Late Prehistoric period (Sutton et al. 2007). These lakeside camps are also possible contributors to the PTN Cultural Landscape.

The historic-period resources include 22 archaeological sites, with 4 additional multi-component sites containing historic-period components, and 46 isolated artifacts. Most of these sites and artifacts reflect movement through the area by automobile and military maneuvers associated with the DTC/C-AMA. These sites are primarily debris scatters. Some are mainly domestic debris and may have been dumped by passing travelers or off-road vehicle drivers. Others are a mix of domestic military debris, suggesting they are the remains of temporary military camps that were part of the DTC/C-AMA. Occasional military features such as earthen mounds and possible foxholes have also been noted. The historic-period isolates reflect these same kinds of activities. Other known, common historic activities, including mining and ranching, are not well represented.

Through its analysis, staff believes the World War II-Era DTC/C-AMA sites described above contribute to a potentially eligible cultural landscape (historic district) whose boundaries include the entire proposed GSEP's APEs.

Only one possible ethnographic resource was identified, McCoy Spring National Register District. This site was originally nominated to the NRHP for its archaeological information potential. However, it appears to be an important place to local Native American groups, as discussed in "Results of Native American Consultation" (CARE 2009a). While the site would not be physically impacted by the GSEP, indirect impacts related to the proposed project may be possible.

Two linear built-environment resources were identified within the proposed linear facilities corridor: Blythe-Eagle Mountain Transmission Line and Wiley's Well Road. The transmission line is associated with regional population growth during the 1950s. Wiley's Well Road is associated with transportation and regional mining efforts, beginning in the 1860s and continuing until the 1960s.

CULTURAL RESOURCES Table 5
Cultural Resources Located in the Vicinity of the Proposed Project

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
Prehistoric Archaeological Resources				
P-33-1517	Prehistoric Site: Small Lithic Scatter of jasper and quartz at 120 meters elevation.	Previously known	Prehistoric	E. Ritter 1975
CA-Riv-53T	Prehistoric Trail segment with ceramic distribution along trail.	Previously known	Prehistoric	McCarthy 1993
P-33-1222	Prehistoric Site: Temporary Camp located near dry lake shore: 7 loci of metates/manos, also few quartz/chalcedony cores/flakes. Site disturbed by ORV.	Previously known	Late Prehistoric	J. Cook 1976
P-33-1516	Prehistoric Site: Large Temporary Camp along dry lake shoreline: ground stone, lithic scatter, thermal fractured rock. Some WW II military artifacts noted, no details regarding type.	Previously known	Late Prehistoric Also historic	E. Ritter 1975
P-33-2159	Prehistoric Site: Temporary Camp/Lithic Scatter along gravel terraces of dry lake bed: metate/manos fragments, hammerstone/choppers, lithic flakes; rhyolite, basalt, chalcedony, agate, jasper, chert, granite, andesite.	Previously known	Late Prehistoric	S. Cardenas 1981

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
P-33-1216	Prehistoric Site: Widely dispersed lithic scatter along maximal shoreline upon the gravel terrace: 7 flakes of chert/jasper, 1 hammerstone/core. Potential Pinto/Amargosan period site.	Previously known	Prehistoric	D. McCarthy 1977
CA-Riv-6170 (P-33-8655)	Prehistoric Site: Lithic Scatter along dry lake bed: lithic flakes of quartzite, agate, chalcedony, chert, jasper, 1 chert rose spring project point, 1 point and drill fragment.	Previously known	Late Prehistoric	M. Mitchell 1998
P-33-663	Prehistoric Site: An extensive series of shoreline temporary camps: metate/mano fragments of green shale, fire affected rock, lithic reduction flakes (jasper, quartzite, rhyolite, chert, and chalcedony), pottery (Parker buff ware and Tizon brown ware, and greyware), rock alignment, 1 corner notched projectile point fragment, 1 biface fragment.	Previously known	Late Prehistoric	D. Pallette et al., 1989
P-33-2206	Prehistoric Site: Sparse Lithic Scatter: 6 flakes (chalcedony, quartz, opal), 1 quartzite cobble core.	Previously known	Prehistoric	S. Hammond 1981
P-33-2157	Prehistoric Site: Temporary Camp near dry lake shore: ceramic (buff/brown ware), ground stone fragments (metates/manos), lithic flakes (quartz/green andesitic meta-volcanic).	Previously known	Late Prehistoric	S. Cardenas 1981
P-33-1543	Prehistoric Site: Lithic Scatter (temporary camp): 3 metate fragments-2 flakes.	Previously known	Late prehistoric	M. Morim 1976
P-33-3802	Prehistoric Site: Temporary Camp near dry lake shore: 1 metate fragment, 2 chalcedony flakes, 1 quartzite hammerstone, fractured cobbles, and possible green shale hearth feature.	Previously known	Late Prehistoric	D. Pallete et al. 1989
P-33-1131	Prehistoric Site: Widely dispersed low density ceramic drop: 50 reddish brown “Tizon” pottery shreds, 1 mano/core fragment.	Previously known	Late Prehistoric	E. Dittman 1981
P33-00260	Prehistoric Site: Lithic Scatter (temporary camp): metate fragments, flakes.	Previously known	Late Prehistoric	R. Rameriz 2008 (update)

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
P33-00663	Prehistoric Site: Widely dispersed lithics, ground stone, pottery.	Previously known	Late Prehistoric	D. Pallette 1989
P33-001543	Prehistoric Site: 3 metates, lithic flakes	Previously known	Late Prehistoric	M. Morim 1976
P33-001818	Prehistoric pottery fragments	Previously known	Late Prehistoric	R. Carrico 1980
P33-001840	Prehistoric lithic scatter.	Previously known	Prehistoric	Musser/Boyer 1976
P33-2159	Prehistoric Site: Temporary Camp/Lithic Scatter along gravel terraces of dry lake bed: metate/manos fragments, hammerstone/choppers, lithic flakes; rhyolite, basalt, chalcedony, agate, jasper, chert, granite, andesite.	Previously known	Late Prehistoric	Cardenas 1981
P33-3801	Prehistoric site: pottery scatter	Previously known	Late Prehistoric	Pallette 1989
P33-003802	Prehistoric Site: lithic scatter, lithic tools, and ground stone	Previously known	Late Prehistoric	Pallette 1989
P33-003808	Prehistoric Site: ceramic scatter	Previously known	Late Prehistoric	Mooney & Associates 1990
P33-003809	Prehistoric Site: ceramic scatter	Previously known	Late Prehistoric	Mooney & Associates 1990
CA-Riv-6900	Prehistoric Site: lithic scatter, lithic tools, and ground stone	Previously known	Prehistoric	BLM 1977
P-33-1517	Prehistoric Site: Small Lithic Scatter of jasper and quartz at 120 meters elevation.	Previously known	Prehistoric	E. Ritter 1975
P-33-3129	Trail segment that leads to the southwestern side of the McCoy Mountains.	Previously known	Prehistoric	F. McCarthy 1991
P33-00259	Rock Rings	Previously known	Prehistoric	N. Gester 1965
CA-Riv-9032 (P33-17416)	Lithic Scatter: Debitage (n=14); two cores.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9033 (P33-17417)	Lithic Scatter: Debitage (n=39); two cores.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9034 (P33-17418)	Temporary Camp: Debitage (n=55); mano fragment.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9036 (P33-17420)	Temporary Camp: Debitage (n=3), mano, fire-affected rock (FAR).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9037 (P33-17421)	Temporary Camp: Debitage (n=17), ground stone, ceramics, fire-affected rock (FAR).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9038 (P33-17422)	Temporary Camp: Debitage (n=7), FAR.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9039 (P33-17423)	Temporary Camp: Debitage (n=3), and mano fragment.	New	Prehistoric	Farmer et al. 2009

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
CA-Riv-9040 (P33-17424)	Lithic Scatter: Debitage (n=22), and flake tool.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9041 (P33-17425)	Lithic Scatter: Debitage (n=11), and core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9042 (P33-17426)	Lithic Scatter: Debitage (n=2), core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9043 (P33-17427)	Temporary Camp: Debitage (n=7), a lithic core, and ground stone implements. Speculative chronology.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9044 (P33-17428)	Temporary Camp: Debitage (n=20+), and mano.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9045 (P33-17429)	Lithic Scatter: Debitage (n=4), and cores.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9046 (P33-17430)	Lithic Scatter: Debitage (n=16); FAR, core, hammerstone, mano, metate fragment.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9047 (P33-17431)	Lithic Scatter: Debitage (n=5)	New	Prehistoric	Farmer et al. 2009
CA-Riv-9048 (P33-17432)	Lithic Scatter: Debitage (n=10).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9049 (P33-17433)	Temporary Camp: Debitage (n=2), core, and ground stone fragments.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9050 (P33-17434)	Lithic Scatter: Debitage (n=3).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9051 P33-17435	Lithic Scatter: Debitage (n=4), core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9052 (P33-17436)	Temporary Camp: Debitage (n=2), core, and ground stone].	New	Prehistoric	Farmer et al. 2009
CA-Riv-9053 (P33-17437)	Lithic Scatter: Debitage (n=3), and cores.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9054 (P33-17438)	Lithic Scatter: Debitage (n=5).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9055 (P33-17439)	Temporary Camp: Debitage, ground stone, and ceramic fragments.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9056 (P33-17440)	Lithic Scatter: Debitage (n=3), biface, and hammerstone.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9057 (P33-17441)	Temporary Camp: Debitage (n=6), core, and metate fragment.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9060 (P33-17444)	Temporary Camp: Debitage (n=4), metate and ceramic fragments.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9061 (P33-17445)	Lithic Scatter: Debitage (n=6).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9062 (P33-17446)	Temporary Camp: Debitage (n=16) and mano fragments.	New	Prehistoric	Farmer et al. 2009

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
CA-Riv-9064 (P33-17448)	Temporary Camp: Debitage (n=120+), projectile points, bifaces, and ground stone implements. Speculative chronology. Possibly Archaic period.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9065 (P33-17449)	Temporary Camp: 20+ FAR, 2 metate fragments, and 2 chert flakes.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9066 (P33-17450)	Lithic Scatter: Debitage (n=8).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9067 (P33-17451)	Lithic Scatter: Debitage (n=20+), projectile point, biface, flake tool.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9068 (P33-17452)	Temporary Camp: Debitage (n=50+), ground stone, and a flake tool.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9069 (P33-17453)	Lithic Scatter: Debitage (n=10+).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9070 (P33-17454)	Lithic Scatter: Debitage (n=2), core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9071 (P33-17455)	Temporary Camp: Debitage (n=235+), with associated bifaces, tools and cores, indications of food production (milling stones, possible FAR), and evidence of ceramic technology. Late Prehistoric Period.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9072 (P33-17456)	Temporary Camp: Debitage (n=hundreds), FAR, Rose Spring projectile point, brownware sherds (n=hundreds) hundreds of ground stone fragments, scatter covers several hundred acres.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9073 (P33-17457)	Lithic scatter: Three flakes and one tool.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9075 (P33-17459)	Temporary Camp: Debitage (n=5), a flake tool, and metate.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9076 (P33-17460)	Temporary Camp: Debitage (n=5).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9078 (P33-17462)	Temporary Camp: Lithic scatter, ground stone, projectile points, bifaces, FAR. Site limits incompletely defined; extends east west and south beyond established boundary.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9079 (P33-17463)	Temporary Camp: Site limits incompletely defined. Debitage (n=500); ground stone, flake, core tools, and a marine clam shell fragment.	New	Prehistoric	Farmer et al. 2009

Resource Type and Designation	Known Resource Description (type, age, content)	When Found	Period/ Era	Information Source
CA-Riv-9080 (P33-17464)	Lithic Scatter: Debitage (n=4).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9081 (P33-17465)	Lithic Scatter: Debitage (n=7).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9083 (P33-17467)	Lithic Scatter: Debitage (n=6+).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9084 (P33-17468)	Temporary Camp: Debitage (n=21), ground stone, and an olivella shell bead.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9206 (P33-17775)	Lithic Scatter: Debitage (n=4), mano	New	Prehistoric	Farmer et al. 2009
CA-Riv-9207 (P33-17776)	Lithic Scatter: Debitage (n=5), core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9208 (P33-17777)	Lithic Scatter: Debitage (n=7), core	New	Prehistoric	Farmer et al. 2009
CA-Riv-9209 (P33-17778)	Lithic Scatter: Debitage (n=7), 4 ground stone fragments, core.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9210 (P33-17779)	Lithic Scatter: Debitage (n=10), core, metate fragments.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9212 (P33-17781)	Lithic Scatter: Debitage (n=3), side-notched projectile point.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9215 (P33-17784)	Lithic Scatter: Debitage (n=10), concave-base projectile point.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9216 (P33-17785)	Lithic Scatter: Debitage (n=45), hammerstone, core, 2 manos.	New	Prehistoric	Farmer et al. 2009
CA-Riv-9217 (P33-17786)	Lithic Scatter: Debitage (n=3),	New	Prehistoric	Farmer et al. 2009
CA-Riv-9218 (P33-17787)	Lithic Scatter: Debitage (n=2), scraper	New	Prehistoric	Farmer et al. 2009
CA-Riv-9219 (P33-17788)	Lithic Scatter: Debitage (n=3)	New	Prehistoric	Farmer et al. 2009
CA-Riv-9220 (P33-17789)	Lithic Scatter: Debitage (n=92), metate fragment, projectile point tip, Cottonwood projectile point	New	Prehistoric	Farmer et al. 2009
CA-Riv-9221 (P33-17770)	Lithic Scatter: Debitage (n=7).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9222 (P33-17771)	Lithic Scatter: Debitage (n=3).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9223 (P33-17772)	Lithic Scatter: Debitage (n=16).	New	Prehistoric	Farmer et al. 2009
CA-Riv-9226	Lithic and ceramic Scatter: Debitage (n=10); FAR, metate fragment. brownware sherds (n=3), 2 cobble choppers, badly deflated	New	Prehistoric	Farmer et al. 2009
CA-Riv-9227 (P33-17796)	Lithic and ceramic Scatter: Debitage (n=3); brownware sherds (n=14), marine shell fragment	New	Prehistoric	Farmer et al. 2009
CA-Riv-9229 (P33-17798)	Lithic Scatter: Debitage (n=6); mano, metate fragment, cobble choppers	New	Prehistoric	Farmer et al. 2009

C.3.5.1.3.7. NRHP and CRHR Evaluations of Cultural Resources in the APEs

Energy Commission staff has determined for each cultural resource subject to potential impacts from the GSEP both its CRHR eligibility and its NRHP eligibility. Staff has considered only archaeological sites, and has not considered isolates, as distinguished by Tetra Tech.

For this project, staff's standard cultural resources evaluation process is being abbreviated by means of a procedural maneuver, described as "approach 3" above (see "Methodology and Thresholds for Determining Environmental Consequences"). Under "approach 3," staff does not necessarily evaluate the historical significance of each individual resource, but, rather, assumes that many of the known resources subject to project impacts are eligible for the NRHP, the CRHR, or both. Then, under "approach 3," the project's impacts to all assumed register-eligible resources would have to be mitigated by means of avoidance or mitigation in the form of data recovery.

For any resources where staff has sufficient information to determine the resource's eligibility for either register, staff will make that determination. If, on the basis of data staff has in hand, staff can determine that a resource is not eligible for either register, then no avoidance or data recovery as mitigation would be necessary for project impacts to the resource. If staff can determine, on the basis of data in hand, that a resource is eligible for either register, then avoidance or data recovery would be necessary. Similarly, if staff cannot determine, on the basis of data in hand, whether a resource is register-eligible or not, staff would assume register eligibility, and impacts to the resource would have to be avoided or mitigated.

The applicant originally determined that there were 34 archaeological sites and 2 built environment resources that could be potentially impacted by the construction of GSEP. All of these resources were identified during the intensive pedestrian cultural resources surveys conducted by Tetra Tech (Farmer et al 2009), since no previously recorded sites were present within the site footprint or linear facilities corridor. On the basis of archival research and surface observation during pedestrian surveys Tetra Tech recommended that two of the original 36 resources (CA-Riv-9072 and CA-Riv-9224) may be eligible for listing in the NRHP and the CRHR.

The proposed route of the GSEP linear facilities corridor has since been changed (TTEC 2010c), and five of the original archaeological sites would be avoided (CA-Riv-9224, CA-Riv-9225, CA-Riv-9226, CA-Riv-9229, CA-Riv-9230), including CA-Riv-9224, one of the sites Tetra Tech recommended as eligible for listing in the NRHP and the CRHR. Therefore, the applicant considers that 29 archaeological sites (not including the 2 built-environment resources), will possibly be impacted by the proposed project. Tetra Tech consequently recommends only one of these resources (CA-Riv-9072) is potentially eligible for listing in the NRHP and the CRHR. The cultural resources survey for the new proposed linear facilities corridor has not yet been completed. However, additional sites may be added to this total based on the results of this survey.

The above calculations were the result of a number of communications between Tetra Tech and Energy Commission staff (CEC 2009a, CEC 2009c, CEC 2009f). Staff concurs with the conclusions reached by the applicant, with three additions. First, staff

concludes that the proposed project has the potential to indirectly impact the McCoy Spring National Register District. This resource was nominated to the NRHP for its contribution to Mojave Desert prehistory, and it may also be eligible for listing on the NRHP under Criterion A as a traditional cultural property. Second, staff further concludes that the proposed project has the potential to directly impact prehistoric cultural resources that are potential contributing elements in the Prehistoric Trails Network Cultural Landscape. McCoy Spring National Register District is a potential contributor to the PTN Cultural Landscape. Finally, staff concludes that the proposed project may directly impact historic-period cultural resources that are potential contributing elements to the World War II Desert Training Center California-Arizona Maneuver Area (DTC/C-AMA) Cultural Landscape. The portions of the two linear built-environment resources within the built-environment APE are not considered eligible for listing on the NRHP or the CRHR. Other portions of Wiley's Well Road, however, are considered eligible.

Therefore the proposed project has the potential to impact 29 resources and 2 cultural landscapes within the archaeological APE and 1 resource or historic district within the ethnographic APE.

Currently (without consideration of any additional resources that may be identified during the new linear facilities corridor survey), the resources that the GSEP could impact include 26 archaeological resources in the GSEP site footprint that would be subject to physical impacts, 3 further archaeological resources along the linear facilities corridor that the applicant may be able to actively avoid, 1 archaeological site that is also a possible TCP, the impacts to which remain to be evaluated, and potential 2 cultural landscapes that would be subject to physical impacts. Twenty-three of the 30 archaeological resources are prehistoric-to-early-historic-period Native American archaeological sites (including McCoy Spring), 6 are historical archaeological sites, and 1 is a multiple-component archaeological site that includes both prehistoric and historic-period components. The portions of the two linear built-environment resources within the GSEP built-environment APE do not appear to be subject to physical impacts.

The evaluations of whether archaeological resources are eligible for listing in the NRHP and the CRHR and are, therefore, historical resources under CEQA include only the 32 resources that the Energy Commission staff understands, at this time, to be potentially subject to impacts from the proposed project. Of the 32 cultural resources subject to evaluation, below, staff recommends that 2 resources (CA-Riv-9072 and Wiley's Well Road) are eligible for listing in the NRHP and CRHR, that 15 individual resources are not eligible for such listing, that 14 individual resources and two possible cultural landscapes are assumed eligible for listing in the NRHP and the CRHR (Cultural Resources Table 6). The remaining cultural resource, McCoy Spring, is already listed on both the NRHP and the CRHR.

CULTURAL RESOURCES Table 6
NRHP- and CRHR-Eligible Known Cultural Resources for Which Avoidance or Mitigation of Project Impacts Would Be Required

Resource Type, Designation	Resource Description (type, size, content)	NRHP/CRHR Eligibility
Cultural Landscapes		
DTC/C-AMA Cultural Landscape	Not all contributors located in GSEP APE: potentially includes some sites listed below.	Assumed Eligible
Prehistoric Trails Network Cultural Landscape	Not all contributors located in GSEP APE: potentially includes some sites listed below.	Assumed Eligible
Prehistoric Archaeological Resources		
CA-Riv-9072	Temporary Camp: 300 acres, features, 1000s artifacts. PTN Cultural Landscape contributor	Eligible
CA-Riv-9084	Temporary Camp: Debitage (n=21), ground stone, and an olivella shell bead.	Assumed Eligible
CA-Riv-9209	Artifact Scatter: Debitage (n=7), 4 ground stone fragments, core.	Assumed Eligible
CA-Riv-9215	Artifact Scatter: Debitage (n=10), concave-base projectile point.	Assumed Eligible
CA-Riv-9216	Artifact Scatter: Debitage (n=45), hammerstone, core, 2 manos.	Assumed Eligible
CA-Riv-9220	Artifact Scatter: Debitage (n=92), metate fragment, projectile point tip, Cottonwood projectile point .	Assumed Eligible
CA-Riv-9223	Artifact Scatter: Debitage (n=16).	Assumed Eligible
CA-Riv-9227	Artifact Scatter: Debitage (n=3); brownware sherds (n=14), marine shell fragment.	Assumed Eligible
Ethnographic Resources		
	McCoy Spring National Register District: largest petroglyph site in Mojave Desert, midden, multiple trails. PTN Cultural Landscape contributor	Listed on both
Historical Archaeological Resources		

Resource Type, Designation	Resource Description (type, size, content)	NRHP/CRHR Eligibility
CA-Riv-9203H	Refuse Scatter: Approximately 84 food and beverage cans, can fragments, glass bottles, and plastic. Dual component? Post 1950? Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
CA-Riv-9204H	Refuse Scatter: Can scatter, bottles (1932-1953). Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
CA-Riv-9211H	Refuse Scatter: Cans, bottle glass, 1934 penny. Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
CA-Riv-9213H	Refuse Scatter: Approximately 60 cans. Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
CA-Riv-9214H	Refuse Scatter: Approximately 10 cans. Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
CA-Riv-9228H	Refuse Scatter: 10 cans, bottle base (1938-1951), bottle base (1916-1931), razor blade, glass fragments. Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
Dual Component Resources		
CA-Riv-9205H	Refuse Scatter/Lithic Scatter: Debitage (n=4); mano, 2 metate fragments. Glass bottles (post 1945), auto parts (1930-1940), condensed milk cans. Possible contributor to DTC/C-AMA Cultural Landscape.	Assumed Eligible
Built-Environment Resources		
No Number	Blythe-Eagle Mountain Transmission Line	Not Eligible
No Number	Wiley's Well Road	Eligible

The descriptions and the evaluations of the NRHP or CRHR eligibility of the 32 individual resources, and the 2 possible cultural landscapes that the proposed project would impact are presented below. The information for the descriptions and the evaluations is drawn from a number of sources that include preliminary technical reports (Farmer et al. 2009 and app. G, DPR 523 forms; TTEC 2010e), email correspondence, and discussions that were held at the December 31, 2009, and January 6, 2010, Data Response workshops.

C.3.5.1.3.7.1. Prehistoric Archaeological Resources

CA-Riv-9047 (P33-17431)

This site is an oblong prehistoric archaeological deposit approximately 2,025 square meters (m) (0.5 acre) in area. It is located near the southern boundary of the site footprint. The long axis of the deposit parallels a north-south trending ephemeral wash cutting through the sand and gravel of the site surface. The predominant vegetation on the site appears to be Mojave creosote bush scrub. Other information about the physical character of the site surface is unspecified. The surface component of the site measures approximately 62 m from north to south and 35 m from east to west. It consists of a sparse scatter of 5 artifacts which includes 1 cortical and 3 interior flakes of quartz and 1 cortical flake of chert. Further character of the artifacts at this site is unreported. The depth of the site deposit is undetermined.

The more particular physical context for site CA-Riv-9047, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be the edge of the oldest lakeshore (Ql) where it intersects with the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit. The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no age or functional interpretation for the site, but suggest that the dearth of cultural constituents indicates that prehistoric activity at the site was very brief in duration. The archaeologists recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9047 (P33-17431) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9048 (P33-17432)

This site is an oblong prehistoric archaeological deposit oriented north-south approximately 2,025 square m (0.5 acre) in area. It is located near the near the southern boundary of the site footprint. The predominant vegetation on the site appears to be Mojave creosote bush scrub. Other information about the physical character of the site surface is unspecified. The surface component of the site measures approximately 78 m from north to south and 31 m from east to west. It consists of a sparse scatter of 10 lithic artifacts which includes 3 chert flakes, 1 chalcedony flake, 1 rhyolite flake, 3 quartz flakes, and 2 quartzite flakes. The depth of the site deposit is undetermined.

The more particular physical context for site CA-Riv-9048, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be edge of the oldest lakeshore (Ql) where it intersects with the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit. The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no age or functional interpretation for the site. The archaeologists recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9048 (P33-17432) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9051 (P33-17435)

This site is an oblong prehistoric archaeological deposit oriented northwest-southeast approximately 810 square m (0.2 acre), in area. The deposit is near the southern boundary of the site footprint. The predominant vegetation on the site appears to be Mojave creosote bush scrub. Other information about the physical character of the site surface is unspecified. The surface component of the site measures approximately 49 m from northwest to southeast and 19 m from northeast to southwest. It consists of a low density scatter of 5 prehistoric artifacts including 3 chert cortical flakes, 1 quartzite interior flake and 1 multi-directional chert core. The presence of a chert core and similar chert flakes raised the possibility that this site was potentially a single-use lithic work station. However, an in-field refit analysis revealed that none of the chert debitage co-joined with one another, or with the core. The depth of the site deposit is undetermined.

The more particular physical context for site CA-Riv-9051, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials.

Nonetheless, materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no age or alternative functional interpretation for the site. Further, the archaeologists recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9051 (P33-17435) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9072 (P33-17456)

This site is an oblong prehistoric archaeological deposit approximately 15,246,000 square m (350 acres) in area. It is located in the southwest corner of the site footprint. Only a small portion of the east end of the site overlaps with the proposed GSEP facility footprint. Multiple minor seasonal drainages run from north to south through the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface consists of a mosaic of desert pavement interspersed with sand and gravel alluvium. The surface component of the site measures approximately 1,820 m from east to west and 980 m from north to south. The site was originally recorded during the Class II survey. Its boundaries were subsequently enlarged when it was revisited during the Class III survey.

The site includes a low to moderate density artifact scatter and three artifact concentrations. Due to the size of the site the total number of artifacts was estimated. It appears to consist of at least 1,000 artifacts, predominantly prehistoric lithics. The lithic material types present include chert, jasper, quartzite, and crystalline quartz. The lithic scatter is sparse but is characterized by intermittent pockets of elevated artifact density which could represent intensified activity areas or, given the dynamic landform (e.g. sheet flow, seasonal drainages, to erosion), an increased surface visibility. All stages of reduction were in abundant evidence, suggesting that a full range of lithic industry (from testing/procurement to biface/tool manufacture and finishing) was practiced here. At least 12 lithic tools were identified including 1 black chert Rose Spring projectile point, 1 chert Cottonwood Triangular point, 2 quartz bifaces, 3 stage-1 black chert bifaces, 1 chert scraper, 2 chert cores, 2 quartzite cores, and an unknown number of core and flake-based tools. Other artifacts noted at the site included 33 quartzite metates or metate fragments, 5 quartzite manos, and 1 fragment of marine clam shell (species unknown). No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

Two artifact concentrations were noted in the western half of the site and a third along the north central site boundary. Concentration 1 consists of 10 brownware sherds within a 4 square-meter area. Nine body sherds and 1 base sherd were noted. Concentration 2 is located 10 m to the south of Concentration 1. This concentration consists of 11 brownware sherds within a 2-square-meter area. Nine body sherds, 1 neck sherd, and 1 rim sherd were observed. Four additional sherds were noted several meters to the south. The archaeologists for the applicant suggest that both of these concentrations

represent single, broken ceramic vessels, or pot drops. Staff notes that pot drops in non-random patterns have been associated with trails along main travel routes as well as trails that approach springs and tanks (Schaefer and Laylander 2007, p. 254). No evidence of a trail was noted near this site, but the close presence of prehistoric trails known to follow the I-10 corridor, McCoy Spring, and Ford Dry Lake itself, suggest that ceremonial pot drops may be present in the vicinity. These patterns are discussed in more detail in subsection C.3.5.1.3.6.4. “Summary of Identified Cultural Resources in the APEs and Vicinity.” Concentration 3 is a deflated hearth with approximately 21 pieces of fire-affected rock (FAR); it was identified within a north-south trending seasonal drainage. The hearth measures 98 centimeters (cm) from northeast to southwest and 68 cm southeast to northwest. In addition, two quartzite choppers, seven quartzite hammerstones, a rhyolite dome scraper, and an unmodified fragment of marine clam shell were observed.

The more particular physical context for site CA-Riv-9072, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to include the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline as well as the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the Qal and Qsr units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is located in an area characterized by low-energy sheet wash which is conducive to the preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant do not specify a function for the site. They do suggest that the presence of ceramics is generally consistent with the Late Prehistoric (1100 cal BC to Contact). The presence of a Cottonwood Triangular projectile point supports this suggestion. Staff notes that the presence of a Rose Spring projectile point may indicate that this was a multi-component site. The Rose Spring style is associated with the Rose Spring complex which dates between cal AD 200 and cal AD 1100 (Sutton et al. 2007, p. 236). Sites from this time are often found near springs, along washes, and sometimes on lakeshores, and can include evidence of intensive occupation such as house remains.

The archaeologists for the applicant recommend that this site be found eligible for listing in the NRHP under Criterion D. They note that the artifacts at the site appear to have well preserved spatial relationships, include datable materials, and include sufficient quantity of artifacts to allow statistically significant research (Farmer et al. 2009, p. 88). In addition previous research in the region suggests that the presence of pot drops within the boundaries of larger prehistoric sites indicates the presence of a trail. As such, this site may be a contributor to the PTN Cultural Landscape. The above considerations lead staff to recommend that site CA-Riv-9072 (P33-17456) is eligible for

listing in the NRHP under Criterion D, and the CRHR under Criterion 4, because the resource has yielded and has potential to yield information important to the middle-to-late prehistory of the Mojave Desert.

Staff considers possible mitigation measures for GSEP impacts to this site, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9073 (P33-17457)

This site is an oblong prehistoric archaeological deposit approximately 602 square feet (0.014 acres) in area. It is located near the southwest border of the proposed GSEP linear facilities corridor approximately 2.3 miles directly north of I-10. An intermittent drainage is located to the northwest of the site. The present site surface is a slightly elevated northeast-to-southwest-trending desert pavement. Further information about the present site surface is unspecified. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 17 m from northeast to southwest and 4 m from northwest to southeast. This sparse scatter of 4 prehistoric artifacts includes 1 quartzite primary flake, 1 retouched chert flake, 1 chert interior flake, and 1 chert flake tool. All of the artifacts are wind or water worn, suggesting great age. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9073, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in an area noted for low-energy sheet wash which may have resulted in correspondingly good preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no age or functional interpretation for the site. They further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9073 (P33-17457) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9084 (P33-17468)

This site is an irregularly shaped prehistoric archaeological deposit approximately 1,219,680 square m (28 acres) in area. It is located on the southern boundary of the site footprint. Two minor seasonal drainages run from north to south through the northern portion of the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface consists of a mosaic of desert pavement interspersed with sand and gravel alluvium. The surface component of the site

measures approximately 38 m from east to west and 70 m from north to south. The site was originally recorded during the Class II survey. Its boundaries were subsequently enlarged when it was revisited during the Class III survey. It includes a light scatter of prehistoric artifacts and two artifact concentrations in the northern part of the site. In total, it appears that 96 artifacts were present. Artifact totals for each concentration and for the site as a whole were difficult to calculate using the information provided by the archaeologists for the applicant.

Concentration 1 is an amorphous scatter of artifacts located in the central part of the site. It measures 81 m by 81 m and includes 55 predominately interior and cortical flakes of crystalline quartz, basalt, quartzite, chert, jasper, and chalcedony. Concentration 2 is located at the north end of the site 255 m northeast of Concentration 1. This feature measures 10 m by 6 m and consists of 5 chert, crystalline quart, quartzite, and basalt flakes. The presence of a “historical military part” was noted west of Concentration 2 on the site sketch map. Further information about this artifact was not specified. The remainder of the site is covered with a light scatter of artifacts which include 21 flakes, 2 complete quartzite manos, 3 complete metates (2 possible schist, 1 rhyolitic), 3 metate fragments (1 quartzite, 2 rhyolitic), 1 piece of marine shell, 1 Olivella shell bead, 1 crystalline quartz block core, 1 quartzite multi-directional core, 1 jasper multi-directional core 1 quartz biface, and 1 quartz biface fragment. Overall, interior flakes comprised the greatest share of the debitage (at 50 percent), while shatter and cortical flakes together make up about 38 percent of the scatter, indicating that primary and secondary flake production were the principal activities. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9084, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant note that one function of the site may have been stone tool manufacture and repair. Staff adds that the presence of ground stone suggests that food processing also took place here possibly indicating the site was a temporary camp. The archaeologists for the applicant further suggest that Concentrations 1 and 2 may represent two separate activity loci. It is unclear if they consider the ground stone scatter in the southern part of the site a possible third activity locus. The temporal relationships between the various parts of the site are unclear. However, the archaeologists for the applicant mention that the presence of ground stone indicates that at least some of the deposit was created during or after the Late Archaic period (8000 to 6000 cal BC). In addition, the Olivella shell bead in the

northeastern corner of the site links it to the Late Prehistoric (1100 cal BC to Contact) period.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage and the apparent absence of materials that would clarify the temporal relationships between the site components, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9084 (P33-17468) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9206 (P33-17775)

This site is an oblong prehistoric archaeological deposit oriented north-south approximately 161 square m (0.04 acres), in area. The deposit is in the southeastern portion of the site footprint near the southern boundary, 116 m north of CA-Riv-9205/H (P33-17773). The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface consists of sandy and gravelly soils with numerous small ephemeral dry channels traversing the area. The surface component of the site measures approximately 11 m from east to west and 25 m from north to south. Observed surface cultural constituents consist of 1 cortical quartzite flake, 2 interior chert flakes, 1 chalcedony flake, and 1 granitic mano fragment. There was apparently no evidence of a subsurface deposit at the site, but its actual depth is undetermined.

The more particular physical context for site CA-Riv-9206, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest that the presence of ground stone at the site may indicate a date of as early as the Late Archaic times (8000 to 6000 cal BC) or as late as the Late Prehistoric (1100 cal BC to Contact). However, they provide no functional interpretation for the site. Further, they recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation.

Considering the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit more specifically in time, the site does not appear to have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9206 (P33-17775) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9207 (P33-17776)

This site is a trapezoidal prehistoric archaeological deposit approximately 2,711 square m (0.7 acres) in area. It is located in the southeastern portion of the site footprint near the southern boundary, approximately 40 m north of CA-Riv-9206 (P33-17775). The present site surface consists of relatively flat sandy and gravelly soils with numerous small erosion channels. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 86 m from east to west and 73 m from north to south. This light scatter of 8 artifacts includes 4 chert cortical flakes, 1 quartzite cortical flake, 1 quartzite core, 1 chert tested cobble, and 1 soluble coffee can. The artifact scatter appears to be primarily a surface deposit, but its actual depth is undetermined.

The more particular physical context for site CA-Riv-9207, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be edge of the oldest lakeshore (Ql) where it intersects with the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The function of the site is unspecified, however the archaeologists for the applicant note that the prehistoric lithic artifacts appear to be randomly scattered across the surface rather than clustered into tight loci. This pattern suggests that the site did not serve as a flint-knapping location. The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. They also recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9207 (P33-17776) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9208 (P33-17777)

This site is an oblong prehistoric archaeological deposit approximately 647 square m (0.2 acres) in area. It is located in the southeastern portion of the site footprint near the southern boundary, approximately 86 m north of CA-Riv-92010 (P33-17778). The present site surface consists of relatively flat sandy and gravelly soils with numerous small erosion channels. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 25 m from east to west and 24 m from north to south. This light scatter of 8 prehistoric artifacts includes 4 chert cortical flakes, 1 quartzite cortical flake, 1 chalcedony cortical flake, 1 jasper cortical flake, and 1 chalcedony core. No evidence of a subsurface deposit was noted, but the actual depth of the site is undetermined.

The more particular physical context for site CA-Riv-9208, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant do not specify the function of the site however they note that the prehistoric lithic artifacts appear to be randomly scattered across the surface rather than clustered into tight loci. This pattern suggests that the site did not serve as a flint-knapping location. The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. The archaeologists recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9208 (P33-17777) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9209 (P33-17778)

This site is an oblong prehistoric archaeological deposit approximately 7,689 square m (2 acres) in area. It is located in the southeastern portion of the site footprint near the southern boundary, approximately 86 m south of CA-Riv-9208 (P33-17777). The present site surface consists of relatively flat sandy and gravelly soils, with numerous small erosion channels. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 85 m from east to west and 100 m from north to south. This light scatter of 24 prehistoric artifacts includes 7 interior flakes and 1 cortical flake of chert, 1 interior flake of quartz, 1

piece of chalcedony shatter, 3 interior flakes of jasper, 4 cortical flakes of quartzite, 2 multi-directional chert cores, 1 quartzite hammer stone, and 4 quartz monzonite metate fragments. The scatter appears to be primarily a surface deposit with some partial subsurface artifacts, most likely the result of the movement of wind and waterborne sediment.

The more particular physical context for site CA-Riv-9209, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant do not specify a function for the site. They do suggest that the presence of ground stone is generally consistent with a Late Archaic period occupation (8000 to 6000 cal BC), but do not explain why this site could not also be consistent with other time periods when ground stone was used, such as the Late Prehistoric (1100 cal BC to Contact). Further, they recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9209 (P33-17778) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9210 (P33-17779)

This site is an irregularly shaped prehistoric archaeological deposit approximately 1,982 square m (0.5 acres) in area. It is located in the southeastern portion of the site footprint near the southern boundary, approximately 95 m south of CA-Riv-9209H (P33-17778). The present site surface consists of a slightly elevated terrace of alluvium, with patches of desert pavement. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 50 m from east to west and 90 m from north to south. This sparse scatter of 13 prehistoric artifacts includes 10 lithic flakes, 2 monzonite metate fragments, and 1 depleted chalcedony core with cortex. The scatter appears to be primarily a surface deposit, but the actual depth of the site is undetermined.

The more particular physical context for site CA-Riv-9210, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. They further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit more specifically in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9210 (P33-17779) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9212 (P33-17781)

This site is an oblong prehistoric archaeological deposit approximately 202 square m (0.06 acres) in area. It is located near the center of the southeastern portion of the proposed site footprint, approximately 50 m north of CA-Riv-9211H (P33-17780). The present site surface consists of sandy and gravelly soils within a minor dune and pan like area. A minor dry wash runs parallel to the long axis of the site and numerous small ephemeral dry channels traverse the area. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 32 m from north to south and 8 m from east to west. This sparse scatter of 6 prehistoric artifacts includes 1 interior chert flake, 2 quartzite cortical flakes, 1 rhyolite tested cobble, 1 chalcedony core with cortex, and 1 Desert Side Notched chert projectile point. No evidence of a subsurface deposit was noted, but the actual depth of the site is undetermined.

The more particular physical context for site CA-Riv-9212, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials.

Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. However, the presence of a Desert Side Notched projectile point suggests that the site dates to the Late Prehistoric period (cal AD 1100 to European contact) (Sutton et al. 2007, p. 236). They further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage seems to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9212 (P33-17781) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9215 (P33-17784)

This site is an irregularly shaped prehistoric archaeological deposit approximately 14,568 square m (3.6 acres) in area. It is located near the southwest corner of the southeastern portion of the proposed site footprint, north of CA-Riv-9220 (P 33-17789). A large unnamed dry wash apparently crosses the site, however the location of the wash is not marked on the sketch map. The present site surface is described as consisting of sand and gravel. Further information about the condition of the present site surface is unspecified. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 129 m from east to west and 169 m from north to south. This sparse scatter of 25 prehistoric artifacts includes 21 lithic flakes, 1 chert projectile point shoulder and base fragment (concave base, undetermined chronology), 1 biface fragment, 1 rhyolite tested cobble, and 1 6-sided quartz crystal were observed. The scatter appears to be primarily a surface deposit, but the actual depth of the site is undetermined.

The more particular physical context for site CA-Riv-9215, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. They further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for

the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9215 (P33-17784) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9216 (P33-17785)

This site is an oblong prehistoric archaeological deposit approximately 16,511 square m (4 acres) in area. It is located along the western boundary of the southeastern portion of the proposed site footprint, approximately 205 m west of CA-Riv-9209 (P33-17778). A large unnamed dry wash apparently crosses the site, however the location of the wash is not marked on the site map. The present site surface is relatively flat and consists of the sand and gravel. Evidence of aeolian (wind-produced) processes is also present, including lag deposits and small mounds of sand next to creosote bushes. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 83 m from east to west and 317 m from north to south. Overall this site consists of approximately 78 prehistoric and 2 historic-period artifacts. Scattered across the site are 46 lithic flakes, 3 tested cobbles (1 chalcedony, 2 quartzite), 1 exhausted chert core, and 1 granitic mano. Two isolated cans, one soluble coffee can and one rectangular oil can (puncture opened) were also noted. One concentration of 27 prehistoric artifacts is present at the southern end of the site: it measures 15 m from east to west by 35 m from north to south. This concentration consists of approximately 25 flakes, 1 quartzite hammerstone, and 1 possible quartz crystal biface fragment. Both within the concentration and across the site in general, lithic flakes are primarily interior and cortical flakes of a broad range of materials including basalt, chert, chalcedony, quartzite, quartz crystal, and jasper. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9216, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-footshoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. However, the presence of ground stone at the site may indicate that it dates to between the Late Archaic (8000 to 6000 cal BC) and the Late

Prehistoric (1100 cal BC to Contact) periods. Further, a high density lithic concentration suggests that stone tool production and/or maintenance took place in this location. The broad mix of activities taking place at this site, including food preparation and tool production and/or maintenance, suggests that it may have functioned as a temporary camp.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit more specifically in time, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9216 (P33-17785) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

CA-Riv-9217 (P33-17786)

This site is an oblong prehistoric archaeological deposit approximately 971 square m (0.3 acres) in area. In contrast to other sites in the proposed site footprint, its long axis runs from east to west rather than from north to south. It is located near the center of the southeastern portion of the site footprint, approximately 40 m south of CA-Riv-9212 (P33-17781). The present site surface is relatively flat and consists of sand and gravel. Small, dry seasonal drainages are present to the east on west of the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 58 m from east to west and 21 m from north to south. This sparse scatter of 3 prehistoric artifacts includes 1 black chert interior flake, 1 red quartzite cortical flake, and 1 brownware pottery sherd. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9217, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. However, the presence of ceramics at the site may indicate that it dates to the Late Prehistoric (1100 cal BC to Contact) period. The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage seems to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9217 (P33-17786) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9218 (P33-17787)

This site is an oblong prehistoric archaeological deposit approximately 161 m (0.04 acres) in area. It is located near the center of the southeastern portion of the site footprint, approximately 153 m east of CA-Riv-9219 (P33-17788). The present site surface is relatively flat and consists of sand and gravel alluvium. A small, dry seasonal drainage running from north to south cuts across the southern end of the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 13 m from east to west and 17 m from north to south. This sparse scatter of 3 prehistoric artifacts includes 1 chert interior flake, 1 cortical quartzite flake, and 1 chert bifacial scraper. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9218, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit more specifically in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9218 (P33-17787) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9219 (P33-17788)

This site is an oblong prehistoric archaeological deposit approximately 404 square m (0.1 acres) in area. It is located near the center of the southeastern portion of the site

footprint, approximately 153 m west of CA-Riv-9217 (P33-17786). A small, dry seasonal drainage running from north to south cuts across the site in an unspecified location. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 43 m from northeast to southwest and 17 m from northwest to southeast. This sparse scatter of 3 prehistoric chert artifacts includes 2 cortical flakes and 1 interior flake. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9219, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see "Present Process Geomorphology" and "Results of Geoarchaeological Investigations" subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9219 (P33-17788) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9220 (P33-17789)

This site is an irregularly shaped prehistoric archaeological deposit approximately 38,162 square m (9.4 acres) in area. It is located along the southern boundary of the northwestern portion of the site footprint, approximately 171 m south of CA-Riv-9215 (P33-17784). A small, dry seasonal drainage running from north to south cuts across the site in an unspecified location. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium with subdued bar and swale topography. The surface component of the site measures approximately 221 m from east to west and 199 m from north to south. This scatter of 94 prehistoric artifacts includes 92 flakes, 1 brown chert projectile point (Cottonwood Leaf-shaped), and 1 quartz monzonite metate fragment. In general, lithic flakes are primarily interior and cortical flakes of chert and quartzite. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9220, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the

lake deposits of the Ql unit between the 377-foot shoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. However, the presence of ground stone and a diagnostic projectile point suggest several possibilities for its age and function. The prehistoric use of milling equipment in the Mojave Desert has a broad temporal range, between the Late Archaic (8000 to 6000 cal BC) and the Late Prehistoric (1100 cal BC to Contact) periods. Several kinds of leaf shaped points have been used in the region over time, however. Cottonwood Leaf-shaped points tend to be smaller (approximately 3 cm in length) and some scholars associate them with the Late Cottonwood phase (AD 1840 to 1900) in the northwest Mojave Desert (Moratto 1984, p. 376). Other scholars associate leaf-shaped points primarily with the Pinto Complex of the Middle Holocene (7000 to 3000 cal BC) (Sutton et al. 2007, p. 236). These early artifacts tend to be larger (approximately 5 cm in length), like the chert projectile point found at CA-Riv-9220. The broad mix of activities taking place at this site, including food preparation and possibly tool production and/or maintenance, suggests that it may have functioned as a temporary camp.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit more specifically in time, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9220 (P33-17789) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9221 (P33-17770)

This site is a trapezoidal shaped prehistoric archaeological deposit approximately 1,618 square m (0.4 acres) in area. It is located near the southwest corner of the southeastern portion of the site footprint, approximately 160 m west of CA-Riv-9215 (P33-17784). Numerous minor seasonal drainages run across the site. The predominant vegetation

on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium with subdued bar and swale topography. The surface component of the site measures approximately 33 m from east to west and 58 m from north to south. This sparse scatter of 8 prehistoric artifacts includes 5 chert cortical flakes, 1 chert pressure flake, 1 chert interior flake, and 1 cortical quartz crystal flake. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9221, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the377-foot shoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9221 (P33-17790) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9222 (P33-17771)

This site is an oblong prehistoric archaeological deposit oriented east/west and with an area of approximately 1902 square m (0.5 acres). It is located in the northwestern corner of the southeastern portion of the site footprint approximately 722 m northeast of CA-Riv-9223 (P33-17772). Numerous minor seasonal drainages run across the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium with subdued bar and swale topography. The surface component of the site measures approximately 60 m from east to west and 39 m from north to south. This sparse scatter of 4 prehistoric artifacts includes 2 chert cortical flakes, 1 chert interior flake, and 1 quartz cortical flake. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9222, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is

expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is located in an area characterized by low-energy sheet wash which is conducive to the preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest no temporal association or functional interpretation for the site. The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9222 (P33-17791) is not eligible for listing in the NRHP or the CRHR.

CA-Riv-9223 (P33-17772)

This site is a triangular shaped prehistoric archaeological deposit 3,327 square m (0.8 acres) in area. It is located near the western border of the southeastern portion of the site footprint approximately 722 m southwest of CA-Riv-9222 (P33-17771). Numerous minor seasonal drainages run across the site and the immediate vicinity. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium with subdued bar and swale topography. The surface component of the site measures approximately 79 m from east to west and 75 m from north to south. This sparse scatter of 20 quartz prehistoric artifacts includes 13 interior flakes and 3 cortical flakes. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9223, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be located on the Holocene sand sheet of the Qsr unit and the Holocene alluvium of the Qal unit (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within these units is expected to be moderate within approximately 2 feet of the modern ground surface, in sediments stratigraphically above the Qoaf alluvium. The potential for artifacts within the Qoaf alluvial deposits, in consideration of the apparent Pleistocene age of those deposits, is considered slight. This site is located in an area characterized by low-energy sheet wash which is conducive to the preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest that the site represents single flintknapping episode. However, no temporal association is suggested for the site. The archaeologists for the applicant further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be

tied to the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. Staff therefore recommends that site CA-Riv-9223 (P33-17792) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9227 (P33-17796)

This site is a triangular shaped prehistoric archaeological deposit more than 3 acres (130,680 square feet) in area. It is located on the northeastern border of the proposed GSEP linear facilities corridor approximately 1.5 miles directly north of I-10. Several small north/south trending drainages cut through the site in unspecified locations. Further information about the present site surface is unspecified. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The surface component of the site measures approximately 176 m from east to west and 111 m from north to south. This sparse scatter of 18 prehistoric artifacts includes 14 brownware pottery sherds (body, rim, and neck), 1 split chert cobble, 1 chert cortical flake, 1 chert biface thinning flake, and 1 marine shell fragment (species unknown). The marine shell was found in the northern portion of the site. It exhibited polish, but the source of the abrasion, either human or natural, was undetermined. No evidence of a subsurface deposit was noted, but the actual depth of the site has not been determined.

The more particular physical context for site CA-Riv-9227, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-foot shoreline and the 370–373-foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in an area noted for high-energy wave action which may have resulted in correspondingly poor preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless, subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The archaeologists for the applicant suggest the presence of ceramics at the site may indicate that it dates to the Late Prehistoric (1100 cal BC to Contact) period. However, they provide no functional interpretation for the site. The presence of body, rim, and neck sherds suggests that these ceramic artifacts may represent a disturbed pot drop. Pot drops in non-random patterns have been associated with trails along main travel routes as well as trails that approach springs and tanks (Schaefer and Laylander 2007, p. 254). No evidence of a trail was noted near this site, but the close presence of prehistoric trails known to follow the I-10 corridor, McCoy Spring, and Ford Dry Lake

itself, suggest that ceremonial pot drops may be present in the vicinity. The chert artifacts, suggest that that lithic tool manufacture or maintenance took place in this location. The temporal relationship between these two activities is uncertain, however.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The rationale may be tied to the sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time, indicating that the site does not have the potential to yield information important to prehistory. Without primary field data on the presence of a subsurface component for the site, staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to prehistory. In addition, the presence of a pot drop suggests that this site may be a contributor to the PTN Cultural Landscape. Staff therefore recommends that site CA-Riv-9227 (P33-17796) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other prehistoric artifact scatters, and one other potential contributor to the PTN Cultural Landscape below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

C.3.5.1.3.8.2. Historical Archaeological Sites Evaluations

CA-Riv-9203H (P33-17772)

This site is an oblong historic-period refuse deposit approximately 21,084 square m (5.2 acres) in area. It is located near the southeast corner of the southeastern section of the proposed site footprint, within and adjacent to a northeast/southwest trending seasonal dry wash. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium. Further details about the site surface are unspecified. The surface component of the site measures approximately 100 m from east to west and 370 m from north to south. This site consists of a sparse scatter of more than 84 food and beverage cans, can fragments, glass bottles, and plastic. The can assemblage is reported to include 3 hole-in-top cans (knife- or ice-pick-opened), 3 church-key-opened beverage cans, 50 14.5-ounce food cans (round, key-opened or knife-cut-opened), 2 aluminum pull-tab cans (ring pull tab, c. 1965–1975), 3 15-ounce food cans (opened with a rotary can opener), 1 36-ounce can, and more than 20 can fragments. The glass assemblage is reported to include 1 clear glass condiment bottle with an “I within an O” Owens-Illinois (c. 1954–present) maker’s mark embossed on the base. Finally, 1 yellow plastic tape dispenser was also noted.

In addition to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of any historic dwellings and/or structures on or within several miles of CA-Riv-9203H (P33-17772). The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, most likely from a single dumping episode, and dating from the mid-1950s to the mid-1970s. This trash deposit could be the result of recent historic

activities such as sheep and cattle ranching, “Desert Strike” military training (1960s), and off-highway-vehicle recreational use. The archaeologists for the applicant propose that the source of trash was not associated with a specific homestead, individual, or group but do not discuss which aspects of the site lead them to this conclusion.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. The information present suggests that this site consists of a single episode of domestic trash disposal to sometime after 1950. However, the details provided by the archaeologists for the applicant do not rule out the possibility that this is a dual component site which includes a deposit associated with the DTC/C-AMA Cultural Landscape. Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9203H (P33-17772) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape (Historic District) below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9204H (P33-17773)

This site is an oblong historic-period refuse deposit approximately 3,156 square m (0.8 acres) in area. It is located near the southern boundary of the southeastern section of the proposed site footprint. Seasonal drainages were noted to the east and west of the site at unspecified distances. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium. Further details about the site surface are unspecified. The surface component of the site measures approximately 97 m east to west and 30 m north to south. This site consists of a sparse can scatter and two artifact concentrations approximately 88 m apart. Concentration 1 is located within the eastern portion of the site and measures approximately 20 m by 20 m. It consists of 8 hole-in-top cans with their tops cut off and 1 soluble coffee can. Concentration 2 is within the western portion of the site, 88 m west of Concentration 1. It measures approximately 12 m by 10 m and consists of 7 hole-in-top cans with the tops cut off and 1 machine-made, external-thread-lipped, clear glass jar, with “14 over 3824” Knox Glass Bottle Co. (c. 1932–1953) maker’s mark embossed on bottom. The remainder of the site includes a light scatter of 7 hole-in-top cans. In total, 24 historic-period artifacts were identified at the site. The site appears to be primarily a surface deposit with some partial subsurface artifacts, but the actual depth of the site has not been determined.

In additional to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of

any historic dwellings and/or structures on or within several miles of CA-Riv-9204H (P33-17773). The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, most likely from a single dumping episode, and dating from the mid 1930s to early 1950s. Additionally, the artifacts appear to represent common domestic food and/or military issue rations (e.g., the soluble coffee can).

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, arguing that these items are unlikely to yield information important to the historic development of the region. They further point out that the artifacts at the site have been rearranged by erosion, and therefore do not offer the potential to yield information important to history. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. However, the information that is present suggests that this site may be a contributing element to the DTC/C-AMA Cultural Landscape. Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9204H (P33-17773) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9211H (P33-17780)

This site is a triangular-shaped historic-period refuse deposit approximately (808 square m (0.2 acres) in area. It is located near the center of the southeastern section of the proposed site footprint. Several seasonal drainages were noted to pass through the site in unspecified locations. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is composed of sand and gravel alluvium. Further details about the site surface are unspecified. The surface component of the site measures approximately 37 m from east to west and 37 m from north to south. This site consists of a sparse scatter of 25 cans, bottles, and related fragments. The can assemblage includes 1 aluminum beverage can (pull tab, c. 1962–1978), 3 round key-opened food cans (key winder inscribed “ESTAB. 95 9/PACKED”), 1 large food can (46 ounces), and 1 small food can (12 ounces). The glass assemblage includes 1 clear glass “Coca Cola” bottle body and base fragment with an embossed base (Owens-Illinois c.1929 to approximately 1959), 1 brown glass bottle embossed base (Owens-Illinois c. 1929 to approximately 1959), and 15 brown and clear glass bottle fragments. In addition, 1 crown bottle cap and 1 1934 American ”wheat” penny were also noted. The site appears to be primarily a surface deposit, but the actual depth of the site has not been determined.

In addition to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of any historic dwellings and/or structures on or within several miles of CA-Riv-9211H (P33-17780). The archaeologists for the applicant could not associate the source of trash with a specific homestead and/or individual or group. The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, dating from the mid-1930s to the mid-1970s. Refuse could be associated with World War II training activities, and/or the combination of recent historic activities such as sheep and cattle ranching, "Desert Strike" military training (1960s), and off-highway-vehicle recreational use.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. However, the information that is present suggests that this site may be a contributing element to the DTC/C-AMA Cultural Landscape (Historic District). Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9211H (P33-17780) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape (Historic District) below (see C.3.5.2.1.5., "Possible Mitigation Measures for Individual Sites").

CA-Riv-9213H (P33-17782)

This site is an oblong historic-period refuse deposit approximately 7,487 square m (1.9 acres) in area. It is located on the eastern boundary of the southeastern section of the proposed site footprint. A north-south trending seasonal drainage passes through the western half of the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is described as sand and gravel alluvium. Further details about the site surface are unspecified. The surface component of the site measures approximately 117 m from east to west and 90 m from north to south. This site consists of a sparse scatter of 58 metal artifacts including 40 round, key-opened food cans (16 ounce), 10 condensed milk cans (14.5 oz, church-key-opened), 4 rectangular food cans, 2 soluble coffee cans, 1 one-gallon-size gas can, and 1 key winder inscribed "ESTAB. 95 9/PACKED." The site appears to be primarily a surface deposit with some partially buried artifacts, but the actual depth of the site has not been determined.

In addition to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of any historic dwellings and/or structures on or within several miles of CA-Riv-9213H

(P33-17782). The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, probably from a single dumping episode. In addition, the artifacts appear to represent common domestic food and/or military issue rations (e.g. soluble coffee can, key-wind-opened cans). The date range for these artifacts and the kind of activities that might have resulted in their disposal, are unspecified.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, arguing that these items are unlikely to yield information important to the historic development of the region. They further point out that the artifacts at the site have been rearranged by erosion and therefore do not appear to be associated with events that made a significant contribution to our history, or associated with the life of a significant person, and do not exhibit characteristics that would yield important information to history. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents and therefore its potential association with important historic themes. However, the information that is present suggests that this site may be a contributing element to the DTC/C-AMA Cultural Landscape (Historic District). Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9213H (P33-17782) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9214H (P33-17783)

This site is an irregularly shaped historic-period refuse deposit approximately 2,832 square m (0.7 acres) in area. It is located in the center of the northwestern section of the proposed site footprint. Several small seasonal drainages pass through the site in unspecified locations. The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is described as sand and gravel alluvium alternating with hardpan. Further details about the site surface are unspecified. The surface component of the site measures approximately 49 m from east to west and 69 m from north to south. This site consists of a sparse scatter of 34 metal and glass artifacts. The metal assemblage includes 15 hole in-top cans (12 ounce), 15 24-ounce cans (opened with a rotary can opener), 1 pocket tobacco can, 1 metal chain link/hook, and 1 cylindrical container top etched “The J.B. Williams Co./Eft. 1850/Glastonbury Conn.U.S.A.” (possible shaving stick or talcum powder, c. 1853–1956). The glass assemblage consists of a single broken brown glass jar embossed “Vaseline/Chesebrough/New York.” The site appears to be primarily a surface deposit with some partially buried artifacts, but the actual depth of the site has not been determined.

In addition to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of any historic dwellings and/or structures on or within several miles of CA-Riv-9214H (P33-17783). The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, probably from a single dumping episode. In addition, the artifacts appear to represent common domestic food and/or military issue rations. The date range for these artifacts and the kind of activities that might have resulted in their disposal, are unspecified.

The archaeologists for the applicant recommend that this site be found ineligible for listing in the NRHP, arguing that these items are unlikely to yield information important to the historic development of the region. They further point out that the artifacts at the site have been rearranged by erosion, and therefore do not appear to be associated with events that made a significant contribution to our history, or associated with the life of a significant person, and do not exhibit characteristics that would yield important information to history. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. However, the information that is present suggests that this site may be a contributing element to the DTC/C-AMA Cultural Landscape (Historic District). Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9214H (P33-17783) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

CA-Riv-9228H (P33-17797)

This site is a roughly circular historic-period refuse deposit approximately 2,827 square m (0.06 acres) in area. It is located on the eastern boundary of the proposed linear facilities corridor approximately 1.5 miles directly north of I-10. A north-south trending seasonal drainage is located in an unspecified location within the site. The predominant vegetation on the site appears to be Mojave creosote bush scrub. No details about the present site surface were provided. The surface component of the site measures approximately 64 m from east to west and 60 m from north to south. This site consists of a sparse scatter of 21 metal and glass artifacts. The metal assemblage at the site includes 6 sanitary cans (crimp seam), 1 hole-in-top sanitary can, 1 rectangular can (possibly for olive oil, with crimp seam, base embossed “URUGUAY”), 1 key-wind-opened can (embossed “ESTAB.315/PACKED/2”), 1 painted can (crimp seam, body painted with “NES”, snap/friction lid imprinted “Keep Tightly Closed”), and 1 GEM BLADE razor blade (“PAT 1739280” c. 1929 and later). The glass assemblage includes 5 aqua Coca Cola bottle fragments (1 base embossed “SAN BERNARDINO CALIF” and

“BOTTLE PAT. D 105529,” c. 1938–1951), and 5 or more clear glass bottle fragments including a base fragment with an “S”-in-star marker’s mark (Southern Glass Company, Vernon, CA; c. 1916–1931). The site appears to be primarily a surface deposit, but the actual depth of the site has not been determined.

The archaeologists for the applicant do not propose a date range for this deposit or associated activities that might have resulted in its placement within the proposed site footprint. The archaeologists for the applicant further recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. Staff notes that these artifacts date to within the period of significance for the DTC/C-AMA Cultural Landscape (Historic District), 1942 to 1944, suggesting that this site may be a contributing element to the district. Without further primary field data on the integrity of the deposit, possible use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9228H (P33-17797) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape below (see C.3.5.2.1.5., “Possible Mitigation Measures for Individual Sites“).

C.3.5.1.3.8.3. Multiple-Component Archaeological Sites Evaluations

CA-Riv-9205H (P33-17773)

This is an oblong dual component site measuring 3,844 square m (1 acre) in area. It is located near the southern boundary of the southeast portion of the proposed GSEP site footprint, approximately 116 m south of CA-Riv-9204H (P33-17773). The predominant vegetation on the site appears to be Mojave creosote bush scrub. The present site surface is a slightly raised alluvial terrace of desert pavement. The surface component of the site measures approximately 66 m from east to west and 100 m from north to south.

The more particular physical context for site CA-Riv-9205H, extrapolating information from Cultural Resources Figure 1 to the location of the site, appears to be within the lake deposits of the Ql unit between the 377-foot shoreline and the 370-to–373 foot shoreline (see “Present Process Geomorphology” and “Results of Geoarchaeological Investigations” subsections, above). The possibility of buried cultural resources within the lake deposits is expected to be moderate. However, the depth of these deposits is undetermined. This site is also located in the valley between the McCoy Mountains and Palen Mountains where steeper slopes result in higher-energy sheet wash and in correspondingly poorer preservation of the spatial associations that reflect the behavior of people who made, used, or discarded archaeological materials. Nonetheless,

subsurface materials that offer the potential to yield information important to prehistory or history may be present here.

The prehistoric component consists of a light scatter of 8 prehistoric artifacts in the southern portion of the site. The artifacts present include 1 obsidian interior flake, 3 cortical chert flakes, 1 interior basalt flake, 2 quartz monzonite metate fragments, and 1 quartzite mano fragment. This component appears to be primarily a surface deposit, but its actual depth has not been determined.

The historic-period component forms a refuse concentration in the central portion of the site measuring 20 m from east to west and 37 m from north to south. The metal assemblage consists of 50 hole-in-top cans (16 oz, condensed milk, hole-punched), 5 crown bottle caps, 1 smashed metal box, 1 car lamp mount (etched “S+M Lamp Co./MADE IN USA/Los ANGELES/No. 28”), and 1 1983 American penny. The glass assemblage includes more than 50 clear glass bottle fragments (inc. 2 jar rims), more than 20 brown glass bottle fragments (6 bases and 1 jar with maker’s mark). Also present were 5 milky white ceramic dish fragments (melted). This component appears to be primarily a surface deposit, but its actual depth is unknown.

In addition to the field investigation, the archaeologists for the applicant also examined historic maps, BLM records, and other historic documents. They found no evidence of any historic dwellings and/or structures on or within several miles. The specific documentary sources examined for this site were unspecified. Artifact types and chronological indicators suggest that the refuse scatter is domestic in type, probably from a single dumping episode between the 1920s and 1960s. In addition, the artifacts appear to represent common domestic food and/or military issue rations. The kind of activities that might have resulted in the disposal of these artifacts, are unspecified.

The archaeologists for the applicant suggest no age or functional interpretation for the prehistoric component of this site. However, staff notes that the presence of ground stone may indicate a date of as early as the Late Archaic times (8000 to 6000 cal BC) or as late as the Late Prehistoric (1100 cal BC to Contact). The archaeologists recommend that this site be found ineligible for listing in the NRHP, but do not state their reasons for this recommendation. The sparse character of the surface assemblage and the apparent absence of materials that would facilitate the placement of the deposit in time seem to indicate that the site does not have the potential to yield information important to prehistory. Staff therefore recommends that the prehistoric component of site CA-Riv-9205 (P33-17431) is not eligible for listing in the NRHP or the CRHR.

The archaeologists for the applicant further recommend that the historic-period component should also be found ineligible for listing in the NRHP as it does not appear to be associated with events that made a significant contribution to our history, or with the life of a significant person, and does not exhibit characteristics that would yield additional important information to history. The resolution of the documentation for the deposit makes it difficult to assess the actual date range that it represents, and therefore its potential association with important historic themes. Staff notes that these artifacts date to within the period of significance for the DTC/C-AMA Cultural Landscape (Historic District), 1942 to 1944, suggesting that this site may be a contributing element to the district. Without further primary field data on the integrity of the deposit, possible

use of these artifacts during World War II maneuvers, and potential evidence of characteristic military-style trash disposal practices (Bischoff 2000), staff cannot evaluate the site sufficiently to reasonably dismiss the possibility that it may retain the potential to yield information important to history. Staff therefore recommends that site CA-Riv-9205 (P33-17797) be assumed eligible for listing in the NRHP and the CRHR, for the purpose of the present analysis.

Staff considers possible mitigation measures for GSEP impacts to this site and six other historic-period artifact scatters which are potentially contributing elements to the DTC/C-AMA Cultural Landscape below (see C.3.5.2.1.5., "Possible Mitigation Measures for Individual Sites").

C.3.5.1.3.8.4. Cultural Landscape Evaluations

A cultural landscape consists of "geographic area, including both natural and cultural resources, associated with a historic event, activity or person" (NPS 28). The National Park Service has defined four overlapping categories of cultural landscapes: historic designed, historic vernacular, historic site, and ethnographic. Historic designed landscapes are deliberate artistic creations, reflecting recognized styles, and are often associated with important builders, building trends, or events in the history of the construction of these kinds of landscapes. Historic vernacular landscapes illustrate people's values and attitudes towards the land and reflect patterns of settlement, use, and development over time. Historic sites are significant for their associations with important events, activities, and persons. Existing features and conditions are defined and interpreted in terms of what happened there at particular times in the past. Finally, ethnographic landscapes can be spaces rather than things that can be owned. These spaces or places are given meaning through their association with local and regional histories, cultural identities, beliefs, and behaviors. Ethnographic landscapes can include horizons, unmarked spiritual corridors, and places of connection between the earth's surface and the upper and lower realms. While these kinds of landscapes are often associated with Native Americans, they can be associated with any cultural group or belief system. Cultural landscapes can be determined eligible and nominated for inclusion on the NRHP, as either sites or districts. As such, these landscapes can be contiguous or noncontiguous (Evans et al. 2001; NPS 28). Staff has identified sites which are contributing elements to two noncontiguous cultural landscapes within the GSEP APEs.

The Prehistoric Trails Network Cultural Landscape

Energy Commission staff here proposes the designation of a cultural landscape that incorporates prehistoric archaeological sites associated with the Halchidhoma Trail (CA-Riv-53T), referred to here as the Prehistoric Trails Network (PTN) Cultural Landscape. This landscape consists of important destinations in the Colorado Desert near Blythe, CA; the network of trails that tie them together; and the features and sites associated with the trails.

In the 1990s McCarthy and a group of volunteers recorded 20 km of the Halchidhoma Trail as it curves around the southern and western side of the McCoy Mountains leading from the Blythe Intaligos (geoglyphs) to McCoy Spring. They identified 227 trail-associated sites and subsidiary trails associated with the Halchidhoma Trail. Staff

proposes to use the definitions and site types described in McCarthy's report (1993) as the basis of the boundaries, thematic associations, property types, and significance period of the PTN Cultural Landscape. The boundaries of this cultural landscape will need to be refined, but in broad terms it extends along the historically known route of the Halchidhoma Trail from where it begins near Blythe at the Colorado River, continuing to the west through the Chuckwalla Valley towards modern Los Angeles. The period of significance will also need to be refined, but it appears that the trail systems of southern California were used for thousands of years. Therefore, as a preliminary measure the period of significance is defined as the entire prehistoric and early historic periods. The thematic associations may also need to be expanded in the future, but currently include travel, trade, and ritual. Resource exploitation, particularly the collection of stone tool and ground stone raw materials, is also an important theme.

Characteristic site types for the PTN Cultural Landscape have been described by archaeologists working in the Colorado and Mojave Deserts for decades. Although the discussion here relies on McCarthy (1993), numerous other descriptions that are just as useful are available (Apple 2005; Cleland 2005). The following list is not comprehensive; it should be added to as needed as new patterns are discovered. The PTN site types are divided into three categories: destinations, trails, and trail-associated sites or features. Destinations primarily include water sources, but also include residential, religious, and resource-collection sites. Water-oriented destinations include natural features such as rivers, springs, lakes, rainwater tanks, as well as man-made wells. Residential sites include villages and camps with evidence of a full range of activities. Religious sites include geoglyphs and petroglyphs. The importance of particular destinations is indicated by the web of multiple trails that converge on certain places, often mountain passes or water sources. Trails can either be created by the movement of traveling feet or formally constructed. They average 30 centimeters in width and can be traced for many kilometers, interrupted only by gullies and washes. Trails are usually the shortest and most convenient routes from one point on the landscape to another. Trails are frequently associated with other features or sites including: concentrations of ceramics/pot drops, cleared circles, rock rings, rock clusters, rock cairns, rock alignments, petroglyphs, and geoglyphs. When the trail itself is not preserved, its route can often be traced by distinctive patterns of trail-associated sites and features.

The foundation of this cultural landscape would be the 227 sites recorded by McCarthy including McCoy Spring and McCoy Mountain Tanks A-D. Natural features that are likely to be associated with this cultural landscape include: the Colorado River, Ford Dry Lake, Palen Dry Lake, and possibly Corn Springs just south of Desert Center.
Other cultural resources should be added as a connection to the Halchidhoma Trail or the web of associated smaller trails can be demonstrated. Energy Commission staff identified potential contributors to the PTN Cultural Landscape using the following criteria:

1. The site consists entirely of prehistoric ceramics;

2. The site contains a concentration of ceramics similar to a "pot drop";

3. An existing trail leads in the direction of a site;

4. The site is near a steady supply of water;

5. The site is large, has evidence of a broad range of activities, and otherwise has evidence it was a habitation site; and/or

6. The site is a trail.

Energy Commission staff recommends that the PTN Cultural Landscape is eligible for listing on the NRHP under Criteria A and D and for the CRHR under Criteria 1 and 4. With respect to Criterion A/1, the Halchidhoma Trail was an essential trade, transportation, and ritual route for Native American peoples in the Colorado Desert during prehistoric times. This route was an essential connection between people living on the Pacific Coast and people living the Southwestern deserts of Arizona and New Mexico. In addition, Native American peoples of the region accord mythological importance to trail systems. Trails across the desert mark the locations of travels of ancestral groups as they migrated to the confluence of the Gila and Colorado Rivers. Trails also facilitate dream travel to these places and the times when events mentioned in story and song occurred (Cleland 2005, p. 132). As such, for both of these reasons this cultural landscape is significant under Criteria 1 (Criteria A), for its tie to important events in American history. However, most property types associated with the PTN exist today as archaeological resources, such as petroglyphs, pot drops, cleared circles, and webs of intersecting trails. These sites should be considered primarily register-eligible under Criterion D/4 for their ability to yield information important in history and prehistory.

Energy Commission staff concludes that GSEP impacts to the contributors to this cultural landscape, if unavoidable, must be mitigated.

Fifteen cultural resources identified during Tetra Tech's CHRIS survey of previous research in the GSEP vicinity and two cultural resources within the GSEP APEs are potentially contributing elements to the PTN Cultural Landscape (Cultural Resources Table 7). Site CA-Riv-9072 is considered eligible as an individual resource in addition to its possible contribution to the PTN. However, for site CA-Riv-9227, the information provided in the AFC was not sufficient to allow staff to be certain that this site is a contributor to the PTN. Therefore, staff recommends that this site be assumed eligible for inclusion in the NRHP and the CRHR.

CULTURAL RESOURCES Table 7
Potential Contributors to the Prehistoric Trails Network Cultural Landscape in the Vicinity of the GSEP

Resource Designation	Resource Description (type, age, content)	Location	Information Source
CA-Riv-53T	Prehistoric Primary Trail	20 km on south and west edges of McCarthy Mountains	McCarthy 1993
P-33-1516	Prehistoric Site: Large Temporary Camp along dry lake shoreline: ground stone, lithic scatter, thermal fractured rock. Some WW II military artifacts noted, no details regarding type.	GSEP vicinity	E. Ritter 1975
P-33-2159	Prehistoric Site: Temporary Camp/Lithic Scatter along gravel terraces of dry lake bed: metate/manos fragments, hammerstone/choppers, lithic flakes; rhyolite, basalt, chalcedony, agate, jasper, chert, granite, andesite.	GSEP vicinity	S. Cardenas 1981
P-33-663	Prehistoric Site: An extensive series of shoreline temporary camps: metate/mano fragments of green shale, fire affected rock, lithic reduction flakes (jasper, quartzite, rhyolite, chert, and chalcedony), pottery (Parker buff ware and Tizon brown ware, and greyware), rock alignment, 1 corner notched projectile point fragment, 1 biface fragment.	GSEP vicinity, shores of Dry Ford Lake	D. Pallette et al., 1989
P-33-1131	Prehistoric Site: Widely dispersed low density ceramic drop: 50 reddish-brown “Tizon” pottery shreds, 1 mano/core fragment.	GSEP vicinity	E. Dittman 1981
P33-001818	Prehistoric pottery fragments	GSEP vicinity	R. Carrico 1980
P33-3801	Prehistoric site: pottery scatter	GSEP vicinity	Pallette 1989
P33-003808	Prehistoric Site: ceramic scatter	GSEP vicinity	Mooney & Associates 1990
P33-003809	Prehistoric Site: ceramic scatter	GSEP vicinity	Mooney & Associates 1990
P-33-3129	Prehistoric trail segment	SW side of McCoy Mountains	F. McCarthy 1991
P33-00259	Prehistoric rock rings	GSEP vicinity	N. Gester 1965
CA-Riv-9064 (P33-17448)	Temporary Camp: Debitage (n=120+), projectile points, bifaces, and ground stone implements. Speculative chronology—possibly Archaic period.	GSEP vicinity	Farmer et al. 2009

Resource Designation	Resource Description (type, age, content)	Location	Information Source
CA-Riv-9072 (P33-17456)	Temporary Camp: Debitage (n=hundreds), FAR, Rose Spring projectile point, brownware sherds (n=hundreds) hundreds of ground stone fragments, scatter covers several hundred acres.	GSEP Site Footprint, shores of Dry Ford Lake	Farmer et al. 2009
CA-Riv-9078 (P33-17462)	Temporary Camp: Lithic scatter, ground stone, projectile points, bifaces, FAR. Site limits incompletely defined; extends east west and south beyond established boundary.	GSEP vicinity, shores of Dry Ford Lake	Farmer et al. 2009
CA-Riv-9079 (P33-17463)	Temporary Camp: Site limits incompletely defined. Debitage (n=500); ground stone, flake, core tools, and a marine clam shell fragment.	GSEP vicinity, shores of Dry Ford Lake	Farmer et al. 2009
CA-Riv-9227 (P33-17796)	Lithic and ceramic Scatter: Debitage (n=3); brownware sherds (n=14), marine shell fragment	GSEP vicinity	Farmer et al. 2009
CA-Riv-0132	McCoy Spring National Register District, focus of entire region during prehistoric times	West side of McCoy Mountains	McCarthy 1986, 1993

Desert Training Center California-Arizona Maneuver Area

Energy Commission staff here proposes the designation of a cultural landscape (historic district) that incorporates historical archaeological sites associated with Gen. Patton's World War II Desert Training Center California-Arizona Maneuver Area (DTC/C-AMA). The BLM has nominated this district to the NRHP several times. Each time the nomination was rejected mainly because the resource was not yet 50 years old at the time of the nomination. As part of the nomination process, BLM sponsored a detailed archaeological study of the resource which resulted in the publication of a cultural context (Bischoff 2000).

Staff notes that the resource is currently more than 50 years old and proposes to accept the boundary, thematic associations, property types, and significance period as laid out in Bischoff's (2000) context. The relevant themes include U.S. Preparation for World War II, U.S. Military Training, Gen. George S. Patton. Jr., and Gen. Walton Walker. Depots, airfields, ranges, bivouacs, maneuver areas, camps, and hospitals are among some of the property types included in the district. Following Bischoff (2000), the significance period is defined as 1942–1944.

Energy Commission staff recommends that Desert Training Center California-Arizona Maneuver Area (DTC/C-AMA) is eligible for listing on the NRHP and the CRHR under all four NRHP and CRHR eligibility criteria. The DTC/C-AMA was the largest and the only such military training facility in American military history. The training that took place here undoubtedly helped to win World War II. As such, it is significant under NRHP Criterion A (CRHR Criterion 1), for its tie to important events in American history. The facility was also central to the lives of people important in our past, specifically Gen. George S. Patton, Jr. and Gen. Walton Walker, both of whom served as facility commanders. Therefore the DTC/C-AMA is eligible for listing on the NRHP under

Criterion B (CRHR Criterion 2). The distinctive layouts of the camps and of maneuver areas are also clearly examples of a distinctive type of construction making the DTC/C-AMA eligible for listing in the under NRHP Criterion C (CRHR Criterion 3). However, most property types associated with the DTC/C-AMA exist today as archaeological resources such as refuse deposits, tank tracks, foxholes, and bivouacs. These sites will be considered primarily eligible under NRHP Criterion D (CRHR Criterion 4) for their ability to yield information important in history.

Military records report that the Chuckwalla Valley and portions of the proposed project were primarily used as maneuver areas, campsites, and small group training areas. Here soldiers practiced desert survival and infiltration techniques. The remains of these smaller exercises are undoubtedly more ephemeral than those involving 15,000 men, however, evidence may still be present. Artifacts and features associated with them will most likely be shell casings, grenade containers, foxholes, C-ration cans, and other refuse (Bischoff 2000, p .116). Wiley's Well was used as a campsite on multiple occasions. The presence of water at the site undoubtedly contributed to its importance. During maneuvers in 1943, the signal company's pigeon detachment set up a false camp at Wiley's Well, fooling the opposing side into thinking that there was a full headquarters at the camp (Bischoff 2000, p. 117). Evidence of these specific activities may still be present within the GSEP site footprint.

Seven sites already identified within the GSEP site footprint and the linear facilities corridor are potentially contributing elements to the DTC/C-AMA Cultural Landscape (Historic District) (see Cultural Resources Table 6). The information provided in the AFC was not sufficient to allow staff to determine the eligibility of these resources. Therefore, staff recommends that these sites be assumed eligible for inclusion in the NRHP and the CRHR.

C.3.5.1.3.8.5. Ethnographic Resource Evaluation

Staff includes McCoy Spring National Register District (CA-Riv-132) as a potential ethnographic resource that may be indirectly affected by the proposed project. The site is located on the west side of the McCoy Mountains approximately 5 miles from the Wiley's Well Rest Area. Access to the GSEP site footprint and linear facilities corridor for construction workers and permanent staff will share the rest area as an access point. Possible effects to the site include vandalism as the result of increased visitation and changes in the integrity of setting, integrity of feeling, and integrity of association.
