Incubation and rearing: Natural origin adult winter steelhead will continue to be released into the Minto Dam to Big Cliff Dam reach of the North Santiam to spawn. Incubation periods do not overlap with this operation therefore effects are the same as those assumed for the NAA. Juveniles rearing below Big Cliff Dam could be exposed to high TDG however this is expected to be minimal since juveniles are highly mobile and can avoid exposure by moving within the local river channel or moving downstream where high TDG levels are known to dissipate.

***Effects on UWR Chinook during the fall/winter operation:***

Upstream Passage Rates and Survival: Under this action, upstream migrating marked (hatchery) fish will continue to be collected at the new Minto Adult Fish Collection Facility, where they can be loaded onto a truck and translocated above Detroit Dam. Unmarked (natural origin) fish would be released into the river between Minto and Big Cliff dams. There are no changes from the NAA expected with implementation of this near-term action on adult collection rates. Exposure to elevated TDG levels could increase for adults migrating upstream to Minto, and particularly for natural origin adults released into the reach between Minto and Big Cliff. This exposure is not expected to increase pre-spawn mortality rates since adults are highly mobile and can avoid prolonged exposure.

Incubation and rearing: Natural origin adult spring Chinook will continue to be released into the Minto Dam to Big Cliff Dam reach of the North Santiam to spawn. Exposure to elevated TDG levels could increase for incubating eggs and fry as a result of this near-term measure. If TDG levels are high enough and exposure duration long enough, injury or mortality can be expected. Data is not available to quantify this potential effect.

Downstream passage rates and survival: Beeman and Adams (2015) estimated survival from the forebay of Detroit Dam to Big Cliff forebay at 62.2% in the fall of 2013 when 120 of 122 fish that passed used the turbines. Turbine flows were generally greater than 1000 cfs. For regulating outlets (ROs), Alden (2014) summarized survival rates, which were based on Normandeau (2010) using rainbow trout as a surrogate for subs/yearlings in their study. Based on this information, survival rates for sub-yearling and yearling Chinook passing through the RO would be expected to range between 70% and 95%. If additional juvenile Chinook pass through the RO than the turbines under this operation in comparison to the NAA, this could result in an increase in survival. It is uncertain however if passage rates through the RO will increase with this action, or if juveniles will instead pass through the turbines during the day because the reservoir elevation over the RO will remain high.

Monitoring recently occurred using rotary screw traps to collected fish moving downstream from Big Cliff Dam when Detroit and Big Cliff dams were operated in the fall 2021 similar to the near-term action. Catch rates of juvenile spring Chinook salmon increased in the late fall (Cramer Fish Sciences 2022), as observed in previous years (Romer et al. 2016). There did not appear to be any clear relationships between dam operations at Detroit Dam and catch of juvenile Chinook salmon below Big Cliff Dam (Cramer Fish Sciences 2022). Catch rates reported from screwtraps need to be interpreted with caution since they vary considerably within and between years, and typically they are less than 3%. This monitoring data also does not permit an estimate of the numbers of fish passing downstream during the targeted operational period, which routes through the dam in operations that were used to pass, or survival of those passing.

Juvenile fish passing downstream of Detroit Dam must also pass-through Big Cliff Reservoir and Dam. Beeman and Adams (2015) estimated juvenile Chinook survival from Detroit Dam tailrace downstream to Minto Dam as 67% to 74%, or inversely a mortality of 26% to 33%. We assume this estimate includes mortality occurring below Big Cliff Reservoir. Fischer et al. 2019 estimated mortality through Dexter Reservoir (which reregulates flows below Lookout Point Dam), at about 2%. Big Cliff Reservoir is smaller than Dexter. Oligher and Donaldson (1966) conducted Big Cliff Kaplan turbine unit tests to determine what effect various operating conditions would have on survival of fish passing through this type of turbine. Average survival from all tests in Oct. 1964 was 91.1 percent at 91 ft. head, 94.5 percent at 81 ft. head, and 89.7 percent at 71 ft. head. Average survival from all tests in May 1966 was 92.2 percent at 91 ft. head, 89.8 percent at 81 ft. head, and 90.6 percent at 71 ft. head. Therefore, we expect the 26%-33% mortality rate range is likely high since it also includes mortality occurring below Big Cliff.

Based on review of the recent information collected using screwtraps and previous screwtrapping results, it is assumed the near-term action will result in similar passage rates and some improvement in downstream passage survival for juvenile Chinook in comparison to the NAA.

Hatchery Program and effects on ESA-listed natural origin production: The HGMP (2016) for the North Santiam hatchery spring Chinook program indicates until the long-term juvenile fish downstream passage solution at Detroit is implemented and approved by NMFS that only hatchery UWR Chinook salmon will be transported above Detroit Dam unless genetic pedigree indicates there is greater than a 1:1 ratio of recruits to spawners in the pedigree data for adults released above the dams for five complete years of data, or if fish managers determine there are special circumstances leading to a decision to outplant natural origin adults above Detroit Dam (e.g. lower survival of adults or their progeny is expected due to weather or habitat conditions below dams). Therefore we assume pHOS will in most, if not all years, will remain at 100% above the dam during implementation of this near-term action, and will remain the same below Minto Dam as under the NAA.

**South Santiam Subbasin**

The near-term operations measure within the South Santiam Subbasin include outplanting of adult Chinook above Green Peter Reservoir, downstream fish passage at Green Peter Dam via the spillway in the spring and fall, and downstream fish passage at Foster via the spillway in the spring and fall.

Effects on UWR Steelhead from spring/summer spill operation:

UWR steelhead are passed upstream of Foster Dam but not Green Peter Dam, and there would be no plans to begin doing until a long-term downstream passage solution is implemented at Green Peter. Therefore, effects of this action would be limited to steelhead downstream of Green Peter Dam in the South Santiam River.

Upstream Passage Rates and Survival: Under this action, upstream migrating fish will continue to be collected at the Foster Adult Fish Collection Facility, where they can be loaded onto a truck and translocated above Foster Dam. There are no changes from the NAA expected with implementation of this near term action on adult collection rates. Exposure to elevated TDG would be same as under the NAA.

Incubation and rearing: Natural origin adult winter steelhead will continue to be released above Foster Dam. Exposure of eggs and fry to elevated TDG below Foster Dam would be same as under the NAA.

Downstream Passage and Survival: Juvenile winter steelhead would experience the same passage conditions as exists in the NAA, and therefore there would be no change in effects expected.

***Effects on UWR Chinook from spring/summer spill operation:***

Upstream Passage Rates and Survival: Under this action, upstream migrating fish will continue to be collected at the Foster Adult Fish Collection Facility, where they can be loaded onto a truck and translocated above Foster or Green Peter dams. Unmarked adults will be released above Foster Dam, and adult hatchery fish would be transported and released above Green Peter Dam or taken as brood for hatchery production. Beginning four years after hatchery adults are released upstream of Green Peter Dam, surviving adult progeny will begin returning to Foster Dam. These returning adult progeny will be unmarked and will either need to be held and genetically tested to determine if they originated above Green Peter or released to spawn with natural origin fish above Foster. If the former approach is taken, there is a risk that pre-spawn mortality rates could increase from increased handling and delayed passage upstream. If the latter approach is taken, this could decrease fitness of the wild population occurring above Foster Dam. However, this genetic effect is expected to be similar to that which occurs under the NAA since many progeny returning from naturally spawning hatchery fish already occurs in the Sub-basin considering the high level of pHOS below Foster Dam, and since up to 30% of the unmarked outplanted Chinook have been found to be hatchery origin.

Incubation and rearing: No changes in effects would be expected when compared to the NAA for Chinook spawned above or below Foster Dam. Offspring of adult hatchery Chinook outplanted above Green Peter will now rear upstream or within Green Peter Reservoir prior to seeking to pass downstream of Green Peter Dam.

Downstream passage rates and survival: Data is not available on the passage rates or survival of juvenile Chinook at Green Peter Dam. Since the dam has a similar configuration to Detroit Dam, passage and survival rates are expected to be similar when depths to outlets and discharge rates are similar. Juvenile passage survival rates for Chinook are expected to be intermediate between those assessed under Alternatives 2A, 2B and 3A at Green Peter and Foster Dams.

Hatchery Program and effects on ESA-listed natural origin production: The HGMP (2016) for the South Santiam hatchery spring Chinook program states the outplanting protocols have not been fully developed. We assume they would be similar to the North Santiam. Until the long-term juvenile fish passage solution for downstream fish passage at Green Peter is implemented and approved by NMFS, we assume that only hatchery UWR Chinook salmon will be transported above Green Peter Dam unless genetic pedigree indicates there is greater than a 1:1 ratio of recruits to spawners in the pedigree data for adults released above the dams for five complete years of data, or if fish managers determine there are special circumstances leading to a decision to outplant natural origin adults above Green Peter Dam (e.g. lower survival of adults or their progeny is expected due to weather or habitat conditions below dams). Therefore we conclude that pHOS will in most, if not all years, will remain at 100% above the dam during implementation of this near-term action, and will remain the same below Foster Dam as under the NAA.

Based on the above considerations, it is assumed the near-term action may increase returns of unmarked adult Chinook as a result of outplanting hatchery adult Chinook above Green Peter Dam and providing surface spill for downstream passage. As a result of surface spill from Green Peter, water temperatures in Foster Reservoir and in the South Santiam below Foster Dam could be warmer at times and very similar to those assessed under Alternative 2A, 2B and 3A. Other effects are expected to be very similar to the NAA.

**Long Tom Subbasin**

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin, therefore, there would be no effects of this measure to ESA-listed spring Chinook salmon, winter steelhead or bull trout in this subbasin.

**McKenzie Subbasin**

The near-term operations measure within the McKenzie Subbasin includes that Cougar reservoir will have a drawdown target below minimum conservation elevation (1532 ft) during the spring (1505 ft) and fall (1520 ft). The operation also limits releases to less than about 900 cfs for water quality concerns. This results in the reservoir only meeting the drawdown target elevations in dry years and only for relatively brief periods.

***Effects on UWR Chinook from spring/summer spill operation:***

The near-term operation is very similar to those included in Alternative 3A for Cougar Dam, however the fall reservoir elevation target is 1520 instead of 1505.

Upstream Passage Rates and Survival: Under this action, upstream migrating fish will continue to be collected at the Cougar Adult Fish Collection Facility, where they can be loaded onto a truck and translocated above Cougar Dam. The extent and timing that Cougar Reservoir will be refilled will affect water temperatures downstream. Water temperatures and their effects on adult Chinook migration and pre-spawn mortality would be expected to be similar to Alternative 3A given the similarities with the near-term operation.

Incubation and rearing: Discharge rates and water temperatures from Cougar Dam resulting from the near-term operation may affect incubation of Chinook below Cougar Dam. These effects would be expected to be similar to Alternative 3A given the similarities with the near-term operation.

Downstream passage rates and survival: Effects in spring would be assumed to be the same as assessed for Alternative 3A. In the fall, the reservoir elevation target is 15 ft higher. This elevation change could reduce juvenile Chinook passage rates and survival somewhat compared to effects assessed in alternative 3A.

Monitoring occurred using rotary screw traps to collect fish moving downstream from Cougar Dam for operations in the fall of 2021 that are similar to the near-term operations proposed (Cramer Fish Sciences 2022). Catch rates of juvenile Chinook salmon were low during spring and summer when most flow was through the turbine penstocks. In fall, catch rates of juvenile Chinook increased between early October and mid-November, when more water was passed through the RO. This pattern in catch rates is very similar to those observed in previous years (Romer et al. 2013, 2014, 2015, 2016). Catch rates reported from screwtraps need to be interpreted with caution since they vary considerably within and between years, and typically catch rates of screwtraps are extremely low (<5%). Monitoring data from screwtraps also rarely permits an estimate of the numbers of fish passing downstream during the targeted operational period due to the extremely low catch rates, and also does not permit assessment of which routes through the dam in operation that were used to pass or the survival of those passing.

Hatchery Program and effects on ESA-listed natural origin production: Effects of the near-term operations on outplanting of adult hatchery Chinook above Cougar Dam and on pHOS levels above and below Cougar Dam in the McKenzie Sub-basin would be expected to be the same as assessed under Alternative 3A.

Based on the above considerations, as a result of drafting the reservoir in spring and fall and use of the RO, juvenile passage and survival rates are expected to improve somewhat in comparison to the NAA, similar to that assessed in Alternative 3A. Under these improvements it is assumed the near-term action may increase returns of unmarked adult Chinook as a result of outplanting hatchery adult Chinook above Cougar Dam. Other effects of this measure are assumed to be the same as those assessed for Alternative 3A at Cougar Dam for spring Chinook salmon.

***Effects on McKenzie Sub-basin bull trout from spring/summer spill operation:***

Effects of the near-term action on bull trout would also be similar to those assessed for Alternative 3A. Operations could allow more bull trout to pass below the dam and utilize additional rearing/foraging habitat. Those moving downstream however must survive, and then be trapped and trucked back upstream in order to contribute to the population. Demographic risks of bull trout moving downstream would be considered moderate for the currently stable population of bull trout above Cougar Dam since many bull trout would likely continue to rear in the reservoir and spawn upstream.

**Middle Fork Willamette River Subbasin**

The near-term operations measure within the Middle Fork Willamette Subbasin includes prioritized use of the regulating outlet for downstream fish passage at Hills Creek in fall, use of the spillway for fish passage at Lookout Point in the spring, deep drawdown for fish passage at Lookout Point in fall, and deep drawdown for fish passage in the fall at Fall Creek. For the operations at Lookout Point, storage at Hills Creek would be used for refilling Lookout Point in early March. The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam.

***Effects on UWR Chinook from spring/summer operations:***

The near-term operation is very similar to those included in Alternative 3B for fish passage at Lookout Point Dam and Hills Creek Dam, however there is not a delayed refill/deep drawdown of Hills Creek Reservoir in spring. Instead, refill will be affected by using Hills Creek storage for refilling Lookout Point Reservoir in early March with maximum pool elevations dictated by the rule curve for Hills Creek Reservoir.

Upstream Passage Rates and Survival: Under this action, upstream migrating adult Chinook salmon will continue to be collected at the Dexter Adult Fish Collection Facility, where they can be sorted and either taken for hatchery brood stock or loaded onto a truck and translocated above WVS dams to spawn naturally. The extent and timing that Hills Creek and Lookout Point Reservoirs will be refilled will affect water temperatures downstream. Water temperatures and their effects on adult Chinook migration and pre-spawn mortality would be expected to be similar to Alternative 3A given the similarities with the near-term operation.

Incubation and rearing: Discharge rates and water temperatures from Lookout Point and Hills Creek dams resulting from the near-term operation can affect incubation of Chinook below each dam. These effects would be expected to be similar to Alternative 3A given the similarities with the near-term operations.

Downstream passage rates and survival: For juvenile Chinook salmon, effects in spring would be assumed to be the very similar as assessed for Alternative 3A at Lookout Point in the spring and fall. At Hills Creek, passage and survival rates will be like those assessed for the NAA. In the fall, passage and survival rates will be like those assessed for Alternative 3A and 3B. For both dams, juvenile downstream passage rates and survival are expected to increase compared to the NAA.

Hatchery Program and effects on ESA-listed natural origin production: Effects of the near-term operations on outplanting of adult hatchery Chinook above Lookout and Hills Creek dams and on pHOS levels above and below these dams in the Middle Fork Sub-basin would be expected to be the same as assessed under Alternative 3A and 3B. Increases in unmarked (natural origin) Chinook salmon to the sub-basin resulting from improved downstream passage may reduce pHOS somewhat above dams, however outlplanting of hatchery adult Chinook will likely continue. No change in pHOS is expected below Lookout Point dam compared to the NAA.

Based on the above considerations, juvenile passage and survival rates are expected to improve somewhat in comparison to the NAA, similar to that assessed in Alternative 3A. Under these improvements it is assumed the near-term action may increase returns of unmarked adult Chinook as a result of outplanting hatchery adult Chinook above Lookout Point and Hills Creek dams. Other effects of this measure are assumed to be the same as those assessed for Alternative 3A in the Middle Fork.

Effects on Middle Fork Sub-basin bull trout from interim operations:

Effects of the near-term action on bull trout would also be similar to those assessed for Alternative 3A or 3B. Operations could allow more bull trout to pass below the dam and utilize additional rearing/foraging habitat. Those moving downstream however must survive, and then be trapped and trucked back upstream in order to contribute to the population. Demographic risks of bull trout moving downstream of Hills Creek Dam would be considered high for the currently growing population of bull trout above Hills Creek Dam since currently bull trout rear in Hills Creek Reservoir and spawn upstream.

**Coast Fork Subbasin**

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin, therefore, there would be no effects of this measure to ESA-listed spring Chinook, winter steelhead or bull trout in this subbasin.

**Mainstem Willamette River**

Flows and water temperatures would be similar to the NAA, with additional releases for water temperature management. Flows and water temperatures as assessed provide for improved water temperatures and maintain habitat conditions for migrating and rearing fish similar to the NAA, and at a much greater flow level in summer and early fall when compared to unregulated conditions. Peak winter flows are reduced for flood risk management at the same level as for the NAA, resulting in less floodplain habitat for juvenile fish present, or for channel-forming process which maintain and create habitat conditions for native fish.

Habitat improvements below WVP dams, specifically large wood placement and sediment placement will be completed as part of the near-term actions. Dams serve as a catchment for large woody debris and for sediments, decreasing the incidence of both in rivers downstream and disrupting sediment storage and fluvial processes. The placement of both large woody debris and sediments in downstream reaches would increase habitat complexity and subsequently provide an increase in suitable rearing and spawning habitat for UWR Chinook and steelhead.

### 3.8.2.6 Alternative 2B

#### 3.8.2.6.1 North Santiam

In the North Santiam, measures being implemented for Alternative 2B are the same as those as for Alternative 2A. For downstream fish passage, construction of structural downstream fish passage (#392) would be implemented at Detroit Dam. For upstream passage, fish would be collected at the existing Minto adult fish facility and trucked upstream. The structural fish passage improvements allow Chinook and steelhead to access habitat above Detroit Dam, and support increased abundance and productivity compared to the NAA. Passage improvements would also support passage of a re-introduced bull trout population above Detroit Dam to access habitat below the dam and return back upstream to re-enter the spawning population, but there are a greater number of limiting factors downstream increasing potential for mortality for individuals that move downstream. Since there is not any spawning habitat available downstream of the dam, individuals must survival and migrate back upstream, be collected and trucked above Detroit Dam, in order to re-enter the spawning population.

**Chinook**

Effects of Alternative 2B to spring Chinook salmon in the North Santiam would be similar to effects described for Alternative 2A. See Table 3.8-41. Refer to Section 3.10.2.4.1 North Santiam for a description of the impacts to spring Chinook salmon in the North Santiam. Like Alternative 2A, Alternative 2B would be expected to have MINOR adverse impacts on spring Chinook salmon in the North Santiam.

**Table 3.8-41. North Santiam Alternative 2B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 2 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

Effects of Alternative 2B to winter steelhead in the North Santiam would be similar to effects described for Alternative 2A. See Table 3.8-42. Refer to Section 3.10.2.4.1 North Santiam for a description of the impacts to winter steelhead in the North Santiam. Like Alternative 2A, Alternative 2B would have MINOR adverse impacts to winter steelhead in the North Santiam.

**Table 3.8-42. North Santiam Alternative 2B winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

Effects of Alternative 2B to bull trout in the North Santiam would be similar to effects described for Alternative 2A. See Table 3.8-43. Refer to Section 3.10.2.4.1 North Santiam for a description of the impacts to winter steelhead in the North Santiam. As with Alternative 2A, is expected that Alternative 2B would have MODERATE adverse impacts on bull trout in the North Santiam.

**Table 3.8-43. Summary of bull trout habitat scoring and relative risk under Alternative 2B in the North Santiam**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| North Santiam | Above Detroit (rearing/foraging and spawning) | 42.47 | High |
| | Below Detroit (rearing/foraging only) | 38.48 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.6.2 South Santiam*

In the South Santiam, measures being implemented for Alternative 2B are the same as those as for Alternative 2A. For downstream fish passage at Foster Dam, construction of structural downstream fish passage (#392) would be implemented. At Green Peter Dam, a deeper fall reservoir drawdowns for fish passage (#40) and spring spill would be implemented to provide downstream fish passage. An adult fish facility would also be constructed at the base of Green Peter Dam. These fish passage improvements allow Chinook and steelhead to access habitat above both Foster and Green Peter dams, supporting the potential for increased abundance and productivity compared to the NAA. Compared to above other WVS dams, the relatively lower elevation habitat above these dams may constrain productivity and survival.

**Chinook**

Effects of Alternative 2B on spring Chinook salmon in the South Santiam would be similar (but not identical) to effects described for Alternative 2A. See Table 3.8-44. Refer to Section

3.10.2.4.2 South Santiam for a description of the impacts to spring Chinook salmon in the South Santiam. It is predicted that like Alternative 2A, Alternative 2B would have MINOR adverse impacts on spring Chinook salmon in the South Santiam.

**Table 3.8-44. South Santiam Alternative 2B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 3 |
| EDT Normal | 3 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

Effects of Alternative 2B on winter steelhead in the South Santiam would be similar to effects described for Alternative 2A. See Table 3.8-45. Refer to Section 3.10.2.4.2 South Santiam for a description of the impacts to winter steelhead in the South Santiam. It is expected that like Alternative 2A, Alternative 2B would have MINOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-45. South Santiam Alternative 2B winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

### *3.8.2.6.3 McKenzie*

Under Alternative 2B, the diversion tunnel at Cougar would be used for downstream passage. The reservoir will be drafted to 25 feet over the diversion tunnel during both spring and fall. This will results in a very small residual reservoir pool during these season, and limited opportunity to refill the reservoir to supplement downstream flows during spring to fall seasons. Most Chinook would be expected to pass downstream as fry in spring. It is uncertain how bull trout may respond, however some would be expected to move upstream of the reservoir while others downstream. Forage opportunity will change over time for bull trout with repeated reservoir deep drawdowns, with the potential for less prey food availability in the reservoir potentially requiring bull trout to move downstream.

**Chinook**

Alternative 2B differs from Alternative 2A in how downstream passage is implemented at Cougar. In Alternative 2B, fish are passed through a diversion tunnel at Cougar. The performance metrics for spring Chinook salmon in the McKenzie under Alternative 2B are summarized in Table 3.8-46. The life cycle models disagree in two dimensions: recruits per spawner and quasi-extinction risk. Interestingly, the LCM predicts a lower productivity but a corresponding low extinction risk. This may reflect the timeline that the LCM considers below dam natural origin populations as well as above dam natural origin spawners. More extreme operations may have impacts on viable populations downstream. Again, the EDT output predicts resiliency in the life history diversity parameter but expected performance for recruits per spawner and equilibrium spawner abundance. Under Alternative 2B, spring Chinook in the McKenzie benefit from increased passage rates through the diversion tunnel and adequate temperature control to manage prespawn mortality and better attract upmigrating adults to the Cougar adult facility. Extreme drawdowns to the diversion tunnel may impact the ability to control downstream flows and habitat opportunities downstream for outmigrating juveniles and self-sustaining populations below the project. It is expected that Alternative 2B will have MODERATE adverse impacts on spring Chinook salmon in the McKenzie.

**Table 3.8-46. McKenzie Alternative 2B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the McKenzie under Alternative 2B are summarized in Table 3.8-47. In general, there are good habitat opportunities above and below Cougar. However, the uncertainty about the effectiveness of passage through the diversion tunnel poses high demographic risk if bull trout forage opportunity is decreased due to reservoir drawdowns or, if those moving downstream do not get collected and moved back upstream of Cougar Dam to spawn. Cougar Reservoir would largely be drained in spring and only partially refilled in summer, resulting in significant reduction in rearing/foraging opportunity within the reservoir. Many bull trout would be expected to move upstream into the South Fork McKenzie, or below Cougar Dam to rear. Suitable habitat for bull trout exists above and below Cougar Dam and Reservoir, however carry capacity and other effects of redistribution on survival and spawning is uncertain. It is expected that Alternative 3B would have MODERATE adverse impacts on bull trout in the McKenzie.

**Table 3.8-47. Summary of bull trout habitat scoring and relative risk under Alternative 2B in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 12.16 | Moderate |
| | Below Cougar (rearing/foraging only) | 14.74 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.6.4 Middle Fork*

Fish passage conditions are the same as under Alternative 2A. The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. Construction of structural downstream fish passage (#392) would be implemented at Lookout Point Dam but not Hills Creek Dam. Upstream passage would occur using the existing adult fish facility at the base of Dexter Dam. The structural fish passage improvements allow Chinook to access habitat above Lookout Point Dam, supporting increased abundance and productivity compared to the NAA. The existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. At Hills Creek Dam, downstream passage occurs through existing outlets where on average downstream fish passage survival is low under the NAA dam operational regime. The existing bull trout population above Hills Creek Dam would be expected to perform the same as under the NAA.

**<u>Chinook</u>**

Effects of Alternative 2B to spring Chinook salmon in the Middle Fork will be similar to effects described for Alternative 2A. See Table 3.8-48. Refer to Section 3.10.2.4.4 Middle Fork for a description of the impacts to spring Chinook salmon in the Middle Fork. It is expected that like Alternative 2A, Alternative 2B would have MAJOR adverse impacts on spring Chinook salmon in the Middle Fork.

**Table 3.8-48. Middle Fork Alternative 2B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

Effects of Alternative 2B to bull trout in the Middle Fork will be similar to effects described for Alternative 2A. See Table 3.8-49. Refer to Section 3.10.5.5 Middle Fork for a description of the impacts to bull trout in the Middle Fork. It is expected that like Alternative 2A, Alternative 2B would have NEGLIGIBLE impacts to bull trout in the Middle Fork.

**Table 3.8-49. Summary of bull trout habitat scoring and relative risk under Alternative 2B in the Middle Fork**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 10.11 | Low |
| | Below Hills Creek (rearing/foraging only) | 0 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

*3.8.2.6.5 Near-term Operations Measure for Alternatives 2A, 2B, 3A, 3B, 4, 5*

See Alternative 2A, Section 3.10.2.4.5, for a description of predicted potential effects due to the Near-Term Operations Measure.

### *3.8.2.7 Alternative 3A*

*3.8.2.7.1 North Santiam*

Under Alternative 3A, at Detroit Dam a spring reservoir drawdown for downstream fish passage (#720) and deeper fall reservoir drawdowns for fish passage (#40) would be implemented for downstream passage. Upstream passage would be provided using the existing Minto adult fish facility where fish are collected and trucked upstream of the Detroit Dam.

**Chinook**

The performance metrics for spring Chinook salmon in the North Santiam under Alternative 3A are summarized in Table 3.8-50. The LCM predicts an inviable population with respect to productivity and quasi-extinction risk while the IPA predicts viability across all dimensions. The discrepancy between the two models is likely due to the aforementioned sensitivity of the LCM to structural versus operational downstream passage. The EDT output shows some resiliency with respect to diversity but not with respect to equilibrium abundance or recruits per spawner. This may reflect the availability of water to operate the alternative as intended in all year types. Under Alternative 3A, spring Chinook in Detroit may demonstrate improved performance over the No Action Alternative due to increased downstream passage rates. It is expected that extreme drawdown as proposed under Alternative 3A may impede the ability to control downstream flows for fish and limit the ability to accomplish temperature control. This may result in distorted emergence and run timing and may limit the ability to manage prespawn mortality. It is expected that Alternative 3A would have MODERATE adverse impacts on spring Chinook salmon.

**Table 3.8-50. North Santiam Alternative 3A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 3 | NA | 1 |
| EDT Dry | 3 | 1 | NA | 2 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the North Santiam under Alternative 3A are summarized in Table 3.8-51. The life cycle models indicate a dissimilar pattern as for spring Chinook salmon. The patterns appear to be inverse among the two models with respect to each species. Again, both life cycle models disagree with respect to quasi-extinction risk but this may be attributable to the different timelines each model considers. This seems a less credible explanation since the LCM timeline is nearly 70 years longer in most cases. It is more likely that the IPA predicts poorer prognosis in the other dimensions (abundance and productivity). The EDT output indicate some resiliency with respect to recruit per spawner but not with respect to equilibrium spawner abundance or diversity. Similar to Chinook, while downstream passage rates are expected to increase under Alternative 3A, the ability to control downstream flows and temperature may be limited. This could result in emergence and migration timing shifts. It is expected that Alternative 3A would have MODERATE adverse impacts on winter steelhead in the North Santiam.

**Table 3.8-51. North Santiam Alternative 3A winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the North Santiam under Alternative 3A are summarized in Table 3.8-52. There would be adequate habitat available for bull trout above and below Detroit. However, the limited and potentially unsafe passage conditions at Detroit under Alternative 3A for bull trout could put the population at higher demographic risks if those fish attempting to move downstream were unable to return to the parent population to contribute to productivity. Demographic risk based on the hydrology, angling, and predation may be much higher, particularly if fish that pass below Detroit Dam do not survival or ultimately collected and trucked back upstream and spawn. It is expected that Alternative 3B would have MODERATE adverse impacts on bull trout in the North Santiam.

**Table 3.8-52. Summary of bull trout habitat scoring and relative risk under Alternative 3A in the North Santiam**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| North Santiam | Above Detroit (rearing/foraging and spawning) | 42.79 | High |
| | Below Detroit (rearing/foraging only) | 28.44 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.7.2 South Santiam*

Under Alternative 3A, spring spill at Foster would continue to facilitate downstream passage. A deeper fall reservoir drawdown (#40) and spring spill would be implemented for downstream passage at Green Peter. An adult fish facility would also be constructed at the base of Green Peter Dam. These fish passage improvements allow Chinook and steelhead to access habitat above both Foster and Green Peter dams, supporting the potential for increased abundance and productivity compared to the NAA. Compared to above other WVS dams, the relatively lower elevation habitat above these dams may constrain productivity and survival.

**Chinook**

The performance metrics for spring Chinook salmon in the South Santiam under Alternative 3A are summarized in Table 3.8-53. In general, life cycle models agree that populations in the South Santiam would not be viable under Alternative 3. The EDT output demonstrates that this Alternative would likely not be resilient to annual hydrology. Similar to the No Action Alternative, spill for passage has been implemented at Foster. Under Alternative 3A, similar performance is expected due to limited downstream passage and lack of adequate temperature control which could contribute to ongoing prespawn mortality levels. At Green Peter, variability in operations and resulting passage rates may lead to uncertain performance; adult productivity above Green Peter is not well documented in the literature. For purposes of this exercise, it is assumed that productivity of spawners outplanted above Green Peter will be similar to those outplanted above Foster (since Foster fish will be the founding stock) but the rate of straying is unknow. It is expected that Alternative 3A would have MAJOR adverse impacts to spring Chinook salmon in the South Santiam.

**Table 3.8-53. South Santiam Alternative 3A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for steelhead in the South Santiam under Alternative 3A are summarized in Table 3.8-54. Both life cycle models agree with respect to recruits per spawner and quasi-extinction risk. Equilibrium spawner abundance differs between the two models: the LCM predicts higher spawner abundance than the IPA; however, both models predict that this population would go extinct, even at higher equilibrium numbers. The EDT output indicate best performance in wet and normal years and slightly worse performance in dry years, likely because the system may not have enough water to operate as intended. Similar to Chinook, steelhead under Alternative 3A may experience lack of adequate downstream passage, particularly for kelts (repeat adult spawners) which are more vulnerable to spill operations due to the configuration of the spillway at Foster. Similar to Chinook, adult productivity above Green Peter is uncertain but assumed to be similar to spawners outplanted above Foster. It is expected that Alternative 3A would have MAJOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-54. South Santiam Alternative 3A winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 2 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

### *3.8.2.7.3 McKenzie*

Under Alternative 3A, the regulating outlet at Cougar would be used to facilitate downstream passage. Upstream fish passage at Cougar Dam would occur using the existing fish facility at the base of the dam. A deeper fall reservoir drawdown (#40) would be implemented at Blue River for downstream passage and a new adult fish facility (#722) would be constructed to capture returning adults.

**Chinook**

The performance metrics for spring Chinook salmon in the McKenzie under Alternative 3A are summarized in Table 3.8-55. Both life cycle models indicate some elements of viability but taken together, operational passage at Cougar does not produce viable spring Chinook salmon populations. It is likely that the viability status under the LCM in the equilibrium spawner abundance category stems from the persistence of natural origin spawners downstream of Cougar dam. The EDT output indicates little resilience to hydrology year type except with respect to diversity. However, in other alternatives, EDT indicated that the diversity metric was resilient across water year type where Alternative 3A shows poorer performance in the normal water years type. Under Alternative 3A, spring Chinook performance may be slightly improved due to enhanced passage rates through the regulating outlet. However, downstream survival may be limited due to the need for construction modifications to the regulating outlet to make it safer for fish passage. This could limit success in the earlier years following implementation. It is expected that Alternative 3A would have MAJOR adverse impacts on spring Chinook in the McKenzie. Access to additional habitat is provided at Blue River Dam, using adult trap and haul for upstream passage and deep reservoir draw down in the fall for downstream fish passage. This combination of actions was successfully used at Fall Creek Dam to re-establish Chinook salmon, and would be expected to result in similar performance at Blue River Dam.

**Table 3.8-55. McKenzie Alternative 3A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the McKenzie under Alternative 3A are summarized in Table 3.8-56. Overall, habitat access may be increased but moderate demographic risk exists due to incomplete or potentially unsafe downstream passage conditions at Cougar, however it is uncertain if the rate of downstream fish passage, but with changes in RO use downstream passage would only somewhat increase when compared to the NAA. Since the population has been stable under operations similar to those assumed for the NAA, it is expected that Alternative 3A would have MODERATE impacts on bull trout in the McKenzie.

**Table 3.8-56. Summary of bull trout habitat scoring and relative risk under Alternative 3A in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 11.95 | Moderate |
| | Below Cougar (rearing/foraging only) | 10.83 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.7.4 Middle Fork*

Under Alternative 3A, the existing adult facility at Fall Creek Dam will be used to collect and truck Chinook upstream of this dam. Downstream passage at Fall Creek Dam would be by a combination of operational downstream passage by way of a fall reservoir deep drawdown and a spring spill. It is uncertain if the addition of a spring spill will result in an increase or decrease in adult returns since there will be a change from larger smolts emigrating in fall, to a combination of fry in spring and smolts in fall passed downstream. A deeper fall reservoir drawdown (#40) and spring spill would be implemented at Lookout Point to facilitate passage. A deeper fall reservoir drawdown (#40) and spring reservoir drawdown (#720) would be implemented at Hills Creek to facilitate downstream passage, and a new adult fish facility built at the base of Hills Creek Dam to collect and truck Chinook and bull trout upstream of the dam.

## Chinook

The performance metrics for spring Chinook salmon in the Middle Fork under Alternative 3A are summarized in Table 3.8-57. The life cycle models mostly agree with respect to viability. Performance is predicted to be very poor under operational passage strategies, in particular for Lookout Point. It is unclear whether additional operations at Fall Creek would improve performance there since this population is already considered healthy under the NAA, and passage analysis was not considered in the weighting of this alternative. The EDT output reflects low resilience across water year types. Deep drafts at Lookout and Hills Creek will further limit the ability to control temperatures operationally which will likely further contribute to the lack of productivity and high prespawn mortality below Dexter. Although Hills Creek may be drawn upon to refill Lookout Point to support spring spill, refill probability is uncertain and the ability to conduct spring spill in every year is unlikely, particularly if the elevation at Lookout Point is still low following the fall draft. This could lead to juvenile oversummering and higher prespawn mortality. It is expected that Alternative 3A would have MAJOR adverse impacts to spring Chinook salmon in the Middle Fork.

**Table 3.8-57. Middle Fork Alternative 3A spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

## Bull Trout

The performance metrics for bull trout in the Middle Fork under Alternative 3A are summarized in Table 3.8-58. While habitat is available above and below Hills Creek, there is uncertainty in the effectiveness of operational downstream passage and therefore the effects on connectivity and production for the spawning population above Hills Creek. It is expected that Alternative 3A would have MAJOR adverse impacts on bull trout in the Middle Fork, primarily due uncertainty in downstream passage survival and return rates. For bull trout moving downstream which then migrate back up to Hills Creek Dam, an adult facility will allow for their collection and transport above Hills Creek Dam to re-enter the spawning population.

**Table 3.8-58. Summary of bull trout habitat scoring and relative risk under Alternative 3A in the Middle Fork**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 9.3 | High |
| | Below Hills Creek (rearing/foraging only) | 10.12 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

##### *3.8.2.7.5 Near-term Operations Measure for Alternatives 2A, 2B, 3A, 3B, 4, 5*

See Alternative 2A, Section 3.10.2.4.5, for description of effects due to the Near-Term Operations Measure.

### ***3.8.2.8 Alternative 3B***

#### *3.8.2.8.1 North Santiam*

Under Alternative 3B, a deeper fall reservoir drawdown (#40) and spring spill would be implemented to facilitate passage at Detroit.

**Chinook**

The performance metrics for spring Chinook salmon in the North Santiam under Alternative 3B are summarized in Table 3.8-59. The life cycle model outputs are similar to results for Alternative 3A. The LCM predicts an inviable population with respect to quasi-extinction risk while the IPA predicts viability across all dimensions. Fish Benefits Workbook predicts that drawdowns at Detroit for downstream passage would be expected to provide some benefit. However, other measures may be more effective. The EDT output shows some resiliency with respect to diversity but not with respect to equilibrium abundance or recruits per spawner. This may reflect the availability of water to operate the alternative as intended in all year types. The effects on spring Chinook salmon would be similar to those described in 3A. It is expected that Alternative 3B would have MODERATE adverse impacts on spring Chinook salmon.

**Table 3.8-59. North Santiam Alternative 3B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 2 | NA | 1 |
| EDT Dry | 3 | 1 | NA | 2 |
| EDT Normal | 2 | 3 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the North Santiam under Alternative 3B are summarized in Table 3.8-60. The life cycle models disagree on viability in all dimensions. However, among alternatives 3A and 3B, the outputs were near the thresholds for viability. Slight changes in hydrology are likely responsible for the discrepancies between the outcomes for alternatives 3A and 3B. This is also reflected in the EDT output that show resiliency in the diversity metric for wet and normal years and slightly worse performance in dry years since water availability may be more limiting. The effects on winter steelhead would be similar to those described in Alternative 3A. It is expected that Alternative 3B would have MODERATE adverse impacts on winter steelhead in the North Santiam.

**Table 3.8-60. North Santiam Alternative 3B winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout under Alternative 3B in the North Santiam are summarized in Table 3.8-61. There would be adequate habitat available for bull trout above and below Detroit. However, the limited and potentially unsafe passage conditions at Detroit under Alternative 3B for bull trout could put the population at higher demographic risks if those fish attempting to move downstream were unable to return to the parent population to contribute to productivity. It is expected that Alternative 3B would have MODERATE adverse impacts on bull trout in the North Santiam.

**Table 3.8-61. Summary of bull trout habitat scoring and relative risk under Alternative 3B in the North Santiam**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| North Santiam | Above Detroit (rearing/foraging and spawning) | 41.49 | High |
| | Below Detroit (rearing/foraging only) | 28.4 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.8.2 South Santiam*

Under Alternative 3B, a spring spill would continue to be implemented at Foster and a spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) would be implemented to facilitate passage at Green Peter. A deeper fall reservoir drawdown (#40) and spring spill would be implemented for downstream passage at Green Peter. Upstream passage at Foster Dam would utilize the existing fish facility. An adult fish facility would also be constructed at the base of Green Peter Dam. These fish passage improvements allow Chinook and steelhead to access habitat above both Foster and Green Peter dams, supporting the potential for increased abundance and productivity compared to the NAA. Compared to above other WVS dams, the relatively lower elevation habitat above these dams may constrain productivity and survival.

**Chinook**

The performance metrics for spring Chinook salmon in the South Santiam under Alternative 3B are summarized in Table 3.8-62. Neither life cycle model predicts viability in all dimensions and it is expected performance would be similar to that predicted for Alternative 3A. The South Santiam is a two dam system where wild fish sanctuary is only designated above one of the two dams (Foster). There is uncertainty about how successful reintroduction above Green Peter would be given the proposed operational passage at both projects. While available data suggest that operational passage could be successful at Foster Dam, there is more uncertainty in operational downstream passage at Green Peter Dam given limited data. It is also possible that the higher number of hatchery outplants (800) assumed at Green Peter relative to other projects, directly affects productivity of wild fish, since fitness differences between the two groups are assumed in both life cycle models. The EDT output indicate some resiliency with respect to recruits per spawner, equilibrium spawner abundance and diversity are subject to the availability of water which would be limited under Alternative 3B. It is expected that Alternative 3B would have MAJOR adverse impacts on spring Chinook salmon in the South Santiam.

**Table 3.8-62. South Santiam Alternative 3B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | See 3a | See 3a | See 3a | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the South Santiam under Alternative 3B are summarized in Table 3.8-63. In general, the life cycle models are in agreement regarding viability in the South Santiam under Alternative 3B. Steelhead may respond less well to operational passage at Green Peter. The EDT outputs indicate a similar pattern of resiliency for Chinook. The effects on winter steelhead are similar to those described for Chinook. It is expected that Alternative 3B would have MAJOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-63. South Santiam Alternative 3B winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

#### *3.8.2.8.3 McKenzie*

Under Alternative 3B, a drawdown to the diversion tunnel would facilitate downstream fish passage at Cougar for Chinook and bull trout. The existing adult fish facility would be used to truck collected fish upstream of Cougar Dam. A deeper fall reservoir drawdown (#40) would be implemented for downstream passage at Blue River and a new adult fish facility (#722) would be constructed to collect returning adults.

## Chinook

The performance metrics for spring Chinook salmon in the McKenzie under Alternative 3B are summarized in Table 3.8-64. The IPA predicts viability in all dimensions. Recall that the LCM considers natural origin spawners below Cougar as well as above and downstream impacts from operational effects upstream of the population. There may be uncertainty around the efficiency of using the diversion tunnel at Cougar for downstream juvenile passage given that this operation lacks a robust data set to inform. Similar to other alternatives, the EDT output shows resiliency in the diversity metric likely due to the broader spectrum of life histories observed to outmigrate from the McKenzie sub-basin. A drawdown to the diversion tunnel at Cougar Dam would have similar effects to those described under Alternative 2B. Access to additional habitat is provided at Blue River Dam, using adult trap and haul for upstream passage and deep reservoir draw down in the fall for downstream fish passage. This combination of actions was successfully used at Fall Creek Dam to re-establish Chinook salmon, and would be expected to result in similar performance at Blue River Dam. It is expected that Alternative 3B would have MODERATE adverse impacts on spring Chinook salmon in the McKenzie.

**Table 3.8-64. McKenzie Alternative 3B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Fails | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 2 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

## Bull Trout

The performance metrics for bull trout in the McKenzie under Alternative 3B are summarized in Table 3.8-65. In general, there are good habitat opportunities above and below Cougar. However, the uncertainty about the effectiveness of passage through the diversion tunnel poses high demographic risk if bull trout are not able to return to their natal upstream reach to spawn. Cougar Reservoir will largely be drained in spring and only partially refilled in summer due to summer inflow, resulting in significant reduction in rearing/foraging opportunity within the reservoir. Many bull trout would be expected to move upstream into the South Fork McKenzie, or below Cougar Dam to rear. Suitable habitat for bull trout exists above and below Cougar Dam and Reservoir, however carry capacity and other effects of redistribution on survival and spawning is uncertain. It is expected that Alternative 3B would have MODERATE adverse impacts on bull trout in the McKenzie.

**Table 3.8-65. Summary of bull trout habitat scoring and relative risk under Alternative 3B in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 12.07 | High |
| | Below Cougar (rearing/foraging only) | 10.95 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.8.4 Middle Fork*

Under Alternative 3B, the existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. A deeper fall reservoir drawdown (#40) and spring spill would be implemented at Lookout Point to facilitate passage. At Hills Creek Dam, a spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) would be implemented for downstream passage. Upstream passage would include use of the existing adult fish facility at Dexter for Chinook and construction of a new adult fish facility at the base of Hills Creek Dam for Chinook and bull trout.

**Chinook**

The performance metrics for spring Chinook salmon in the Middle Fork under Alternative 3B are summarized in Table 3.8-66. The IPA demonstrates poor performance with respect to equilibrium spawner abundance and quasi-extinction risk. Recruits per spawner indicates viability but the numerical outputs show that this value is nearly non-viable. The EDT output show patterns similar to other alternatives in that Alternative 3B is not resilient to hydrology year type. This is likely due to temperature limitations in the Middle Fork and the inability to adequately manage temperatures using operations. The effects on spring Chinook would be similar to those described under Alternative 3A. It is expected that Alternative 3B would have MAJOR adverse impacts on spring Chinook salmon in the Middle Fork.

**Table 3.8-66. Middle Fork Alternative 3B spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the Middle Fork under Alternative 3B are summarized in Table 3.8-67. While habitat is available above and below Hills Creek, there is uncertainty in the effectiveness of operational downstream passage and therefore the effects on connectivity and production for the spawning population above Hills Creek. It is expected that Alternative 3A would have MAJOR adverse impacts on bull trout in the Middle Fork, primarily due uncertainty in downstream passage survival and return rates. For bull trout moving downstream which then migrate back up to Hills Creek Dam, an adult facility will allow for their collection and transport above Hills Creek Dam to re-enter the spawning population.

**Table 3.8-67. Summary of bull trout habitat scoring and relative risk under Alternative 3B in the Middle Fork**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 10.09 | High |
| | Below Hills Creek (rearing/foraging only) | 10.3 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

##### *3.8.2.8.5 Near-term Operations Measure for Alternatives 2A, 2B, 3A, 3B, 4, 5*

See Alternative 2A, Section 3.10.2.4.5, for description of effects due to the Near-Term Operations Measure.

### *3.8.2.9 Alternative 4*

#### *3.8.2.9.1 North Santiam*

Under Alternative 4, a structural collector (measure #392) would be implemented to facilitate downstream passage at Detroit. Upstream migrating fish would be collected at Minto adult fish facility and trucked above Detroit Dam.

**Chinook**

The performance metrics for spring Chinook salmon in the North Santiam under Alternative 4 are summarized in Table 3.8-68. Alternative 4 proposes a structural passage solution at Detroit. In general, both models predict viability. This is consistent with the prior patterns demonstrated for structural downstream passage and overall performance of populations in the North Santiam for most Action Alternatives. The EDT outputs show some resiliency with respect to diversity but not with respect to equilibrium spawner abundance or recruit per spawner. This is a surprising result given that the passage structure is able to operate in most types of hydrology. This result could reflect the consideration of below dam components that also contribute to the metrics. Effects on spring Chinook salmon under Alternative 4 would be functionally similar to those described in Alternative 2B. It is expected that Alternative 4 would have MINOR adverse impacts on spring Chinook salmon in the North Santiam.

**Table 3.8-68. North Santiam Alternative 4 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Meets | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 2 |
| EDT Normal | 2 | 3 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the North Santiam under Alternative 4 are summarized in Table 3.8-69. The life cycle models predict high steelhead performance with the implementation of a structure at Detroit. Both models predict reasonable performance; however, the IPA predicts somewhat higher quasi-extinction risk than the LCM. The EDT outputs indicate resiliency with respect to recruit per spawner but not with respect to equilibrium spawner abundance and diversity. Effects on winter steelhead under Alternative 4 would be functionally similar to those described under Alternative 2B. It is expected that Alternative 4 would have MINOR adverse impacts to winter steelhead.

**Table 3.8-69. North Santiam Alternative 4 winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Meets | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the North Santiam under Alternative 4 are summarized in Table 3.8-70. It is expected that high quality habitat would be available above and below Detroit dam. However, since there is no spawning habitat below Detroit Dam, the effectiveness would be dependent upon the ability of bull trout to survive while in habitat downstream of Detroit and Big Cliff dams, and then be collected and trucked back up to their natal streams above Detroit and spawn. It is expected that Alternative 4 would have MODERATE adverse impacts on bull trout in the North Santiam.

**Table 3.8-70. Summary of bull trout habitat scoring and relative risk under Alternative 4 in the North Santiam**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| North Santiam | Above Detroit (rearing/foraging and spawning) | 41.69 | High |
| | Below Detroit (rearing/foraging only) | 37.79 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

*3.8.2.9.2 South Santiam*

Under Alternative 4, downstream passage at Foster Dam would be provided by a dedicated fish pipe or weir (measure #392). Upstream fish passage at Foster Dam would occur using the existing adult fish facility. No fish passage would be implemented at Green Peter Dam.

**Chinook**

The performance metrics for spring Chinook salmon in the South Santiam under Alternative 4 are summarized in Table 3.8-71. Although the LCM is more optimistic than the IPA, both ultimately predict non-viable populations. This may reflect the fact that passage at Green Peter is not included under Alternative 4. The EDT output shows resiliency with respect to equilibrium spawner abundance and recruit per spawner but not diversity. This may reflect that fact that there is no population unit above Green Peter and fish above Foster only leave the system through a dedicated fish pipe or weir in the spring or summer at larger size. Under Alternative 4, structural downstream passage does not result in viable populations. This could be due to a lack of adequate temperature control in the adult fish ladder or low assumed intrinsic productivity. It is expected that Alternative 4 would have MAJOR adverse impacts on spring Chinook salmon in the South Santiam.

**Table 3.8-71. South Santiam Alternative 4 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | See 2A | See 2A | See 2A | NA |
| IPA | Fails | Fails | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 2 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Steelhead**

The performance metrics for winter steelhead in the South Santiam under Alternative 4 are summarized in Table 3.8-72. The life cycle models do not agree in all dimensions. The LCM does not predict viability with respect to quasi-extinction risk while the IPA predicts poor performance with respect to spawner abundance and quasi-extinction risk. This may reflect differences in sensitivity between the two models to structural versus operational downstream passage. The EDT outputs indicate some resiliency with respect to recruits per spawner. Unlike spring Chinook, one model predicts viability across performance dimensions. This could be to the assumed higher resiliency of winter steelhead compared to Chinook, the flexibility of reservoir types to adopt anadromy under effective passage conditions, or the ability of kelts to safely pass downstream. It is expected that Alternative 4 would have MINOR adverse impacts on winter steelhead in the South Santiam.

**Table 3.8-72. South Santiam Alternative 4 winter steelhead performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 2 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

### *3.8.2.9.3 McKenzie*

Under Alternative 4, a structural collector would be implemented at Cougar for downstream passage. The existing adult fish facility at the base of Cougar Dam would be used for upstream fish passage.

## Chinook

The performance metrics for spring Chinook salmon in the McKenzie under Alternative 4 are summarized in Table 3.8-73. Passage is indicated at Cougar and both life cycle models indicate Poor performance in both models. The EDT outputs indicate resiliency with respect to diversity, as in previous alternatives, due to the broader spectrum of life history strategies observed to outmigrate from the McKenzie. The effects on spring Chinook salmon under Alternative 4 are functionally similar to those described under Alternative 2A. It is expected that Alternative 4 would have MODERATE impacts on spring Chinook salmon in the McKenzie.

**Table 3.8-73. McKenzie Alternative 4 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Fails | Meets | NA |
| IPA | Fails | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 3 | NA | 1 |
| EDT Normal | 2 | 2 | NA | 1 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

## Bull Trout

The performance metrics for bull trout in the McKenzie under Alternative 4 are summarized in Table 3.8-74. In general, Alternative 4 provides good bull trout habitat above and below Cougar Dam and only poses a moderate demographic risk relating to the uncertainty in downstream passage and survival rates of bull trout that move below the dam. Safe downstream passage is assumed for those bull trout collected in the at-dam passage structure, and safe upstream passage for those collected at the adult facility downstream, then transported above Cougar to contribute to population productivity. Under this alternative, the reservoir is maintained providing forage habitat for bull trout. It is expected that Alternative 4 would have MODERATE adverse impacts on bull trout in the McKenzie.

**Table 3.8-74. Summary of bull trout habitat scoring and relative risk under Alternative 4 in the McKenzie**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| McKenzie | Above Cougar (rearing/foraging and spawning) | 11.86 | Moderate |
| | Below Cougar (rearing/foraging only) | 14.27 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

### *3.8.2.9.4 Middle Fork*

Under Alternative 4, the existing adult facility at Fall Creek Dam in combination with the operational downstream passage by way of a fall reservoir deep drawdown will support maintaining the re-established Chinook sub-population above Fall Creek Dam. The construction of structural downstream fish passages (#392) would be implemented at Lookout Point and Hills Creek dams. Adults would be passed from the base of Dexter Dam above Lookout Point Reservoir using the existing adult facility. A second adult fish facility would be used to collected and transport adult Chinook and bull trout upstream of Hills Creek Dam.

**Chinook**

The performance metrics for spring Chinook salmon in the Middle Fork under Alternative 4 are summarized in Table 3.8-75. Recall that the LCM is not calibrated to natural origin spawners in the Middle Fork so output represent a relative comparison across alternatives. For this reason, the IPA was relied upon in the Middle Fork. Chinook performance in Alternative 4 is similar to that of Alternative 2A: the model demonstrates viability with respect to equilibrium spawner abundance and recruit per spawner but not with respect to quasi-extinction risk. In fact, Alternative 4 predicted the second lowest extinction risk in the Middle Fork (65%). Under Alternative 2A, extinction risk was only marginally improved. These results indicate that no alternative produced a viable population in the Middle Fork. This is likely due to the low elevation in the sub-basin, the limiting temperatures, and high observed pre-spawn mortality (sometimes up to 100%). The EDT outputs are similar to 2A, which also proposes an at-dam structure for downstream passage. Under Alternative 4, effective passage would result in higher downstream passage rates with some ability to control downstream temperatures using a structural temperature control tower. However, the ability to fully address high temperatures in the Middle Fork is limited and current rates of prespawn mortality are likely to continue limiting this population. It is expected that Alternative 4 would have MAJOR adverse impacts on spring Chinook salmon in the Middle Fork.

**Table 3.8-75. Middle Fork Alternative 4 spring Chinook salmon performance across each model**

| Model | Spawner Abundance | Recruit per Spawner | Quasi-extinction Risk | Diversity |
|---|---|---|---|---|
| LCM | Meets | Meets | Fails | NA |
| IPA | Meets | Meets | Fails | NA |
| EDT Wet | 1 | 1 | NA | 1 |
| EDT Dry | 3 | 2 | NA | 3 |
| EDT Normal | 2 | 3 | NA | 2 |

Note: as indicated by viability rating (viable, nearly viable, not viable). EDT outputs are ranked according to performance across year type.

**Bull Trout**

The performance metrics for bull trout in the Middle Fork under Alternative 4 are summarized in Table 3.8-76. Alternative 4 provides good bull trout good habitat access above and below Hills Creek Dam however poses a high demographic risk relating to the uncertainty in downstream passage and survival rates of bull trout that move below the dam. Safe downstream passage is assumed for those bull trout collected in the at-dam passage structure, and safe upstream passage for those collected at the adult facility downstream, then transported above Hills Creek Dam to contribute to population productivity. It is expected that Alternative 4 would have MODERATE adverse impacts on bull trout in the Middle Fork.

**Table 3.8-76. Summary of bull trout habitat scoring and relative risk under Alternative 4 in the Middle Fork**

| Sub-basin | Region | Score | Demographic Risk |
|---|---|---|---|
| Middle Fork | Above Hills Creek (rearing/foraging and spawning) | 10.03 | High |
| | Below Hills Creek (rearing/foraging only) | 13.48 | |

Note: given fisheries, predation, temperature, and connectivity. Scores are indicated by region above or below project.

*3.8.2.9.5 Near-term Operations Measure for Alternatives 2A, 2B, 3A, 3B, 4, 5*

See Alternative 2A, Section 3.10.2.4.5, for description of effects due to the Near-Term Operations Measure.

***3.8.2.10 Alternative 5***

Alternative 5 is functionally similar Alternative 2B except that there is slightly more water released from the Santiam in the spring of dry years. Non-exceedance plots were compared for alternatives 2B and 5 (see Appendix B). Based on this assessment, it was determined that the flow management differences between alternatives 2B and 5 would be insignificant with respect to fish performance.

### 3.8.3 Climate Change

Crozier et al. (2019) (herein Crozier) conducted a comprehensive climate vulnerability assessment for Pacific salmon and steelhead (*Oncorhynchus* spp.) for distinct population segments (DPSs) in the U.S. They followed the climate vulnerability assessment method developed by Hare et al. (2016), which is now being implemented for U.S. marine and anadromous species by NOAA Fisheries (Link et al. 2015). The Crozier assessment was based on three components of vulnerability (i.e. relative threats) to climate change for each DPS: 1) biological sensitivity, which is a function of individual species characteristics; 2) climate exposure, which is a function of geographical location and projected future climate conditions; and 3) adaptive capacity, which describes the ability of a DPS to adapt to rapidly changing environmental conditions. Crozier found that in general, DPSs with the highest sensitivity and exposure and lowest adaptive capacity were the most vulnerable to climate change.

Access to high elevation habitat to reduce effects of climate change has been found important by others (Myers et al. 2018; Fitzgerald et al. 2021). Myers et al. (2018) summarized that climate change is expected to reduce UWR Chinook adult abundance and increase the risk of extinction in the North Santiam River, South Santiam River, McKenzie River, and Middle Fork Willamette River. Compared to UWR Chinook, Upper Willamette River winter steelhead (UWR steelhead) were found to have a high overall vulnerability, high biological sensitivity, high climate exposure and moderate adaptive capacity.

**Table 3.8-77. Climate change vulnerability assessment results from Crozier et al. (2019) for UWR Chinook and UWR steelhead.**

| | UWR Chinook | UWR steelhead |
|---|---|---|
| Overall vulnerability | Very high | High |
| Biological sensitivity | Very high | High |
| Climate exposure | High | High |
| Adaptive capacity | Moderate | Moderate |

Since vulnerability was assessed as higher for UWR Chinook than for UWR steelhead, we focused our assessment of climate change for the WVS EIS on this species and assumed results from this approach would be somewhat conservative for considering effects for UWR steelhead. We further assumed the scoring for spring Chinook would be relatively similar for bull trout, although somewhat underestimated for bull trout due to their greater dependence on cold water (Reiman and McIntyre 1995). Finally, since Alternatives 2B and 5 are comprised of the same measures (only differing in minimum flow targets), and hydrologic modeling showed very little to no differences in resulting reservoir and downstream river flows, these two alternatives were treated as equivalent for purposes of this assessment.

Using the attribute definitions from Crozier, we assumed the following specific attributes would not differ among EIS alternatives, and therefore applied results for these from Crozier et al. 2019:

- ocean acidification
- sea surface temperature
- hydrologic regime
- cumulative life-cycle effects
- adaptive capacity

#### *3.8.3.1 Stream Temperatures*

Bond et al. 2016 estimated changes in redd capacity for UWR Chinook populations affected by WVS dams in future water temperature scenarios. Water temperature effects below dams are accounted for in extinction risk estimates from life cycle models applied for assessing population viability. Criteria for categorizing the vulnerability of UWR Chinook to stream temperatures based on the percentage of spawning habitat available in each WVS EIS alternative under future climate change scenarios:

**Table 3.8-78.**

| | Percent of accessible future Chinook spawning habitat above WVS dams | | | |
|---|---|---|---|---|
| | <25% | 25-49% | 50-74% | >=75% |
| Vulnerability criteria | Very High | High | Moderate | Low |

#### *3.8.3.2 Summer Water Deficit*

Crozier used the evapotranspiration differential (potential minus actual), also known as the summer water deficit. For above dam reaches, we applied a moderate categorization for summer water deficit for all sub-basins (see Appendix X). For below dam reaches, reservoirs have an important effect on summer flows and therefore we applied a qualitative assessment of reservoir storage availability with future climate change as a proxy for stream flow below dams (see WVS EIS Appendix B).

When developing this approach, we also considered including changes in summer temperatures, and the availability of High Cascade base flows, in the Santiam, McKenzie and Middle Fork Willamette sub-basins. There was little difference in the estimated change in summer temperatures between subbasins (Appendix F1 Summary and Conclusions, Appendix F2 3.2.3, Figures 11-54). Redd capacities changed very little in the North Santiam and McKenzie above WVS dams under future climate change temperature scenarios (Bond et al. 2017; see Additional Information Section below), and so we assumed the resiliency to summer water deficit, due to the greater contribution of High Cascade base flow in these sub-basins, is reasonably reflected in the assessment under the attributes where redd capacities are applied.

#### *3.8.3.3 Adult Freshwater Stage*

The adult freshwater stage attribute as assessed by Crozier considered stressors encountered during upstream migration, holding and spawning. Considerations included migration distance and duration and climate stressors encountered including temperature and flow constraints. Resiliency (i.e. the ability to anticipate, prepare for, and adapt to changing conditions) for fish passage and temperature management at dams, for purposes of this assessment was considered in terms of operational flexibility. Downstream fish passage resiliency of each alternative was assessed based on the type of downstream fish passage operations included (specifically the number of spring deep drawdowns) and the number of downstream fish passage structures included in each alternative.

**Table 3.8-79. Criteria applied to assess the resiliency of downstream fish passage (DSP) at dams to climate change.**

| | Vulnerability | | |
|---|---|---|---|
| | **Very High to High** | **Moderate** | **Low** |
| Resiliency | Very Low to Low | Moderate | High |
| Flexibility in DSP ops | spring deep drawdowns at 1 or fewer dams | spring deep drawdowns at 2-3 dams | spring deep drawdowns at 4-5 or more dams |
| # of DSP structures | 0-1 dams | 2-2.5 dams | 3 or more dams |

### *3.8.3.4 Population Viability*

For a low viability criteria, we assumed 3 populations need to be at low extinction risk. This is a conservative application of the UWR 2011 Recovery Plan delisting criteria.

Criteria for categorizing the vulnerability of UWR Chinook viability based on the number of populations affected by the WVS at low risk of extinction in each WVS EIS alternative(Table 3.8-80).

**Table 3.8-80.**

| | Number of WVS-effected populations with low risk of extinction | | | |
|---|---|---|---|---|
| | **3** | **2** | **1** | **0** |
| Vulnerability criteria | Low | Moderate | High | Very High |

### *3.8.3.5 Hatchery influence*

The same scores applied for population viability were applied for hatchery influence.

### *3.8.3.6 Other stressors*

We assessed the change in "other stressor" attributes highlighted by Crozier for UWR Chinook.

### *3.8.3.7 Results*

The cumulative vulnerability of UWR Chinook was rated as high to very high across the WVS EIS alternatives (Table 3.8-81 and 3.8-82). These high and very high ratings reflect high vulnerability scores for ocean acidification, seas surface temperature, hydrologic regime and cumulative life-cycle effects, as determined by Crozier et al. 2019 for UWR Chinook. Alternatives 2A and 4 received the lowest cumulative vulnerability scores (10.0). These results were driven by better (lower) scores for population viability and hatchery influence as compared to the other alternatives. Alternative 3A and 3B had the highest vulnerability scores (16.0). Vulnerability scores for 3A and 3B reflect the poor results for summer water deficit below dams, population viability and hatchery influence attributes. Alternative 2B scored intermediate among the alternatives.

Depending on how climate change impacts hydrology and temperatures above and below WVS dams in each sub-basin specifically, implementing more structural measures similar to those included in Alternatives 2A or 4 may be necessary to avoid unacceptable effects from climate change in the future, where resiliency of operational measures is found insufficient. However, if additional measures need to be considered in the future, it will be important to review the performance of downstream structural fish passage measures in particular before they are employed at additional dams, given the uncertainty in their ability to improve passage rates and survival of Chinook salmon more so than operational measures at high head dams with large fluctuating forebays (see Section 3.10.3.1 Estimation of Uncertainty; Kock et al. 2019).

**Table 3.8-81. Attribute categorization results for assessment of climate vulnerability of Upper Willamette spring Chinook salmon. Results for the NAA and attributes marked with a (1) are adopted from Crozier et al. 2019.**

| Attribute | NAA[1] | Alt1 | Alt2A | Alt2B/Alt 5 | Alt3A | Alt3B | Alt4 |
|---|---|---|---|---|---|---|---|
| **Exposure Attributes** | | | | | | | |
| ocean acidification[1] | Very high | Very high | Very high | Very high | Very high | Very high | Very high |
| stream temperature | Very High | Moderate | Low | Low | Low | Low | Low |
| sea surface temperature[1] | High | High | High | High | High | High | High |
| hydrologic regime[1] | High | High | High | High | High | High | High |
| summer water deficit above dams[1] | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate |
| summer water deficit below dams | Moderate | Moderate | Moderate | Moderate | High | High | Moderate |
| **Sensitivity Attributes** | | | | | | | |
| adult freshwater stage | Very High | Moderate | Moderate | Moderate | High | High | Moderate |
| cumulative life-cycle effects[1] | Very High | Very High | Very High | Very High | Very High | Very High | Very High |
| population viability | Very High | Moderate | Low | Moderate | High | High | Low |
| hatchery influence | Very High | Moderate | Low | Moderate | High | High | Low |
| other stressors | High | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate |
| **Adaptive Capacity**[1] | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate |

**Table 3.8-82. Overall vulnerability results based on conversion of assessment categories to numeric scores. Results from Crozier et al. (2019) are applied for the NAA. Results for attributes noted with a superscript 1 are also from Crozier et al. (2019), assuming these attributes would not be changing under each WVS EIS alternative.**

| Attribute | NAA[1] | Alt1 | Alt2A | Alt2B/Alt 5 | Alt3A | Alt3B | Alt4 |
|---|---|---|---|---|---|---|---|
| Exposure Attributes | High | 2.7 | 2.5 | 2.5 | 2.7 | 2.7 | 2.5 |
| ocean acidification[1] | Very high | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 | 4.0 |
| stream temperature | Very High | 2.0 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |
| sea surface temperature[1] | High | 3.0 | 3.0 | 3.0 | 3.0 | 3.0 | 3.0 |
| hydrologic regime[1] | High | 3.0 | 3.0 | 3.0 | 3.0 | 3.0 | 3.0 |

| Adaptive Capacity[1] | Moderate | 2.0 | 2.0 | 2.0 | 2.0 | 2.0 | 2.0 |
| Overall Vulnerability | Very High | 12.8 | 10.0 | 12.0 | 16.0 | 16.0 | 10.0 |
| | | Very High | High | Very High | Very High | Very High | High |

#### *3.8.3.8 Estimation of Uncertainty*

All models demonstrate considerable uncertainty among alternatives. This is most evident in tradeoff analyses between critical evaluation criteria. Such tradeoff analyses were available for the Integrated Passage Assessment. Given the sensitivity of spring Chinook relative to winter steelhead, spring Chinook were the focus of uncertainty analyses. Spring Chinook abundance was regressed against maximum recruits per spawner by alternative to demonstrate the considerable overlap in management strategy. Abundance informs the extinction risk so only abundance versus maximum recruits per spawner is given for each sub-basin below.

#### *3.8.3.9 North Santiam*

The tradeoff graphic for North Santiam Chinook salmon by alternative is given in Figure 3.8-16. Alternatives 2A, 2B, and 4 nearly completely overlap and demonstrate the broadest distribution of possible performance values; however, performance is overall better than 3A and 3B in most cases, and better than the NAA in all cases. The NAA demonstrated the smallest range of possible outcomes but also produced the worst performance.

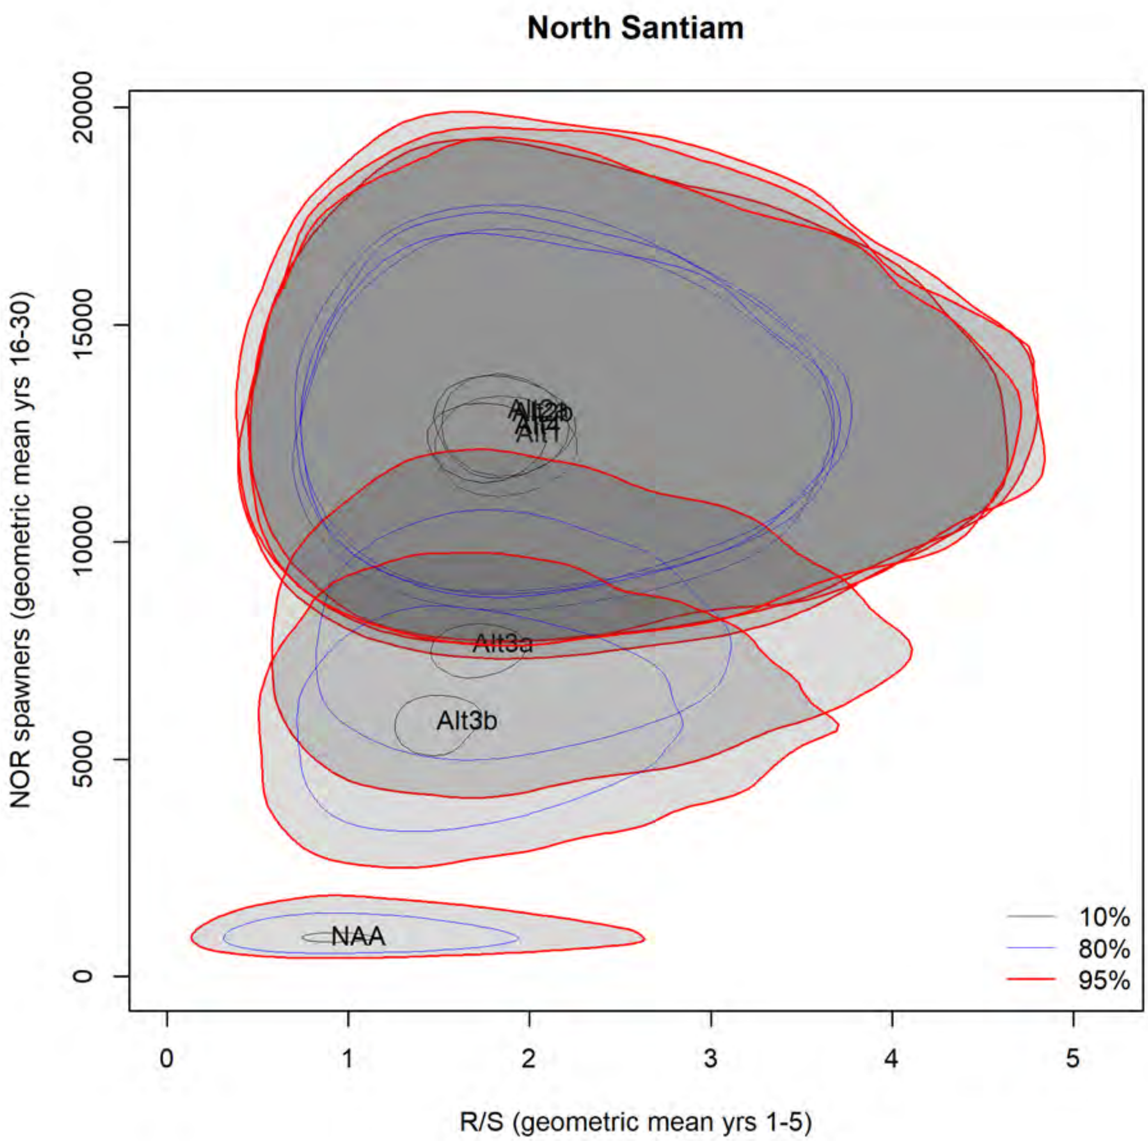

**Figure 3.8-16. Tradeoff plot for North Santiam Chinook salmon showing abundance regressed against maximum recruits per spawner. Alternatives are shown by bubbles and represent the range of possible values in each evaluation metric. Confidence bands are given by each color (10%, 80%, and 95% confidence).**

### *3.8.3.10 South Santiam*

The tradeoff graphic for South Santiam Chinook salmon by alternative is given in Figure 3.8-17. Alternatives show far more overlap in 95% confidence than in the North Santiam. In general, Alternative 1, 2A, and 2B performed best but they all overlap with 3A and 3B in some cases. The NAA demonstrated the smallest range of possible outcomes but also produced the worst performance and did not overlap with the performance of any of the action alternatives. In contrast to the North Santiam, Alternative 1 performed better in the South Santiam overall but still substantially overlapped the other top two performing alternatives, 2A and 2B. Alternative 4 completely overlaps the NAA performance. Alternative 4 includes structural passage at Green Peter but does not predict sustainability with respect to evaluation thresholds.

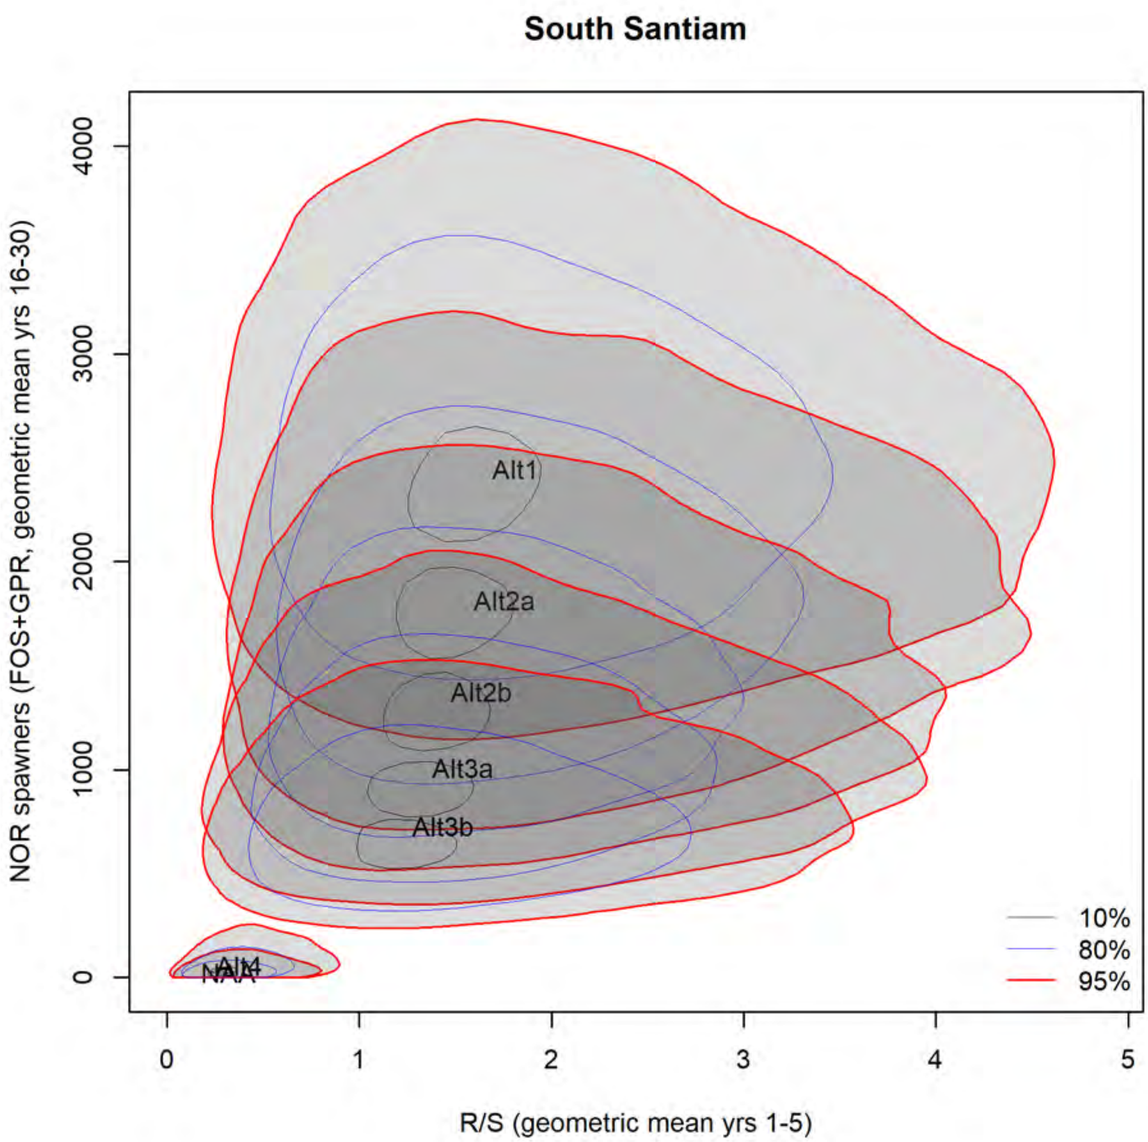

**Figure 3.8-17. Tradeoff plot for South Santiam Chinook salmon showing abundance regressed against maximum recruits per spawner. Alternatives are shown by bubbles and represent the range of possible values in each evaluation metric. Confidence bands are given by each color (10%, 80%, and 95% confidence).**

### *3.8.3.11 McKenzie*

The tradeoff graphic for McKenzie Chinook salmon by alternative is given in Figure 3.8-18. Alternatives demonstrated more discrete performance in 95% confidence intervals in the

McKenzie, than either the North and South Santiam. Alternatives 4 and 2A performed the best overall, though there is overlap with 2B in some cases. This is likely because alternatives 2A and 4 include structural passage at Cougar, while alternatives 2B, 3A, and 3B include operational passage. Alternatives 1, 3A, and 3B are compressed with respect to abundance, but can take on a wide range of recruit per spawner values, similar to alternatives 2B, 2A, and 4.

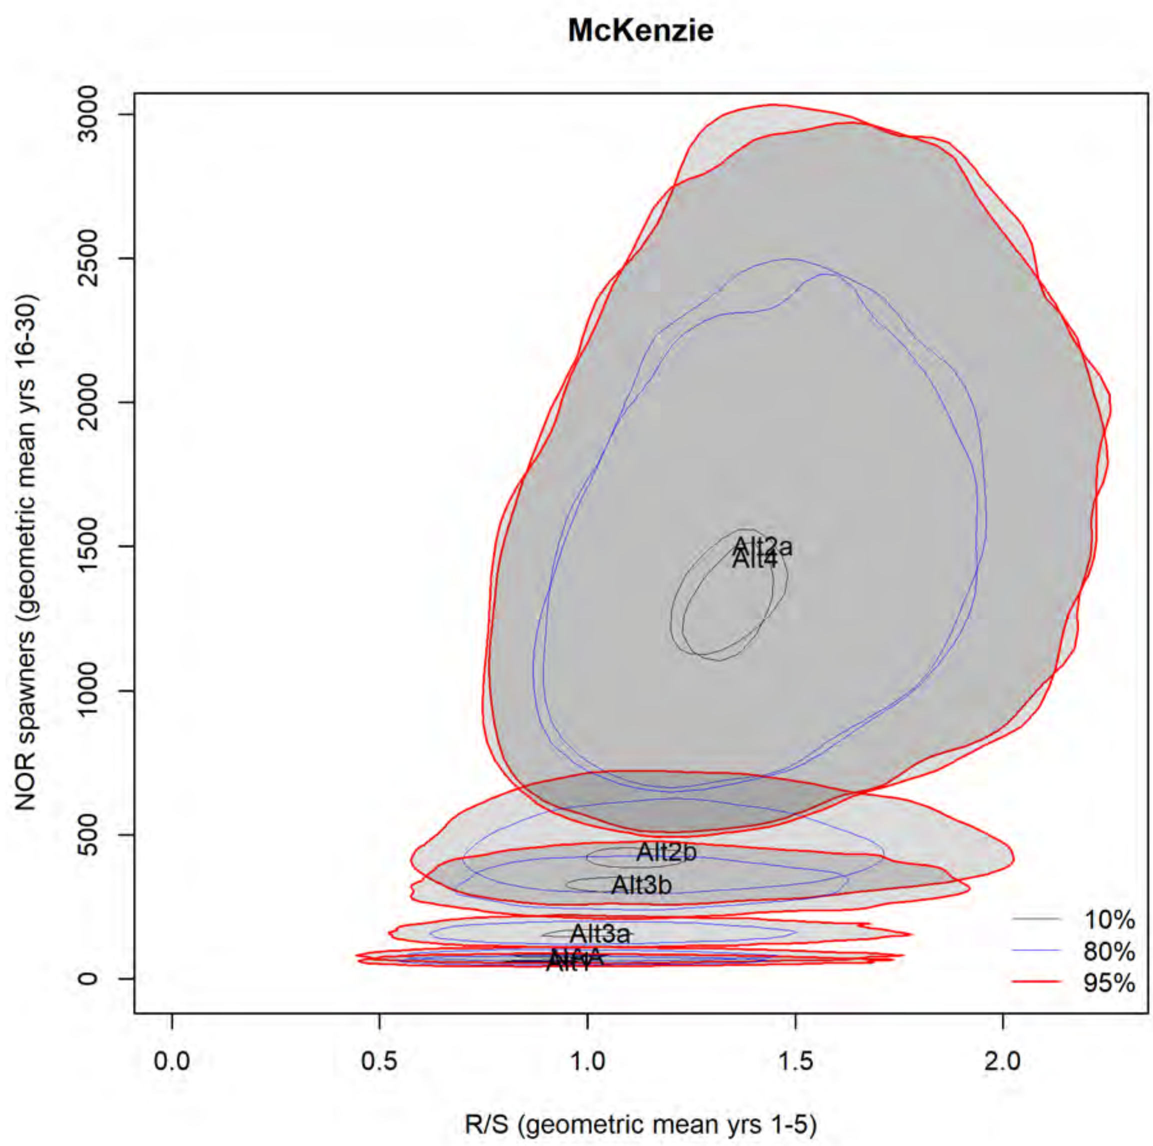

**Figure 3.8-18. Tradeoff plot for McKenzie Chinook salmon showing abundance regressed against maximum recruits per spawner. Alternatives are shown by bubbles and represent the range of possible values in each evaluation metric. Confidence bands are given by each color (10%, 80%, and 95% confidence).**

### *3.8.3.12 Middle Fork*

The tradeoff plot for the Middle Fork is given by Figure 3.8-19. Alternative 4 demonstrates the greatest uncertainty and the remaining alternatives are compressed relative to the output for the other sub-basins. The top performing alternatives are 4, 2A, and 2B and there is complete overlap between Alternative 4 and alternatives 2A and 2B.

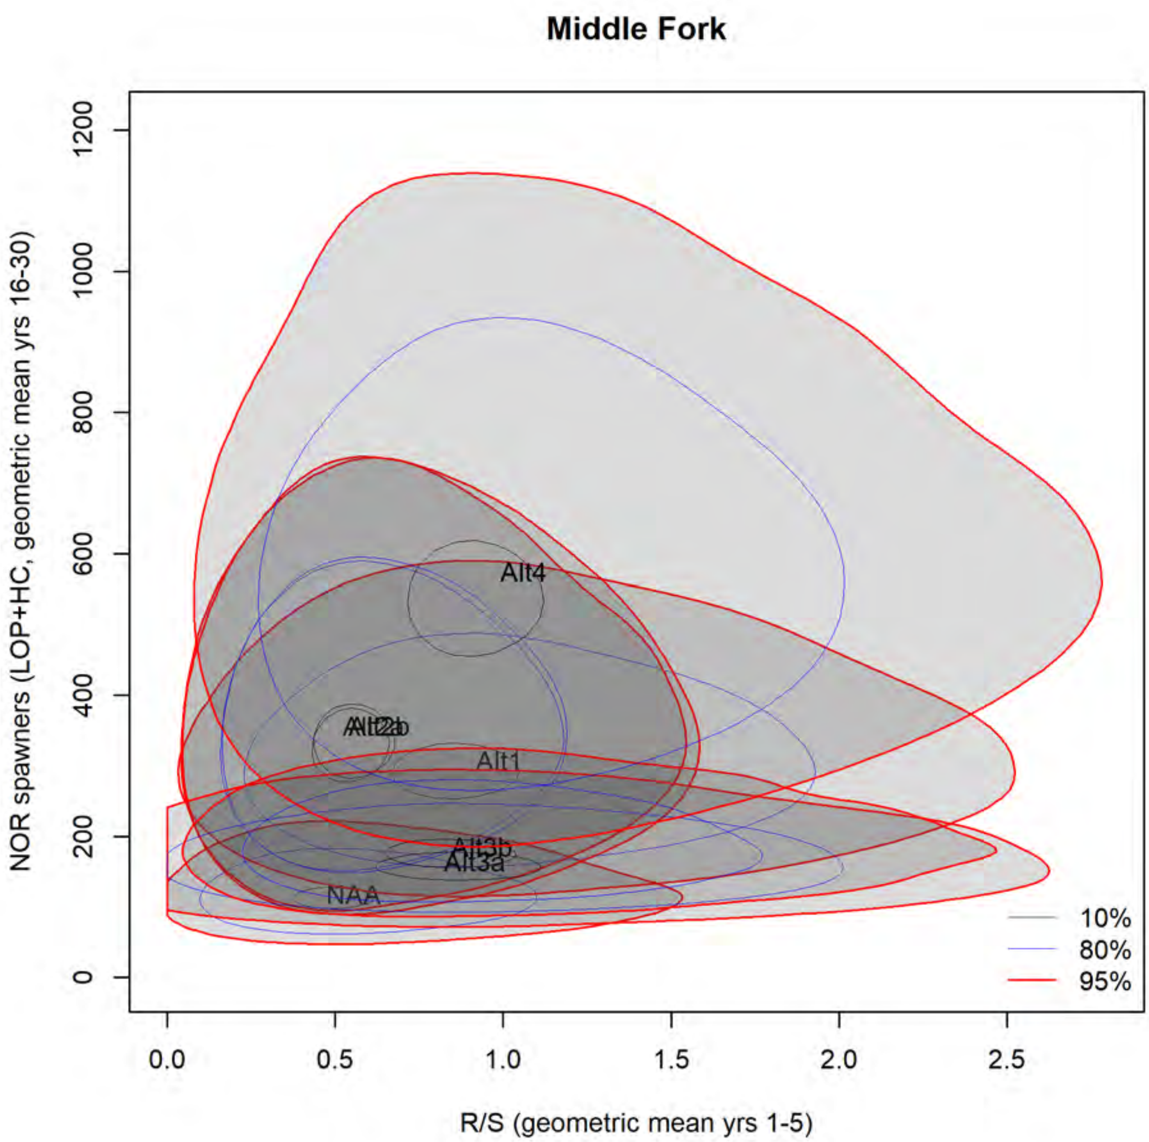

**Figure 3.8-19. Tradeoff plot for McKenzie Chinook salmon showing abundance regressed against maximum recruits per spawner. Alternatives are shown by bubbles and represent the range of possible values in each evaluation metric. Confidence bands are given by each color (10%, 80%, and 95% confidence).**

## 3.9 WILDLIFE AND HABITAT

The Willamette River Basin historically consisted of a multitude of aquatic and terrestrial habitat types that sustained rich assemblages of wildlife species. These assemblages include species that live year-round in its waters and associated floodplains, migratory species using seasonal habitat (e.g., breeding, wintering), wildlife movement corridors, and non-breeding/foraging habitats. Aquatic habitats are considered here to include open water (i.e., reservoir, main channel, secondary channels, backwaters, oxbows, and lakes/ponds) of varying depths. Terrestrial habitats generally include wetlands, forests, oak savannas, grasslands, and shrublands.

### 3.9.1 Affected Environment

The area of analysis for wildlife and their habitat (excludes fish, see Section 3.8) consists of all reservoirs up to the maximum pool elevation and the associated riverine and riparian habitat. A more detailed description of the Willamette River Basin and the associated subbasins can be found in Chapter 1. The Willamette River Basin is primarily composed of two EPA ecoregions: Willamette Valley and Western Cascades (see detailed ecoregions discussion in Section 3.6.1).

Open water habitat offers a diverse range of flows, depths, and temperature regimes, which provides habitat for mustelids, amphibians, reptiles, freshwater mussels, migratory birds, resident waterfowl, bats, and macroinvertebrates. Freshwater ecosystems support foraging, overwintering, reproduction, metamorphosis, and protection from predators for freshwater species.

Terrestrial habitats include grasslands, mixed deciduous and conifer riparian forest, mixed upland conifer forest, and oak-savannah habitats. The constantly changing and complex canopy structure produces changes in biomass and other ecosystem functions that effect faunal biodiversity. Upland systems provide species support by way of reproductive habitat for nesting and denning; refuge for roosting and overwintering; vertical and horizontal canopy structure for sunning and basking; and a variety of food resources throughout the seasons.

More specifically, grasslands and oak-savanna habitats provide browsing for native ungulates; seeds and insects for grassland birds; roots and fruits for rodents; and wildflowers for pollination and nectaring, and open space for invertebrates.

Tables 3.9-1 and 3.9-2 include species that have the potential to be present in the Willamette River Basin. Source data for tables in 3.9 include Oregon Biodiversity Information Center (ORBIC 2019), Oregon Department of Fish and Wildlife Sensitive Species list and Conservation Strategy, and USACE and USFWS species experts. This list does not include fish species (see Section 3.8)

Table 3.9-1 Representative common species that have the potential to be present in the Willamette River Basin, Oregon.

**Table 3.9-1. Common Species Present in all Subbasins**

| Taxon | Common Name | Scientific Name | North Santiam | South Santiam | McKenzie | Middle Fork | Coast Fork | Long Tom |

* Occurs in the Willamette Valley River Basin, but presence data are lacking in these 6 subbasins.

**Could be present in the Willamette Valley Basin, but systematic surveys are lacking in these 6 subbasins.

[1]ORBIC, 2019; ODFW Oregon Sensitive Species List and Conservation Strategy

[2] LE = Listed Endangered; LT = Listed Threatened; SOC = Species of Concern; P = Petitioned for listing; C = Candidate for listing

[3] LT = Listed Threatened; S = Sensitive; SC = Sensitive Critical; CS = Conservation Strategy

### *3.9.1.1 North Santiam Subbasin*

The North Santiam Subbasin includes aquatic and terrestrial habitat associated with the Detroit Reservoir, the Big Cliff Reservoir, and the North Santiam River downstream of Big Cliff Dam to the confluence with the South Santiam River (see detailed subbasin descriptions in Chapter 1).

The North Santiam Subbasin sits at an elevation of approximately 1,565 feet NGVD (National Geodetic Vertical Datum) and is with in the Cascade Mountain region. Therefore, seasonal temperatures tend to be cooler than other subbasins in the Willamette Valley and will thus affect the species present.

Sensitive species such as the inland distribution of Pacific marten (*Pekania pennanti*) or red tree vole (*Arborimus longicaudus*) may acquire food and shelter in the dense canopy of the Cascades. Riverine and open water habitat in the North Santiam Subbasin provides cold, freshwater for common species such as the American beaver (*Castor canadensis*) and American mink (*Neovison vison*). These species use debris to build shelter and find a variety of food resources (fish, snakes, crustaceans, amphibians) in and around the Detroit and Big Cliff reservoirs.

Invertebrate surveys have not been conducted at the Foster and Green Peter Reservoirs by Corps staff, therefore we recognize there are a variety of data deficient species that could be present in these areas that are not presented here.

### *3.9.1.2 South Santiam Subbasin*

The South Santiam Subbasin includes the Green Peter and Foster Dams and Reservoirs (see Chapter 1). It is located within the western slope of the Cascades. Areas of urban development can be seen near Sweet Home, Oregon, which is located downstream of Green Peter Dam and adjacent to Foster Dam. Additionally, agricultural lands are interspersed along the South Santiam River northwest to Jefferson, Oregon.

Aquatic habitat, as in other subbasins, includes wetlands and open water associated with Green Peter and Foster reservoirs and the Middle Santiam and South Santiam rivers. Predominant habitat near Green Peter and Foster Dams consists of old growth, mixed coniferous forest, a mixed deciduous, and conifer riparian forest. Complex, thick forest structure and canopy cover provides an abundance of biomass and moist areas ideal for rough-skinned newts (*Taricha granulosa*) and secretive forest birds.

Common avian species include bald eagles (*Haliaeetus leucocephalus*), osprey (*Pandion haliaetus*), mallards (*Anas platyrhynchos*), common mergansers (*Mergus merganser)*, and buffleheads (*Bucephala albeola*) (Table 3.9-1). These species use the reservoirs for food resource and refuge.

Northwestern pond turtles (*Actinemys marmorata*), a State sensitive species and petitioned for Federal listing, are present at Sunnyside Park at Foster Reservoir (Table 3.9-2). Historic sightings of Northwestern pond turtles have been reported in other locations around Foster Reservoir, although no pond turtles have ever been located at Green Peter Reservoir. Additionally, Northern red-legged frogs (*Rana aurora)* are found at the Foster quarry and elsewhere around the reservoir. Foothill yellow-legged frog has been present historically, but no recent surveys have been conducted for this species. These reptiles and amphibians have been observed near the river and in satellite ponds managed by both the Corps and Linn County Parks.

Invertebrate surveys have not been conducted at the Foster and Green Peter Reservoirs by Corps staff, therefore we recognize there are a variety of data deficient species that could be present in these areas that are not presented here.

#### *3.9.1.3 McKenzie Subbasin*

The McKenzie Subbasin includes Cougar and Blue River Dams and Reservoirs (see Chapter 1) and are considered part of the EPA Ecoregion 4a (see Section 3.7.1). Like the North Santiam Subbasin, these dams are higher in elevation (1,558 and 1350 ft NGVD, respectively) than most Willamette Valley dams, and therefore the McKenzie Subbasin may include a different suite of species than lower elevation dams. This Western Cascades ecoregion is predominately comprised of western hemlock and Douglas fir forests.

Common game species such as Roosevelt elk (*Cervus canadensis roosevelti*), black-tailed deer, black bear (*Ursus americanus*), and cougar (*Puma concolor*) inhabit the region. Upland game birds include sooty grouse (*Dendragapus fuliginosus*), ruffed grouse (*Bonasa umbellus*), mountain quail (*Oreortyx pictus*), and band-tailed pigeon (*Patagioenas fasciata*). Furbearers include American beaver, raccoon (*Procyon lotor*) and, less commonly, North American river otter (*Lontra canadensis*), bobcat (*Lynx rufus*), and mink. Resident waterfowl such as mallards, common mergansers, and wood ducks (*Aix sponsa*) inhabit the river, reservoir, and riparian areas of the subbasin (Table 3.9-1).

Non-game wildlife commonly observed in this ecoregion include small mammals (chipmunks, squirrels, rabbits, and mice), bald eagles, osprey, and pacific treefrogs (*Pseudacris regilla*). Sensitive species include Harlequin ducks (*Histrionicus histrionicus),* Oregon slender salamanders (*Batrachoseps wrighti*), and the Townsend's big-eared bat (C*orynorhinus townsendii*) (Table 3.9-2). Bats forage along the reservoir and tributaries during warmer months and use tree cavities, bark, leaf litter, and artificial structures for roosting.

Systematic faunal surveys have not been conducted in and around Cougar and Blue River Reservoirs by Corps staff, therefore we recognize there are a variety of data deficient species that could be present that are not discussed here.

#### *3.9.1.4 Middle Fork Willamette River*

The Middle Fork Willamette Subbasin includes Hills Creek, Lookout Point, Dexter, and Fall Creek Dams and Reservoirs. This subbasin is located within the western slope of the Cascade Mountains. Most urban development is limited to the towns of Lowell and Oakridge, Oregon. Lowell is adjacent to Dexter Reservoir and within 10 miles of Fall Creek and Lookout Point Reservoirs. Oakridge and West Fir are near Hills Creek Dam. Hills Creek Dam is higher in elevation (1,545 ft NGVD) and closer the Cascade Mountains than the other three dams, therefore a unique suite of species, such as Northern red-legged frogs and the Harlequin ducks occur at Hills Creek.

Upland habitats found within the Middle Fork Subbasin include grasslands, riparian and mixed conifer forest, and a limited amount of oak savanna habitats. Vegetative heterogeneity and varying elevations near these dams provide habitat complexity that supports unique breeding, denning, roosting, basking, and foraging environments for a variety of wildlife species.

Common avian species observed at these reservoirs include bald eagles, osprey, bufflehead, Western grebes (*Aechmophorus occidentalis*), tree swallows (*Tachycineta bicolor*), and spotted towhees (*Pipilo maculatus*) (Table 3.9-1). Amphibians well-represented at Fall Creek and surrounding areas include rough-skinned newts and Oregon ensatinas (*Ensatina eschscholtzii oregonensis*), along with more unique salamanders such as the Dunn's (*Plethodon dunni*) and long-toed salamanders (*Ambystoma macrodactylum*). Moist soil and forested understory provide ideal habitat for salamander species around Fall Creek, Hills Creek, and Lookout Point Reservoirs.

Northwestern pond turtles (*Actinemys marmorata*), a State sensitive species and petitioned for Federal listing, occur in each of these four reservoirs and are typically found in protected reservoir coves or tributaries containing basking structures (logs or rocks). Other sensitive species present at these reservoirs include clouded salamanders (*Aneides ferreus*) and western bluebirds (*Sialia mexicana*) (Table 3.9-2).

Populations of waterfowl, both resident and migratory, use the reservoirs for foraging and refuge. Mesopredators such as bobcats (*Lynx rufus*) and coyotes (*Canis latrans*) are also found around the reservoirs.

#### *3.9.1.5 Coast Fork Willamette River*

The Coast Fork Willamette Subbasin includes Cottage Grove and Dorena Dams and Reservoirs. The forests within the subbasin are dominated by Douglas fir with some remnant oak forests (see Chapter 1). The town of Cottage Grove, Oregon lies within 7 miles of both reservoirs and is the most developed urban area near the reservoirs. Private properties also line the perimeter of these reservoirs. The Coast Fork Willamette River riparian corridor consists of agricultural fields with limited forested habitat up to confluence with the Middle Fork Willamette River near Eugene, Oregon.

The upland habitats near these reservoirs include grasslands, riparian forest, mixed conifer forest, agricultural lands, and oak savanna habitats. More specifically, mixed deciduous and conifer riparian forests make up most of the habitat at Dorena and Cottage Grove Reservoirs.

Common avian species observed at these reservoirs include bald eagles, osprey, and hooded mergansers (*Lophodytes cucullatus*)**.** Amphibians include long-toed salamanders, rough-skinned newts, and Oregon ensatinas (Table 3.9-1).

Sensitive species, such as the Northwestern pond turtle, have historically been seen in and around Dorena and Cottage Grove Reservoirs (Table 3.9-2). A small population of western purple martins (*Progne subis arboricola*) is supported by artificial nest boxes at Cottage Grove Reservoir.

Systematic faunal surveys have not been conducted in and around Dorena and Cottage Grove Reservoirs by Corps staff, therefore we recognize there are a variety of data deficient species that could be present in these areas that are not discussed here.

#### *3.9.1.6 Long Tom*

The Long Tom River Subbasin includes Fern Ridge Dam and the Long Tom River upstream of its confluence with the Willamette River (see Chapter 1). The Long Tom River downstream of Fern Ridge Dam was modified for conveyance soon after Fern Ridge Dam was built in the 1940s. To promote high flows through the modified channel of the Long Tom River, large trees including cottonwood, oak, and Oregon ash were removed along with smaller shrubs (e.g., various willow species). In addition, the channel was modified by straightening it through the floodplain; however, unmodified portions of the Long Tom River channel remain. Natural occurring oxbows and sloughs are connected to the current Long Tom River channel via culverts. In other portions of the Long Tom River, the original channel was cut off from the constructed channel to decrease channel length and are no longer connected to the current Long Tom River channel. Those oxbows and sloughs provide off-channel wetland and open water habitat.

Adjacent land use along the Long Tom River is predominately agriculture, with grass seed propagation the dominant crop. Remnant native oak riparian forest areas dot the landscape along the unmodified portion of the Long Tom River channel south of Monroe, Oregon.

Adjacent land use around Fern Ridge Reservoir includes a mix of residential and agricultural. Habitat types within Fern Ridge Reservoir include upland Willamette Valley prairie, Willamette Valley wet-prairie, oak woodland, riparian forest remnants, emergent vegetation, and open water. Constructed wetland cells at the southeastern end of Fern Ridge Reservoir are managed for winter waterfowl use by the Oregon Department of Fish and Wildlife (ODFW).

Common species include voles, chipmunks, bats, and rabbits. Roosevelt elk and black-tailed deer are also seen along the reservoir shores (Table 3.9-1). Resident and migratory waterfowl use the reservoir for both breeding and wintering. Various shorebirds forage in the exposed lakebed during the winter reservoir drawdowns. A variety of secretive marsh birds use the emergent lake vegetation for breeding. Fern Ridge Reservoir and surrounding wetlands are renowned for the abundance and diversity of avian species. Occasional migrant raptors like snowy owls (*Bubo scandiacus*) and migrating winter shorebirds such as dunlin (*Calidris alpina*) and black-bellied plovers (*Pluvialis squatarola*) can be observed.

Unique and sensitive species found in and around Fern Ridge Reservoir and the Long Tom River channel include Northwestern pond turtles, grasshopper sparrows (*Ammodramus savannarum*), western purple martins, Fender's blue butterflies (*Icaricia icarioides fender*), and streaked horned larks (*Eremophila alpestris strigata*) (Table 3.9-2). Northwestern pond turtles are seen throughout the reservoir and are concentrated in Kirk Pond and Park, directly north of the dam. Grasshopper sparrows and Fender's blue butterflies inhabit the remanent native upland prairie that surrounds the reservoir. Every spring and summer, migratory western purple martins take advantage of artificial nest boxes that surround Fern Ridge Reservoir. This population is thought to be the largest population of inland nesting purple martins in Oregon. A small breeding assemblage of streaked horned larks are found at the southern end of the reservoir, south of Highway 126. Periodic reports of streaked horned lark calls have been reported near the Fisher Butte unit, just north of the highway. Streaked horned larks require large expanses of open ground with sparse vegetation and vernal pools for breeding and foraging. Fern Ridge's Coyote units provide this essential habitat.

### 3.9.2 Environmental Consequences

This section discusses the potential effects of the alternatives on wildlife and associated habitats. The area of analysis, as previously mentioned, consists of all reservoirs up to the maximum pool elevation (a.k.a., "full pool"), the terrestrial habitat around the reservoirs, riverine habitat downstream of the dams, and the associated riparian corridors along the project stream reaches listed below.

- Middle Fork Willamette River downstream of Hills Creek Dam to the confluence with the Coast Fork Willamette River;
- Coast Fork Willamette River downstream of Cottage Grove Dam to the confluence with the Middle Fork Willamette River;
- Row River from downstream of Dorena Dam to the confluence with the Coast Fork Willamette River;
- South Fork McKenzie River downstream of Cougar Dam to the confluence with the McKenzie River;

- McKenzie River from the South Fork McKenzie River confluence to the confluence with the Willamette River;
- Blue River downstream of Blue River Dam to the confluence with the McKenzie River;
- Long Tom River downstream of Fern Ridge Dam to the confluence with the Willamette River (includes Coyote Creek from Fern Ridge Dam to the confluence with the Willamette River);
- South Santiam River downstream of Foster Dam to the confluence with the North Santiam River;
- North Santiam River downstream to the confluence with the South Santiam River;
- Santiam River to the confluence with the Willamette River; and
- Willamette River mainstem to Willamette Falls.

The discussion below includes the qualitative methods used to evaluate effects to wildlife and associated habitat.

#### *3.9.2.1 Methodology*

The method used to assess the existing conditions and the alternatives' effects to wildlife, birds, and associated habitat was a qualitative analysis based on species presence or absence or suitable habitat present as shown in ORBIC, USFWS, and ODFW conservation strategy data as well as direct coordination with USFWS species experts. In addition, it should be noted that the Corps employs biologists in the Willamette Valley who have expertise in both common and rare species and habitats throughout the Willamette River Valley and they reviewed species included in the DPEIS.

Potential effects to wildlife and associated habitats within the WVS analysis area entail indirect effects related to hydrology, water quality, and fish passage measures proposed for each alternative. The following measures (described in Chapter 2) have effects on wildlife and associated habitat that will be evaluated in this Draft PEIS:

- Gravel augmentation below dams (#384);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b);
- Construct water temperature control (WTC) tower (#105);
- Augment instream flows by using inactive pool (#718);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Augment instream flows by using the power pool (#304);

- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Structural improvements to reduce total dissolved gas (#174)
- Foster Fish Ladder Temperature Improvement (#479)
- Use spillway for surface spill in summer (#721)
- Construct structural downstream fish passage (#392);
- Pass water over spillway in spring for fish passage (#714);
- Provide Pacific lamprey passage and infrastructure (#52);
- Restore upstream and downstream passage at drop structures (#639);
- Deeper fall reservoir drawdowns for fish passage (#40); and
- Spring reservoir drawdown for downstream fish passage (#720).

Measures that would be not likely to affect wildlife and wildlife habitat as part of the WVS O&M program include the following: Adapt Hatchery Program (#719), Maintenance of existing and new fish release sites above dams (#726), and Construct adult fish facility (#722) (pertaining to fisheries management activities). These measures are not discussed further in regard to effects to wildlife and wildlife habitat.

Direct effects to wildlife or associated habitats may be included as part of specific construction activities; however, this Draft PEIS will discuss general qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss the detailed site-specific effects. At that time, site-specific biological data would be reviewed to determine species presence and suitable habitat located within a specific project action area to determine the direct effects. Applicable permits, approvals, and environmental clearances would be obtained prior to action implementation. If ESA Section 7 formal or informal consultation with USFWS for a particular ESA-listed species or its designated critical habitat would be required for a particular action, this would be pursued at that time.

**All comparisons of magnitude or duration in the effects analysis for each action alternative are in comparison to the NAA unless stated otherwise.**

Table 3.9-23 below describes the criteria for the scale of effects for wildlife and associated habitat within the WVS.

**Table 3.9-3. Evaluation Criteria for Potential Effects**

| Effect Scale | Definition |
|---|---|
| **Magnitude** | |
| None/negligible | Species and/or habitat would not be affected and no effects (e.g., noise disturbance, physical harm, etc.) would be detectable. |
| Minor | Effects to the species and/or habitat would be detectable (e.g., vacated habitats, evidence of a lethal effect to individuals, improvement of habitat function); however, effects would be only to a small number of individuals and would be localized. |
| Moderate | Effects to the species and/or habitat would be measurable and include effects (e.g., lethal wildlife effects, loss of suitable habitat) at the population and subbasin scale. |
| Major | Effects to species and/or habitat (e.g., lethal wildlife effects, loss of habitat for special status species, effects to designated critical habitat) would be measurable and would have substantial ecological consequences at the population scale for multiple subbasins within the WVS. Mitigation measures to reduce the adverse effects would be required, though long-term population effects would be anticipated. |
| **Duration** | |
| Short-term | Effect to species and/or habitat would be short in duration lasting only as long as a discreet construction project or single event, e.g., construction noise. |
| Long-term | Effect to species and/or habitat would be ongoing or lasts beyond operation changes or the completion of construction projects. |

### *3.9.2.2 No Action Alternative*

The NAA hydrologic regime is the opposite of the natural hydrologic regime. The WSE is the highest within the reservoirs from May through September when the maximum conservation pool is being maintained, whereas naturally this would be the driest time of year within the reservoir area. This serves as a source of hydrology that helps sustain wetland and aquatic habitats along the edges and within the reservoirs, respectively, during the year when precipitation is at its lowest. Maximizing open water aquatic habitat within the summer months benefits a range of species including amphibians such as the northern red-legged frog, reptiles such as the northwestern pond turtle, wading birds, aquatic diving birds, waterfowl, and furbearers such as the American beaver. In addition, amphibians benefit from maintaining water levels in late winter through spring when egg masses require inundation to keep the eggs from drying out. Wetland fringe habitat supports the wildlife species by providing foraging, breeding, rearing, nesting, and sheltering habitat. Keeping the reservoirs full during the summer also provides easier access to water for a variety of upland wildlife species including, but not limited to, black-tailed deer, raccoons, voles, and Pacific martens (*Martes caurina*). Maximizing aquatic habitat available to wildlife species during summer months has moderate long-term benefits to both aquatic and terrestrial species.

Within the WVS, downstream flows are managed so that wintertime flooding, which would naturally occur without the dams, is mitigated. In addition, revetments within the WVS help ensure that banks are not overtopped in any sort of high flow event. These flood mitigation actions, limit the hydrologic connectivity across the floodplains of WVS streams. Therefore, adjacent aquatic and wetland habitats experience drier conditions than they would outside of a managed system. This limits the size and diversity of habitat within the riparian corridors that would be available to wildlife species during winter and spring months, which has moderate long-term adverse effects to aquatic wildlife and their habitat. Though this may be limiting to species that depend primarily on aquatic and wetland habitat, this likely has minor long-term benefits for upland species by expanding habitat otherwise unusable to them during winter months if there was widespread flooding within the floodplain.

No fish passage improvements would be proposed as part of the NAA. This would continue to limit foraging opportunities for piscivorous wildlife species such as river otters, muskrats (*Ondatra zibethicus*), and eagles within stream reaches upstream of the WVS dams where passage has not been provided for native migratory fish, including salmonids and Pacific lamprey (*Lampetra tridentata*). This would result in long-term, minor, adverse effects to piscivorous wildlife species and overall habitat function in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins.

Climate change is anticipated to lead to wetter Climate change is anticipated to lead to wetter, shorter winters with more punctuated precipitation events (greater intensity). Climate change will also yield longer, drier summers (increased temperature and evapotranspiration) which would adversely affect wildlife species and habitat in the Willamette Valley independent of the WVS operation and maintenance actions over the course of the next 30 years. Vegetation types present in upland habitat that support terrestrial wildlife species would shift to more drought-tolerant species. Wetland habitats within the riparian corridor would be drier during summer months, shrinking available habitat earlier in the year and will significantly affect species amphibians, reptiles, and those terrestrial species that rely on water bodies for foraging such as birds and bats. These changes to habitat may increase stress on wildlife species to find suitable habitat. In the case of amphibians, breeding success would be adversely affected, reptile foraging will be altered, and raptor prey-base will be diminished Additionally, climate change is anticipated to continue to increase water temperature over time as ambient temperatures increase and snowmelt contributes less runoff or earlier runoff within the basin, which could adversely affect wildlife prey species, such as fish. Increased water temperatures would cause a greater frequency of algal blooms, which can introduce toxins both to prey species (e.g., fish) as well as species higher up in the food chain that ingest these toxins. The seasonality of wildlife species (e.g., birds, reptiles, insects, etc.) life histories will be forced to adapt to the changing climate patterns, which is anticipated to have a number of adverse effects to species, interactions between species, and interactions with their habitats. Overall, climate change is anticipated to cause major, long-term, adverse effects to wildlife species and their habitat independent of the WVS operation and maintenance actions associated with the NAA as well as any other alternative.

### *3.9.2.3 Measures Common to All Action Alternatives*

Measures that are common to all action alternatives that would provide minor long-term benefits to wildlife habitat within the WVS include gravel augmentation below the dams (#384) and maintaining revetments using nature-based engineering or altering revetments for aquatic ecosystem restoration (#9).

Gravel augmentation below dams within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins is intended to improve instream spawning habitat for ESA-listed UWR Chinook and steelhead as well as other native fish; however, there would be minor indirect effects that benefit wildlife species and habitat. Improving conditions for fish and other aquatic organisms may improve foraging opportunities for piscivorous wildlife species such as osprey, diving ducks, river otters, and eagles. In addition, by adding gravel to these streams, there is more potential for sediment transport and accumulation along the stream margins, which may serve to better connect riverine wetlands to instream flows. In these areas, wetlands would benefit through improved hydrologic conditions over time. Wildlife species that would benefit from improvements to wetland habitat, include species such as American beavers, great blue herons (*Ardea Herodias*), frogs (*Rana* sp.), and turtles (painted and northwestern pond turtles). These beneficial effects are anticipated to be minor and long-term within the downstream reaches of the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

In addition to the beneficial impacts to wildlife and habitat by the placement of gravel, there would some minor, short-term impacts to water quality and streambed habitat within the gravel placement areas and downstream of the placement sites. Placement of gravel would result in an increase to turbidity within the placement area and could impact aquatic invertebrates and native freshwater mussels within the placement area and those areas immediately downstream. Placement of gravel would also impact amphibian breeding areas (e.g. red-legged frog) within off-channel areas where suspended sediments would deposit. Dependent on the timing of the placement of gravel, there would be minor, short-term impacts to in-stream overwintering northwestern pond turtle.

In the same way, maintaining or altering revetments (through the Continuing Authority Program Section 1135 Project Modifications for Improvement of the Environment) is anticipated to improve habitat connectivity between upland and riparian vegetative communities along the stream margins, allowing for easier access to water for mammals (e.g., black-tailed deer, voles, ermine [*Mustela erminea*], muskrats, American beaver, etc.) and overland migration for amphibian species (e.g., Pacific giant salamanders [*Dicamptodon tenebrosusis*], rough-skinned newts [*Taricha granulosa*], etc.). These bio-engineered areas would provide better habitat for American beaver and river otter slides and nesting habitat for ground nesting birds through the incorporation of plants. The logs incorporated into the designs could potentially provide basking opportunities for turtles. These improvements to the revetments are anticipated to provide minor long-term beneficial effects for wildlife species and habitat. It should also be noted that it is uncertain how much of this could occur since the revetments are engineered bank stabilization and a limited number of these could be modified as discussed in Chapter 2.

#### *3.9.2.4 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

One measure associated with Alternative 1 that would affect aquatic and adjacent wetland wildlife habitat over the NAA is reducing minimum flows to the Congressionally authorized minimum flow requirements (#723) to benefit reservoir refill objectives within the entire WVS. Therefore, there would be a slight overall decrease in flows at the North Santiam and South Santiam rivers as well as Fall Creek, which flows into the Middle Fork Willamette. However, the decrease in flow is very minor and therefore, hydrologic effects to the aquatic and riverine wetland habitat along these streams would be negligible and long-term. There would though be a slight increase of downstream flows from the Dexter and Lookout Point Dams, which are along the Middle Fork Willamette. This increase in downstream flow would slightly improve hydrologic conditions for the aquatic and riverine wetland habitat, though the benefit to wildlife species is anticipated to be negligible and long-term over the NAA conditions.

Augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water's edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor, long-term, adverse effects to terrestrial wildlife species within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins. Impacts to amphibians and reptiles, notably northwestern pond turtle, would be moderate, long-term adverse effects. The lowering of reservoir level would impact northwestern pond turtles that overwinter within the reservoir lakebed causing them to move throughout the drawdown period leading to an increase in energy expenditure. For those turtles that overwinter in upland areas adjacent to the reservoirs, lower reservoir elevations would increase travel distance to overwintering habitat leading to an increase in energy expenditure.

Alternative 1 includes measures to Provide Pacific lamprey passage and infrastructure (#52) at Dexter Dam; Restore upstream and downstream passage at drop structures (#639) at Long Tom River downstream of Fern Ridge; and downstream fish passage at Detroit (operation not a structure), Foster, Green Peter, and Lookout Point Dams (Measure 392). In addition, Alternative

1 measures that would improve salmonid survival by improving TDG levels include structural improvements to reduce TDG (#174) and by improving water temperature include constructing WTC towers (#105); using ROs to discharge colder water (#166); the Foster Fish Ladder Temperature Improvement (#479); and using the spillway for surface spill in summer (#721). Fish passage and water quality measures would improve lamprey populations in the Middle Willamette subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, Long Tom, and Middle Willamette subbasins. Improving fish populations would provide long-term minor benefits in terms of increased foraging opportunities for piscivorous wildlife species including but not limited to river otters, snakes, raccoons, ermine, eagles, osprey, great blue herons, etc. In addition, improving anadromous salmonid populations in the North Santiam, South Santiam, Long Tom, and Middle Willamette subbasins would have minor long-term benefits to habitat functions related to nutrient cycling as a result of fish decaying in these subbasins after spawning.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

#### *3.9.2.4.1 Climate Change*

The climate change effects in addition to the NAA (Section 3.9.2.2.), Alternative 1 has climate change concerns as well. The climate change effects regarding the NAA are concerns for Alternative 1 as well. However, maximizing water storage while also providing fish passage benefits to wildlife and wildlife habitat by providing maximum hydrologic support for aquatic and wetland habitats and increasing foraging opportunities for wildlife species upstream of the dams is anticipated to support wildlife species and habitat to the extent possible while these regional changes occur. Alternative 1 would not avoid the effects of climate change to wildlife and associated habitats but would potentially decrease the effects. However, major long-term adverse effects to wildlife species and habitat as a result of climate change would still be anticipated.

#### *3.9.2.4.2 Alternative 1 Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-24 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 1.

**Table 3.9-4. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 1 as Compared to the Alternative 1 – Improve Fish Passage Through Storage-Focused Measures**

| Subbasin | Alternative 1 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with minor benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter, Detroit, Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Green Peter, Foster, and Detroit – downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Long Tom – downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Cougar – water quality improvements with minor benefits for foraging wildlife<br>Cougar - drawdowns with minor effects to aquatic and wetland habitat at the reservoirs |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Dexter, Lookout Point Green Peter, Detroit, Foster – water quality improvements with minor benefits for foraging wildlife<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to aquatic and wetland habitat at the reservoirs<br>Lookout Point and Dexter - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Cottage Grove and Dorena – drawdowns with minor effects to aquatic and wetland habitat at the reservoirs |

| Subbasin | Alternative 1 |
|---|---|
| Mainstem Willamette River | Negligible change |

### *3.9.2.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

In terms of effects to wildlife, birds, and terrestrial habitat, as a hybrid of the rest of the alternatives, Alternative 2A includes minor changes to habitat, habitat access, and foraging opportunities. The integrated temperature and habitat flow regime (#30a) would have negligible effects to riverine wetlands and aquatic habitat within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Long Tom subbasins.

Augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, changes to peak flow event timing could impact reproduction timing of amphibian species, freshwater mussels, and other native aquatic species. Within reservoirs, the seasonal drawdown may cause wildlife to seek alternative water sources near the reservoirs during the drawdown time periods. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor long-term adverse effects to wildlife species within the Middle Fork Willamette, Coast Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

In addition, a measure that would affect wildlife, birds, and terrestrial habitat within the WVS as part of Alternative 2A includes a deeper fall reservoir drawdown for fish passage (#40) at Green Peter reservoir (October 15 to December 15). The drawdown would affect wildlife species' access to the water during these time periods within the South Santiam and McKenzie subbasins. Species such as black-tailed deer, elk, raccoons, ermine, coyotes (*Canis latrans*), etc. would need to travel farther to get to the water's edge and in some areas, may need to cross steep unvegetated slopes. The seasonal drawdown may cause wildlife attempting to access the water's edge to access alternative water sources in the vicinity of the reservoirs during the drawdown time periods. In addition, the drawdowns would affect wildlife species that build lodges, burrows, or dens along the water's edge such as beavers, muskrats, otters, etc. The dramatic changes in water surface elevations in these reservoirs throughout the year would flood these habitat structures at certain times of year and leave them high and dry at other times. This may cause animals to build multiple habitat structures throughout the year in these locations. Increasing the distance that wildlife would need to travel to access the water's edge and potentially damaging wildlife habitat structures through water level fluctuations would have long-term moderate effects on wildlife species, primarily mammalian species in the South Santiam subbasin.

Alternative 2A would include providing Pacific lamprey passage and infrastructure (#52) at Green Peter and constructing structural downstream fish passage (#392) at Detroit, Foster, Cougar, and Lookout Point. In addition, Alternative 2A measures that would improve water temperature include constructing WTC towers (#105); using ROs to discharge colder water (#166); the Foster Fish Ladder Temperature Improvement (#479); and using the spillway for surface spill in summer (#721) that would improve salmonid survival. These measures would improve fish passage, water quality, and would improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations would provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

#### *3.9.2.5.1 Near-term Operations Measure*

The descriptions of the near-term operations measure can be found within Chapter 2. The analysis of effects of the near-term operations measure on wildlife, birds, and terrestrial habitat is broken down into subbasins.

**North Santiam Subbasin**

The near-term operations measure within the North Santiam Basin includes fall/winter downstream fish passage through the upper ROs and spring fish passage through strategic use of spillway and turbines at Detroit Dam and spreading spill to reduce TDG at Big Cliff Dam.

The use of the upper ROs for downstream fish passage in the fall may result in an increase in TDG downstream of Detroit Dam. Changes in fish survivorship could indirectly affect piscivorous wildlife; however, improving fish passage is anticipated to improve overall fish survivorship. Increases to fish survival would provide long-term minor beneficial effects to piscivorous wildlife species in terms of increased foraging. Wildlife species that would benefit include, but are not limited to, river otters, bald eagles, osprey, mergansers, and great blue herons.

Using the spillway for spring fish passage could lower reservoir elevations, resulting in changes to access to the reservoir for wildlife species during the conservation season. Wildlife species would need to find alternate water sources other than the reservoir or traverse steep, unvegetated slopes to get to the reservoir, which would have short-term, minor, adverse effects. Impacts to amphibians and reptiles, notably northwestern pond turtle, would be moderate, long-term adverse effects. The lowering of reservoir level would impact northwestern pond turtles that overwinter within the reservoir lakebed causing them to move throughout the drawdown period leading to an increase in energy expenditure. For those turtles that overwinter in upland areas adjacent to the reservoirs, lower reservoir elevations would increase travel distance to overwintering habitat leading to an increase in energy expenditure.

**South Santiam Subbasin**

The near-term operations measure within the South Santiam Subbasin includes outplanting of adult Chinook above Green Peter Reservoir, downstream fish passage at Green Peter Dam via the spillway in the spring and fall, and downstream fish passage at Foster via the spillway in the spring and fall.

The outplanting of Chinook salmon above Green Peter Dam would have a minor long-term benefit to piscivorous wildlife through increased foraging opportunities. Wildlife species impacted would include, but not limited to, bald eagles, river otters, great blue heron, osprey, and mergansers.

The use of the spillway for spring fish passage would affect wildlife species access to water within the reservoir. Wildlife species would need to find alternate water sources other than the reservoir or traverse steep, unvegetated slopes to get to the reservoir, which would have short-term, minor, adverse effects. Impacts to amphibians and reptiles, notably northwestern pond turtle, would be moderate, long-term adverse effects. The lowering of reservoir level would impact northwestern pond turtles that overwinter within the reservoir lakebed causing them to move throughout the drawdown period leading to an increase in energy expenditure. For those turtles that overwinter in upland areas adjacent to the reservoirs, lower reservoir elevations would increase travel distance to overwintering habitat leading to an increase in energy expenditure.

The deep fall drawdown at Green Peter from September to mid-December for fish passage would further impact wildlife access to available surface water during the fall and early winter months. Wildlife structures (e.g., lodges and burrows) would likely be constructed at multiple elevations within the reservoir. The dramatic changes in water elevation between the spring spill for downstream fish passage and the fall drawdown and spill for fish passage would result in long-term minor effects to wildlife.

The use of the spillway at Foster in the spring would occur from February 1 to May 15 and in the fall would occur from approximately Labor Day to December 15. The effects to wildlife are similar to the fish passage near-term operations measure at Green Peter. Wildlife would either have to travel farther or traverse steep unvegetated slopes of the reservoir to access surface water.

**Long Tom Subbasin**

There are no local operations proposed under the near-term operations measure within the Long Tom subbasin, therefore, there would be no effects of this measure to wildlife in this subbasin.

**McKenzie Subbasin**

The near-term operations measure within the McKenzie Subbasin include spring and fall/winter drawdown at Cougar Reservoir to a target elevation of 1,505 feet. This action would affect wildlife species access to water within the reservoir. Wildlife would have to either travel farther to access surface water or traverse steep, unvegetated slopes of the reservoir. Wildlife that construct burrows (e.g. river otters) or lodges (beaver) would have to construct additional wildlife structures at various elevations to adjust to the change in the reservoir elevation. The increase in fish passage survival would have a minor affect to piscivorous wildlife in the long-term with an increase in abundance of prey within the subbasin. Impacts to amphibians and reptiles, notably northwestern pond turtle, would be moderate, long-term adverse effects. The lowering of reservoir level would impact northwestern pond turtles that overwinter within the reservoir lakebed causing them to move throughout the drawdown period leading to an increase in energy expenditure. For those turtles that overwinter in upland areas adjacent to the reservoirs, lower reservoir elevations would increase travel distance to overwintering habitat leading to an increase in energy expenditure.

**Middle Fork Willamette Subbasin**

The near-term operations measure within the Middle Fork Willamette Subbasin include use of the regulating outlet for downstream fish passage at Hills Creek, deep drawdown for fish passage at Lookout Point in fall/winter, use of the spillway for fish passage at Lookout Point in the spring, use of the Lookout Point ROs for temperature management in the summer and fall, and a deep drawdown for fish passage in the fall at Fall Creek. For the operations at Lookout Point, storage at Hills Creek would be used for refilling Lookout Point in early March.

Similar to other near-term operations measure, the lower reservoir elevations at Lookout Point and at Hills Creek would affect wildlife access to water within the reservoir. Wildlife would either have to travel farther to access surface water or traverse steep, unvegetated slopes of the reservoir.

Northwestern pond turtles would have to travel longer distances to reach suitable upland nesting areas within Lookout Point, Hills Creek, and Fall Creek. Other wildlife species which build burrows or other structures would have to build multiple structures at various elevations to adjust to the changes in reservoir elevation.

The increase in fish passage within the Middle Fork subbasin would have a minor effect to piscivorous wildlife in the long-term with an increase in prey abundance within the subbasin.

**Coast Fork Subbasin**

There are no local operations proposed under the near-term operations measure within the Coast Fork subbasin, therefore, there would be no effects of this measure to wildlife in this subbasin.

**Mainstem Willamette River**

The primary effect within the mainstem Willamette River would be a minor long-term improvement to fish populations that provide foraging opportunities for piscivorous wildlife species such as bald eagles, river otters, great blue heron, osprey, and mergansers.

*3.9.2.5.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2) are concerns for Alternative 2A as well. However, providing water quality measures, adaptive fish flows, and fish passage in several subbasins so that fish can access cooler water would support wildlife species by supporting habitat function in the form of foraging opportunities and cool water downstream of the dams. On the other hand, deep drawdowns (the deep fall drawdown at Detroit) are anticipated to exacerbate climate change effects (longer drier summers) to wildlife species and habitat. The drawdown would effectively signal to salmonid to move downstream, but the wildlife species that depend on the reservoirs as a source of water and foraging opportunities, would be left with less water (harder to access), water more prone to algal blooms (warmer temperatures), and fewer foraging opportunities (for piscivorous species) compounding stressors on these animals. Regardless, major, long-term, adverse effects to wildlife species and habitat are anticipated as a result of climate change, but the drawdown at Detroit would exacerbate these effects within the North Santiam subbasin.

*3.9.2.5.3 Alternative 2A Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-25 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 2A.

**Table 3.9-5. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 2A as Compared to the Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)**

| Subbasin | Alternative 2A |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Green Peter – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat around reservoir<br>Green Peter, Detroit, and Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter – lamprey passage minor beneficial effects<br>Detroit and Foster- downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Cougar and Blue River - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Cougar - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |

| Coast Fork of the Willamette Subbasin | Negligible change |

| Subbasin | Alternative 2A |
|---|---|
| Mainstem Willamette River | Negligible change |

#### *3.9.2.6 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

As in other action alternatives, the integrated temperature and habitat flow regime (#30a) would have negligible effects to riverine wetlands and aquatic habitat within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Long Tom subbasins.

The primary difference between Alternatives 2A and 2B is at Cougar Dam, the diversion tunnel will be used for fish passage for Alternative 2B whereas for Alternative 2A, an FSS will be used. There could be slight differences in fish survivorship which could indirectly affect piscivorous wildlife; however, the differences in these effects are anticipated to be negligible, though there is much uncertainty at this point. In addition, there would be differences in lake levels within Cougar Reservoir at different points during the year as in Alternative 2B the spring and fall drawdowns would be down to the diversion tunnel. This would have different indirect hydrologic effects to wetlands and off-channel areas that provide wildlife habitat for amphibians and reptiles around Cougar Reservoir and downstream on the South Fork McKenzie and mainstem McKenzie River. The spring reservoir drawdown for downstream fish passage (#720) at Cougar would occur May 1 to July 1 and the deeper fall reservoir drawdowns for fish passage (#40) at Cougar (also at Green Peter which was included in Alternative 2A) would occur October 15 to December 15. The effects of the spring and fall drawdowns to the diversion tunnel at Cougar would likely include a loss of wetland habitat acreage within the reservoir. This is anticipated to have minor to moderate, long-term, adverse effects to wetland habitat and wildlife species that depend on this habitat, namely amphibians and reptiles. The spring drawdown could also create higher flows that dislodge amphibian egg masses and larvae downstream. Furthermore, higher flows in spring could result in inundation of turtle nesting areas resulting in either mortality of eggs or failure to nest depending on nest timing of individual turtles. The fall drawdown could result in mortality of eggs and hatchlings still within the nest cavity. Other effects of the drawdowns to wildlife were discussed in regard to Alternative 2A. These include increasing the distance that wildlife would need to travel to access the water's edge and potential to negatively alter wildlife habitat. These drawdown effects to wildlife species and habitat would be long-term, moderate, and adverse and would occur in the South Santiam and McKenzie subbasins.

As for Alternative 2B, augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek and Blue River. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water's edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring), so these measures are anticipated to have minor, long-term, and recurring adverse effects to wildlife species within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

Alternative 2B would include providing Pacific lamprey passage and infrastructure (#52) at Green Peter; and constructing structural downstream fish passage (#392) at Detroit, Foster, and Lookout Point. As previously mentioned, downstream passage at Cougar is provided through the spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) to the diversion tunnel. In addition, Alternative 2B measures that would improve water temperature include constructing WTC towers (#105); using ROs to discharge colder water (#166); the Foster Fish Ladder Temperature Improvement (#479); and using the spillway for surface spill in summer (#721) would improve salmonid survival. Measures included are focused on improving water quality and fish passage. This should improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations would provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

###### *3.9.2.6.1 Near-term Operations Measure*

See Alternative 2A, Section 3.9.2.5.1, for description of effects due to the near-term operations measure.

###### *3.9.2.6.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2.) are concerns for Alternative 2B as well. As with Alternative 2A, providing water quality measures, adaptive fish flows, and fish passage in several subbasins so that fish can access cooler water would support wildlife species by supporting habitat function in the form of foraging opportunities and cool water downstream of the dams. On the other hand, deep drawdowns (at Cougar and Green Peter) are anticipated to exacerbate climate change effects (longer drier summers) to wildlife species and habitat. The drawdowns would effectively signal to salmonid to move downstream, but the wildlife species that depend on the reservoirs as a source of water and foraging opportunities, would be left with less water (harder to access), prone to algal blooms (warmer temperatures), and fewer foraging opportunities compounding stressors on these animals. Regardless, major long-term adverse effects to wildlife species and habitat are anticipated as a result of climate change but the drawdowns at Cougar and Green Peter would exacerbate these effects within the McKenzie and North Santiam subbasins.

#### *3.9.2.6.3 Alternative 2B Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-26 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 2B.

**Table 3.9-6. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 2B as Compared to the Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)**

| Subbasin | Alternative 2B |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Green Peter – deep fall season drawdown with long-term moderate adverse effects to wildlife and wildlife habitat around reservoir<br>Green Peter, Detroit, and Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter – lamprey passage minor beneficial effects<br>Detroit and Foster - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Cougar and Blue River - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Cougar – deep spring and fall season drawdowns with long-term moderate effects to wildlife and wildlife habitat around reservoir |

| Subbasin | Alternative 2B |
|---|---|
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Lookout Point - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Negligible change |
| Mainstem Willamette River | Negligible change |

#### *3.9.2.7 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Measures that would affect wildlife species and habitat within the WVS as part of Alternative 3A include a spring reservoir drawdown for downstream fish passage (#720) at Cougar, Detroit, and Lookout Point reservoirs (May 1 to July 1) as well as a deeper fall reservoir drawdown for fish passage (#40) at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point reservoirs (October 15 to December 15). The spring drawdown at Lookout Point could affect northwestern pond turtles that nest at the reservoir. These turtles would have to adjust their normal nesting locations which would cause them to expend more energy in finding a new nesting location. For amphibians that breed within shallow water alcoves and at the confluences of tributaries, the spring drawdowns could lead to desiccation of egg masses and stranding of larvae. Alternately, they might nest further out into the lakebed, which would then potentially be flooded as the reservoir refills. The drawdowns would also affect other wildlife species' access to the water during these time periods. Species such as black-tailed deer, elk, raccoons, ermine, coyotes, etc. would need to travel farther to get to the water's edge and in some areas, may need to cross steep unvegetated slopes. The seasonal drawdown may cause wildlife attempting to access the water's edge to access alternative water sources in the vicinity of the reservoirs during the drawdown time periods. In addition, the drawdowns would affect wildlife species that build lodges, burrows, or dens along the water's edge such as beavers, muskrats, otters, etc. The dramatic changes in water surface elevations in these reservoirs throughout the year would flood these habitat structures at certain times of year and leave them perched, away from open water at other times. This may cause animals to build multiple habitat structures throughout the year in these locations. Increasing the distance that wildlife would need to travel to access the water's edge, potentially damaging wildlife habitat structures through water level fluctuations, and potentially impacting northwestern pond turtle nesting would have long-term, moderate, adverse effects on wildlife species within the McKenzie, North Santiam, Middle Fork Willamette, and North Santiam subbasin.

The downstream impacts of the spring reservoir drawdown for downstream fish passage and the deeper fall reservoir drawdown for fish passage could include the burying of freshwater mussel beds, the movement of non-native fish from the reservoirs to off-channel habitats which could lead to increased predation of native fish, amphibians, and turtle hatchlings. Additionally, sediment moved downstream during the deep drawdowns could reduce connectivity of off-channel habitats or degrade the quality of off-channel habitats for aquatic wildlife and vegetation. Many of these sediments could be flushed out of the off-channel habitats in subsequent high flow events.

For Alternative 3A, the integrated temperature and habitat flow regime (#30a) would have negligible effects to riverine wetlands and aquatic habitat within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Long Tom subbasins.

In addition, augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water's edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor, long-term, adverse effects to wildlife species within the Middle Fork Willamette, Coast Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

Alternative 3A will also provide Pacific lamprey passage and infrastructure (#52) at Blue River, Green Peter, and Hills Creek Dams; and pass water over spillway in spring for fish passage (#714) at Big Cliff, Dexter, Fall Creek, Green Peter, and Hills Creek Dams. In addition, Alternative 3A measures that would improve water temperature include using ROs to discharge colder water (#166) and using spillway for surface spill in summer (#721) would improve salmonid survival. Fish passage and water quality measures would improve lamprey populations in the McKenzie, South Santiam, and Middle Fork Willamette subbasins and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations would provide long-term, minor, beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. that use habitat upstream of the dams in these subbasins.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

#### *3.9.2.7.1 Near-term Operations Measure*

See Alternative 2A, Section 3.9.2.5.1, for description of effects due to the near-term operations measure.

#### *3.9.2.7.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2.) are concerns for Alternative 3A as well. Providing water quality measures, adaptive fish flows, and fish passage in several subbasins so that fish can access cooler water would support wildlife species by supporting habitat function in the form of foraging opportunities and cool water downstream of the dams. On the other hand, deep drawdowns (at Cougar, Blue River, Lookout Point, Hills Creek, Green Peter, and Detroit) are anticipated to exacerbate climate change effects (longer drier summers) to wildlife species and habitat. The drawdowns would effectively signal to salmonid to move downstream, but the wildlife species that depend on the reservoirs as a source of water and foraging opportunities, would be left with less water (harder to access), prone to algal blooms (warmer temperatures), and fewer foraging opportunities (for piscivorous species) compounding stressors on these animals. Regardless, major long-term adverse effects to wildlife species and habitat are anticipated as a result of climate change but the drawdowns would exacerbate these effects within the McKenzie, Middle Fork Willamette, South Santiam, and North Santiam subbasins.

#### *3.9.2.7.3 Alternative 3A Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-27 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 3A.

**Table 3.9-7. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 3A as Compared to the Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)**

| Subbasin | Alternative 3A |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter, Detroit, and Foster – water quality improvements with minor benefits for foraging wildlife |

| Subbasin | Alternative 3A |
|---|---|
| | Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Detroit – fall and spring drawdowns with long-term moderate effects to wildlife and wildlife habitat around reservoir<br>Green Peter – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat around reservoir<br>Green Peter - lamprey passage with minor benefits in the form of foraging and nutrient cycling<br>Big Cliff and Green Peter - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Blue River – water quality improvements with minor benefits for foraging wildlife<br>Cougar and Blue River - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Cougar – deep spring and fall season drawdowns with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Blue River – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Blue River - lamprey passage with minor benefits in the form of foraging and nutrient cycling |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Lookout Point and Hills Creek – water quality improvements with minor benefits for foraging wildlife<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Lookout Point – deep spring and fall season drawdowns with long-term moderate effects to wildlife and wildlife habitat at reservoir |

| Subbasin | Alternative 3A |
| --- | --- |
| | Hills Creek – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Hills Creek - lamprey passage with minor benefits in the form of foraging and nutrient cycling<br>Hills Creek, Fall Creek, and Dexter – downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Negligible change |
| Mainstem Willamette River | Negligible change |

#### *3.9.2.8 Alternative 3B – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

In terms of wildlife species and habitat effects, Alternative 3B is very similar to Alternative 3A; however, one of the differences is that the spring reservoir drawdown for downstream fish passage (#720) would occur at Cougar, Green Peter, and Hills Creek reservoirs instead of Cougar, Detroit, and Lookout Point reservoirs. Therefore, the effects of spring reservoir drawdowns would be realized at those reservoirs and the McKenzie, North Santiam, and Middle Fork Willamette subbasins, where South Santiam had been included before instead of North Santiam. The spring drawdown at Hills Creek and Lookout Point could affect northwestern pond turtles that nest at the reservoir. These turtles would have to adjust their normal nesting locations which would either cause them to expend more energy in finding a new nesting location. For amphibians that breed within shallow water alcoves and at the confluences of tributaries, the spring drawdowns could lead to desiccation of egg masses and stranding of larvae. Fall drawdowns are proposed at Lookout Point, Hills Creek, Cougar, Blue River, Green Peter, and Detroit. Similar to the drawdown effects discussed as part of Alternative 3A, increasing the distance that wildlife would need to travel to access the water's edge, potentially damaging wildlife habitat structures through water level fluctuations, and potentially impacting northwestern pond turtle nesting would have long-term, moderate, adverse effects on wildlife species within the McKenzie, North Santiam, Middle Fork Willamette, and North Santiam subbasin with the implementation of Alternative 3B.

The downstream impacts of the spring reservoir drawdown for downstream fish passage and the deeper fall reservoir drawdown for fish passage could include the burying of freshwater mussel beds, the movement of non-native fish from the reservoirs to off-channel habitats which could lead to increased predation of native fish, amphibians, and turtle hatchlings. Additionally, sediment moved downstream during the deep drawdowns could reduce connectivity of off-channel habitats or degrade the quality of off-channel habitats for aquatic wildlife and vegetation. Many of these sediments could be flushed out of the off-channel habitats in subsequent high flow events.

There are also differences in terms of fish passage improvements. Alternative 3B would improve fish passage by passing water over spillway in spring for fish passage (#714) at Big Cliff, Detroit, Dexter, and Lookout Point Dams as well as through the drawdowns previously discussed. Providing Pacific lamprey passage and infrastructure (#52) will occur at Hills Creek, Blue River, and Green Peter. Alternative 3B measures that would improve water temperature include using ROs to discharge colder water (#166) and using spillway for surface spill in summer (#721) would improve salmonid survival. Improving lamprey and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins would provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including but not limited to river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. upstream of the dams in these subbasins.

As with Alternative 3A, Alternative 3B would implement an integrated temperature and habitat flow regime (#30a) which would have negligible effects to riverine wetlands and aquatic habitat within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Long Tom subbasins. Effects would depend on the type of water year. In low flow, high water temperature years off-channel habitats (including wetland areas) downstream of the dams could experience late-spring to early-summer flows which could inundate these areas that could impact plant growth and available nesting habitat for turtles. For years where there would be high flow, low water temperature, the flow regime could provide more connectivity of off-channel habitats which is comparable to spring flood events.

In addition, augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water's edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor, long-term, adverse effects to wildlife species within the Middle Fork Willamette, Coast Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

#### *3.9.2.8.1 Near-term Operations Measure*

See Alternative 2A, Section 3.9.2.5.1, for description of effects due to the near-term operations measure.

#### *3.9.2.8.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2.) are concerns for Alternative 3B as well. Providing water quality measures, adaptive fish flows, and fish passage in several subbasins so that fish can access cooler water would support wildlife species by supporting habitat function in the form of foraging opportunities and cool water downstream of the dams. On the other hand, deep drawdowns (at Cougar, Blue River, Lookout Point, Hills Creek, Green Peter, and Detroit) are anticipated to exacerbate climate change effects (longer drier summers) to wildlife species and habitat. The drawdowns would effectively signal to salmonid to move downstream, but the wildlife species that depend on the reservoirs as a source of water and foraging opportunities, would be left with less water (harder to access), prone to algal blooms (warmer temperatures), and fewer foraging opportunities (for piscivorous species) compounding stressors on these animals. Regardless, major long-term adverse effects to wildlife species and habitat are anticipated as a result of climate change but the drawdowns would exacerbate these effects within the McKenzie, Middle Fork Willamette, South Santiam, and North Santiam subbasins.

#### *3.9.2.8.3 Alternative 3B Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-28 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 3B.

**Table 3.9-8. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 3B as Compared to the Alternative 3B – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)**

| Subbasin | Alternative 3B |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter, Detroit, and Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Green Peter – deep fall and spring season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir |

| Subbasin | Alternative 3B |
|---|---|
| | Detroit – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Detroit - downstream fish passage with minor benefits in the form of foraging and nutrient cycling<br>Green Peter – lamprey passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Blue River – water quality improvements with minor benefits for foraging wildlife<br>Blue River - drawdown with minor effects to wildlife and wildlife habitat at the reservoirs<br>Cougar – deep spring and fall season drawdowns (down to the diversion tunnel) with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Blue River – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Blue River – lamprey passage with minor benefits in the form of foraging and nutrient cycling |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Lookout Point and Hills Creek – water quality improvements with minor benefits for foraging wildlife<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Hills Creek – deep spring and fall season drawdowns with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Lookout Point – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat at reservoir<br>Hills Creek – lamprey passage with minor benefits in the form of foraging and nutrient cycling |

| Subbasin | Alternative 3B |
|---|---|
| | Dexter and Lookout Point – downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Cottage Grove and Dorena – drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs |
| Mainstem Willamette River | Negligible change |

#### *3.9.2.9 Alternative 4 – Improve Fish Passage with Structures-Based Approach*

Effects to wildlife species and habitat for Alternative 4 would be similar to that of Alternative 1 since these both intend to meet the purpose and need without spring or fall drawdowns. This alternative would include providing Pacific lamprey passage and infrastructure (#52) at Hills Creek; restoring upstream and downstream passage at drop structures (#639) within the Long Tom River downstream of Fern Ridge; and constructing structural downstream fish passage (#392) at Cougar, Detroit, Foster, Hills Creek, and Lookout Point (fish collection around Dexter). In addition, Alternative 4 measures that would improve salmonid survival by improving TDG levels include structural improvements to reduce TDG (#174); and by improving water temperature include constructing WTC towers (#105); using ROs to discharge colder water (#166); the Foster Fish Ladder Temperature Improvement (#479); and using the spillway for surface spill in summer (#721). Measures included are focused on improving water quality and fish passage. This would improve lamprey populations in the Middle Willamette subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, Long Tom, and Middle Willamette Fork subbasins. Improving fish populations would provide long-term, minor, beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, raccoons, weasels, eagles, osprey, great blue herons, etc. upstream of the dams in these subbasins.

Alternative 4 would implement an integrated temperature and habitat flow regime (#30a), which would have negligible effects to riverine wetlands and aquatic habitat within the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, Middle Fork Willamette, and Long Tom subbasins.

Augmenting instream flows by using the power pool (#304) and augmenting instream flows by using the inactive pool (#718) are proposed to augment stream flows during the late summer and fall. Augmenting instream flows by using the power pool (#304) is proposed for Lookout Point, Hills Creek, Cougar, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Augmenting instream flows by using the inactive pool (#718) is proposed for Fall Creek, Blue River, Cottage Grove, and Dorena. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water’s edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor long-term adverse effects to wildlife species within the Middle Fork Willamette, Coast Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

#### *3.9.2.9.1 Near-term Operations Measure*

See Alternative 2A, Section 3.9.2.5.1, for description of effects due to the near-term operations measure.

#### *3.9.2.9.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2.) are concerns for Alternative 4 as well. However, meeting water storage objectives while also providing fish passage and water quality benefits to wildlife and habitat by providing hydrologic support for aquatic and wetland habitats, improving instream water quality to support aquatic species, and increasing foraging opportunities for wildlife species upstream of the dams is anticipated to support wildlife species and habitat to the extent possible while these regional changes occur. Alternative 4 would not avoid the effects of climate change to wildlife and associated habitats but would potentially decrease the effects. However, major long-term adverse effects to wildlife species and habitat as a result of climate change would still be anticipated.

#### *3.9.2.9.3 Alternative 4 Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-29 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 4.

**Table 3.9-9. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 4 as Compared to the Alternative 4 – Improve Fish Passage with Structures-Based Approach**

| Subbasin | Alternative 4 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter, Detroit, Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter and Detroit - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs |

| Subbasin | Alternative 4 |
|---|---|
| | Detroit and Foster – downstream passage with minor benefits in the form of foraging and nutrient cycling<br>Detroit – WTC tower with minor beneficial effects |
| Long Tom Subbasin | Fern Ridge – upstream and downstream passage with minor benefits in the form of foraging and nutrient cycling |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>Cougar – water quality improvements with minor benefits for foraging wildlife<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to streamside aquatic and wetland habitat<br>Cougar and Blue River - drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs<br>Cougar – downstream passage with minor benefits in the form of foraging and nutrient cycling |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Dexter, Lookout Point, and Hills Creek – water quality improvements with minor benefits for foraging wildlife<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Hills Creek – lamprey passage with minor benefits in the form of foraging and nutrient cycling<br>Hills Creek and Lookout Point – downstream passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Cottage Grove and Dorena – drawdowns with minor effects to wildlife and wildlife habitat around the reservoirs |
| Mainstem Willamette River | Negligible change |

#### *3.9.2.10 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 is nearly identical to Alternative 2B. However, similar to Alternative 2B, Alternative 5 stream flows will be adapted to fish survival and passage needs except that the integrated temperature and habitat flow regime (#30a) has been replaced by the refined integrated temperature and habitat flow regime (#30b). Neither of these measures would have a measurable effect to the frequency of inundation and therefore, would have negligible effects to aquatic and riverine wetland habitat within the downstream reaches of the North Santiam, South Santiam, McKenzie, Coast Fork Willamette, and Middle Fork Willamette subbasins.

In terms of wildlife and wildlife habitat effects around the reservoirs, the deep spring season drawdown at Cougar would occur May 1 to July 1 and the deep fall season drawdown at Cougar and Green Peter would occur October 15 to December 15. The effects of the spring and fall drawdowns to the diversion tunnel at Cougar would likely include a loss of wetland habitat acreage. This is anticipated to have moderate long-term adverse effects to wetland habitat and wildlife species that depend on this habitat, namely amphibians and reptiles. Other effects of the drawdowns to wildlife were discussed in regard to Alternative 2A. These include increasing the distance that wildlife would need to travel to access the water's edge and potentially damaging wildlife habitat structures through water level fluctuations. These drawdown effects to wildlife species and habitat would be long-term, moderate, and adverse and would occur in the South Santiam and McKenzie subbasins.

Like Alternatives 2A and 2B, Measures 304 and 718 are proposed to augment stream flows during the late summer and fall. Measure 304 is proposed for Lookout Point, Hills Creek, Green Peter, and Detroit and would allow these projects to drawdown below the power pool and respective rule curves for these projects. Measure 718 is proposed for Fall Creek and Blue River. These measures would have negligible long-term effects to riverine wetland and aquatic habitats downstream of the dams because water levels in downstream reaches would not be measurably affected. However, within the reservoirs there would be an effect to wildlife access to the water's edge during the late summer and fall, which is typically a dry time of year. Wildlife species would have to travel slightly farther than usual. However, these slight drawdowns would not occur during the wildlife breeding season (spring) so these measures are anticipated to have minor long-term adverse effects to wildlife species within the Middle Fork Willamette, McKenzie, South Santiam, and North Santiam subbasins.

Alternative 5 would include adding lamprey passage at Green Peter (Measure 52); and downstream passage structures (Measure 392) at Detroit, Foster, and Lookout Point. As previously mentioned, downstream passage at Cougar is provided through the spring and fall drawdowns to the diversion tunnel (Measures 40 and 720). In addition, Alternative 5 measures that would improve water temperature (Measures 105, 166, 479, 721) would improve salmonid survival. Measures included are focused on improving water quality and fish passage. This should improve lamprey populations in the South Santiam subbasin and salmonid populations in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette subbasins. Improving fish populations would provide long-term minor beneficial effects in terms of increased foraging opportunities for piscivorous wildlife species including, but not limited to, river otters, snakes, racoons, weasels, eagles, osprey, great blue herons, etc.

As compared with the NAA, conditions for terrestrial wildlife would remain status que as upland habitats would have negligible effects. Conditions for aquatic and semi-aquatic wildlife would also remain status que long-term for many species. Impacts to turtles and amphibians within the reservoirs could see a decline over the long-term.

*3.9.2.10.1 Near-term Operations Measure*

See Alternative 2A, Section 3.9.2.5.1, for description of effects due to the near-term operations measure.

*3.9.2.10.2 Climate Change*

The climate change effects discussed in regard to the NAA (Section 3.9.2.2.) are concerns for Alternative 5 as well. As with Alternative 2A and 2B, providing water quality measures, adaptive fish flows, and fish passage in several subbasins so that fish can access cooler water would support wildlife species by supporting habitat function in the form of foraging opportunities and cool water downstream of the dams. On the other hand, deep drawdowns (at Cougar and Green Peter) are anticipated to exacerbate climate change effects (longer drier summers) to wildlife species and habitat. The drawdowns would effectively signal to salmonid to move downstream, but the wildlife species that depend on the reservoirs as a source of water and foraging opportunities, would be left with less water (harder to access), prone to algal blooms (warmer temperatures), and fewer foraging opportunities (for piscivorous species) compounding stressors on these animals. Regardless, major long-term adverse effects to wildlife species and habitat are anticipated as a result of climate change but the drawdowns at Cougar and Green Peter would exacerbate these effects within the McKenzie and North Santiam subbasins.

*3.9.2.10.3 Alternative 5 Wildlife, Birds, and Terrestrial Habitat Effects Summary Table*

Table 3.9-30 below presents a summary of the effects to wildlife and wildlife habitat within the WVS as a result of implementation of Alternative 5.

**Table 3.9-10. Summary of Effects for Wildlife, Birds, and Terrestrial Habitat under Alternative 5 as Compared to the Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)**

| Subbasin | Alternative 5 |
|---|---|
| Santiam Subbasin | North and South Santiam rivers - gravel augmentation downstream of Big Cliff and Foster Dams with benefits to aquatic and wetland habitat<br>North and South Santiam rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Green Peter and Detroit - drawdowns with minor hydrological effects to wildlife and wildlife habitat at the reservoirs<br>Green Peter – deep fall season drawdown with long-term moderate effects to wildlife and wildlife habitat around reservoir<br>Green Peter, Detroit, and Foster – water quality improvements with minor benefits for foraging wildlife<br>Green Peter – lamprey passage minor beneficial effects<br>Detroit and Foster - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Long Tom Subbasin | Negligible change |
| McKenzie Subbasin | South Fork McKenzie and Blue rivers - gravel augmentation downstream of Cougar and Blue River Dams with benefits to aquatic and wetland habitat<br>South Fork McKenzie and Blue rivers - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Blue River - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Cougar – deep spring and fall season drawdowns with long-term moderate effects to wildlife and wildlife habitat around reservoir |
| Middle Fork of the Willamette Subbasin | Middle Fork Willamette - gravel augmentation downstream of WVS dams with benefits to aquatic and wetland habitat<br>Middle Fork Willamette - minor decreases to downstream flows with negligible effects to aquatic and wetland habitat<br>Lookout Point, Hills Creek, and Fall Creek - drawdowns with minor effects to wildlife and wildlife habitat at the reservoirs<br>Lookout Point - downstream fish passage with minor benefits in the form of foraging and nutrient cycling |
| Coast Fork of the Willamette Subbasin | Negligible change |

| Subbasin | Alternative 5 |

| Mainstem Willamette River | Negligible change |

## 3.10 AIR QUALITY

Air quality is the measure of the atmospheric concentration of defined pollutants in a specific area. Air quality is affected by pollutant emission sources, as well as the movement of pollutants in the air via wind and other weather patterns. An air pollutant is any substance in the air that can cause harm to humans or the environment. Pollutants may be natural or human-made and may take the form of solid particles, liquid droplets, or gases. Natural sources of air pollution include smoke from wildfires, dust, and wind erosion. Human-made sources of air pollution include emissions from vehicles; dust from unpaved roads or construction sites; and smoke from human-caused fires.

The area of analysis for air quality are the USACE project locations within three counties of the Oregon's Willamette Valley: Lane, Linn, and Marion Counties. Within these counties, USACE projects currently include thirteen dams and reservoirs, five adult fish facilities (AFF), five fish hatcheries, and trap-and-haul fish trucking operations that transport fish above and below existing reservoirs. Air quality would primarily be affected by air emissions generated from diesel trucks during fish trucking operations, and diesel-powered generator usage at project locations. Air quality would also be affected by construction or maintenance activities including vehicles, machinery, and other heavy equipment, and fugitive dust emissions from reservoir drawdowns due to exposure of previously submerged sediments. This section provides a discussion of the sources of air emissions and the regulatory framework as it applies to the USACE projects within the WVS.

### 3.10.1 USACE Air Emissions

This section addresses the USACE projects and activities that generate air emissions within the WVS. It also describes the impact of those air emissions, specifically diesel emissions, and the federal and state programs in place to help reduce diesel emissions.

#### *3.10.1.1 Sources of Air Emissions within USACE Projects*

USACE projects and vehicles generate air emissions through the operation and maintenance of the WVS. The two primary sources of air emissions within the WVS are diesel generator usage at various project locations and trucking fish during trap-and-haul operations using light- and medium-duty diesel trucks. Facilities use diesel generators to supply electricity to heat and cool their buildings and equipment, or to power equipment and machinery needed for operation. Emergency diesel powered generators are located at all dams and hatcheries and are individually operated less than 50 hours per year. Trap-and-haul operations utilize light- and medium-duty trucks to transport fish, and generate air emissions through internal combustion of the truck's diesel engine. Construction or maintenance activities also generate air emissions via the vehicles, machinery, and other types of equipment used; however, these emissions are limited and specifically pertain to each individual construction project as they occur. Table 3.10-1 provides a general summary table of each USACE project in each county. Overall, fish trucking accounts for nearly 92,000 miles worth of diesel fuel emissions, while 22 diesel powered generators account for additional diesel air emissions.

**Table 3.10-1. USACE Projects Pertaining to Air Quality**

| Dam and Reservoir | AFF | Hatchery | Trap-and-Haul Routes | Fish Trucking Mileage Per Year | Emergency Diesel Generators |
|---|---|---|---|---|---|
| **Lane County** | | | | | |
| Cougar | Cougar Adult Fish Collection Facility | None | 30-mile round trip | 8,294 | 2 |
| Dexter | Dexter Adult Fish Facility | None | 30-, 70-, 80-, and 100-mile round trips | 23,040 | 1 |
| Hills Creek | None | Willamette Fish Hatchery | None | 7,680 | 2 |
| Fall Creek | Fall Creek Adult Fish Facility | None | 18-mile round trip | 4,608 | 2 |
| Blue River | None | Leaburg Hatchery[1]; McKenzie Hatchery[2] | None | 4,352 | 2 |
| Lookout Point | None | None | None | 20,915 | 2 |
| Dorena | None | None | None | None | 1 |
| Cottage Grove | None | None | None | None | 1 |
| Fern Ridge | None | None | None | None | 1 |
| **Linn County** | | | | | |
| Foster | Foster Dam Adult Fish Facility | South Santiam Fish Hatchery | 40- and 50-mile round trip | 4,480 | 2 |
| Green Peter | None | Marion Forks Hatchery[3] | None | 2,560 | 2 |
| **Marion County** | | | | | |
| Big Cliff | Minto Adult Fish Facility | None | 40- and 60-mile round trip | 12,416 | 2 |
| Detroit | None | None | None | 3,635 | 2 |
| **TOTAL** | | | | **91,980** | **22** |

[1] Leaburg Hatchery is approximately 19 miles away from Blue River Dam.

[2] McKenzie Hatchery is approximately 20 miles away from Blue River Dam.

[3] Marion Forks Hatchery is approximately 60 miles from Green Peter Dam. This is the closest dam to the facility within Linn County.

### *3.10.1.2 Diesel Air Emissions*

Diesel is the dominant fuel used by the commercial transportation sector because it offers fuel economy, power, and durability. In the United States, approximately 80 percent of all freight is moved by diesel engines, while most non-road equipment used in construction, agriculture, marine, and locomotive sectors are powered by diesel. However, diesel engines emit large amounts of nitrogen oxides, particulate matter (in particular $PM_{2.5}$), carbon, and other toxic air pollutants. Diesel particulate matter is linked to a number of serious health problems including aggravating asthma, heart and lung disease, cancer, and premature mortality. In 2012, diesel exhaust was classified as a known carcinogen to humans based on sufficient evidence that exposure to diesel engine exhaust is associated with increased lung cancer risk. Diesel exhaust also has environmental significance as a global warming contributor due to black carbon particulate, about 70 percent of the particulate emitted by a diesel engine. Black carbon only lasts in the atmosphere for a few weeks to months, but is second only to carbon dioxide as a potent climate change forcing agent. Diesel engines are the largest source of black carbon in North America (ODEQ No Date-f).

Figure 3.10-1 shows that in Oregon, over half of all diesel particulate emissions are from on-road vehicles, such as trucks, buses, and other traffic; 30 percent of diesel particulate matter is generated from non-road vehicles, such as construction equipment; and 14 percent is comprised of trains, ships, and generators (ODEQ No Date-j). USACE projects within the WVS would contribute to all categories of diesel particulate emissions under the Proposed Action and alternatives.

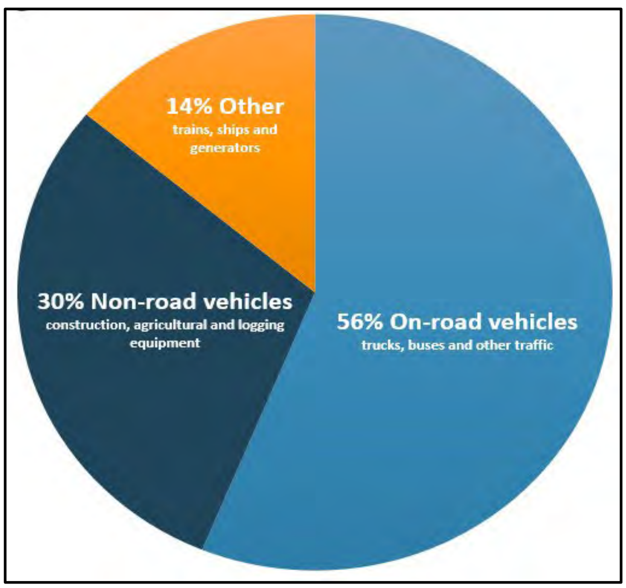

**Figure 3.10-1. Oregon Statewide Diesel Particulate Matter Emissions**

Source: ODEQ No Date-j

#### *3.10.1.3 Construction Activities and Fugitive Emissions*

Construction activities such as bulldozing, hauling, and construction vehicle travel utilize diesel equipment to provide the power needed for almost all construction activities. Environmental Protection Agency (EPA) regulations apply to new engines, while older diesel engines can remain in operation for 30 years or more. EPA offers funding, as appropriated annually by Congress, for projects that reduce emissions from existing diesel engines. EPA's *Clean Construction* provides information on strategies for reducing emissions from older engines, including idle-reduction practices that save money and fuel while reducing emissions (EPA 2021a). Portland, OR adopted the *Clean Air Construction* contracting standard in 2018, which is an initiative that reduces diesel emissions related to government-funded construction projects. Since then, Multnomah and Washington counties and Portland Metro have each adopted identical standards, and the Oregon Department of Environmental Quality (ODEQ) continues to offer technical assistance during implementation (ODEQ No Date-b).

Construction activities and reservoir drawdowns can also produce fugitive dust emissions. Fugitive dust is a type of particulate matter that becomes airborne by wind or other similar forces (EPA 2021b). This can become an issue while operating or driving on unpaved roads or during reservoir drawdowns due to exposed sediments. Oregon Administrative Rules (OAR) 340-208-0210 provides the requirements for fugitive emissions, which stipulates that no person may cause or permit any materials to be handled or transported; any building or road to be used, constructed, altered, repaired, or demolished; or any equipment to be operated – without taking reasonable precautions to prevent particulate matter from becoming airborne. Precautions may include but are not limited to using water or chemicals for dust control during demolition or construction of buildings or structures, the grading of roads, or the clearing of lands; covering open bodied trucks transporting materials likely to become airborne; and full or partial enclosure of material stockpiles to prevent particulate matter from becoming airborne. If fugitive particulate emissions escape the containment source, ODEQ may order the owner or operator to abate the emissions, including the development of a fugitive emission control plan (OregonLaws 2021).

#### *3.10.1.4 Oregon Diesel Reduction Programs*

To reduce diesel emissions in Oregon, ODEQ provides grants and programs to incentivize businesses, governments, and equipment owners to replace older and more polluting diesel engines with new, cleaner technologies and exhaust control retrofits. The Diesel Emissions Mitigation Fund is a program that provides $8 million to public, private, and tribal diesel equipment owners to replace their current diesel vehicles or equipment with equivalent, cleaner burning engines or power sources (ODEQ No Date-e).

The 2019 Oregon Legislature addressed concerns regarding significant pollution from older on-road diesel engines by passing House Bill (HB) 2007 to reduce diesel emissions across the state. Among other directives, HB 2007 requires ODEQ to establish retrofit technologies for diesel engines that power certain on-road vehicles and the process for issuing a certificate of compliance. The two vehicle weight classifications categorized in HB 2007 include medium-duty vehicles, such as certain box trucks and flatbed or service trucks, and heavy-duty vehicles, such as tractor-trailer trucks (ODEQ No Date-c). In addition, Oregon Governor Kate Brown signed a Memorandum of Understanding (MOU) in 2020, which committed Oregon to work towards the goal of 100% of all new medium- and heavy-duty vehicles sales to be zero emissions by 2050. Emissions from medium- and heavy-duty vehicles, such as large pickup trucks, vans, delivery trucks, and long-haul delivery trucks are among the fastest growing source of greenhouse gases. The MOU includes a commitment to identifying barriers and proposing solutions to support widespread adoption of these vehicles (ODEQ No Date-h).

### 3.10.2 Regulatory Framework

This section addresses the federal and state regulations regarding air quality. It includes a discussion of current air quality statuses within each county and any applicable permits pertaining to the Proposed Action and alternatives.

#### *3.10.2.1 National Ambient Air Quality Standards*

The Clean Air Act (CAA), as amended, assigns the EPA responsibility to establish National Ambient Air Quality Standards (NAAQS) (40 C.F.R. Part 50) for six principal pollutants that can be harmful to public health and the environment, for additional information see Chapter 7. These six principal pollutants include particulate matter (PM; measured in two size categories: less than or equal to 10 microns in diameter [$PM_{10}$]; and less than or equal to 2.5 microns in diameter [$PM_{2.5}$]); sulfur dioxide ($SO_2$); carbon monoxide (CO); nitrogen dioxide ($NO_2$); ozone ($O_3$); and lead (Pb).

The CAA identifies two types of NAAQSs: primary standards that provide public health protection and safeguards the health of sensitive populations such as asthmatics, children, and the elderly; and secondary standards that provide public welfare protection against decreased visibility and damage to animals, crops, vegetation, and buildings (EPA 2021c). Short-term NAAQS (1-, 8-, and 24-hour periods) have been established for pollutants that contribute to acute health effects. In contrast, long-term NAAQS (annual period) have been established for pollutants contributing to chronic health effects. These air quality standards are summarized in Table 3.10-2 below.

**Table 3.10-2. National Ambient Air Quality Standards**

| Pollutant | Primary/Secondary | Averaging Time | Level* | Form |
|---|---|---|---|---|
| Carbon Monoxide (CO) | primary | 8 hours | 9 ppm | Not to be exceeded more than once per year |
| | | 1 hour | 35 ppm | |
| Lead (Pb) | primary and secondary | Rolling 3-month average | 0.5 $\mu g/m^3$ | Not to be exceeded |
| Nitrogen Dioxide ($NO_2$) | primary | 1 hour | 100 ppb | 98th percentile of 1-hour daily maximum concentrations, |

| Pollutant | | Primary/Secondary | Averaging Time | Level* | Form |
|---|---|---|---|---|---|
| | | | | | averaged over 3 years |
| | | primary and secondary | 1 year | 53 ppb | Annual Mean |
| Ozone ($O_3$) | | primary and secondary | 8 hours | 0.070 ppm | Annual fourth-highest daily maximum 8-hour concentration, averaged over 3 years |
| Particle Pollution (PM) | $PM_{2.5}$ | primary | 1 year | 12.0 µg/m$^3$ | Annual mean, averaged over 3 years |
| | | secondary | 1 year | 15.0 µg/m$^3$ | Annual mean, averaged over 3 years |
| | | primary and secondary | 24 hours | 35 µg/m$^3$ | 98$^{th}$ percentile, averaged over 3 years |
| | $PM_{10}$ | primary and secondary | 24 hours | 150 µg/m$^3$ | Not to be exceeded more than once per year on average over 3 years |
| Sulfur Dioxide ($SO_2$) | | primary | 1 hour | 75 ppb | 99$^{th}$ percentile of 1-hour daily maximum concentrations, averaged over 3 years |
| | | secondary | 3 hours | 0.5 ppm | Not to be exceeded more than once per year |

Source: EPA 2021c

*Units of measure for the standards are parts per million (ppm) by volume, parts per billion (ppb) by volume, and micrograms per cubic meter of air (µg/m$^3$).

Federal regulations designate areas with pollution levels below the NAAQS as attainment areas, and areas with pollution levels above the NAAQS and in violation of these standards as nonattainment areas. For nonattainment areas, states must develop a State Implementation Plan (SIP) that details the path to attainment and maintain the NAAQS (EPA 2021d). If an area was in nonattainment, but now attains the standard and has an approved plan to maintain the standard, it is designated a maintenance area. All states in the Pacific Northwest, including Oregon, have EPA-approved SIPs. The Oregon SIP (40 CFR Subpart MM) helps to attain and maintain air quality in the Willamette Valley. A state’s SIP must also contain control measures for emissions that cross state lines.

#### *3.10.2.2 State Ambient Air Quality Standards*

Each state has the authority to adopt standards stricter than those established under the federal program. The State of Oregon's air quality laws are codified in the Oregon Revised Statutes, Chapter 468A, and its corresponding regulations are in the OAR, Chapter 340. ODEQ operates the ambient monitoring network for the entire state except for Lane County, which is operated by the Lane Regional Air Protection Agency (LRAPA). The EPA has delegated most implementation requirements to the ODEQ except in Lane County, where the LRAPA has primary jurisdiction. The EPA retains oversight of Oregon and regularly audits air quality management by ODEQ to ensure that federal requirements are being met. Tribal lands are sovereign and do not fall under ODEQ or LRAPA jurisdiction, although several tribes operate their own monitoring networks (EPA 2008).

The ambient air quality standards for the State of Oregon are listed in OAR 340-202-0050 through 340-202-0130. These state standards are an established concentration, exposure time, and frequency of occurrence of an air contaminant or multiple contaminants in the ambient air that must not be exceeded, as displayed in Table 3.10-3. These standards are included in the State of Oregon Clean Air Act Implementation Plan that the Oregon Environmental Quality Commission adopted under OAR 340-200-0040 (Oregon Secretary of State 2022).

**Table 3.10-3. Oregon Ambient Air Quality Standards**

| Pollutant | | Averaging Time | Level* | Form |
|---|---|---|---|---|
| Carbon Monoxide (CO) | | Same as NAAQS | | |
| Lead (Pb) | | Rolling 3-month average | 0.15 µg/m$^3$ | Not to be exceeded over a 3-year period |
| Nitrogen Dioxide ($NO_2$) | | Same as NAAQS (Table 3.10-2) | | |
| Ozone ($O_3$) | | 8 hours | 0.070 ppm | Annual fourth-highest daily maximum 8-hour concentration |
| Particle Pollution (PM) | $PM_{2.5}$ | Same as NAAQS (Table 3.10-2) | | |
| | $PM_{10}$ | Same as NAAQS (Table 3.10-2) | | |
| Sulfur Dioxide ($SO_2$) | | 1 hour | 0.075 ppm | 99$^{th}$ percentile of 1-hour daily maximum concentration, averaged over 3 years |
| | | 3 hours | 0.50 ppm | Not to be exceeded more than once per year |
| | | 24 hours | 0.10 ppm | Not to be exceeded more than once per year |
| | | 1 year | 0.02 ppm | Annual mean |
| Particle Fallout | | 1 month | 3.5 g/m$^2$ | In industrial areas |
| | | 1 month | 5 g/m$^2$ | In residential and commercial areas; in industrial areas if visual observations show the presence of wood waste/soot and the volatile fraction of the sample > 70% |

| Pollutant | Averaging Time | Level* | Form |
|---|---|---|---|
| | 1 month | 10 $g/m^2$ | In residential and commercial areas if visual observations show the presence of wood waste/soot and the volatile fraction of the sample > 70% |

Source: Oregon Secretary of State 2022

*Units of measure for the standards are parts per million (ppm) by volume, micrograms per cubic meter of air ($\mu g/m^3$), and grams per square meter of air ($g/m^2$).

### *3.10.2.3 Attainment Status in Lane, Linn, and Marion counties*

Lane, Linn, and Marion counties generally meet the NAAQS, which translates to relatively good air quality throughout the area, as geographically represented in Figure 3.10-2 (ODEQ No Date-g and ODEQ No Date-i). Linn County meets all NAAQS. Marion County meets all NAAQS, but contains one maintenance area in the Greater Salem-Kaiser Area for CO. This maintenance area is located 34 miles away from Big Cliff Dam. The county maintenance plan for CO is titled the "Salem-Kaiser Area Limited Maintenance Plan". Lane County meets all NAAQS, but contains one nonattainment area in Oakridge for $PM_{2.5}$ and $PM_{10}$. This nonattainment area contains the Willamette Fish Hatchery, and is located 1.8 miles away from Hills Creek Dam. ODEQ and the LRAPA have petitioned the EPA to concur with its determination that 2020 data for $PM_{2.5}$ and $PM_{10}$ from September 11 to September 16 should be declared an exceptional event and excluded from the 2020 dataset for NAAQS compliance. Exceptionally high values for $PM_{2.5}$ and $PM_{10}$ during this period were a result of multiple wildfires, including the Holiday Farm and Thielsen wildfires (ODEQ 2021a and ODEQ 2021b). Lane County also contains one maintenance area in the Greater Eugene-Springfield Area for $PM_{10}$. This maintenance area is located 4 miles away from Fern Ridge Dam and four miles away from Dexter and Fall Creek Dams. The county maintenance plan is called "Eugene-Springfield Urban Growth Area". Therefore, while these counties contain nonattainment and maintenance areas, none of the USACE project locations are located within confirmed nonattainment or maintenance areas.

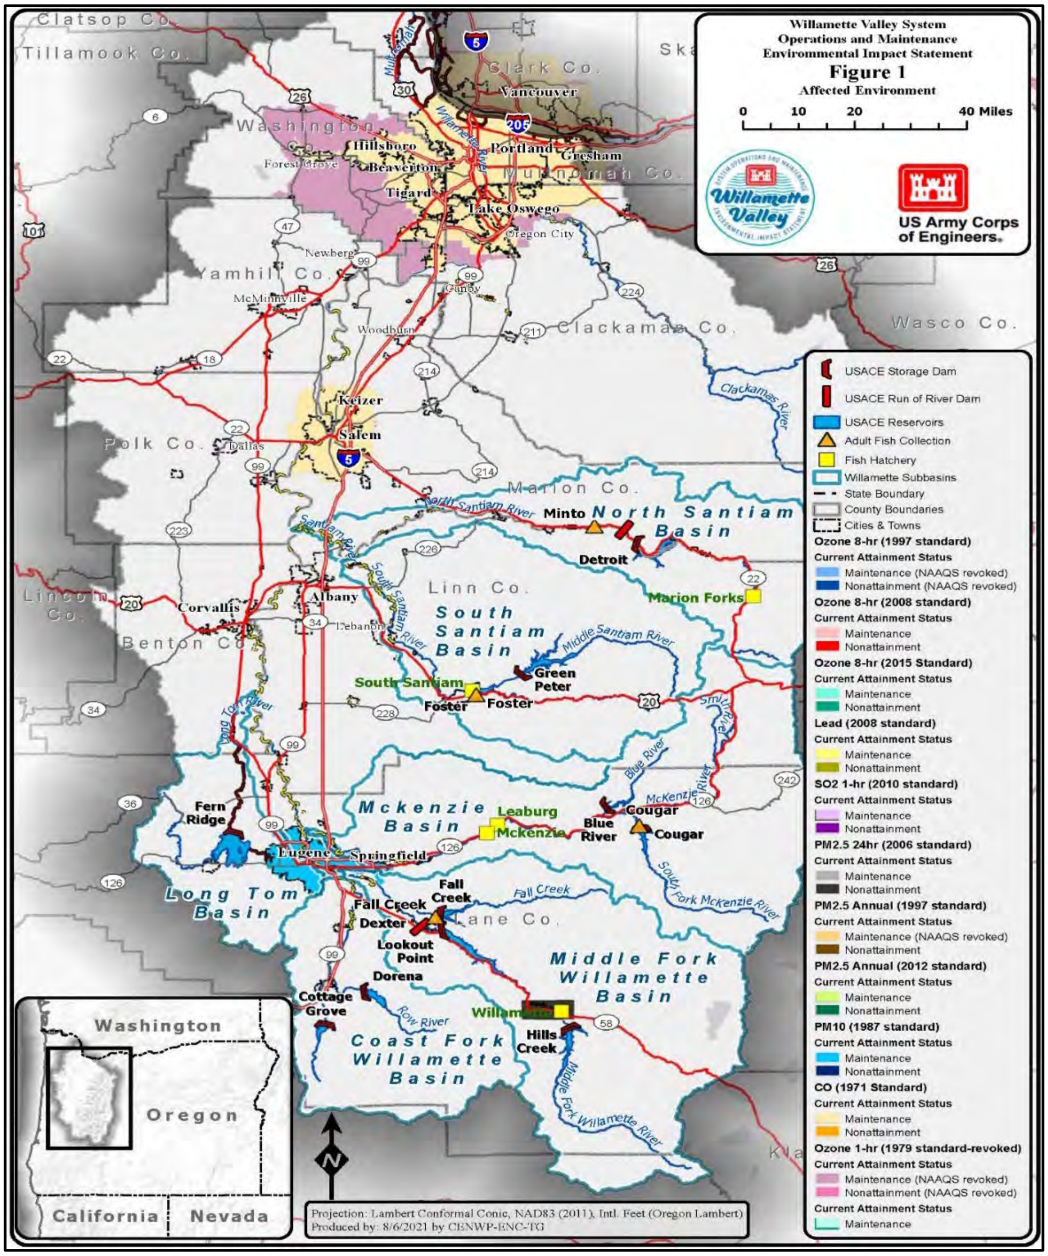

**Figure 3.10-2. Attainment, Nonattainment, and Maintenance Areas in the Willamette Valley System**

### *3.10.2.4 CAA General Conformity for Federal Actions*

Section 176(c)(1) of the CAA requires Federal agencies to assure that their actions conform to applicable implementation plans for achieving and maintaining the NAAQS for criteria pollutants, which include sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. For there to be conformity, a Federal action must not contribute to new violations of standards for ambient air quality, increase the frequency or severity of existing violations, or delay timely attainment of standards in the area of concern. This applies to emissions of criteria air pollutants that would occur in locations designated as nonattainment or maintenance areas for the emitted pollutants (DOE 2000).

The first phase of the general conformity requirements is the conformity review process, which evaluates whether the conformity regulations would apply to an action and whether a determination is needed. While the three counties contain two maintenance areas and one nonattainment area, none of the USACE project locations are situated within any of these areas. For this reason, a general conformity analysis is not required and may be dismissed from further discussion.

#### *3.10.2.5 Reciprocating Internal Combustion Engines (RICE)*

RICEs are combustion engines that use pistons alternatively moving back and forth to convert pressure into rotating motion. They are commonly used at power and manufacturing plants to generate electricity and to power pumps and compressors. RICEs are also used in emergencies to produce electricity and pump water for flood and fire control. Recently, EPA finalized new air quality regulations that place requirements on owners and operators of a wide variety of stationary RICEs (ADEQ No Date). While USACE project locations utilize RICEs in the forms of operational or emergency generators, they are operated under the limit allowed; therefore, no air emissions reporting is required.

#### *3.10.2.6 Oregon Air Quality Permits*

This section discusses Oregon's air quality permits that strictly relate to the Proposed Action and alternatives. The primary sources of air emissions are diesel generator usage and diesel trucks during fish trucking operations. There are no new or preexisting major stationary sources included in the Proposed Action or alternatives. Major sources are defined by the CAA as facilities that emit or have the potential to emit 10 tons of any one toxic air pollutant or 25 tons of more than one toxic air pollutant per year (EPA 2021d). In addition, all USACE project locations are located within attainment areas, as discussed in Section 3.10.2.2. Therefore, Prevention of Significant Deterioration (PSD) permits, nonattainment New Source Review (NSR) permits, minor NSR permits, and Title V permits are not applicable and may be dismissed from further discussion. Only permits that would be applicable to USACE projects and emission sources will be discussed below.

#### *3.10.2.7 Air Contaminant Discharge Permits*

ODEQ and LRAPA set permit rules and limits based on the size and type of the emission source and the type of pollutant emitted. Facilities that emit air pollution above certain levels are required to have air quality permits that specify the pollutant limits they must meet and what records they must keep and submit to ODEQ to show they are in compliance (ODEQ No Date-d). Air Contaminant Discharge Permits (ACDP) are primarily used to regulate minor sources of air contaminant emissions, but are also required for any new major source or major modification at a major source. Types of air contaminant discharge permits can vary based on the source category, size of the facility, and types of emissions discharged (ODEQ No Date-a).

General ACDPs authorize the operation of electrical power generators, and are issued for a period of up to ten years. Device and Equipment Form Series 200, AQ 213 'Electric Power Generators' provides the application form that must include information for each generator used, including the size of the generator, type of fuel used, and projected maximum number of hours to be operated in one year.

Construction ACDPs include requirements for the construction or modification of stationary sources or air pollution control equipment at sources that are required to obtain a Standard ACDP or Oregon Title V Operating Permit. None of the construction activities under the Proposed Action or alternatives would result in a stationary source that would require either of these permits. Therefore, a construction ACDP would not be required under the Proposed Action and alternatives.

### 3.10.3 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on air quality. The discussion includes the methodology, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis for each alternative.

#### *3.10.3.1 Methodology*

The two primary existing sources of air emissions in the WVS are fish trucking operations and generator usage. These sources would likely contribute air pollutants that have been identified by federal and state standards (Sections 3.10.2.1. and 3.10.2.2., respectively), with regulatory thresholds that cannot be exceeded in order to maintain attainment status. To analyze these sources, USACE project data were assessed to qualitatively determine how the Proposed Action and alternatives would affect air quality. The current total mileage of all fish trucking operations and the total number of WVS emergency diesel generators were accounted for in the Affected Environment (Section 3.10.1.1). Both of these parameters would likely change based on the proposed measures in each alternative. In general, more fish trucking mileage and generator usage would directly correlate with higher emissions of carbon dioxide and other criteria pollutants, thereby potentially affecting the air quality in the WVS. Therefore, the changes in total fish trucking mileage and total generators per alternative were qualitatively assessed below to determine how each alternative would potentially affect air quality, and if any alternative would potentially exceed any federal or state standard.

Table 3.10-4 describes the evaluation criteria for magnitude, duration, and extent, and provides a definition for the scale of each effect factor. Note that the definitions for short term, medium term, and long term are the same for all resources.

**Table 3.10-4. Evaluation Criteria for Potential Effects to Air Quality**

| Term | Definition |
| --- | --- |
| **Magnitude** | |
| Negligible | Changes would be nondetectable and indistinguishable from ambient air quality conditions. |
| Minor | Change would not exceed 50% of a federal or state standard. |
| Moderate | Change would exceed 50% of a federal or state standard. |
| Major or Significant | Change would exceed a federal or state standard. |
| **Duration** | |
| Short term | Effects lasts for the duration of a small construction project, and is continuous for less than 2 years. |
| Medium term | Effects lasts for the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long term | Effects are permanent or last continuously beyond operation changes or the completion of all construction projects; the effects recur at regular intervals (i.e., trap-and-haul trucking operations that occur weekly or monthly); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Effects would be confined to the project location. |
| Medium | Effects would be confined to a single county. |
| Large | Effects would extend to multiple counties or throughout the entire WVS, state, or beyond. |

Secondary sources of air emissions include construction activities and fugitive dust. The use of construction vehicles and equipment, such as bulldozers, cranes, and other heavy equipment, results in tailpipe emissions to the air through the internal combustion of diesel engines. To analyze construction activities, a qualitative approach was implemented that considers the amount of equipment used, the duration of equipment used, and the area of construction activities. Windblown fugitive dust from unpaved roads and heavy construction equipment or as a result of reservoir drawdowns could expose sediment and result in air emissions. To analyze fugitive dust, a qualitative approach was implemented that considered average wind speeds at locations within the WRB in conjunction with the duration of equipment used or reservoir drawdowns and the area of construction activities or reservoir drawdowns to assess potential fugitive dust emissions.

#### *3.10.3.2 Measures Analyzed for Air Quality*

Measures under the action alternative that could have an effect on air quality include construction of water temperature control (WTC) towers (#105), construction of adult fish facilities (AFF) (#722), construction of structural downstream fish passages (#392), restoring upstream and downstream passage at drop structures (#639), providing Pacific lamprey passage and infrastructure (#52), deeper fall reservoir drawdowns for fish passage (#40), and spring reservoir drawdowns for downstream fish passage (#720).

The following measures would have no effect on air quality, and are therefore not discussed further.

- Gravel augmentation below dams (#384);
- Foster fish ladder temperature improvement (#479);
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Use spillway for surface spill in summer (#721);
- Structural improvements to reduce total dissolved gas (#174);
- Augment instream flows by using the inactive pool (#718);
- Augment instream flows by using the power pool (#304);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b); and
- Pass water over spillway in spring for fish passage (#714).

Operation, maintenance, repair, replacement, and rehabilitation can range from regular maintenance activities to major maintenance and rehabilitation activities, such as the repair, replacement, or rehabilitation of an entire facility. Major maintenance projects that take power lines off-line or shut down generators would likely reduce air emissions and could have beneficial effects to air quality. Alternatively, construction vehicles and equipment used during major rehabilitation or restoration projects would likely generate additional air emissions and adversely affect air quality. As such, major maintenance and rehabilitation activities would likely have **negligible**, **medium-term** effects to air quality; however, more information is needed to conduct a full analysis. These actions should undergo further analysis under the tiered NEPA process.

A summary of the effects to air quality discussed in the following section is provided in Table 3.10-5. Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Discussion of all adverse and beneficial effects are included in the discussion below.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.10-5. Summary of Effects to Air Quality Under Each Alternative**

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | **NAA** | **1** | **2A** | **2B** | **3A** | **3B** | **4** | **5** |
| | **Short-Term** | | | | | | | |
| Magnitude | negligible adverse | minor adverse | minor adverse | minor adverse | minor adverse | minor adverse | minor adverse | minor adverse |

In the following subsections, the effects are discussed for the measures analyzed in the alternatives, the No Action Alternative, and for each of the action alternatives.

### *3.10.3.3 Discussion of Effects by Measure(s)*

This section applies the methodology described above to each measure analyzed for air quality to determine the potential effect. Where possible, discussion of the magnitude, duration, and extent of effects is grouped by measures that would have similar effects. The effects by measure or measures will then be referenced in the action alternatives analysis that follows.

This Draft PEIS discusses general, qualitative effects from construction at the programmatic level, and all structural measures that include construction phases would require tiered NEPA reviews. Structural measures pertaining to air quality include construction of WTC towers, construction of AFFs, construction of structural downstream fish passage, restoring upstream and downstream passage at drop structures, deeper fall reservoir drawdowns (only at Cougar for the drawdown operation to the DT), and spring reservoir drawdowns (only at Cougar for the drawdown operation to the DT). Because air quality effects from each individual construction project analyzed in subsequent tiered NEPA documents are expected to be lower than those from the sum of all projects analyzed in this PEIS, the analysis in subsequent tiered NEPA documents is not expected to be more detailed or quantitative. It is expected that the air quality analysis in the tiered EAs or EISs would be able to incorporate by reference the applicable parts of the analysis from this PEIS. However, if site-specific project details for construction measures determined during the implementation phase indicate potentially higher air emissions than those discussed in this PEIS, a quantitative analysis may be considered in that tiered EA or EIS.

#### *3.10.3.3.1 Construct water temperature control (WTC) towers (#105), Construct structural downstream fish passages (#392), Construct adult fish facilities (AFFs) (#722), and Provide Pacific lamprey passage and infrastructure (#52)*

The magnitude of effects from the construction of WTC towers (#105), structural downstream fish passages (#392), AFFs (#722), and Pacific Lamprey passage and infrastructure (#52) would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent at all dams. These potential effects are determined below and referred back to under all alternatives.

**Construction Activities and Fugitive Dust**

Construction vehicles and equipment, such as bulldozers, cranes, and other heavy equipment, would be required to complete the proposed measures. The effects to air quality would include the combustion of diesel fuel to power construction vehicles and machinery. During combustion, diesel engines emit large amounts of nitrogen oxides, particular matter (in particular $PM_{2.5}$) carbon, and other toxic air pollutants. Given the nature and scale of these proposed construction projects, the effects to local and regional air quality would be expected to be minimal and the magnitude of adverse effects would be negligible to minor because air emissions would not exceed 50% of a federal or state standard. There would be a medium-term effect because the construction activities would take two to five years to complete. The extent of effects would be small because construction activities typically result in localized air pollution emissions, and would be confined to the project location.

Fugitive dust emissions are caused by two basic factors: the pulverization and abrasion of surface materials by the application of a mechanical force (wheels, blades, etc.), and/or the entrainment of dust (sediment) particles by turbulent air currents, such as wind erosion of an exposed surface by wind speeds over 12 miles per hour (mph) (EPA 1995). Average wind speeds for 2021 in Eugene and Salem were 6.9 and 6.5 mph, respectively (NOAA 2022a, 2022b). The magnitude of adverse effects would be negligible because average wind speeds would not be high enough to entrain dust particles into surface winds. Furthermore, Oregon Administrative Rules (OAR) 340-208-0210 provides the management requirements for fugitive emissions, including disciplinary action that would be taken by Oregon Department of Environmental Quality (ODEQ) (see Section 3.10.1.3). There would be a medium-term effect because construction activities would take two to five years to complete. The extent of effects would be small because construction activities typically result in localized air pollution emissions, and would be confined to the project location.

**Operational Activities**

Each of these measures would increase the number of fish collected at each project site and increase the need for transportation to release sites, thereby increasing fish trucking mileage and associated air emissions. New facilities and structures at each project site would also require emergency diesel generators to supply power to these measures, thereby increasing associated air emissions.

The total fish trucking mileage and the number of generators would vary by alternative, as each alternative contains a different combination of measures and project sites that would affect these totals. While these parameters are analyzed per alternative, it is not likely that total fish trucking mileage and emergency diesel generators would exceed 50% of a federal or state standard in any alternative. Under routine operations, the WVS accounts for 22 emergency diesel generators and an estimated 92,000 vehicle miles traveled from fish trucking operations as stated in the Affected Environment (Section 3.10.1.1). By comparison, the Rose Quarter Freeway, which is the section of I-5 near Portland in Willamette Valley, carries about 120,000 vehicles per day and accounts for about 35 million vehicles miles of travel per year (Cortright 2019). Under each alternative, fish trucking mileage would only increase by about 576 to 1,216 miles, which is an increase of about one percent; similarly, each alternative would only add between seven to ten new generators. Therefore, the magnitude of adverse effects would be negligible to minor because the additional air emissions from truck mileage and generators would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographical region of the WVS. There would be a long-term, recurring effect because while the structures would be permanent, the fish trucking operations would be recurring. The extent of effects would be large because the release sites for trucked fish would potentially be located in various counties across the WRB.

#### *3.10.3.3.2 Restoring upstream and downstream passage at drop structures (#639)*

The magnitude of effects from restoring upstream and downstream passage at drop structures (#639) would be negligible to minor in the short term and small in extent, and minor in the long term (permanent) and small in extent at Fern Ridge Dam. These potential effects are determined below and referred back to under Alternatives 1 and 4.

Infrastructure would be improved downstream of the Fern Ridge Dam at Monroe, Stroda, and Cox Butte. Infrastructure improvements include fish ladders, notching or direct modifications to drop structures, bypass channels, or dam removal and replacement with pool and riffle systems. Construction vehicles and equipment, such as bulldozers, cranes, and other heavy equipment, would be required to complete the proposed improvements. Given the nature and scale of these proposed construction projects, the effects to local and regional air quality would be expected to be minimal. Therefore, the magnitude of adverse effects would be negligible to minor because air emissions would not exceed 50% of a federal or state standard. There would be a short-term effect because the construction activities would take less than two years to complete. The extent of effects would be small because construction activities typically result in localized air pollution emissions, and would be confined to the project location.

Fugitive dust emissions would be negligible because average wind speeds for 2021 in Eugene and Salem were 6.9 and 6.5 mph, respectively (NOAA, 2022a; NOAA, 2022-b), and would not be high enough to entrain dust particles into surface winds. There would be a short-term effect because construction activities would take less than two years to complete. The extent of effects would be small because construction activities typically result in localized air pollution emissions, and would be confined to the project location.

Once construction is complete, the infrastructure would provide passage for fish to the mainstem Long Tom River and tributaries between the confluence with the Willamette River and Fern Ridge Dam. The magnitude of beneficial effects would be minor because fish passage measures would allow fish to pass through the Fern Ridge Dam without being trapped and hauled, reducing the amount of total fish trucking mileage. There would also be no additional generators added to this measure. These effects would occur in the long-term because the structures would be permanent and fish would no longer require transportation. The extent of effects would be small because the fish passage infrastructure at the drop structures would be localized and confined to that project location.

#### *3.10.3.3.3 Deeper fall reservoir drawdowns for fish passage (#40) and spring reservoir drawdowns for downstream fish passage (#720)*

The magnitude of effects from deeper fall reservoir drawdowns (#40) and spring reservoir drawdowns (#720) would be negligible in the short and long term (recurring) and small in extent at all reservoirs. These potential effects are determined below and referred back to under Alternatives 2, 3A, 3B, and 5.

As reservoir elevations are drawn down for extended periods of time, methane could be released from the sediments and potentially represent a substantial contribute of methane to the atmosphere. However, the magnitude of these effects would likely be negligible because methane released specifically during drawdowns have been measured to only contribute a small fraction of the total amount of methane emitted at reservoirs throughout the year (Beaulieu et al. 2018). Sediments from the shoreline to the benthic zone can also become exposed and dried out as reservoir elevations fall, and would likely be susceptible to atmospheric weather conditions. Fugitive dust emissions could be caused by the entrainment of dust (sediment) particles by turbulent air currents, such as wind erosion of an exposed surface by wind speeds over 12 mph (EPA 1995). Average wind speeds for 2021 in Eugene and Salem were 6.9 and 6.5 mph, respectively (NOAA 2022a, 2022b). The magnitude of adverse effects would be negligible because average wind speeds would not be high enough to entrain dust particles into surface winds. Reservoir drawdowns would only be maintained for 3-week periods in the spring and fall; this short time span would make it highly unlikely for sediments to be completely dried out, and for wind speeds to reach above average speeds. Furthermore, OAR 340-208-0210 provides the management requirements for fugitive emissions, including taking precautions to prevent particular matter from being airborne, such as using water, chemicals or enclosures and covers for dust control, and disciplinary action that would be taken by ODEQ (see Section 3.10.1.3). There would be **short-term** and long-term, recurring effects because while reservoir elevations would only be held for three weeks, it would occur annually. The extent of effects would be small because reservoir drawdowns would be confined to the project location.

##### *3.10.3.3.4 Near-Term Operations*

The magnitude of effects from near-term operations would be negligible in the short term or medium term at Green Peter Dam. These potential effects are determined below and referenced under Alternatives 2A, 2B, 3A, 3B, 4, and 5.

Near-term operations that would potentially affect air quality include the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam. While the outplanting plan could increase the total fish trucking mileage occurring at Green Peter Dam, it is unlikely to cause a substantial change to the overall total fish trucking mileage occurring within the WVS. Therefore, potential adverse effects would be negligible in magnitude. It should be noted that duration of near-term operations ultimately would depend on when the operations each location in the action alternatives can be implemented; therefore, duration of effects would be short term and/or medium term, depending on the implementation process of measures in the action alternatives. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB.

Near-term operations would also include deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek. Drawdowns would expose previously submerged sediments and dry them out, leaving them susceptible to atmospheric conditions that could entrail the sediments and create fugitive dust emissions. Similar to 3.10.3.3.3, the magnitude of adverse effects would be negligible because average wind speeds would not be high enough to entrain dust particles into surface winds. While these drawdowns would last longer than three weeks and could potentially dry out sediments even further, low wind speeds would make fugitive dust very unlikely. Duration of effects would be short term and/or medium term, depending on the implementation process of measures in the action alternatives. The extend of effects would be small because reservoir drawdowns would be confined to the project location.

#### *3.10.3.4 No Action Alternative*

Under the NAA, the adaptive hatchery program (#719) would occur at Detroit, Big Cliff, Green Peter, Foster, Blue River, Cougar, Dexter, Lookout Point, Fall Creek, and Hills Creek Dams. In addition, the continued operation of AFFs would occur at Dexter Dam, Cougar, Foster, and Fall Creek Dams, and Minto Fish Collection Facility, and the maintenance of existing and new fish release sites (#726) would occur at Detroit, Green Peter, Foster, Cougar, Lookout Point, Fall Creek, Hills Creek, and Big Cliff Dams. The magnitude of adverse effects from these activities would be negligible in the long term because these activities would not change the total truck mileage or the number of generators from current levels, and therefore, would not cause a change in air emissions different from what was already occurring. The extent of effects would be large because the hatcheries, AFFs, and release sites for outplanted fish would potentially be located in various counties across the WRB.

Under the NAA, Fall Creek reservoir would continue to be drawn down annually to its lowest outlet (elevation 690) for a few weeks in November, potentially lasting into December. As discussed above in Section 3.10.3.3.3 (Reservoir Drawdowns), the potential adverse **short-** and long-term, recurring effects from these drawdowns would be negligible in magnitude and small in extent.

##### *3.10.3.4.1 Climate Change*

Climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release pollutants such as particulate matter, carbon monoxide, and carbon dioxide into the air and affect air quality in the surrounding area. Ambient air temperature changes, such as the one-to-two-degree Fahrenheit warming experienced in the Pacific Northwest (See Appendix F1), could increase ground-level ozone and make wildfires more common due to drier conditions from higher evapotranspiration rates. Likewise, these air pollutants could also contribute to climate change; carbon dioxide released during wildfires would contribute to greenhouse gases increasing in the atmosphere, while particulate matter and ozone could create smog that blocks sunlight and could be harmful to human health. Therefore, climate change would amplify the effects to air quality already occurring under the

NAA to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### *3.10.3.5 Alternative 1. Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, adverse effects on air quality from the construction of WTC towers, structural downstream fish passages, AFFs, and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Potential adverse effects from restoring upstream and downstream passage at drop structures would be negligible to minor in magnitude in the short term and small in extent. Potential beneficial effects from restoring upstream and downstream passage at drop structures would be minor in magnitude in the long term (permanent) and small in extent. Alternative 1 would have the same general effect as all other alternatives.

##### *3.10.3.5.1 Construction of WTC Towers, Structural Downstream Fish Passages, AFFs, and Pacific Lamprey Passage and Infrastructure*

Under Alternative 1, the construction of WTC towers would occur at Detroit Dam, Green Peter Dam, and Lookout Point Dam. Downstream fish passage structures would occur at Detroit Dam, Green Peter Dam, Lookout Point Dam, and Foster Dam. The construction of AFFs would occur at Green Peter Dam. Pacific Lamprey passage and infrastructure would occur at Fern Ridge Dam and Green Peter Dam. As discussed above in Section 3.10.3.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, AFFs, and Pacific Lamprey Passage and Infrastructure), the potential adverse medium- and long-term, recurring effects from these structures would be negligible to minor in magnitude and small and large in extent. New structures would require nine new emergency diesel generators, and measures would add a total of 576 miles to fish trucking operations, while is a mileage increase of less than one percent. These additional air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographical region of the WVS.

##### *3.10.3.5.2 Restoring Upstream and Downstream Passage at Drop Structures*

Under Alternative 1, restoring upstream and downstream passage at drop structures would occur at Fern Ridge. As discussed above in Section 3.10.3.3.2 (Restoring Upstream and Downstream Passage at Drop Structures), the potential adverse short-term effects would be negligible to minor in magnitude and small in extent. Potential beneficial long-term, permanent effects would be minor in magnitude and small in extent.

##### *3.10.3.5.3 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 1. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 1 to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### ***3.10.3.6 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)***

Under Alternative 2A, adverse effects on air quality from the construction of WTC towers, downstream passage structures, AFFs, and Pacific Lamprey passage and infrastructure would be negligible to minor in magnitude in the medium term and long term (recurring) and small and large in extent. Reservoir drawdowns would have negligible, **short-term** and long-term, recurring effects and would be small in extent. Alternative 2A would have the same general effect as all other alternatives.

##### *3.10.3.6.1 Construction of WTC Towers, Structural Downstream Fish Passages, AFFs, and Pacific Lamprey Passage and Infrastructure*

Under Alternative 2A, the construction of WTC towers would occur at Detroit Dam. Construction of downstream fish passage structures would occur at Detroit Dam, Lookout Point Dam, Cougar Dam, and Foster Dam. The construction of AFFs would occur at Green Peter Dam. Pacific Lamprey passage and infrastructure would occur at Green Peter Dam. As discussed above in Section 3.10.3.3.1 (Construction of WTC Towers, Downstream Fish Passages, AFFs, and Pacific Lamprey Passage and Infrastructure), the potential adverse medium- and long-term, recurring effects from these structures would be negligible to minor in magnitude and small and large in extent. New structures would require eight new emergency diesel generators, and measures would add a total of 736 miles to fish trucking operations, which is a mileage increase of less than one percent. These additional air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographical region of the WVS.

##### *3.10.3.6.2 Reservoir Drawdowns*

Under Alternative 2A, deeper fall reservoir drawdowns to 25 feet over the ROs would occur at Green Peter Dam. As discussed above in Section 3.10.3.3.3 (Reservoir Drawdowns), the potential adverse **short-term** and long-term, recurring effects from these drawdowns would be negligible in magnitude and small in extent.

#### *3.10.3.6.3 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

#### *3.10.3.6.4 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 2A. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 2A to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

### ***3.10.3.7 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 2B, the effects to air quality would be the same as those described under Alternative 2A. Potential adverse effects from the construction of WTC towers, structural downstream fish passages, AFFs, and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Reservoir drawdowns would have negligible, **short-term** and long-term, recurring effects and would be small in extent. Under this alternative, a downstream passage structure would not be constructed at Cougar Dam; and deep fall and spring reservoir drawdowns down to 25 feet over the top of the diversion tunnel would occur at Cougar Dam. Similar to Alternative 2A, total fish trucking mileage would increase by 736 miles and emergency diesel generators would increase by seven new generators under Alternative 2B. Alternative 2B would have the same general effect as all other alternatives.

#### *3.10.3.7.1 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

#### *3.10.3.7.2 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 2B. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 2B to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

### ***3.10.3.8 Alternative 3A. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)***

Under Alternative 3A, adverse effects on air quality from the construction of AFFs and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Reservoir drawdowns would have negligible, **short-term** and long-term, recurring effects and would be small in extent. Alternative 3A would have the same general effect as all other alternatives.

#### *3.10.3.8.1 Construction of AFFs and Pacific Lamprey Passage and Infrastructure*

Under Alternative 3A, the construction of AFFs would occur at Blue River Dam, Green Peter Dam, and Hills Creek Dam. Pacific Lamprey passage and infrastructure would occur at Blue River Dam, Green Peter Dam, and Hills Creek Dam. As discussed above in Section 3.10.3.3.1 (Construction of WTC Towers, Downstream Fish Passages, AFFs, and Pacific Lamprey Passage and Infrastructure), the potential adverse medium- and long-term, recurring effects from these structures would be negligible to minor in magnitude and small and large in extent. New structures would require seven new emergency diesel generators, and measures would add a total of 1,216 miles to fish trucking operations, which is a mileage increase of almost 1.5

percent. These additional air emissions would not exceed 50% of a federal or state standard and would likely be undetectable compared to the entire geographical region of the WVS.

##### *3.10.3.8.2 Reservoir Drawdowns*

Under Alternative 3A, deeper fall reservoir drawdowns to 10 feet over the ROs would occur at Lookout Point Dam, Hills Creek Dam, Cougar Dam, Blue River Dam, Green Peter Dam, and Detroit Dam. Spring reservoir drawdowns to 10 feet over the ROs would occur at Lookout Point Dam, Cougar Dam, and Detroit Dam. As discussed above in Section 3.10.3.3.3 (Reservoir Drawdowns), the potential adverse **short-term** and long-term, recurring effects from these drawdowns would be negligible in magnitude and small in extent.

##### *3.10.3.8.3 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

##### *3.10.3.8.4 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 3A. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 3A to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### ***3.10.3.9 Alternative 3B. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 3B, the effects to air quality would be the same as those described under Alternative 3A. Potential adverse effects from the construction of AFFs and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Reservoir drawdowns would have negligible, **short-term** and long-term, recurring effects and would be small in extent. Under this alternative, spring reservoir drawdowns would occur at Green Peter and Hills Creek instead of at Detroit and Lookout Point under Alternative 3A. In addition, Cougar would be drafted down to 25 ft over the top of the diversion tunnel, similar to Alternative 2B. Similar to Alternative 3A, total fish trucking mile would increase by 1,216 miles and emergency diesel generators would increase by seven new generators under Alternative 3B. Alternative 3B would have the same general effect as all other alternatives.

##### *3.10.3.9.1 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

##### *3.10.3.9.2 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 3B. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 3B to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### ***3.10.3.10 Alternative 4. Improve Fish Passage with Structures-Based Approach***

Under Alternative 4, the effects to air quality would be the same as those described under Alternative 1. Potential adverse effects from the construction of WTC towers, structural downstream fish passages, AFFs, and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Potential adverse effects from restoring upstream and downstream passage at drop structures would be negligible to minor in magnitude in the short term and small in extent. Potential beneficial effects from restoring upstream and downstream passage at drop structures would be minor in magnitude in the long term (permanent) and small in extent. Under this alternative, a WTC tower and new AFF would be constructed at Hills Creek instead of Green Peter under Alternative 1; and structural downstream fish passages would be constructed at Hills Creek and Cougar instead of Green Peter, in addition to those listed under Alternative 1. Pacific Lamprey passage and infrastructure would also be constructed at Hills Creek instead of Green Peter, in addition to those already listed under Alternative 1. Under Alternative 4, ten new emergency diesel generators would be added, and 800 miles would be added to total fish trucking. Alternative 4 would have the same general effect as all other alternatives.

##### *3.10.3.10.1 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

##### *3.10.3.10.2 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 4. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 4 to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### ***3.10.3.11 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 5, the effects to air quality would be the same as those described under Alternative 2B. Potential adverse effects from the construction of WTC towers, structural downstream fish passages, AFFs, and Pacific Lamprey passage and infrastructure would be negligible to minor in the medium term and small in extent, and negligible to minor in the long term (recurring) and large in extent. Reservoir drawdowns would have negligible, **short-term** and long-term, recurring effects and would be small in extent. Under this alternative, spring reservoir drawdowns would not occur at Cougar Dam. Similar to Alternative 2B, total fish trucking mile would increase by 736 miles and emergency diesel generators would increase by seven new generators under Alternative 5. Alternative 5 would have the same general effect as all other alternatives.

##### *3.10.3.11.1 Near-Term Operations*

As discussed in Section 3.10.3.3.4, potential adverse short- or medium-term effects from near-term operations from the outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam would be negligible in magnitude. Effects would be medium and/or large in extent because the release sites for trucked fish could potentially be located in various areas within the country or across the WRB. In addition, short- or medium-term effects from deep drawdown and RO prioritization at Lookout Point, Green Peter, and Cougar; delayed refill at Fall Creek, Foster, and Cougar; and extended deep drawdown and RO prioritization at Fall Creek would be negligible in magnitude at all dams. Effects would be small in extent because reservoir drawdowns would be confined to the project location.

##### *3.10.3.11.2 Climate Change*

As discussed in Section 3.10.3.4.1, climate change would potentially affect air quality within the WVS. More intense and frequent wildfires would release more air pollutants, such as carbon dioxide, particulate matter, and ozone, while ambient air temperatures changes could increase ground-level ozone and make wildfires (and their associated emissions) more common. These effects would exacerbate the effects to air quality already occurring under Alternative 5. Therefore, climate change would amplify the effects to air quality already occurring under Alternative 5 to minor adverse effects. Effects would be long-term in duration due to the ongoing nature of climate change, and large in extent depending on the size of wildfires and the distance pollutants would travel, along with the widespread effects air pollutants such as carbon dioxide, particulate matter, and ozone have on greenhouse gases in the atmosphere.

#### ***3.10.3.12 Conclusion***

In summary, all alternatives would potentially have the same general effect to air quality. All alternatives would include adverse, minor, short-term, medium-term and long-term effects. Alternatives 1 and 4 would also include beneficial, long-term, permanent, minor effects. Among all alternatives, the total fish trucking mileage and the number of generators would increase, thereby increasing associated air emissions. That said, none of the alternatives would exceed 50% of a federal or state standard. Therefore, all alternatives would generally have the same effect and maintain the relatively good air quality found throughout the WVS.

## 3.11 SOCIOECONOMIC RESOURCES

The analysis of socioeconomic resources identifies those aspects of the social and economic environment that are sensitive to changes and that may be affected by actions associated with structural and nonstructural changes to the dams, including installation of fish passages and spillway modifications, installation of water temperature control towers, and modifications to planned discharges throughout the Willamette Valley System (WVS). All the proposed structural measures and the vast majority of corresponding revenue flows would occur in Lane, Linn, and Marion counties. Social impacts, for example to quality of life and recreational and aesthetic values, would be experienced most by individuals, communities, residents, and workers in these counties, especially residents in areas or municipalities adjacent to the modified structures. Businesses, community services, and economic systems in these counties could change beneficially and adversely in response to the implementation of the Proposed Action and alternatives. Since potential impacts with the greatest magnitude, duration, extent, and likelihood would occur in Lane, Linn, and Marion counties, they are defined as the Region of Influence (ROI) for the analysis of direct and indirect socioeconomic impacts. Adjacent counties in the WVB – including Benton, Clackamas, Columbia, Multnomah, Polk, Washington, and Yamhill counties – are not included in the ROI as USACE does not intend to use local labor for construction activities and the socioeconomic conditions of these areas would likely not be substantially affected by the Proposed Action and alternatives.

While social impacts are addressed in this section, a discussion of those impacts that could disproportionately affect minority and low-income communities are discussed in the Environmental Justice section. Direct effects to visitation, revenue, and experience at the recreation areas throughout the WVS are discussed in Section 3.17, Recreation.

The data supporting this analysis were collected from standard sources, including federal agencies such as the U.S. Census Bureau (USCB), Bureau of Labor Statistics (BLS), and Bureau of Economic Analysis (BEA); state agencies such as the State of Oregon Employment Department (OED) and Oregon Office of Economic Analysis (OEA); as well as other research institutes. Demographic data are presented for Lane, Linn, and Marion counties and compared to the State of Oregon overall. The most recent and best available data are presented throughout the section. These data were grounded through site visits to each of the 13 dams and reservoirs within the ROI.

This section begins by describing the population growth, age, and housing for the ROI. Labor and employment – including the labor force, unemployment, and employment by industry for the ROI – as well as earnings – including per capita personal income and industry compensation – for the ROI are then discussed. Finally, the quality of life, including such as recreational and aesthetic values as well as community concerns, is described.

The demographics described in this section would be affected more or less according to whether or not local firms are hired during the government contract bidding process. The bidding process could also conclude with a combination of local and regional firms being selected. If all local firms using all local labor and machinery were selected, the most economic benefits to local communities would be realized. At the other end of the spectrum, if all contracts were awarded to regional firms using non-local labor and machinery, local economic benefits would still be realized, but to a lesser degree. This is because when all local firms are hired, the multiplier effect of income generally begins at the local level. In contrast, hiring all regional firms would generally result in the multiplier effect of income beginning at in a different area. The multiplier effect of income comes about because one entity's spending becomes another entity's income. For example, when a person spends money on a good or service, it creates income for a business who then pays their employees, who in turn buy goods and services themselves. Even if all regional firms were hired, local economies would still be stimulated in the short term while construction activities were taking place.

### 3.11.1 Population Growth and Age

Table 3. 11-1 shows past and current population data and future population estimates for Lane, Linn, and Marion counties and Oregon overall. Population estimates are sourced from the USCB American Community Survey and the Portland State University Population Research Center.

In all three counties as well as in the state overall, the population increased from 2010 to 2019. On average, from 2010 to 2019, Lane County grew 0.68 percent per year; Linn County 0.79 percent; and Marion County 0.86 percent; compared to the state of Oregon, which grew an average of 0.87 percent per year (see Table 3.11-11 below). In 2019, Lane County's population was the fourth largest in the state; Marion County ranked fifth; and Linn County ranked eighth (USCB 2019). From 2025 to 2035, the population in Lane County is projected to grow at approximately the same rate it grew from 2010 to 2019, respectively 0.68 and 0.67 percent annually (USCB 2010a; USCB 2015a; USCB 2019a; PSU 2021a). On average, Linn County is projected to grow 0.13 percent slower per year from 2025 to 2035 than it did from 2010 to 2019; and Marion County is projected to grow 0.11 percent slower per year, respectively (USCB 2010a; USCB 2015a; USCB 2019a; PSU 2021a). However, the state of Oregon is expected to grow 0.08 percent faster from 2025 to 2035 than it grew from 2010 to 2019 (USCB 2010a; USCB 2015a; USCB 2019a; PSU 2021b).

**Table 3.11-1. Population Growth**

| Location | Population | | | | Projected Population | | | |
|---|---|---|---|---|---|---|---|---|
| | 2010 | 2015 | 2019 | Average Annual Growth Rate (2010-2019) | 2025 | 2030 | 2035 | Average Annual Growth Rate (2020-2035) |
| Lane County | 351,715 | 357,060 | 373,340 | 0.68 | 397,742 | 412,045 | 424,423 | 0.67 |
| Linn County | 116,672 | 118,971 | 125,048 | 0.79 | 134,032 | 139,090 | 142,903 | 0.66 |
| Marion County | 315,335 | 323,259 | 339,641 | 0.86 | 369,983 | 385,366 | 397,723 | 0.75 |
| Oregon | 3,831,074 | 3,939,233 | 4,129,803 | 0.87 | 4,499,224 | 4,721,060 | 4,925,420 | 0.95 |

Source: USCB 2010a; 2015a; 2019a; PSU 2021a; 2021b.

Table 3.1-11-2 shows the age distribution of the population in Lane, Linn, and Marion counties as well as the state overall. In general, the populations of Lane, Linn, and Marion counties are about the same age as the state as a whole and differ by only 3 percent at the greatest across all age categories (USCB 2019b). Marion County has the youngest population of all counties in the ROI, with 1.8 percent more children under the age of five than Lane County and 3.9 percent more children between the ages of five and 19 than Lane County (USCB 2019b). Both Linn and Marion counties have higher proportions of their population younger than 5 and between 5 and 19 years than the state of Oregon (USCB 2019b).

**Table 3.11-2. Summary of Age Distribution (%)**

| Location | Under 5 Years | 5 to 19 Years | 20-44 Years | 45-64 Years | 65 and Older |
|---|---|---|---|---|---|
| Lane County | 4.9 | 16.9 | 34.5 | 25.0 | 18.8 |
| Linn County | 6.0 | 18.7 | 31.0 | 25.9 | 18.3 |
| Marion County | 6.7 | 20.8 | 33.1 | 24.1 | 15.3 |
| Oregon | 5.6 | 17.9 | 33.8 | 25.5 | 17.2 |

Source: USCB 2019b.

*Note: Numbers may not add up to exactly 100 percent due to rounding.

### 3.11.2 Housing

A housing unit refers to a house, an apartment, a mobile home or trailer, a group of rooms, or a single room occupied as separate living quarters, or if vacant, intended for occupancy as separate living quarters. Both occupied and vacant housing units are included in the total housing unit inventory. A housing unit is classified as occupied if it is the usual place of residence of a person or group of people; conversely, a housing unit is classified as vacant if it is not the usual place of residence of a person or group of people.

In Lane County, there are a total of 162,611 housing units, of which 93.7 percent are occupied. As such, the vacancy rate in Lane County is less than 7 percent. Linn County has the lowest number of housing units and vacancy rate of all counties within the ROI – 50,416 and 5.3 percent respectively. Marion County has 126,210 total housing units and a vacancy rate of 6.5 percent, the highest within the ROI. The vacancy rate in Oregon is higher than that of all counties in the ROI by at least 2.4 percent (USCB 2019c). Table 3.11-3 shows the total housing units, occupied housing units, and vacancy rates in Lane, Linn, and Marion counties and Oregon.

**Table 3.11-3. Housing Characteristics**

| Location | Total Housing Units | Occupied Housing Units | Vacancy Rate (%) |
|---|---|---|---|
| Lane County | 162,611 | 152,312 | 6.3% |
| Linn County | 50,416 | 47,762 | 5.3% |
| Marion County | 126,210 | 118,038 | 6.5% |
| Oregon | 1,768,901 | 1,611,982 | 8.9% |

Source: USCB, 2019c.

Fern Ridge Dam, Cottage Grove Dam, and Dexter Dam have at least 100 residential units in the immediate vicinity of the impounded reservoir (Google Earth 2020). Blue River Dam, Dorena Dam, Fall Creek Dam, Foster Dam, Lookout Point Dam, and Hills Creek Dam have at least 100 residential units within 1 mile of the structures and reservoirs (Google Earth 2020). No other structures within the WVS have substantial residential areas within 1 mile of the structure or its impounded reservoir.

### 3.11.3 Labor

Labor force and unemployment figures for the counties in the ROI are presented, as they are the most likely to be directly affected by the Proposed Action and alternatives.

#### *3.11.3.1 Civilian Labor Force*

The size of a county's civilian labor force is measured as the sum of those currently employed and unemployed. People are classified as unemployed if they do not have a job, have actively looked for work in the prior 4 weeks, and are currently available for work (BLS 2015). As shown in Table 3. 411-4, from 2010 to 2019, Lane County's labor force grew at the slowest rate within the ROI, 4 percent slower than the state as a whole. Although all counties within the ROI grew slower than the 6.4 percent growth rate of Oregon, the labor force of Marion County grew at 5 percent, faster than the other two counties within the ROI. Lane County added 4,194 persons to the labor force between 2010 and 2019, Linn County added 2,509 persons, Marion County added 7,507 persons, and the State of Oregon added 125,808 over this same period (BLS 2019a; 2019b; 2019c; 2019d). Table 3.11-4 shows the civilian labor force in Lane, Linn, and Marion counties and the State of Oregon for 2010, 2015, and 2019; as well as the growth rate of the labor forces for the aforementioned from 2010 to 2019.

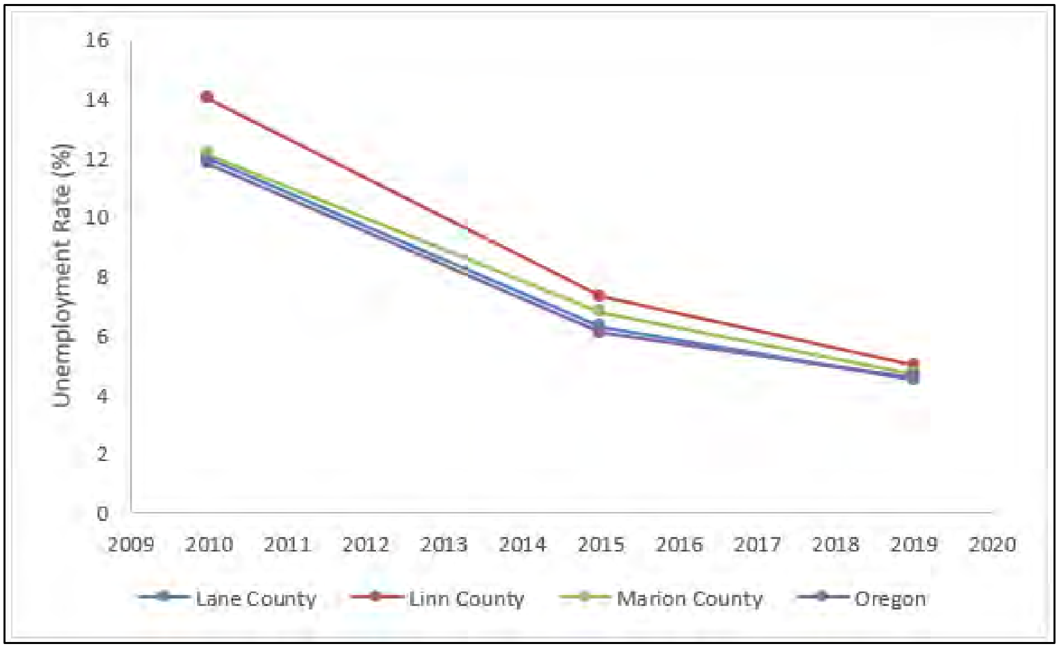
**Table 3.11-4. Civilian Labor Force, 2010-2019**

| Location | 2010 | 2015 | 2019 | Growth Rate of Labor Force (2010-2019) |
|---|---|---|---|---|
| Lane County | 177,650 | 170,048 | 181,844 | 2.4 |
| Linn County | 56,877 | 54,058 | 59,386 | 4.4 |
| Marion County | 151,234 | 148,376 | 158,741 | 5.0 |
| Oregon | 1,957,286 | 1,940,921 | 2,083,094 | 6.4 |

Source: BLS 2019a; 2019b; 2019c; 2019d.

#### *3.11.3.2 Unemployment*

The unemployment rate is calculated based on the number of unemployed persons divided by the labor force, where the labor force is the number of unemployed persons plus the number of employed persons. Figure 3.11-1 exhibits the annual unemployment levels in Lane, Linn, and Marion counties and the state overall for the years 2010, 2015, and 2019. Unemployment rates in all counties of the ROI are very similar to those of the state of Oregon; and both the ROI and state unemployment rates rose and fell with national trends. From 2010 to 2015, unemployment across the ROI and Oregon decreased from 5.3 to 6.7 percent, with unemployment in Linn County decreasing the most. Unemployment rates continued to decrease from 2015 to 2019.



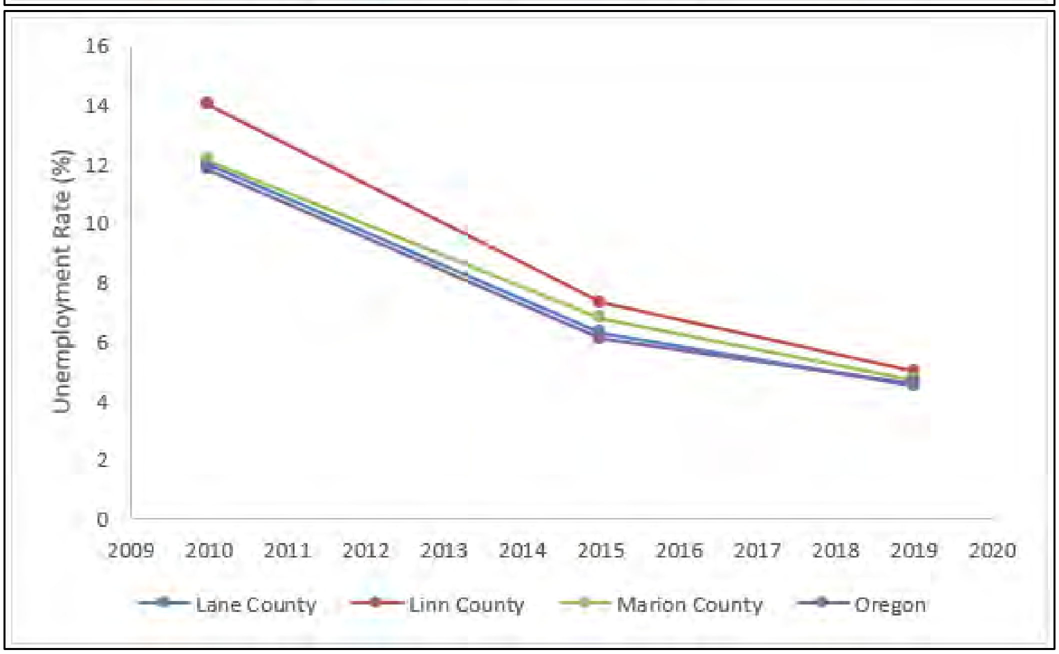


**Figure 3.11-1. Unemployment Rates (2010-2019)**

Source: BLS, 2019e; 2019f; 2019g; and 2019h.

### 3.11.4 Employment by Industry

Health care and social assistance, government, and retail trade employ the most people in Lane and Marion counties, whereas manufacturing, government, and health care and social assistance employ the most people in Linn County. Government employs 24,503 and 35,381 people in Lane and Marion counties, respectively; manufacturing employs 8,650 people in Linn County. Table 3. 11-5 shows the number of people employed by each industry in the ROI (OED 2019a; 2019b; 2019c).

**Table 3.11-5. Employment by Industry in the ROI, 2019**

| Industry | Lane County # Employed | Linn County # Employed | Marion County # Employed |
|---|---|---|---|
| Health Care and Social Assistance | 26,572 | 5,922 | 23,232 |
| Government | 24,503 | 6,498 | 35,381 |
| Retail Trade | 20,292 | 5,332 | 17,224 |
| Accommodation and Food Services | 15,737 | 3,419 | 11,914 |
| Manufacturing | 14,239 | 8,650 | 10,821 |
| Administrative and Waste Services | 8,673 | 1,833 | 8,156 |
| Construction | 7,430 | 3,237 | 10,928 |
| Other Services | 6,724 | 1,960 | 5,976 |
| Wholesale Trade | 6,189 | 1,670 | 3,755 |
| Professional and Technical Services | 5,811 | 931 | 4,465 |
| Finance and Insurance | 3,768 | 698 | 3,728 |
| Transportation, Warehousing, and Utilities | 3,492 | 3,071 | 5,148 |
| Management of Companies and Enterprises | 3,447 | 343 | 1,340 |
| Real Estate and Rental and Leasing | 2,572 | 466 | 1,821 |
| Information | 2,254 | 404 | 1,283 |
| Agriculture, Forestry, Fishing, and Hunting | 2,112 | 2,498 | 9,315 |
| Arts, Entertainment, and Recreation | 2,038 | 314 | 1,704 |
| Educational Services | 1,914 | 600 | 2,298 |
| Mining | 238 | 16 | 269 |
| Unclassified | 72 | 9 | 23,232 |
| **Total** | **158,077** | **47,872** | **158,839** |

Source: OED 2019a; 2019b; and 2019c.

### 3.11.5 Earnings

Several measures are used to describe earnings, including per capita personal income (PCPI), total industry income, and compensation by industry. Personal income data are measured and reported for the county of residence. PCPI, then, is the personal income for county residents divided by the county's total population. Compensation data, however, are measured and reported for the county of work location and are typically reported on a per job basis. Compensation data indicate the wages and salaries for work done in a particular place (e.g., a county), but if the worker does not live in the county where the work occurred then a sizeable portion will be spent elsewhere. These expenditures will not remain in or flow back into that county's economy. Total compensation includes wages and salaries as well as employer contribution for employee retirement funds, social security, health insurance, and life insurance.

### 3.11.5.1 Per Capita Personal Income

Personal income is the income received by a person from all sources. It is the sum of net earnings by place of residence, property income, and personal current transfer receipts or government social benefits (BEA 2016). This includes earnings from work, interest and dividends received, as well as government transfer payments, such as social security checks. It is measured before the deduction of personal income taxes and other personal taxes and is reported in current dollars.

Table 3.11-6 shows 2010, 2015, and 2019 annual PCPI for Lane, Linn, and Marion counties and the State of Oregon. All dollar estimates are in current dollars (not adjusted for inflation).

**Table 3.11-6 Per Capita Personal Income, 2010-2019**

| Location | 2010 | 2015 | 2019 | Average Annual Percent Change (2010-2019) |
|---|---|---|---|---|
| Lane County | $23,869 | $24,960 | $29,705 | 2.7 |
| Linn County | $22,165 | $21,706 | $27,345 | 2.6 |
| Marion County | $21,915 | $22,490 | $27,338 | 2.7 |
| Oregon | $26,171 | $27,684 | $33,763 | 3.2 |

Source: USCB 2010b; 2015b; and 2019d.

Note: All dollar estimates are in current dollars (not adjusted for inflation).

From 2010 to 2019, the PCPI grew at approximately 2.7 percent across the ROI, whereas the state's PCPI increased 3.2 percent over the same period. Similarly, all counties within the ROI had lower PCPIs than the state in 2010, 2015, and 2019.

### 3.11.5.2 Industry Compensation

The term "Total Industry Compensation", often used in economic data, is somewhat of a misnomer in that a portion of the "industry earnings" stems from government-related activity. For example, government and government enterprises account for 19.3 percent of total compensation of employees in Lane County; and government and government enterprises often account for a similar proportion of the compensation of employees in a county. Nevertheless, total industry compensation provides a good picture of the relative sizes of market-related economic activity, or business activity, performed in a county (Table 3.11-7). Income is generated by economic activity in the ROI through a variety of sectors, including various types of business as well as government. This income is not always received by a person living in the county; for example, a person from a neighboring county may cross county lines to go to work. The employee compensation by industry, however, is a measure of economic activity generated in the county, regardless of where the employee resides. The sources of economic activity in the ROI are shown below in Table 3.11-7.

**Table 3.11-7 Compensation of Employees by Industry in the ROI, 2019**

| Industry Description | Lane County Compensation ($000) | Linn County Compensation ($000) | Marion County Compensation ($000) |
|---|---|---|---|
| Government | 1,377,368 | 315,908 | 2,320,193 |
| Health Care and Social Assistance | 1,326,083 | 259,066 | 1,232,032 |
| Manufacturing | 764,321 | 533,490 | 494,078 |
| Retail Trade | 621,340 | 151,750 | 532,806 |
| Construction | 403,534 | 184,652 | 641,083 |
| Wholesale Trade | 357,999 | 93,317 | 229,618 |
| Professional and Technical Services | 337,681 | 53,078 | 300,056 |
| Accommodation and Food Services | 305,497 | 64,199 | 236,894 |
| Administrative and Waste Services | 291,019 | 58,773 | 271,990 |
| Finance and Insurance | 277,775 | 47,552 | 235,511 |
| Management of Companies and Enterprises | 241,715 | 29,355 | 95,323 |
| Other Services | 198,277 | 48,838 | 177,134 |
| Transportation, Warehousing, and Utilities | 161,035 | 145,217 | 296,052 |
| Information | 160,633 | 22,532 | 82,765 |
| Real Estate and Rental and Leasing | 103,058 | 15,410 | 74,624 |
| Agriculture, Forestry, Fishing, and Hunting | 90,145 | 109,374 | 310,361 |
| Educational Services | 69,066 | 25,356 | 92,170 |
| Arts, Entertainment, and Recreation | 39,433 | 5,374 | 33,214 |
| Mining | 14,800 | 779 | 18,626 |
| Unclassified | 4,159 | 332 | 3,337 |
| **Total Compensation of Employees** | **7,144,937** | **2,164,352** | **7,677,865** |

Source: OED 2019a; 2019b; and 2019c.

*Note: Numbers may not add to total due to rounding.

### 3.11.6 Quality of Life

Quality of life can be characterized as a person's well-being and happiness. According to USACE Quality of Life focuses on the extent to which objective human needs are fulfilled in relation to personal or group perceptions of well-being. For this analysis, quality of life considerations focus on those elements that the public generally associates with a high quality of life: education, safety, and could potentially be affected by the Proposed Action and alternatives: recreation opportunities, access to transportation facilities, and a positive general living environment, including aesthetic considerations. Other environmental factors, such as good ambient air quality and low ambient noise levels, could also contribute to a person's sense of quality of life.

#### *3.11.6.1 Recreational and Aesthetic Values*

The recreational value of natural resources can link residents to an area or attract new residents to an area. Environmental amenities such as reservoirs within the WVS contribute to the region's identity, culture and quality of life. Proximity to nature, in particular to public lands such as parks, beaches, national forests, and reservoirs throughout the WVS can influence where people choose to live and how much people are willing to pay for housing (i.e., property values). Research indicates that people make regional housing and labor market decisions based in part on the availability of and proximity to public lands, such as state parks, national forests, recreational lakes, etc. Living near public lands protecting natural habitats provides amenities such as convenient access to recreation and wildlife viewing. Population movement and migration into environmentally desirable areas can be explained by the presence of, and density of, natural resources and associated environmental amenities (Garber-Yonts 2004; Hand et al. 2008).

Landscape appearance and scenery can be important public land amenities, not just as recreational opportunity settings, but also as elements of the region's identity. Factors such as clean air and water, scenery and natural landscape, open space, and the number and proximity of recreational opportunities can be economic assets for local communities. Lane, Linn, and Marion counties foster community health by investing in parks, trails, and open spaces (Lane County 2018; Linn County 2008; Marion County 2010). A more detailed description of recreation opportunities in and around the project area is included in Section 3.14.

#### *3.11.6.2 Community Concerns*

During the scoping process, a number of concerns were expressed by residents of the ROI relating to socioeconomic resources, including impacts on the availability of water for agriculture and/or growing townships and potential impacts to the flood risk management capacity of the system as a whole. Within Lane County specifically, top general priorities for residents identified in a 2019 community needs survey included addressing housing shortages and rising rent prices, shelter space for the rising homeless populations, basic needs (bus passes, gasoline, identification, etc.) for the low-income population and domestic violence shelters and assistance (Lane County HHS 2019). Linn County is largely comprised of small rural communities which are increasingly concerned with water availability for crops and increased wildfire prevalence (Lacobazzi 2021). During scoping, the Marion County Board of Commissioners expressed great concern over lower water levels at Detroit Reservoir which could potentially reduce its recreational value; approximately 70 percent of the jobs in the Detroit Reservoir area are reliant on recreational use of the reservoir (USACE 2019f). Water quality and supply issues are also major concerns of residents of Marion County.

### 3.11.7 Environmental Effects

The effects analysis for socioeconomic resources evaluates the social and economic effects, both adverse and beneficial, of the construction, operation, management, rehabilitation, and replacement of structural measures and the alteration of reservoir outflows and water levels under the NAA and the action alternatives. The discussion includes the methodology; a summary of the effects; the effects by measure(s) that would affect socioeconomic resources; and a detailed analysis for each alternative.

#### *3.11.7.1 Methodology*

Potential effects to socioeconomics were evaluated both quantitatively and qualitatively for Lane, Linn, and Marion counties. The ROI is defined in the Affected Environment for this section as Lane, Linn, and Marion counties because this area is most likely to be affected by the alternatives.

1. Quantitative Analysis – Uses USACE National Economic Development (NED) modelling methods and USACE Regional Economic System (RECONS) to estimate the regional changes in employment, earnings, and total economic value which would result from changes in recreational visitation.
2. Qualitative Analysis – Considers how the proposed measures could affect labor and earnings; population and housing; low-income populations; recreational value and quality of life; irrigation, municipal and industrial, and hydropower production; and the non-use and existence value of the ESA-listed species. It also includes grounding of analysis through site visits and public outreach and engagement.

#### *3.11.7.2 Quantitative Analysis*

Several impact categories – including those associated with recreation (Section 3.14) and hydroelectric power generation (Section 3.12) – were modelled in order to quantify potential effects where possible. Average annual monetary benefits attributable to recreation alone were prepared using hydrographic inputs and USACE NED modelling methods (see Section 3.14 and Appendix K for detailed explanations of NED modelling). Monetary recreational benefit changes were then used as inputs in the USACE Regional Economic System (RECONS) to estimate the regional changes in employment, earnings, and total economic value which would result from changes in recreational visitation. RECONS is a proprietary USACE input-output modelling methodology that allows for the estimation of changes in economic contributions from a given investment (see Section 5.1 of Appendix K for a detailed explanation of RECONS methods). Changes in visitation due to alterations in recreational values associated with increased fish passage, habitat value, and reservoir levels would have indirect and induced effects that are reflected in the model results; they are incorporated below into the socioeconomic effects analysis.

#### *3.11.7.3 Qualitative Analysis*

Relevant case studies, understanding of common revenue or cost flows, and professional judgement concerning impacts typically associated with construction at dams and reservoirs were used to develop the evaluation criteria (discussed in the next section) and determine socioeconomic effects from the proposed measures in this PEIS. Effects to labor income, economic activity, or annual employment and therefore to population, community services (e.g., schools), and housing from the construction expenditures were modeled and are analyzed quantitatively, qualitatively, and programmatically in this Draft PEIS. Modelling results for construction spending economic activity stimulus are shown throughout Appendix I, “Socioeconomics.”

For water supply effects, ResSim flow data at the control points (river gages) downstream of dams and on the mainstem was used to compare flows between the action alternatives and the no action alternative to quantitatively assess impacts to live flow water rights downstream of the dams. Non-exceedance plots shown in Appendix J, “Water Supply”, Chapter 4, “Physical Effects Analysis” are used to illustrate the general trends between action and no action alternatives. As stated in Appendix J, “Water Supply”, Section 3.2” Data Collection and Preparation”, the effects to M&I water supply agreements and irrigation water service contracts were assessed by evaluating the amount of water stored system-wide in the conservation pool by mid-May, at a 75% non-exceedance level. A reliable method to compute NED monetary effects on M&I and irrigation water supply is yet to be determined as of this writing but is anticipated to be prepared for the Final EIS.

USACE uses ER 1105-2-100 and the Institute for Water Resources Handbook on Applying social effects analysis to evaluate qualitative impacts for this project. This includes looking at potentially impacted communities through basic social statistics, social vulnerability and resiliency indicators, social connectedness, economic vitality, leisure and recreation, participation and health and safety. These seven factors are used to formulate a complete qualitative analysis for socioeconomic impacts in the ROI.

The community could experience direct, indirect, or induced economic effects from employment and wages as a result of construction, operation, and maintenance of structures associated with the alternatives; and from differing utility rates, municipal and industrial (M&I) water supply, and irrigation water supply. Additionally, the quality of life for area residents (including low-income populations) and visitors could be affected due to traffic, noise, and emissions associated with construction activities and visual effects from drawdowns. Projected population increases as they relate to housing and quality of life are based on the number of direct jobs anticipated during the construction and operation phases. This section attempts to capture the effects to various community members competing for uses of the water and reservoir; as well as how society might value the very existence of the evolutionarily significant units (ESUs) and distinct population segments (DPSs) for the UWR Chinook salmon and UWR steelhead (respectively) with and without these proposed measures.

#### *3.11.7.4 Evaluation Criteria*

The magnitude of effects is determined using both the quantitative and qualitative portions of the analysis described above, as appropriate. Construction expenditures were also modelled for this Draft PEIS with results being displayed for each of the action alternatives beginning in sub-section 3.11.7.8. Most of the proposed measures (e.g., maintain revetments using nature-based methods, install gravel below dams) would not directly affect visitation; in these cases, the effects were analyzed qualitatively. Effects from changes in flow and reservoir levels that would affect visitation are discussed both qualitatively and quantitatively under each alternative, including the average annual NED recreational benefits, support of jobs, and the added value to the economy.

Evaluation criteria specific to socioeconomic resources, which capture the magnitude, duration, and extent of the potential effect, are provided in the below Table 3.11-8. These criteria are applied to each subcategory of socioeconomic resources relevant to this project (e.g., population and housing, quality of life) identified within the pathway analysis. All effects associated with each alternative are then considered in order to arrive at an overall conclusion for the alternative. The estimated beneficial effects of construction spending induced economic activity are considered to be major across all action alternatives, with total (direct + secondary) jobs supported low values of 7,400, 8,300, and 10,000 (Alt 3B), and high values of 25,900, 38,200, and 34,400 (Alt 1) at the local, state, and national level, respectively.

**Table 3.11-8. Evaluation Criteria for Potential Adverse and Beneficial Effects**

| Effect Factor and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | No appreciable change or measurable effect on the ROI's population and housing; economic activity, labor income, or annual employment; water supply; or quality of life. |
| Minor | A small but noticeable change to population and housing; economic activity, labor income, or annual employment; water supply; or quality of life in the ROI. Change in population would increase demand on housing, but would continue to operate below capacity. |
| Moderate | A substantive and apparent change to population and housing; economic activity, labor income, or annual employment; water supply; or quality of life in the ROI. Change in population would cause available housing to reach capacity. |
| Major | A significant and marked change in population and housing; economic activity, labor income, or annual employment; water supply; or quality of life in the ROI. The change in resident population would cause existing housing to be over capacity. |
| **Duration** | |
| Short Term | Less than the duration of a small construction project and/or is continuous for less than two years. |
| Medium Term (limited or intermittent) | Limited to the duration of large construction projects and/or is continuous for a period of two to five years. |

| Effect Factor and Scale | Definition |
|---|---|
| Long Term | Permanent or lasts continuously beyond operation changes or the completion of all projects or changes which recur either intermittently or at regular intervals annually. |
| **Extent** | |
| Local | Effects would be confined to the dam/reservoir. |
| Regional | Effects are perceived throughout a single county, multiple counties, or the entire WVS. |
| Statewide | Effects are perceived throughout the entire state. |

#### *3.11.7.5 Measures Analyzed for Socioeconomic Resources*

All measures other than adaptation of hatchery programs (#719) could potentially affect socioeconomic resources directly or indirectly.

The following measures would require the construction, modification, and/or operation and maintenance of structural facilities:

- Gravel augmentation below dams (#384)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Maintenance of existing and new fish release sites above dams (#726)
- Operation, Maintenance, Repair, Replacement and Rehabilitation
- Foster Fish Ladder Temperature Improvement (#479)
- Construct water temperature control tower (#105)
- Structural improvements to reduce total dissolved gas (#174)
- Restore upstream and downstream passage at drop structures (#639)
- Construct adult fish facility (#722)
- Provide Pacific lamprey passage and infrastructure (#52)
- Construct structural downstream fish passage (#392)
- Use regulating outlets for temperature management (#166)
- Continued Operation of Existing Adult Fish Facilities

The following measures would alter flows and reservoir levels:

- Fall Creek drawdown
- Augment instream flows by using the inactive pool (#718)

- Augment instream flows by using the power pool (#304)
- Integrated temperature and habitat flow regime (#30a)
- Refined integrated temperature and habitat flow regime (#30b)
- Deeper fall reservoir drawdowns for fish passage (#40)
- Spring reservoir drawdown for downstream fish passage (#720)
- Use spillway for surface spill in summer (#721)
- Pass water over spillway in spring for fish passage (#714)
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)

A summary of the socioeconomic effects discussed in the sections below is provided in Table 3.11-9. Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects reflected in the below is the largest extent that occurs under an alternative, even if the most severe adverse effect or the lesser beneficial effect is localized. This follows the approach to present the most conservative conclusions in this table. Discussion of all adverse and beneficial effects are included below.

### Table 3.11-9. Summary of Effects to Socioeconomic Resources Under Each Alternative

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| | Short-Term | | | | | | | |
| Magnitude | Negligible adverse and beneficial | Moderate adverse; minor beneficial | Minor to moderate adverse; negligible to minor beneficial | Minor to moderate adverse; negligible to minor beneficial | Major adverse; negligible beneficial | Major adverse; negligible beneficial | Moderate adverse; minor beneficial | Minor to moderate adverse; negligible to minor beneficial |
| Extent | Regional | Regional | Regional | Regional | Regional | Regional | Regional | Regional |
| | Medium-Term [1] | | | | | | | |
| Magnitude | Negligible adverse and beneficial | Moderate adverse; minor (non-monetary)/major (monetary) beneficial | Minor adverse; negligible to minor (non-monetary)/major (monetary) beneficial | Minor adverse; negligible to minor (non-monetary)/major (monetary) beneficial | Negligible adverse and beneficial (non-monetary)/major (monetary) | Negligible adverse and beneficial (non-monetary)/major (monetary) | Moderate adverse; minor beneficial (non-monetary)/major (monetary) | Minor adverse; negligible to minor (non-monetary)/major (monetary) beneficial |
| Extent | Regional | Regional | Regional | Regional | Regional | Regional | Regional | Regional |
| | Long-Term (Permanent, Intermittent, or Recurring) | | | | | | | |
| Magnitude | Major adverse | Minor adverse; negligible beneficial | Minor to moderate adverse; negligible beneficial | Minor to moderate adverse; negligible beneficial | Major adverse; negligible beneficial | Major adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor to moderate adverse; negligible beneficial |
| Extent | State-wide | Regional | Regional | Regional | Regional | Regional | Regional | Regional |
| Duration Type | Permanent | Recurring | Recurring | Recurring | Recurring | Recurring | Recurring | Recurring |

[1] Most monetary construction expenditure induced benefits would be realized in the medium term while construction is taking place. Therefore, both monetary (spending induced) and non-monetary (public quality of life) benefit descriptions are included in the medium term section of the table in order to avoid diluting the non-monetary benefits.

In the following subsections, the effects are discussed for the measures analyzed in the alternatives; No Action Alternative; and for each of the action alternatives.

#### *3.11.7.6 Discussion of Effects by Measure(s)*

The magnitude of effects for socioeconomic resources is highly contingent upon the timing and amount of capital expenditures. General trends in population and employment changes would be similar for similar types of measures. As such, this analysis outlines the general pathway (i.e., cascading direct and indirect socioeconomic effects stemming from the implementation of measures) that would occur. In order to avoid redundancy between analyses, measures with similar effect pathways are grouped together and fall into one of two categories: (1) those that would require the construction, modification, operation and maintenance of structural measures or (2) those that would alter flows and reservoir levels.

##### *3.11.7.6.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

This section discusses general, qualitative effects on socioeconomic resources from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects.

Construction, modification, operation and maintenance of 13 structural measures listed above in 3.11.2.3) would adverse and beneficial effects on labor and earnings; population and housing; recreational value; quality of life for local residents; and low-income populations in the short and medium term. The provision of capital expenditures and indirect and induced effects of resulting revenues in the short and medium term would stimulate economic growth within the ROI and have negligible to minor beneficial effects on labor and earnings in the short term and major benefits in the medium term. Any increase in population would be small and housing would be available to meet this increased demand and as such effects would also be negligible to minor. Although reduced recreational values are a substantial source of public concern associated with the project, given the scale and duration of individual projects, substantial adverse impacts to recreational quality from construction disturbance would not occur. As such, the recreational value of reservoirs as well as the quality of life for local residents would be reduced and have negligible, adverse effects for the duration of the construction period(s). In the long term, improved habitat value would increase recreational fishing and visitation and have minor, beneficial, indirect effects on the recreational value of reservoirs. Low-income populations would experience negligible to minor health benefits through economic pathways in the short-and medium term if they are hired as construction workers, but could also experience negligible to minor adverse health effects from air emissions and noise at the job site; these benefits would only persist in the long term if they are hired for maintenance and operation. In the long term, structural improvements and their continued maintenance would have indirect, beneficial effects on the recreational experience and could increase recreational visitation and expenditures. Implementation of the structural measures would benefit or increase the existence value of the ESA-listed species, or the amount the average citizen is willing to pay to avoid jeopardizing the continued existence of ESA-listed species.

**Labor and Earnings**

Construction and maintenance of structural measures would provide economic benefits through direct expenditures to local firms and labor, indirect benefits through expenditures of employees at retail establishments, and induced benefits as those revenues stimulate consumer demand throughout the ROI. Although the majority of the construction labor would be sourced from specialized contractors located outside the ROI, these revenues would likely result in the support of a relatively small number of construction and maintenance jobs sourced from within the ROI for the duration of the construction period. While the majority of the construction labor would be sourced from specialized contractors located outside the ROI, it is assumed that most would commute to project sites daily and a small proportion of these workers would relocate to the ROI (effects to population are discussed below). Construction and maintenance materials would be sourced from local vendors whenever possible and would likely contribute to the indirect support of jobs within the area. Spending of construction and maintenance workers employed on the project would also likely increase revenues at local retail stores and restaurants during the construction period, resulting in induced (i.e., third-order) economic benefits.

The direct, indirect, and induced effects of increased revenues would commensurately increase consumer demand for the duration of the construction period. The expenditures and their associated effects would occur in the short- and medium-term and are not likely to persist beyond the construction period other than the potential support of a small number of maintenance jobs associated with the constructed works of improvement. The magnitude of the benefit is contingent upon the level of expenditure associated with a given measure; larger expenditures will generate substantially larger direct, indirect, and induced economic effects. Capital and design expenditures range from approximately $500million to over $2.6 billion under the various alternatives. Beneficial effects would be major in the medium term, while construction activities are taking place, depending on the amount of the capital expenditure.

**Population and Housing**

As mentioned above, the majority of the construction labor would be sourced from specialized contractors located outside the ROI. It is assumed that most of these construction workers located outside of the ROI would commute to project sites daily, and a small proportion of these workers would relocate to the ROI. Any increase in resident population change would likely be small, and would decrease housing vacancy, but all would continue to operate below capacity. The average vacancy rate in the ROI is six percent. This translates to approximately 21,100 available housing units in Lane, Linn, and Marion counties (USCB 2019c). While it is difficult to estimate the exact level of in-migration for the construction activities, the ROI would likely have housing available to fill any increased demand. As such, effects on population and housing would be negligible to minor in the short and medium term.

**Recreational Value**

During the construction and maintenance activities, increased noise, visual presence of heavy equipment and personnel, and increased emissions would degrade the recreational value of reservoirs and decrease visitation and associated expenditures from current levels. Recreational users contribute to the economy of the ROI through the expenditure of funds in support of their activity of choice, such as specialized sporting equipment, licensing, hiring of guides, fuel, food, and lodging. Construction-related activities using heavy equipment generate relatively high levels of noise and emissions while in use and would be a visual disturbance when present in natural recreation areas such as reservoirs. Indirect, adverse effects could also occur to the quality of recreational fishing in reservoirs and on rivers for some species due to increased turbidity from suspended sediment associated with construction measures. As a result, adverse effects to recreational quality would range from negligible to moderate in the immediate vicinity of the work area for the duration of the given action, and reduce both the number of visitors and their corresponding expenditures (See Section 3.14 for a comprehensive discussion of effects to recreation). Effects would occur in the short and medium term for construction of structural measures. Major maintenance and rehabilitation projects would last longer than two years (i.e., occur in the medium term) and are expected to occur intermittently over the period of analysis for this PEIS.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would allow for the re-opening of recreational fisheries. However, other species including those within recreational fisheries would also benefit from improved habitat value. Angler satisfaction is highly correlated with catch sizes and rates (Beardmore et al. 2015), both of which would likely increase in response to improved recreational habitat within the ROI. Water quality improvements resulting from these works would similarly improve recreational qualities and visitation throughout the ROI. As a result, recreational fishing use and visitation within the ROI would likely increase in the long term, providing increased licensing, retail, and travel revenues for the life of the project. These minor, beneficial effects would be indirect because they would be caused by the action and would occur later in time or be farther removed in distance, but still be reasonably foreseeable.

**Quality of Life**

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 1994 to nearly 10,000. These reservoirs would continue to be slowly developed.

The same factors which degrade recreational quality would similarly be nuisances to local residents, reducing the overall quality of life. Construction and/or structural modification projects would increase air emissions at and near the project site due to project worker commutes and the transport of heavy equipment to and from the dam/reservoir via heavy trucks. Similarly, increased noise levels and visual intrusions would occur from equipment, machinery, and human activity during the construction period, and could disturb nearby residents. Use of local roadways during work periods for transport of workers and materials would temporarily increase traffic levels and average length of transit for nearby communities and could reduce resident access to community resources such as places of worship, recreational facilities, and healthcare. However, effects would be confined largely to the immediate vicinity of project sites during work periods. Negligible to moderate adverse effects would occur in the short and medium term to the quality of life or physical health and well-being of local residents – especially in the towns of Detroit, Lowell, Veneta, and Sweet Home at Detroit, Dexter, Fern Ridge, and Foster Dams, respectively.

In the long term, air emissions, traffic, and noise disturbances from operation and maintenance activities would not affect the quality of life of nearby residents. As discussed in Section 3.23 (Visual Resources), erection of these new structures would not drastically alter any of the basic design elements in the landscape; they would be seen but would not attract attention and would not dominate the landscape and as such would have negligible to minor, adverse effects.

**Low-Income Populations**

Effects that could disproportionately affect minority communities and Tribes are discussed in the Environmental Justice section. As described in Section 3.20.1, low-income populations were not identified as Environmental Justice populations as per EO 12898. However, potential effects to low-income populations are described briefly here in response to public comments. Within Lane County specifically, top priorities for residents identified in a 2019 community needs survey included addressing housing shortages and rising rent prices, shelter space for the rising homeless populations, basic needs (bus passes, gasoline, identification, etc.) for the low-income population and domestic violence shelters and assistance (Lane County HHS 2019).

If low-income populations in Lane, Linn, and Marion counties are hired to work on these projects, they could experience negligible to minor health benefits through economic pathways in the short and medium term. Jobs and income are strongly associated with a number of beneficial health outcomes such as an increase in life expectancy, improved child health status, improved mental health, and reduced rates of chronic and acute disease morbidity and mortality (HDA 2004; Cox et al. 2004). There may also be negligible to minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects. Once construction is complete, workers would not be on-site and therefore there would be no long-term health effects. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. The magnitude of the benefit is contingent upon the effect to labor and income, which as discussed above, is contingent upon the level of expenditure associated with a given measure. Larger expenditures will generate substantially larger direct, indirect, and induced economic effects and therefore larger economic effects on low-income populations. Capital and design expenditures range from approximately $500 million to over $2.6 billion under the various alternatives.

As mentioned above, the ROI may experience a small increase in population and decreased housing vacancy in the short and medium term, but housing would still operate below capacity. The vacancy rate in Lane, Linn and Marion counties is 6.3, 5.3, and 6.5 percent, respectively. This translates to roughly to 10,245, 2,672, and 8,204 available housing units (USCB 2019c). Approximately 50 percent of these units are considered affordable housing (State of Oregon 2022). As such, the short- and medium-term construction projects should not affect any ongoing housing shortages for low-income populations and are not discussed further.

Oregon now has rent control that limits rent increases for existing tenants. Rent cannot be increased during any 12-month period above the existing rent in an amount greater than 7% plus the consumer price index from the previous calendar year (OSB 2019). Furthermore, as discussed above, any in-migration from the construction of structural measures would not likely be substantial. This in-migration should not affect the availability of general or affordable housing within the ROI, is not expected to increase rents in the short or medium term; and therefore, is not discussed further.

As such, both beneficial and adverse effects on low-income populations would be minor in the short and medium term, with the possibility of greater medium term economic activity benefits if local firms are awarded construction contracts. Negligible long-term effects are anticipated.

##### *3.11.7.6.2 Alteration of outflows and reservoir levels*

The ten measures listed in Section 3.11.2.3 would alter flows and reservoir levels, decreasing recreational values, the quality of life of nearby residents, visitation, and the amount of usable water for M&I and irrigation purposes. Reservoir drawdowns would indirectly reduce recreational and agricultural revenues and their resulting induced effects to consumer demand throughout the ROI in the short term and recur in the long term. The magnitude of effects to recreational value would range from minor to major and would be regional in extent. Effects to agricultural revenues would range from negligible to major and be regional in extent. The magnitude for both recreational value and agricultural revenue under each alternative would depend on the number of drawdowns; effects to agricultural revenue would be especially sensitive to the timing of the drawdowns.

In the long term, improved habitat value throughout the region would benefit other fish species in addition to the UWR Chinook salmon and the UWR steelhead, and have indirect, minor benefits to the quality of recreational fisheries and the recreational experience throughout the ROI. Measures that augment instream flows and the integrated temperature and habitat flow regime would improve water quality and also benefit recreational qualities and visitation throughout the ROI. Conversely, the reduction of minimum flows to Congressionally authorized minimum flow requirements (#723) would allow reservoirs to fill more quickly, thereby improving recreational values, visitation, and their ability to supply water for other uses. This measure would generate negligible to minor beneficial socioeconomic effects through indirect and induced revenues associated with recreational use and agricultural without substantially affecting recreational fisheries in the long term. None of the considered outflow measures would substantially affect utility rates due to the relatively low proportion of power provided by WVS to the BPA.

**Recreational Value**

Reservoir drawdowns would reduce water levels and substantially decrease recreational use and the recreational value of the reservoir, indirectly affecting socioeconomic resources throughout the ROI. The change in average annual visits, percent change in total annual benefits, and magnitude of effects from reservoir drawdowns are presented under each alternative in Section 3.14 (Recreation). The full results of the modeled visitation estimates are included in Appendix K – Recreation Technical Report. As discussed at length above, recreational users contribute to the economy of the ROI through the expenditure of funds in support of recreational activities and result in induced effects through increased retail revenue streams. These short- and long-term recurring adverse effects would range from minor to major and be regional in extent. The magnitude of effects under each alternative would depend on the number of drawdowns per year and the number of reservoirs at which they would occur. Effects would be major if they result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI.

Indirect effects from drawdowns to the quality of recreational fishing in reservoirs and on rivers for some species due to increased turbidity from suspended sediment could occur in the short-term and recur in the long-term. In the long term, reservoir drawdowns would improve downstream riverine habitat quality for ESA-listed fish species, recreational fisheries, and water quality throughout the ROI. It is important to note that reservoir visitation provides a far greater proportion of recreational revenues within the ROI than riverine visitation.

**Irrigation, M&I Use, and Hydropower Production**

Drawdowns would affect socioeconomic resources due to the decrease in water available for the other authorized uses: agricultural irrigation, M&I use, and hydropower production. WVS water reservoirs allocate water proportionally based on the authorized uses of the structure. Based on the recommendation in the Willamette Basin Review Feasibility Study Chief's Report, Congress reallocated the conservation storage space in the WVS of reservoirs from all joint-use storage to three specific authorized purposes – fish and wildlife (69%), agricultural irrigation (21%), and municipal and industrial water supply (10%).

Reservoir drawdowns in support of ESA-listed fish passage reduce the amount of water available for other authorized purposes, which in turn increase costs attributable to water supply to WVS water right holders throughout the ROI. M&I users are typically able to supplement water supply with purchases from other areas, however these purchases inevitably increase costs and can have reverberating adverse socioeconomic effects throughout ROI associated with general increases in the cost of living and doing business. In the long term, irrigation water rights holders may be unable to secure additional water rights. Those in the agricultural sector may ultimately be forced to fallow normally productive acreage or suffer extensive crop damages or losses without access to a consistent water supply during the summer irrigation season. See Section 3.13 for a comprehensive discussion of effects to water supply. The magnitude of adverse effects to irrigation and M&I use is contingent upon both the scale (i.e., the drawdown elevation) and timing of the drawdown. Spring drawdowns reduce the recharge ability of WVS system-wide and occur during periods of highest use for both agricultural irrigation and M&I purposes. Hence, spring drawdowns would result in major adverse socioeconomic effects from reduced water availability for agricultural irrigation and M&I purposes. Conversely, fall drawdowns would occur during periods with minimal WVS water use and would only result in negligible to minor socioeconomic effects. As such, adverse effects attributable to water supply would range from negligible to major in the short term and would recur in the long term.

Reservoir drawdowns may also reduce the economic viability of the WVS to generate hydropower. Water reductions from the power pool decrease the ability of WVS generators to produce sufficient wattage to outweigh the costs associated with the construction and maintenance of its requisite equipment and allocations (See Section 3.12 for a comprehensive explanation of hydropower effects.) However, it is unlikely that any drawdowns would measurably affect electricity prices within the ROI. Although reservoir drawdowns compromise the ability of WVS to generate hydropower and in turn lower revenues attributable to WVS reservoirs, BPA determines power rates through a formal evidentiary hearing process based upon the respective associated costs of generation and transmission throughout the entire BPA power grid (BPA No Date). Given that the WVS only provides some 2 percent of the total BPA generation capacity, it is unlikely that the reduced economic viability of WVS generators due to drawdowns would substantially or noticeably affect power rates and therefore socioeconomic resources in the ROI. There would be either no effect to socioeconomic resources as they relate to hydropower and therefore are not discussed further in this section.

Conversely, the reduction of minimum flows to Congressionally authorized minimum flow requirements (#723) would allow reservoirs throughout the WVS to fill more quickly in the long term, thereby improving recreational values, visitation, and their ability to supply water for other uses. These factors would have negligible to minor, beneficial effects for the life of the project through the same mechanisms and pathways discussed at length above. Recreational revenues and visitation would likely increase due to increased recreational quality of reservoirs, and agricultural and M&I reservoir streams would be largely unaffected as reservoirs would be able to fulfill their existing water right obligations.

**Quality of Life**

The loss of surface water during reservoir drawdowns would adversely affect the viewshed and therefore quality of life of nearby residents. Mudflats, substrate, tree stumps, and other submerged littoral zone attributes (submerged vegetation, roots, sediments, rocks, snails, shells, etc.) would also be revealed. There would be minor to moderate short- and long-term effects to the viewshed and therefore quality of life of nearby residents – especially in the town of Detroit, which is located on the shores of Detroit Dam and Reservoir. The town on Detroit is currently in the process of being rebuilt after it was destroyed in the 2020 Beachie Creek Fire. At the time, there were approximately 200 people living in the town. Over 50 percent of the population were forced to move away permanently after the fire, and today the population only numbers 72 (KGW 2022; USCB 2022). (The towns of Lowell, Veneta, and Sweet Home at Dexter, Fern Ridge, and Foster Dams would not be affected because drawdowns are not proposed at these locations under any of the alternatives). After the 3-week drawdown period, the viewshed would return to baseline conditions in the days to weeks that follow; and these effects would recur annually in the long term.

**<u>Suite of Near-Term Operations</u>**

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. For reasons similar to those discussed above as they relate to recreational value; agricultural irrigation and M&I use; and quality of life, effects to socioeconomic resources would range from minor to major and adverse in the short term and long term (recurring). Recreational revenues and visitation would likely further decrease due to decreased recreational quality of reservoirs; costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss or surface water and turbidity would adversely affect the viewshed for nearby residents for longer than three weeks.

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long term.

#### *3.11.7.6.3 Effects Common to All Measures*

Non-use and existence values of the UWR Chinook salmon and UWR steelhead would benefit from both the construction, operation, management, rehabilitation, and replacement of structural measures as well as those that alter outflows and reservoir levels. The larger purpose of all measures is to avoid jeopardizing the continued existence of these ESA-listed species; therefore, their existence values would generally be preserved.

**<u>Non-Use and Existence Values</u>**

The value assigned to natural resources by the public for purposes other than direct use is called non-use value and is well-documented in socioeconomic literature (Brookshire et al. 1983). There is value in knowing that UWR Chinook salmon and UWR steelhead exist, even for those who have never seen one or have no particular or vested interest in either species. The existence value of these species reflects the benefit people receive from knowing that it exists, or its intrinsic value.

In general, it is not possible to use market prices or other revealed preference methods (e.g., consumer behavior) to capture the existence value of the wild UWR Chinook salmon and UWR steelhead, which are genetically distinct from hatchery Chinook and steelhead and are not fished recreationally or commercially. As such, the concept of non-use or existence values are controversial, given the high variance in public opinion regarding protected species and the logistical difficulty of estimating their value. Typically, existence values are estimated using "stated preference" survey methods such as the contingent valuation. These surveys involve directly asking people, based on a specific hypothetical scenario and description of the environmental good or service, how much they would be willing to pay (WTP) for a positive change in that environmental good or service. These valuations provide an approximate monetary baseline for comparisons to other market effects.

Despite the cultural importance of salmon in the Pacific Northwest, there are few empirical economic studies quantifying and monetizing this importance to the general public in the region. There are many competing uses for Oregon's waters, and decision-makers are often faced with trade-offs on how to allocate resources to accommodate these uses. Many of these uses conflict with salmon preservation and to date there is not adequate information to quantify societal values for salmon conservation. In 2015, the EPA Western Ecology Division developed a stated preference nonmarket valuation study to estimate the general Oregon population's preferences and values to protect and restore Chinook salmon and winter steelhead populations in the Willamette Basin (Papenfus and Weber 2015). The results of this study have been requested and will be included in the FEIS, if provided. The magnitude of effects will also be added based on the results of this study. But regardless of the exact dollar value that people would be willing to pay to help preserve these species of salmon, implementation of all the proposed measures would help preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society. Without these proposed measures, these species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – could, quite literally, cease to exist in the WRB; the resulting loss of their existence values would be major and adverse.

It is important to note that implementation of the proposed structural and water management measures is not expected to increase UWR Chinook salmon and steelhead populations such that recreational and commercial fisheries for either species would be available in riverine or oceanic environments. Hence, implementing measures that would help avoid jeopardizing the continued existence of these ESA-listed species would have no effect directly on the other subcategories of socioeconomic resources (e.g., labor and earnings, agricultural irrigation, etc.) in the area.

### *3.11.7.7 No Action Alternative*

Under the NAA, current actions within the WVS and the conditions that would result from continued O&M would persist. Direct and indirect beneficial and adverse effects to socioeconomic resources from short- and medium-term construction measures would be negligible and localized or regional in extent. Effects in the short and long term (recurring) Fall Creek Drawdown would be minor and localized. This alternative would jeopardize the continued existence of the ESA-listed species and therefore have major effects in the long term if they no longer have an existence value because they cease to exist. The extent of these effects would be state-wide and beyond.

#### *3.11.7.7.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

Under the No Action Alternative, short-term construction measures like maintaining or altering revetments (#9) and augmenting gravel below dams (#384), as well as medium-term, major rehabilitation measures would have negligible beneficial effects to labor and earnings. Labor trends – including employment by industry, per capita income, and compensation by industry – would ebb and flow in conjunction with prevailing market conditions within the ROI and the state of Oregon, but would likely continue to trend favorably when considered over the life of the project given standard assumptions of economic growth. The extent of effects to labor and earnings would be regional.

Population growth would continue along current growth trajectories as described in Table 3.11-1, less than 1 percent annually (PSU 2021a; PSU 2021b). Housing availability would continue to scale with population. Effects to population and housing would be negligible and the extent of effects would be regional.

Short- and medium-term construction measures would increase air emissions, noise levels, traffic, or visual disturbances at and near the project site (and therefore effects would be localized) and cause negligible, adverse effects to the physical health and well-being of workers (including low-income workers) hired to work at the project, as well as the quality of life of communities residing in the vicinity of the impacted reservoirs. Workers (including low-income workers) would also experience negligible health benefits through economic pathways. Any increases in air emissions, noise, and traffic would not be appreciable and have negligible effects on recreational value.

#### *3.11.7.7.2 Alteration of outflows and reservoir levels*

The Fall Creek Drawdown would continue to adversely affect the quality of life for nearby residents and the recreational value at Fall Creek. However, there are no cities directly on the shores of the Fall Creek Reservoir, therefore effects to the quality of life would be minor and localized. As discussed in Section 3.14.2.3 of the recreation section, the NAA is the baseline for which visitation estimates are made, therefore there would be no effects to average annual visits or average annual benefits (and to recreational value). There would be negligible, regional, short- and long-term recurring effects to water supply from one drawdown occurring in the fall at one location.

#### *3.11.7.7.3 Effects Common to All Measures – Non-Use and Existence Values*

Measures under the NAA would not meet ESA obligations to avoid jeopardizing the continued existence of ESA-listed species. In the long term, the UWR Chinook salmon and UWR steelhead could cease to exist and therefore would not have an existence value. Society would not have the option to pay to protect the species and therefore effects would be major and occur state-wide and beyond.

#### *3.11.7.7.4 Climate Change*

As discussed in Appendices F1 and F2 (Qualitative Assessment of Climate Change Impacts and Supplemental Climate Change Information, respectively), climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors would contribute to indirect adverse effects to socioeconomic resources through decreased recreational quality and opportunity as well as ability to supply water to irrigation and M&I users.

As discussed in Appendix B, Hydrology and Hydraulics, higher winter reservoir inflows due to more precipitation falling as rain would not be stored until approximately February 1, when WVS reservoirs begin adhering to their rule curves. This would decrease the chance of reservoirs reaching the pool levels they had in previous years, which could shorten the recreational season, lower recreational opportunity, and the ability of reservoirs to provide agricultural irrigation and M&I water supply. Other trends would contribute to these adverse effects: less snowpack would decrease spring reservoir inflows, and drier, hotter summers (in terms of both air and water temperatures) would increase evaporation rates and further limit water quantity. Higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would contribute to decreased water quality from higher turbidity, elevated concentrations of contaminants such as mercury, and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish habitat).

Under the NAA, the Fall Creek Drawdown would have minor effects on recreational value and the quality of life of nearby residents in the short term; these effects would recur in the long term. Decreased reservoir levels and water quality due to climate change would further decrease both the recreational quality of reservoirs and riverine resources as well as the visitation of recreational users, which would indirectly reduce recreational revenues throughout the economy of the ROI. Recreational activity within the ROI is largely dependent upon both water quantity and quality due to the prevalence of water-based activities such as boating, fishing, and swimming. Recreation contributes indirect socioeconomic effects in the forms of recreational visitor expenditures at local retail establishments in support of their activity of choice; recreational expenditures are a function of both the quality of recreational opportunities offered within a given area and the total amount of recreational visits. Decreased recreational quality and lowered visitation rates would decrease recreational expenditures throughout the ROI, thereby contributing indirect, adverse effects to socioeconomic resources. Climate change could exacerbate short-term effects from sediment transport during drawdowns, as increased wildfire ash, HABs, and erosion would further increase turbidity and water quality; affecting the recreational experience and visitation. The overall water level could be further reduced in the long term. As such, the Fall Creek Drawdown in combination with climate change would have minor to moderate effects to recreational value and the quality of life in the short term and recur in the long term. Effects would be localized and would only be felt at the Fall Creek Reservoir.

Under the NAA, adverse effects on water supply from the Fall Creek Drawdown would be negligible in the short term and would recur in the long term. Decreased reservoir levels and water quality due to climate change would further contribute indirect adverse effects through the difficulty of reservoirs to supply agricultural and M&I users with a reliable source of water. However, the Fall Creek drawdown occurs in autumn during periods with minimal WVS water use. As such, the Fall Creek Drawdown in combination with climate change would have negligible effects on water supply for agricultural and M&I users in the short and long term (recurring). The extent of effects would be regional and occur throughout the WVS.

Measures under the NAA would not meet ESA obligations to avoid jeopardizing the continued existence of ESA-listed species. Society would not have the option to pay to protect the species and therefore effects would be major if they cease to exist. Climate change could further exacerbate conditions and move up the timeline for the extinction of these DPS. As such, the NAA in combination with climate change would have even more severe adverse and major effects if the species' existence value is not preserved. Effects would occur state-wide and beyond.

#### *3.11.7.8 Alternative 1 – Storage-Focused Fish Passage Alternative*

Alternative 1 consists of structural improvements and alteration of reservoir outflows measures which maximize refill volumes of spring conservation pools at WVS reservoirs in support of improved survival of ESA-listed fish species in addition to all other authorized project purposes of the structures. Under Alternative 1, beneficial effects to labor and earnings and low-income populations due to construction expenditures for structural measures would be minor in magnitude, regional in extent, and occur in the short term, with major economic activity beneficial effects in the medium term while construction is occurring. These benefits would stem from large capital expenditures and increased water levels. Short- and medium-term adverse effects to population and housing would also be minor and regional. Adverse effects to quality of life and recreational value from construction would be moderate in magnitude in the short and medium term; and could be either localized or regional in extent. Long-term visual effects to quality of life from the erection of new structures would be minor. Beneficial, indirect effects to recreational value from construction measures and reduced flows would be minor in magnitude, regional in extent, and long-term. The alteration of outflows and reservoir levels would have beneficial, moderate effects on water supply in the short and long term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor, beneficial effects to society in the state and beyond. Alternative 1 would have similar effects to socioeconomic resources as Alternative 4, and would have substantially more adverse short- and medium-term effects to labor and earnings and quality of life (and less adverse short and long-term recurring effects to recreational value and M&I use and irrigation) than Alternatives 2A, 2B, 3A, 3B, and 5.

#### *3.11.7.8.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The following measures would substantially increase construction expenditures within the ROI for the duration of the construction phase, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (Basinwide);
- Gravel augmentation below dams (#384) (FOS, CGR, BLU, BCL);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, FOS, GPR, BCL, DET);
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Construction of WTC towers (#105) (LOP, GPR, DET);
- Structural improvements to reduce total dissolved gas (#174) (DEX, LOP, CGR, FOS, GPR, DET);
- Restoration of upstream and downstream passage at drop structures (#639) (FRN);
- Construction of AFFs (#722) (GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (FRN, GPR);
- Construction of structural downstream fish passage (#392) (DEX, LOP, FOS, GPR, BCL, DET); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation (All reservoirs).

**Labor and Earnings**

Construction and design expenditures associated with Alternative 1 are expected to total approximately $42.4B over the life of the project; construction expenditures would be the second highest of the alternatives. Given the scale and duration of construction activities proposed under Alternative 1, the direct, indirect, and induced effects of increased revenues could noticeably increase consumer demand for the duration of the construction period. As discussed above in Section 3.11.2.4.1, these expenditures would provide benefits through direct expenditures to local firms and labor, indirect benefits through expenditures of employees at retail establishments, and induced benefits as those revenues stimulate consumer demand throughout the ROI. However, these expenditures and their associated effects would not persist beyond the construction period other than the potential support of a small number of maintenance jobs associated with constructed works of improvement. These effects would occur in the short and medium term and the effects would be regional in extent.

**Table 3.11-10. Effects of Construction Spending Under Alternative 1**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $1,503,897,497 | 16931.5 | $1,194,676,738 | $674,381,700 |
| Secondary Impact | | $1,440,822,887 | 8921.6 | $482,915,809 | $823,366,932 |
| Total Impact | $1,503,897,497 | $2,944,720,384 | 25853.1 | $1,677,592,546 | $1,497,748,632 |
| **State** | | | | | |
| Direct Impact | | $1,556,941,658 | 17374.6 | $1,287,229,867 | $763,254,019 |
| Secondary Impact | | $1,932,626,691 | 10778.2 | $656,061,797 | $1,099,977,674 |
| Total Impact | $1,556,941,658 | $3,489,568,348 | 28152.8 | $1,943,291,663 | $1,863,231,694 |
| **US** | | | | | |
| Direct Impact | | $1,557,023,568 | 17375.4 | $1,307,603,687 | $782,868,065 |
| Secondary Impact | | $3,656,985,703 | 17014.2 | $1,136,087,229 | $1,963,692,328 |
| Total Impact | $1,557,023,568 | $5,214,009,271 | 34389.6 | $2,443,690,917 | $2,746,560,394 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 1 shown in Table 3.11-10 are explained by project in the following four paragraphs.

**Foster and Green Peter** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $62,490,000. Of this total expenditure, $60,319,377 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $62,490,000 support a total of 995.9 full-time equivalent jobs, $61,912,920 in labor income, $50,750,618 in the gross regional product, and $106,390,923 in economic output in the local impact area. More broadly, these expenditures support 1,407.7 full-time equivalent jobs, $97,889,290 in labor income, $110,230,026 in the gross regional product, and $209,258,233 in economic output in the nation.

**Detroit and Big Cliff** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $708,350,000. Of this total expenditure, $683,377,658 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $708,350,000 support a total of 11,537.7 full-time equivalent jobs, $779,881,320 in labor income, $669,962,926 in the gross regional product, and $1,321,467,789 in economic output in the local impact area. More broadly, these expenditures support 15,567.5 full-time equivalent jobs, $1,114,235,625 in labor income, $1,249,502,938 in the gross regional product, and $2,372,028,636 in economic output in the nation.

**Cougar and Blue River** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $20,700,000. Of this total expenditure, $20,015,454 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $20,700,000 support a total of 350.7 full-time equivalent jobs, $22,005,883 in labor income, $20,458,695 in the gross regional product, and $39,937,721 in economic output in the local impact area. More broadly, these expenditures support 458.5 full-time equivalent jobs, $32,426,121 in labor income, $36,514,027 in the gross regional product, and $69,317,418 in economic output in the nation.

**Hills Creek, Lookout Point, Dexter, Fall Creek** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $765,500,000. Of this total expenditure, $740,185,008 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $765,500,000 support a total of 12,968.8 full-time equivalent jobs, $813,792,423 in labor income, $756,576,393 in the gross regional product, and $1,476,923,951 in economic output in the local impact area. More broadly, these expenditures support 16,955.9 full-time equivalent jobs, $1,199,139,881 in labor income, $1,350,313,403 in the gross regional product, and $2,563,404,984 in economic output in the nation.

**<u>Population and Housing</u>**

As discussed above in Section 3.11.2.4.1, given the current availability of approximately 21,100 housing units within the ROI (USCB 2019c), any small in-migration resulting from construction projects is not expected to substantially affect housing availability for current residents. As such, minor, adverse effects to population and housing would occur under Alternative 1. These effects would occur in the short and medium term and be regional in extent.

**Quality of Life and Recreational Value**

As discussed above in Section 3.11.2.4.1, work-related activities involving heavy equipment would cause visual and auditory disturbance to local residents and recreational users in the vicinity of the project areas, as well as reduce air quality from project-related emissions. Traffic levels would similarly increase during work periods but would be confined to the immediate vicinity of work sites and would not substantially reduce resident access to community resources or visitor access to reservoirs. Work-related noise, emissions, and congestion would reduce resident quality of life and recreational value during the construction phases only and have local, adverse, moderate effects in the short and medium term. Long-term visual effects from the erection of new structures would be minor.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have minor, beneficial, indirect effects on the local recreational value of affected reservoirs.

**Low-Income Populations**

As discussed above in Section 3.11.2.4.1, if low-income populations in Lane, Linn, and Marion counties are hired to work on these projects, they could experience health benefits through economic pathways in the short and medium term. There may also be minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects. Once construction is complete, workers would not be on-site and therefore there would be no long-term health effects. Benefits would similarly only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

#### *3.11.7.8.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels. Reducing minimum flows to Congressionally authorized minimum flow requirements in particular would benefit water-based recreation and water supply for irrigation and M&I purposes.

- Fall Creek drawdown;
- Augment instream flows by using the inactive pool (#718) (CTG, DOR, FCR, BLU);

- Augment instream flows by using the power pool (#304) (LOP, HCR, CGR, GPR, DET); and
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723) (All reservoirs).

**Recreational Value**

Under Alternative 1, the reduction of flows to Congressionally authorized minimum flow requirements (#723) would increase reservoir levels; and increase both the quality of recreational opportunities offered at reservoirs and the ability of reservoirs to support increased numbers of visitors over the life of the project. These visitors would in turn generate indirect beneficial socioeconomic effects through the expenditure of funds in support of their activity of choice. As a result of increased recreational opportunity and quality, average annual NED recreational benefits are expected to increase under Alternative 1 throughout the WVS. These recreational benefits would result in the indirect support of 11.3 jobs to meet increased recreational demand and add $723,000 to the economy of the ROI. These indirect benefits would be minor in magnitude, long term in duration and regional in extent.

**Irrigation and M&I Use**

Under Alternative 1, peak conservation storage would increase 168,000 acre-feet and benefit water users throughout the WVS. Increased availability of irrigation water would allow for increases in the amount of irrigated acreage throughout the ROI and reduced prevalence of crop damages for the life of the project, stimulating indirect and induced socioeconomic benefits throughout the ROI as crops are brought to market. M&I users would also likely be able to use the majority of their water allocations, decreasing costs of living and business throughout the ROI. As such, the increased water supply as a result of the alteration of outflows and reservoir levels would have beneficial effects that are minor in magnitude, regional in extent, and long-term.

As discussed in Section 3.11.2.4.2 and under the NAA, the one drawdown during the fall at one location (Fall Creek) would have negligible, regional, short- and long-term recurring effects to water supply.

**Quality of Life**

As discussed above in Section 3.11.2.4.2 and the No Action Alternative, the Fall Creek Drawdown would continue to adversely affect the quality of life for nearby residents at Fall Creek. However, there are no cities directly on the shores of the Fall Creek Reservoir therefore effects to the quality of life would be minor and localized. Effects would occur in the short term and recur annually in the long term.

**Non-Use and Existence Values**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 1 would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

*3.11.7.8.3 Climate change*

As discussed in Section 3.11.2.5.4, climate change would adversely affect socioeconomic resources due to wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB. These factors would contribute to indirect adverse effects to socioeconomic resources throughout the entirety of the ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I.

Under Alternative 1, construction measures would cause adverse effects to population and housing with an in-migration of workers to the ROI. Increased capital expenditures would benefit labor and earnings and low-income populations. Climate change would not exacerbate these effects and the magnitude, extent, and duration would remain the same. Effects to the recreational value and viewshed (and therefore quality of life) from construction activities and the Fall Creek Drawdown could be exacerbated if wildfires and HABs further affect turbidity and water quality. However, effects from construction activities and the Fall Creek drawdown in combination with climate change would likely remain moderate, localized, and occur in the short, medium, and long term (recurring).

Under Alternative 1, beneficial effects resulting from increased reservoir storage would be minor, regional, and long term. These beneficial effects would offset the adverse effects from climate change on recreational value and water supply described above. As such, the alteration of outflows and reservoir levels in combination with climate change would have long term, regional, negligible to minor, beneficial effects.

### *3.11.7.9 Alternative 2A – Integrated Water Management and ESA-Listed Fish Alternative*

Construction and design expenditures associated with Alternative 2A would total only approximately $1.3B, which is just over half of those which would occur under Alternative 1. Fewer construction and infrastructure improvement activities would be implemented compared to Alternative 1 and would impact fewer project locations. As a result, the magnitude of beneficial socioeconomic impacts to labor and earnings and low-income populations, the adverse effects to recreational value and quality of life due to construction-related emissions, noise generation, and traffic would be less severe compared to Alternative 1.

Beneficial socioeconomic effects to labor and earnings and low-income populations due to construction and maintenance of structural measures would be negligible to minor in magnitude, and regional in extent in the short term, with construction-induced economic activity benefits increasing in the medium term while construction activities are taking place. Adverse effects to population and housing would be negligible to minor, regional in extent, and short and medium term in duration. Adverse effects to quality of life and recreational value from construction would be minor in magnitude, regional in extent, and occur in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be negligible to minor. Beneficial, indirect effects to recreation expenditures from the alteration of outflows and reservoir storage measures under Alternative 2A would be negligible in magnitude, regional in extent, and long-term. Indirect, adverse effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage measures under Alternative 2A would be minor in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 2A would have similar effects to socioeconomic resources as Alternatives 2B and would have effects of substantially lower magnitude than Alternatives 1, 3A, 3B and 4.

###### *3.11.7.9.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The following measures would increase construction expenditures within the ROI for the duration of the construction phase, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, DET, BCL, GPR, FOS);
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Construction of WTC towers (#105) (DET);
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in the summer (#721) (GPR);
- Construction of AFFs (#722) (GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (GPR);
- Construction of structural downstream fish passage (#392) (LOP, CGR, FOS, DET); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation.

**Labor and Earnings**

The socioeconomic effects of construction and design expenditures under Alternative 2A would be similar to those experienced under Alternative 1, but of substantially smaller magnitude. Construction and design expenditures associated with Alternative 2A would total only approximately $1.3B, which is almost half of those which would occur under Alternative 1. Hence, while construction-related expenditures would generate beneficial effects through the mechanisms discussed in Section 3.11.2.4.1, the magnitude of socioeconomic effects would be smaller than those experienced under Alternative 1; direct, indirect, and induced benefits would result from the hiring of labor, purchase of materials, and increased revenues at retail and food service establishments throughout the ROI. Most of these economic activity benefits would be limited to the medium-term duration of individual construction projects included under Alternative 2A, and be regional in extent.

**Table 3.11-11. Effects of Construction Spending Under Alternative 2A**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $1,046,004,077 | 11791.7 | $857,908,409 | $500,734,490 |
| Secondary Impact | | $968,997,926 | 5966.7 | $320,828,677 | $549,682,271 |
| Total Impact | $1,046,004,077 | $2,015,002,002 | 17758.4 | $1,178,737,086 | $1,050,416,762 |
| **State** | | | | | |
| Direct Impact | | $1,083,446,694 | 12401.1 | $903,804,196 | $559,127,504 |
| Secondary Impact | | $1,322,009,115 | 7361.3 | $448,336,474 | $753,163,709 |
| Total Impact | $1,083,446,694 | $2,405,455,808 | 19762.3 | $1,352,140,670 | $1,312,291,212 |
| **US** | | | | | |
| Direct Impact | | $1,083,639,981 | 12488.2 | $917,658,223 | $572,379,979 |
| Secondary Impact | | $2,498,497,903 | 11605.2 | $776,080,790 | $1,342,681,027 |
| Total Impact | $1,083,639,981 | $3,582,137,884 | 24093.5 | $1,693,739,014 | $1,915,061,005 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 2A shown in Table 3.11-11 are explained by project in the following four paragraphs.

**Foster and Green Peter** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $80,247,000. Of this total expenditure, $77,459,579 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $80,247,000 support a total of 1,278.9 full-time equivalent jobs, $79,505,939 in labor income, $65,171,785 in the gross regional product, and $136,622,697 in economic output in the local impact area. More broadly, these expenditures support 1,807.7 full-time equivalent jobs, $125,705,262 in labor income, $141,552,710 in the gross regional product, and $268,720,522 in economic output in the nation.

**Detroit and Big Cliff** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $703,350,000. Of this total expenditure, $678,553,929 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $703,350,000 support a total of 11,456.3 full-time equivalent jobs, $774,376,405 in labor income, $665,233,887 in the gross regional product, and $1,312,140,001 in economic output in the local impact area. More broadly, these expenditures support 15,457.7 full-time equivalent jobs, $1,106,370,617 in labor income, $1,240,683,124 in the gross regional product, and $2,355,285,298 in economic output in the nation.

**Cougar and Blue River** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $174,700,000. Of this total expenditure, $168,758,669 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $174,700,000 support a total of 2,923.2 full-time equivalent jobs, $189,047,713 in labor income, $186,228,972 in the gross regional product, and $329,520,341 in economic output in the local impact area. More broadly, these expenditures support 3,973.6 full-time equivalent jobs, $268,662,724 in labor income, $310,075,141 in the gross regional product, and $557,580,518 in economic output in the nation.

**Hills Creek, Lookout Point, Dexter, Fall Creek** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $125,500,000. Of this total expenditure, $121,231,900 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $125,500,000 support a total of 2,100.0 full-time equivalent jobs, $135,807,029 in labor income, $133,782,118 in the gross regional product, and $236,718,963 in economic output in the local impact area. More broadly, these expenditures support 2,854.5 full-time equivalent jobs,

$193,000,411 in labor income, $222,750,030 in the gross regional product, and $400,551,546 in economic output in the nation.

**Population and Housing**

As discussed above in Section 3.11.2.4.1, given the current availability of approximately 21,100 housing units within the ROI (USCB 2019c), any small in-migration resulting from construction activities under Alternative 2A could be measurable and could be noticeable but would not affect housing availability or pricing for current residents. Any adverse effects which may occur would only persist for the short- or medium-term duration of the construction period depending on the scale of a given project. Approximately $1.3B in construction and design expenditures under Alternative 2A would have negligible to minor, regional, adverse effects to population and housing.

**Quality of Life and Recreational Value**

As with Alternative 1, construction-related activities could potentially reduce the quality of life of residents and recreational value in the vicinity of project sites through increased noise, emission, and traffic levels. Work-related activities involving heavy equipment would cause visual and auditory disturbance to local residents and recreational users in the vicinity of the project areas, as well as reduce air quality from project-related emissions. Traffic levels would similarly increase during work periods but would be confined to the immediate vicinity of work sites and would not substantially reduce resident access to community resources or visitor access to reservoirs. These effects would be most pronounced within the towns of Detroit and Sweet Home, in particular due to the construction of a WTC tower at Detroit and construction of structural downstream fish passages at Detroit and Foster; both of which are relatively larger projects that would occur in the medium-term. Construction-related activities would have local, major effects in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be negligible to minor.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low-Income Populations**

As discussed above in Section 3.11.2.4.1, if low-income populations in Lane, Linn, and Marion counties are hired to work on these projects, they could experience negligible to minor health benefits through economic pathways in the short and medium term. There may also be negligible to minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects. Once construction is complete, workers would not be on-site and therefore there would be no long-term health effects. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

#### *3.11.7.9.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek Drawdown;
- Foster Fish Ladder Temperature Improvement (#479);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in summer (#721) (GPR);
- Augmentation of instream flows by using the inactive pool (#718) (FCR, BLU);
- Augmentations of instream flows by using the power pool (#304) (LOP, HCR, CGR, GPR, DET);
- Integrated temperature and habitat flow regime (#30a) (All reservoirs);
- Deeper fall reservoir drawdowns for fish passage (#40) (GPR);
- Pass water over spillway in spring for fish passage (#714) (GPR).

**Recreational Value**

Deep fall reservoir drawdowns at Green Peter would likely decrease visitation in the short term but would not likely affect revenues due to seasonally low levels of visitation during this timeframe. Hence, these short- and long-term recurring adverse effects would be negligible and localized.

Alteration of outflows and reservoir levels under Alternative 2A would likely improve the recreational quality of the ROI and increase recreational revenues within the ROI for the duration of the project life. Alternative 2A would generate similar negligible, long-term increases in recreational revenues as Alternative 1 from increased habitat values of recreational fisheries resulting from the increase of cool water outflows throughout the WRB system. As a result of increased recreational opportunity and quality, average annual NED recreational benefits are expected to increase under Alternative 2A.2A. These recreational benefits would result in the indirect and support of 7.5 jobs to meet increased recreational demand and add $509,000 of total value to the economy of the ROI. These beneficial effects to socioeconomic resources would be negligible in magnitude, regional, and long-term.

**Irrigation and M&I Use**

Alteration of outflows under Alternative 2A would minorly reduce the availability of water supply for M&I and agricultural users. Peak conservation storage would decrease by 64,000 acre-feet from the NAA. Decreased availability of irrigation water would cause commensurate decreases in the amount of irrigated acreage throughout the ROI and increased prevalence of crop damages for the life of the project, stimulating indirect and induced adverse socioeconomic effects throughout the ROI. M&I users would also need to purchase small amounts of supplemental water from other sources, increasing costs of living and business throughout the ROI. Hence, indirect effects to socioeconomic resources from reduced water availability would be minor in magnitude, regional, and long-term.

**Quality of Life**

As discussed above in Section 3.11.2.4.2, drawdowns under would continue to adversely affect the quality of life for nearby residents at Fall Creek. Additionally, under this alternative, deep fall reservoirs drawdowns at Green Peter would similarly affect the quality of life for nearby residents at Green Peter. There are no cities directly on the shores of Fall Creek or Green Peter and therefore effects to the quality of life would be minor and localized. Effects would occur in the short term and recur annually in the long term.

**Non-Use and Existence Values**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 2A would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

#### *3.11.7.9.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Visitation would likely further decrease due to decreased recreational quality of reservoirs and could affect recreational revenues. Costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss of surface water would adversely affect the viewshed for nearby residents for longer than three weeks. As such, the resulting effects to socioeconomic resources as they relate to agricultural irrigation and M&I water use, quality of life, and recreational value of reservoirs would range from minor to moderate and adverse in the short term and long term (recurring).

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long term.

#### *3.11.7.9.4 Climate change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors in combination with decreased reservoir storage under Alternative 2A would contribute to indirect adverse effects to socioeconomic resources throughout the entire ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I. These adverse effects would be additive, long term, and minor to moderate.

Under Alternative 2A, effects to visitation and the viewshed (and therefore quality of life) from construction activities and the Fall Creek and Green Peter drawdowns could be exacerbated if wildfires and HABs further affect turbidity and water quality. However, effects from construction activities and drawdowns in combination with climate change would likely remain minor, localized, and occur in the short, medium, and long term (recurring).

### *3.11.7.10 Alternative 2B – Integrated Water Management and ESA-Listed Fish Alternative (using diversion tunnel at CGR)*

Alternative 2B2B is functionally similar to Alternative 2A and is $42M lower in construction and design expenditures than Alternative 2A. It differs primarily in the omission of augmentation of instream flows by using the power pool (#304) at Cougar Reservoir, omission of the construction of structural downstream fish passages (#392) at Cougar Reservoir, inclusion of deeper fall reservoir drawdowns for fish passage (#40) at Cougar Reservoir, and the inclusion of spring reservoir drawdowns for downstream fish passage (#720) at Cougar Reservoir.

Under Alternative 2B, beneficial socioeconomic effects to labor and earnings and low-income populations due to construction and maintenance of structural measures would be negligible to minor in magnitude, regional in extent in the short-term and major in the medium-term while construction is taking place. Adverse effects to population and housing would be negligible to minor, regional in extent, and short and medium term in duration. Adverse effects to quality of life and recreational value from construction would be minor in magnitude, regional in extent, and occur in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be negligible to minor. Beneficial, indirect effects to recreation expenditures from the alteration of outflows and reservoir storage measures under Alternative 2B would be negligible in magnitude, regional in extent, and long-term. Indirect, adverse effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage measures under Alternative 2B would be minor in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 2B would have similar effects to socioeconomic resources as Alternatives 2A and would have effects of substantially lower magnitude than Alternatives 1, 3A, 3B and 4.

#### *3.11.7.10.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The same measures as those under Alternative 2A would occur under Alternative 2B, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, FOS, GPR, BCL, DET);
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Construction of WTC towers (#105) (DET);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in summer (#721) (GPR);
- Construction of AFFs (#722) (GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (GPR);
- Construction of structural downstream fish passage (#392) (LOP, FOS, DET); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation. (All reservoirs)

**Labor and Earnings**

Given their functional similarity, the socioeconomic effects of Alternatives 2A and 2B are very similar and are affected by the same mechanisms discussed in Section 3.11.2.4; the primary differences result from $42M lower construction and design expenditures of Alternative 2B. Although these costs are lower than those of Alternative 2A, it is not likely that this reduction would substantially alter the support of jobs, in-migration of populations, or noticeably decrease consumer demand within the ROI from those that would occur under Alternative 2A. As such, beneficial socioeconomic effects due to increased construction expenditures under Alternative 2B would be negligible to minor in magnitude, in the short-term, with economic activity benefits increasing while construction is occurring in the medium-term, and regional in extent.

**Table 3.11-12. Effects of Construction Spending Under Alternative 2B**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $997,969,892 | 12385.5 | $830,633,199 | $543,452,004 |
| Secondary Impact | | $885,571,664 | 5406.8 | $291,828,981 | $503,333,550 |
| Total Impact | $997,969,892 | $1,883,541,557 | 17792.3 | $1,122,462,180 | $1,046,785,555 |
| **State** | | | | | |
| Direct Impact | | $1,033,795,181 | 12933.3 | $873,509,300 | $596,658,309 |
| Secondary Impact | | $1,204,458,756 | 6668.3 | $407,333,294 | $688,004,550 |
| Total Impact | $1,033,795,181 | $2,238,253,937 | 19601.6 | $1,280,842,594 | $1,284,662,859 |
| **US** | | | | | |
| Direct Impact | | $1,034,284,258 | 13023.2 | $886,947,021 | $607,810,246 |
| Secondary Impact | | $2,268,421,224 | 10489.2 | $704,340,219 | $1,221,735,739 |
| Total Impact | $1,034,284,258 | $3,302,705,482 | 23512.3 | $1,591,287,241 | $1,829,545,985 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 2B shown in Table 3.11-12 are explained by project in the following four paragraphs.

**Foster and Green Peter** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $80,247,000. Of this total expenditure, $77,345,223 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $80,247,000 support a total of 1,347.5 full-time equivalent jobs, $80,035,207 in labor income, $71,250,544 in the gross regional product, and $133,543,743 in economic output in the local impact area. More broadly, these expenditures support 1,849.1 full-time equivalent jobs, $123,045,012 in labor income, $141,701,726 in the gross regional product, and $256,119,999 in economic output in the nation.

**Detroit and Big Cliff** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $703,350,000. Of this total expenditure, $677,967,671 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $703,350,000 support a total of 12,241.5 full-time equivalent jobs, $770,596,489 in labor income, $707,757,577 in the gross regional product, and $1,276,182,647 in economic output in the local impact area. More broadly, these expenditures support 15,949.6 full-time equivalent jobs, $1,081,933,836 in labor income, $1,241,989,219 in the gross regional product, and $2,244,844,062 in economic output in the nation.

**Cougar and Blue River** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $125,700,000. Of this total expenditure, $121,425,098 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $125,700,000 support a total of 2,103.3 full-time equivalent jobs, $136,023,455 in labor income, $133,995,316 in the gross regional product, and $237,096,204 in economic output in the local impact area. More broadly, these expenditures support 2,859.1 full-time equivalent jobs, $193,307,982 in labor income, $223,105,010 in the gross regional product, and $401,189,875 in economic output in the nation.

**Hills Creek, Lookout Point, Dexter, Fall Creek** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $125,500,000. Of this total expenditure, $121,231,900 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $125,500,000 support a total of 2,100.0 full-time equivalent jobs, $135,807,029 in labor income, $133,782,118 in the gross regional product, and $236,718,963 in economic output in the local impact area. More broadly, these expenditures support 2,854.5 full-time equivalent jobs, $193,000,411 in labor income, $222,750,030 in the gross regional product, and $400,551,546 in economic output in the nation.

**Population and Housing**

As discussed above in Section 3.11.2.4.1, given the current availability of approximately 21,100 housing units within the ROI (USCB 2019c), any small in-migration resulting from construction activities under Alternative 2B could be measurable and could be noticeable but would not affect housing availability or pricing for current residents. Any adverse effects which may occur would only persist for the short- or medium-term duration of the construction period depending on the scale of the project in question. As such, adverse effects on population and housing would be negligible to minor and regional in extent.

**Quality of Life and Recreational Value**

Quality of life and recreational value of reservoirs would be reduced in the vicinity of project sites during the construction phase due to visual disturbance from the presence of heavy equipment and workers, increased air emissions, noise, and traffic. Effects would be confined to the immediate vicinity of project sites (reservoirs and towns bordering reservoirs) and would only persist for the duration of construction projects. As with Alternative 2A, these effects would be most pronounced in the towns of Detroit and Sweet Home, in particular due to the construction of a WTC tower at Detroit and construction of structural downstream fish passages at Detroit and Foster; both of which are relatively larger projects that would occur in the medium-term. Effects to quality of life and recreational value due to construction-related activity under Alternative 2B would be short- and medium-term, localized, and major. Long-term visual effects to quality of life from the erection of new structures would be negligible to minor.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low Income Populations**

Low-income populations in Lane, Linn, and Marion counties that are hired to work on these projects would experience negligible to minor health benefits through economic pathways in the short and medium term. There may also be negligible to minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects, but these effects would not persist beyond the duration of the construction phase. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

#### *3.11.7.10.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek drawdown;
- Spring reservoir drawdown for downstream fish passage (#720) (CGR);
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);

- Use of spillway for surface spill in summer (#721) (GPR);
- Augmentation of instream flows by using the inactive pool (#718) (FCR, BLU);
- Augmentation of instream flows by using the power pool (#304) (LOP, HCR, GPR, DET);
- Integrated temperature and habitat flow regime (#30a) (All reservoirs);
- Deeper fall reservoir drawdowns for fish passage (#40) (CGR, GPR); and
- Pass water over the spillway in spring for fish passage (#714) (GPR).

**Recreational Value**

As with Alternative 2A, deeper fall reservoirs drawdowns (#40) at Green Peter would likely decrease visitation in the short term but would not likely affect revenues due to seasonally low levels of visitation during this timeframe. Spring reservoir drawdowns (#720) in particular at Cougar Reservoir under would Alternative 2B would reduce recreational expenditures at this reservoir throughout the life of the project compared to those under Alternative 2A due to decreased recreational quality during the spring recreation season for the life of the project. However, Cougar is one of the least visited reservoirs of the 13 reservoirs; and visitors spend the least amount of dollars per visit at this reservoir (USACE 2019g). Hence, these short- and long-term recurring adverse effects from drawdowns at Fall Creek, Green Peter, and Cougar would be negligible and localized.

Conversely, fall and spring reservoir drawdowns would negligibly increase habitat values for recreational fish species throughout the ROI for the life of the project, resulting in increased recreational visitation and expenditures. Average annual NED benefits under Alternative 2B would be slightly higher than the NAA; these benefits would support 5.2 jobs and $356,000 in total economic value. These regional, beneficial effects would ultimately be negligible in magnitude and long-term.

**M&I Use and Irrigation**

Alternative 2B would result in a decrease of 64,000 acre-feet of conservation storage from the NAA. Reduced conservation storage would increase water costs and crop damages to M&I and irrigation users throughout the ROI, resulting in general cost of living increases for the life of the project. These regional, adverse, indirect socioeconomic effects would be minor and long-term.

**Quality of Life**

As discussed above in Section 3.11.2.4.2, drawdowns under this alternative would also adversely affect the quality of life for nearby residents at Fall Creek and Green Peter. Additionally, under this alternative, deep fall and spring reservoirs drawdowns at Cougar would similarly affect the quality of life for nearby residents. There are no cities directly on the shores of Fall Creek, Green Peter, or Cougar and therefore effects to the quality of life would be minor and localized. Effects would occur in the short term and recur annually in the long term.

**Non-Use and Existence Values**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 2B would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

*3.11.7.10.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Visitation would likely further decrease due to decreased recreational quality of reservoirs and could affect recreational revenues. Costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss or surface water would adversely affect the viewshed for nearby residents for longer than three weeks. As such, the resulting effects to socioeconomic resources as they relate to agricultural irrigation and M&I water use, quality of life, and recreational value of reservoirs would range from minor to moderate and adverse in the short term and long term (recurring).

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long-term.

*3.11.7.10.4 Climate change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors in combination with decreased reservoir storage under Alternative 2B2B would contribute to indirect adverse effects to socioeconomic resources throughout the entire ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I. These adverse effects would be additive, long term, and minor to moderate.

Under Alternative 2B, effects to visitation and the viewshed (and therefore quality of life) from construction activities and the Fall Creek, Green Peter, and Cougar drawdowns could be exacerbated if wildfires and HABs further affect turbidity and water quality. However, effects from construction activities and drawdowns in combination with climate change would likely remain minor, localized, and occur in the short, medium, and long term (recurring).

### *3.11.7.11 Alternative 3A3A – Operations-Focused Fish Passage Alternative*

Alternative 3A consists primarily of alteration of outflows and reservoir storage, along with minor structural improvements and maintenance which increase stream flows and enhance fish passage in support of improved survival of ESA-listed fish species. Construction and design expenditures associated with Alternative 3A would total only approximately $470M, which is 36 percent of those of Alternatives 2A and 2B. Construction expenditures would be lowest for this alternative, and as such would result in fewer construction and infrastructure improvement activities compared to all other alternatives. As a result, the magnitude of beneficial socioeconomic impacts to labor and earnings and low-income populations, the adverse effects to recreational value and quality of life due to construction-related emissions, noise generation, and traffic would be less severe compared to all other alternatives. However, adverse effects to recreational value, agricultural irrigation and M&I use, and quality of life from the 10 drawdowns at seven reservoirs would be more severe under this alternative (and Alternative 3B) compared to Alternatives 1, 2A, 2B, 4, and 5.

Under Alternative 3A, beneficial socioeconomic effects to labor and earnings and low-income populations due to construction of structural measures would be negligible in magnitude, regional in extent, and occur in the short and medium term, with construction spending induced economic activity benefits increasing in the medium-term while construction is taking place. Adverse effects to population and housing, quality of life, and recreational value from construction would be negligible in magnitude, regional in extent, and occur in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be negligible. Adverse effects to recreation expenditures from the alteration of outflows and reservoir storage and levels under Alternative 3A would be major in magnitude, regional in extent, and long-term. Adverse effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage and levels under Alternative 3A would be major in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 3A would have greater adverse long-term effects to socioeconomic resources than Alternatives 2A and 2B (but lesser beneficial and adverse short- and medium-term effects), nearly identical effects as Alternative 3B and would have effects of substantially lower magnitude in the short- and medium-term (and more adverse long-term effects) than Alternatives 1 and 4.

#### *3.11.7.11.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The following measures would increase construction expenditures within the ROI for the duration of the construction phase, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, FOS, GPR, BCL, DET);
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (LOP, GPR, DET);
- Use of spillway for surface spill in summer (#721) (LOP, HCR, BLU, FOS, GPR, DET);
- Construction of AFFs (#722) (HCR, BLU, GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (HCR, BLU, GPR); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation (All Reservoirs)

**Labor and Earnings**

Socioeconomic effects due to construction expenditures under Alternative 3A would be similar to those experienced under Alternatives 2A and 2B, but of smaller magnitude. Construction and design expenditures associated with Alternative 3A would total only approximately $470M, which is 36 percent of those of Alternatives 2A and 2B. Hence, while these expenditures would generate beneficial effects through the mechanisms discussed in Section 3.11.2.4.1, the magnitude of socioeconomic effects would be smaller than those experienced under Alternatives 1, 2A, and 2B; direct, indirect, and induced effects would result from the hiring of labor, purchase of materials from vendors, and increased revenues at retail and food service establishments. These beneficial effects would occur in the short and medium term and be regional in extent.

**Table 3.11-13. Effects of Construction Spending Under Alternative 3A**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $319,763,958 | 3708.4 | $254,987,819 | $175,165,073 |
| Secondary Impact | | $297,429,584 | 1834.7 | $100,560,713 | $171,904,667 |
| Total Impact | $319,763,958 | $617,193,543 | 5543.0 | $355,548,532 | $347,069,740 |
| **State** | | | | | |
| Direct Impact | | $330,749,544 | 4093.1 | $278,857,768 | $193,022,266 |
| Secondary Impact | | $385,378,194 | 2138.1 | $130,323,386 | $220,121,625 |
| Total Impact | $330,749,544 | $716,127,739 | 6231.2 | $409,181,155 | $413,143,892 |
| **US** | | | | | |
| Direct Impact | | $330,932,941 | 4184.0 | $283,668,494 | $196,445,931 |
| Secondary Impact | | $725,811,403 | 3356.5 | $225,362,978 | $390,910,524 |
| Total Impact | $330,932,941 | $1,056,744,344 | 7540.5 | $509,031,470 | $587,356,457 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 3A shown in Table 3.11-13 are explained by project in the following four paragraphs.

**Foster and Green Peter** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $32,547,000. Of this total expenditure, $31,370,082 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $32,547,000 support a total of 546.5 full-time equivalent jobs, $32,461,100 in labor income, $28,898,170 in the gross regional product, and $54,163,373 in economic output in the local impact area. More broadly, these expenditures support 750.0 full-time equivalent jobs, $49,905,243 in labor income, $57,472,131 in the gross regional product, and $103,878,495 in economic output in the nation.

**Detroit and Big Cliff** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $1,350,000. Of this total expenditure, $1,301,282 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $1,350,000 support a total of 23.5 full-time equivalent jobs, $1,479,072 in labor income, $1,358,460 in the gross regional product, and $2,449,487 in economic output in the local impact area. More broadly, these expenditures support 30.6 full-time equivalent jobs, $2,076,648 in labor income, $2,383,856 in the gross regional product, and $4,308,722 in economic output in the nation.

**Cougar and Blue River**- The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $165,700,000. Of this total expenditure, $160,064,747 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $165,700,000 support a total of 2,772.6 full-time equivalent jobs, $179,308,564 in labor income, $176,635,035 in the gross regional product, and $312,544,479 in economic output in the local impact area. More broadly, these expenditures support 3,768.9 full-time equivalent jobs, $254,822,057 in labor income, $294,101,036 in the gross regional product, and $528,855,706 in economic output in the nation.

**Hills Creek, Lookout Point, Dexter, Fall Creek** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $131,500,000. Of this total expenditure, $127,027,847 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $131,500,000 support a total of 2,200.4 full-time equivalent jobs, $142,299,796 in labor income, $140,178,075 in the gross regional product, and $248,036,204 in economic output in the local impact area. More broadly, these expenditures support 2,991.0 full-time equivalent jobs, $202,227,522 in labor income, $233,399,434 in the gross regional product, and $419,701,421 in economic output in the nation.

**Population and Housing**

No measurable in-migration of populations would be expected under Alternative 3A. As such, Alternative 3A would have negligible, regional, short- and medium-term, adverse effects to population and housing.

**Quality of Life and Recreational Value**

While construction-related noise, emissions, and congestion could potentially reduce resident quality of life and recreational expenditures during work phases, no measurable short, medium- or long-term quality of life effects are expected under Alternative 3A given the limited number of structural measures. As with Alternatives 1, 2A, and 2B, work-related activities could potentially reduce the quality of life of residents and recreational quality in the vicinity of project sites (reservoirs and towns bordering reservoirs) through increased noise, emission, and traffic levels during the construction phase. However, none of the limited number of works of improvement proposed under Alternative 3A would occur at reservoirs with towns bordering reservoirs, except for a structural modification to the RO at Detroit to be used for temperature management. As such, adverse, short- and medium-term effects to recreational value and quality of life would be negligible in magnitude and localized. Long-term visual effects to quality of life from the erection of new structures would be negligible.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low-Income Populations**

Low-income populations in Lane, Linn, and Marion counties that are hired to work on these projects would experience negligible health benefits through economic pathways in the short and medium term. There may also be negligible adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects, but these effects would not persist beyond the duration of the construction phase. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

*3.11.7.11.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek drawdown;
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (LOP, GPR, DET);
- Use of spillway for surface spill in summer (#721) (LOP, HCR, BLU, FOS, GPR, DET);
- Augmentation of instream flows by using the inactive pool (#718) (CTG, DOR, FCR, BLU);
- Augmentation of instream flows by using the power pool (#304) (LOP, HCR, CGR, GPR, DET);
- Integrated temperature and habitat flow regime (30a) (All reservoirs);
- Deeper fall reservoir drawdowns for fish passage (#40) (LOP, HCR, CGR, BLU, GPR, DET);
- Spring reservoir drawdown for downstream fish passage (#720) (LOP, CGR, DET); and
- Pass water over spillway in spring for fish passage (#714) (DEX, FCR, HCR, GPR, BCL).

**Recreational Value**

Alteration of outflows and reservoir level would likely substantially decrease the recreational expenditures within the ROI and while also significantly reducing the availability of water supply for M&I and agricultural users. Annual deep spring drawdowns at Cougar, Detroit, and Lookout Point reservoirs would substantially reduce their recreational value during the spring/summer recreation season. Deep fall reservoir drawdowns at Lookout Point, Hills Creek, Cougar, Blue River, Green Peter, and Detroit would similarly result in reduced recreational values for fall and winter months, but would not likely affect revenues as substantially due to seasonally low levels of visitation during this timeframe. As a result of reduced recreational opportunity and quality, average annual NED recreational benefits are expected to decrease from the NAA. These reductions would result in the loss of support for 25 jobs due to decreased recreational demand and remove $1.5M of total value to the economy of the ROI over the life of the project. These adverse, long-term, regional effects would be major in magnitude.

**M&I Use and Irrigation**

Similarly, under Alternative 3A peak conservation storage would decrease by 64 percent, a total decrease of 750,910 acre-feet from the NAA. This decrease would induce major adverse effects to water users throughout the WVS; essentially no water would be allocated for M&I and irrigation uses for the life of the project. Decreased availability of irrigation water would cause decreases in the amount of irrigated acreage throughout the ROI and increased prevalence of crop damages for the life of the project, stimulating indirect and induced adverse socioeconomic effects throughout the ROI. It is important to note that only 15 percent of agricultural producers in the WRB are reliant on WVS irrigation water supply, which limits the magnitude of potential direct, indirect, and induced impacts. Therefore, overall adverse water supply impacts to agricultural production in the WRB would only be moderate in magnitude whereas impacts to those producers reliant on WVS water would be major in magnitude. M&I users would also need to purchase large amounts of supplemental water from other sources, substantially increasing costs of living and business throughout the ROI. As such, the overall long-term, regional, adverse effects due to reduced water supply would be moderate to major in magnitude.

**Quality of Life**

Under this alternative, deep fall and spring reservoirs drawdowns at seven reservoirs would affect the quality of life for nearby residents. The city of Detroit is located directly on the shores of Detroit Reservoir, and therefore effects to the quality of life would be major and localized in the short-term and recur annually over the long term in both the fall and spring.

**Non-Use and Existence Value**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 3A would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

*3.11.7.11.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. For reasons similar to those discussed above as they relate to recreational value; agricultural irrigation and M&I use; and quality of life, effects to socioeconomic resources would be major and adverse in the short term and long term (recurring). Recreational revenues and visitation would likely further decrease due to decreased recreational quality of reservoirs; costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss or surface water would adversely affect the viewshed for nearby residents for longer than three weeks.

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long-term.

#### *3.11.7.11.4 Climate Change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors in combination with decreased reservoir storage and levels under Alternative 3A would contribute to indirect adverse effects to socioeconomic resources throughout the entire ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I. These adverse effects would be additive, long term, and major.

Under Alternative 3A, effects to visitation and the viewshed (and therefore quality of life, especially at Detroit) from construction activities and the 10 total drawdowns at seven reservoirs could be exacerbated if wildfires and HABs further affect turbidity and water quality. While the magnitude of effects would still be major, effects from construction activities and drawdowns in combination with climate change would be even more severe. These effects would be regional in extent; and occur in the short, medium, and long term (recurring).

### ***3.11.7.12 Alternative B3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)***

Alternative 3B is functionally similar to Alternative 3A and differs only in its omission of augmentation of instream flows by using the power pool (#304) at Cougar Reservoir, the inclusion of spring reservoir drawdowns for downstream fish passage (#720) at Green Peter and Hills Creek Reservoirs instead of at Detroit and Lookout Point Reservoirs, and the inclusion of passing water over the spillways in spring (#714) at Lookout Point instead of Dexter, Green Peter, and Hills Creek Reservoirs. Construction and design expenditures associated with Alternative 3B would total approximately $592, or $122M in additional construction and design expenditures compared to Alternative 3B.

Under Alternative 3B, beneficial socioeconomic effects to labor and earnings and low-income populations due to construction of structural measures would be negligible in magnitude, regional in extent, and occur in the short- and medium-term. Adverse effects to population and housing, quality of life, and recreational value from construction would be negligible in magnitude, regional in extent, and occur in the short- and medium-term. Adverse effects to recreation expenditures from the alteration of outflows and reservoir storage and levels under Alternative 3B would be major in magnitude, regional in extent, and long-term. Adverse effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage and levels under Alternative 3B would be major in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 3B would have greater adverse long-term effects to socioeconomic resources than Alternatives 2A and 2B (but lesser beneficial and adverse short- and medium-term effects), nearly identical effects as Alternative 3A, and would have effects of substantially lower magnitude in the short- and medium-term (and more adverse long-term effects) than Alternatives 1 and 4.

##### *3.11.7.12.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The following measures would marginally increase construction expenditures within the ROI for the duration of the construction phase, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, FOS, GPR, BCL, DET);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (LOP, GPR, DET);
- Use of spillway for surface spill in summer (#721) (LOP, HCR, BLU, FOS, GPR, DET);
- Construction of AFFs (#722) (HCR, BLU, GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (HCR, BLU, GPR); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation (All reservoirs)

**Labor and Earnings**

Given their functional similarity, the socioeconomic effects of Alternatives 3A and 3B are very similar and are affected by the same mechanisms discussed in Section 3.11.2.8; the primary differences result from the $122M in additional construction and design expenditures of Alternative 3B3B. These costs are 26 percent greater than those of Alternative 3A. Negligible direct, indirect, and induced effects would result from the hiring of labor, purchase of materials from vendors, and increased revenues at retail and food service establishments. These beneficial effects would occur in the short and medium term, but particularly in the medium term while construction activities are occurring, and be regional in extent.

**Table 3.11-14. Effects of Construction Spending Under Alternative 3B**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $426,022,994 | 4925.0 | $339,638,333 | $233,661,186 |
| Secondary Impact | | $398,653,305 | 2458.6 | $134,944,248 | $230,667,781 |
| Total Impact | $426,022,994 | $824,676,299 | 7383.6 | $474,582,581 | $464,328,967 |
| **State** | | | | | |
| Direct Impact | | $440,639,319 | 5448.0 | $371,554,810 | $257,265,204 |
| Secondary Impact | | $513,417,922 | 2848.7 | $173,622,190 | $293,255,209 |
| Total Impact | $440,639,319 | $954,057,242 | 8296.7 | $545,177,000 | $550,520,414 |
| **US** | | | | | |
| Direct Impact | | $440,878,436 | 5570.8 | $377,960,100 | $261,813,218 |
| Secondary Impact | | $966,946,944 | 4471.6 | $300,235,078 | $520,782,307 |
| Total Impact | $440,878,436 | $1,407,825,380 | 10042.4 | $678,195,178 | $782,595,527 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 3B shown in Table 3.11-14 are explained by project in the following four paragraphs.

**Foster and Green Peter** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $32,547,000. Of this total expenditure, $31,370,082 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $32,547,000 support a total of 546.5 full-time equivalent jobs, $32,461,100 in labor income, $28,898,170 in the gross regional product, and $54,163,373 in economic output in the local impact area. More broadly, these expenditures support 750.0 full-time equivalent jobs, $49,905,243 in labor income, $57,472,131 in the gross regional product, and $103,878,495 in economic output in the nation.

**Detroit and Big Cliff** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $1,350,000. Of this total expenditure, $1,301,282 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $1,350,000 support a total of 23.5 full-time equivalent jobs, $1,479,072 in labor income, $1,358,460 in the gross regional product, and $2,449,487 in economic output in the local impact area. More broadly, these expenditures support 30.6 full-time equivalent jobs, $2,076,648 in labor income, $2,383,856 in the gross regional product, and $4,308,722 in economic output in the nation.

**Cougar and Blue River** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $250,700,000. Of this total expenditure, $242,174,002 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $250,700,000 support a total of 4,194.9 full-time equivalent jobs, $271,289,420 in labor income, $267,244,437 in the gross regional product, and $472,872,063 in economic output in the local impact area. More broadly, these expenditures support 5,702.2 full-time equivalent jobs, $385,539,467 in labor income, $444,967,590 in the gross regional product, and $800,145,598 in economic output in the nation.

**Hills Creek, Lookout Point, Dexter, Fall Creek** - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $156,500,000. Of this total expenditure, $151,177,628 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $156,500,000 support a total of 2,618.7 full-time equivalent jobs, $169,352,989 in labor income, $166,827,900 in the gross regional product, and $295,191,376 in economic output in the local impact area. More broadly, these expenditures support 3,559.6 full-time equivalent jobs, $240,673,820 in labor income, $277,771,950 in the gross regional product, and $499,492,565 in economic output in the nation.

**Population and Housing**

No measurable in-migration of populations would be expected under Alternative 3B. As such, Alternative 3B would have negligible, regional, short- and medium-term, adverse effects to population and housing.

**Quality of Life and Recreational Value**

As with Alternative 3A, while construction-related noise, emissions, and congestion could potentially reduce resident quality of life and recreational expenditures during work phases, no measurable short, medium- or long-term quality of life effects are expected under Alternative 3B given the limited number of structural measures. As with Alternatives 1, 2A, and 2B, work-related activities could potentially reduce the quality of life of residents and recreational quality in the vicinity of project sites (reservoirs and towns bordering reservoirs) through increased noise, emission, and traffic levels during the construction phase. However, none of the limited number of works of improvement proposed under Alternative 3B would occur at reservoirs with towns bordering reservoirs, except for a structural modification to the RO at Detroit to be used for temperature management. As such, adverse, short- and medium-term effects to recreational value and quality of life would be negligible in magnitude and localized. Long-term visual effects to quality of life from the erection of new structures would be negligible.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low Income Populations**

Low-income populations in Lane, Linn, and Marion counties that are hired to work on these projects would experience negligible health benefits through economic pathways in the short and medium term. There may also be negligible adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects, but these effects would not persist beyond the duration of the construction phase. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

#### *3.11.7.12.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek drawdown;
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (LOP, GPR, DET);
- Use of spillway for surface spill in summer (#721) (LOP, HCR, BLU, FOS, GPR, DET);
- Augmentation of instream flows by using the inactive pool (#718) (CTG, DOR, FCR, BLU);
- Augmentation of instream flows by using the power pool (#304) (LOP, HCR, GPR, DET);
- Integrated temperature and habitat flow regime (30a) (All reservoirs);
- Deeper fall reservoir drawdowns for fish passage (#40) (LOP, HCR, CGR, BLU, GPR, DET);
- Spring reservoir drawdown for downstream fish passage (#720) (HCR, CGR, GPR); and
- Pass water over spillway in spring for fish passage (#714) (DEX, LOP, BCL, DET).

**Recreational Value**

Spring reservoir drawdowns at Cougar, Green Peter, and Hills Creek Reservoirs under Alternative 3B3B would also substantially reduce water levels of these reservoirs throughout the life of the project, lowering the quality of their recreational experience and total visitation capacity. Deep fall reservoir drawdowns at Lookout Point, Hills Creek, Cougar, Blue River, Green Peter, and Detroit would similarly result in reduced recreational values for fall and winter months, but would not likely affect revenues as substantially due to seasonally low levels of visitation during this timeframe. Reduced recreational opportunity and quality would result in the loss of 44 jobs due to decreased recreational demand and remove $2.5M of total value to the economy of the ROI over the life of the project. These regional, long-term, adverse effects to recreational value of reservoirs would be major in magnitude.

**M&I Use and Irrigation**

Under Alternative 3B peak conservation storage would decrease by 50 percent, a total decrease of 669,000 acre-feet from the NAA. This decrease would induce major adverse effects to water users throughout the WVS throughout the life of the project; essentially no water would be allocated for M&I and irrigation uses. These users would need to purchase large amounts of supplemental water from other sources, substantially increasing costs of living and business throughout the ROI. Irrigation users who cannot source supplemental sources of water will suffer crop damages or furrow normally productive land, further exacerbating cost of living increases. Given that only 15 percent of agricultural producers are reliant on WVS water, overall adverse water supply impacts to agricultural production in the WRB would only be moderate in magnitude whereas impacts to those producers reliant on WVS water would be major in magnitude. As such, the overall long-term, regional, adverse effects of reduced water supply would be moderate to major in magnitude.

**Quality of Life**

Under this alternative, deep fall and spring reservoirs drawdowns at seven reservoirs would affect the quality of life for nearby residents. The city of Detroit is located directly on the shores of Detroit Reservoir, and therefore effects to the quality of life would be major and localized in the short-term and recur annually over the long-term in the fall.

**Non-Use and Existence Value**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 3B3B would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

*3.11.7.12.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Recreational revenues and visitation would likely further decrease due to decreased recreational quality of reservoirs; costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss or surface water would adversely affect the viewshed for nearby residents for longer than three weeks. As such, the resulting effects to socioeconomic resources as they relate to irrigation and M&I water use, quality of life, and recreational value of reservoirs would be major and adverse in the short term and long term (recurring).

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long-term.

*3.11.7.12.4 Climate change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors in combination with decreased reservoir storage and levels under Alternative 3B would contribute to indirect adverse effects to socioeconomic resources throughout the entire ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I. These adverse effects would be additive, long term, and major.

Under Alternative 3B, effects to visitation and the viewshed (and therefore quality of life, especially at Detroit) from construction activities and the 10 total drawdowns at seven reservoirs could be exacerbated if wildfires and HABs further affect turbidity and water quality. While The magnitude of effects would still be major, effects from construction activities and drawdowns in combination with climate change would be even more severe. These effects would be regional in extent; and occur in the short, medium, and long term (recurring).

***3.11.7.13 Alternative 4 – Structures-Based Fish Passage Alternative***

Alternative 4 consists almost entirely of the construction and maintenance of structural improvements which increase stream flows and enhance fish passage in support of improved survival of ESA-listed fish species. Construction and design expenditures associated with Alternative 4 would total approximately $2.6B, which is $200M greater than those of Alternative 1, and the most expensive of the alternatives.

Under Alternative 4, beneficial socioeconomic effects to labor and earnings and low-income populations due to construction of structural measures would be minor in magnitude, regional in extent, and occur in the short and medium term. These benefits would stem from large capital expenditures and increased water levels. Short- and medium-term adverse effects to population and housing would also be minor and regional. Adverse effects to quality of life and recreational value from construction would be moderate in magnitude, either localized or regional in extent, and occur in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be minor. Beneficial effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage measures under Alternative 4 would be minor in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 4 would have similar effects to socioeconomic resources as Alternative 1, and would have substantially more adverse short- and medium-term effects to labor and earnings and quality of life (and less adverse short and long-term recurring effects) than Alternatives 2A, 2B, 3A, 3B, and 5.

##### *3.11.7.13.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The following measures would substantially increase construction expenditures within the ROI for the duration of the construction phase, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);
- Maintenance of existing and new fish release sites above dams (#726) (LOP, FCR, HCR, CGR, FOS, GPR, BCL, DET);
- Construction of WTC towers (#105) (LOP, GCR, DET);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Structural improvements to reduce total dissolved gas (#174) (DEX, LOP, CGR, FOS, GPR, DET);
- Restoration of upstream and downstream passage at drop structures (#639) (FRN);
- Construction of AFFs (#722) (HCR);
- Provide Pacific lamprey passage and infrastructure (#52) (FRN, HCR);
- Construction of structural downstream fish passage (#392) (DEX, LOP, HCR, CGR, FOS, BCL, DET); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation. (All reservoirs)

**<u>Labor and Earnings</u>**

Socioeconomic effects to labor and earnings under Alternative 4 would be similar to those experienced under Alternative 1. Construction and design expenditures associated with

Alternative 4 would total approximately $2.6B, which is $200M greater than those of Alternative 1. Hence, construction-related expenditures under Alternative 4 would generate nearly identical beneficial effects as Alternative 1 through the mechanisms discussed in Section 3.11.2.3.1; minor, direct, indirect, and induced beneficial effects would result from the hiring of labor, purchase of materials from vendors, and increased revenues at retail and food service establishments. These regional, beneficial socioeconomic effects due to increased construction and maintenance expenditures under Alternative 4 would occur in the short to medium term, but will increase in the medium term while construction activities are taking place.

**Table 3.11-15. Effects of Construction Spending Under Alternative 4**

| Area | Local Capture | Output | Jobs* | Labor Income | Value Added |
|---|---|---|---|---|---|
| **Local** | | | | | |
| Direct Impact | | $1,020,644,269 | 12630.2 | $848,862,339 | $556,303,208 |
| Secondary Impact | | $910,100,701 | 5557.0 | $300,314,646 | $517,852,788 |
| Total Impact | $1,020,644,269 | $1,930,744,970 | 18187.2 | $1,149,176,985 | $1,074,155,996 |
| **State** | | | | | |
| Direct Impact | | $1,057,229,501 | 13216.7 | $893,358,404 | $610,458,869 |
| Secondary Impact | | $1,231,762,758 | 6820.1 | $416,566,223 | $703,599,526 |
| Total Impact | $1,057,229,501 | $2,288,992,261 | 20036.8 | $1,309,924,627 | $1,314,058,393 |
| **US** | | | | | |
| Direct Impact | | $1,057,722,638 | 13314.0 | $907,118,160 | $621,836,173 |
| Secondary Impact | | $2,319,826,937 | 10726.8 | $720,301,589 | $1,249,422,042 |
| Total Impact | $1,057,722,638 | $3,377,549,575 | 24041.0 | $1,627,419,749 | $1,871,258,215 |

* Jobs are presented in full-time equivalence (FTE)

The estimated overall regional economic development impacts for Alternative 4 shown in Table 3.11-15 are explained by project in the following four paragraphs.

Foster and Green Peter - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Foster and Green Peter are estimated to be $65,247,000. Of this total expenditure, $62,887,632 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $65,247,000 support a total of 1,095.6 full-time equivalent jobs, $65,074,796 in labor income, $57,932,188 in the gross regional product, and $108,581,363 in economic output in the local impact area. More broadly, these expenditures support 1,503.5 full-time equivalent jobs, $100,045,084 in labor income, $115,214,432 in the gross regional product, and $208,245,312 in economic output in the nation.

Detroit and Big Cliff - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Detroit and Big Cliff are estimated to be $708,350,000. Of this total expenditure, $682,787,232 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $708,350,000 support a total of 12,328.6 full-time equivalent jobs, $776,074,533 in labor income, $712,788,909 in the gross regional product, and $1,285,254,820 in economic output in the local impact area. More broadly, these expenditures support 16,063.0 full-time equivalent jobs, $1,089,625,127 in labor income, $1,250,818,317 in the gross regional product, and $2,260,802,291 in economic output in the nation.

Cougar and Blue River- The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Cougar and Blue River are estimated to be $179,350,000. Of this total expenditure, $173,250,528 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $179,350,000 support a total of 3,001.0 full-time equivalent jobs, $194,079,607 in labor income, $191,185,839 in the gross regional product, and $338,291,203 in economic output in the local impact area. More broadly, these expenditures support 4,079.4 full-time equivalent jobs, $275,813,735 in labor income, $318,328,429 in the gross regional product, and $572,421,671 in economic output in the nation.

Hills Creek, Lookout Point, Dexter, Fall Creek - The expenditures associated with All Work Activities, with Ability to Customize Impact Area and Work Activity at Hills Creek, Lookout Point, Dexter, and Fall Creek are estimated to be $105,300,000. Of this total expenditure, $101,718,877 will be captured within the local impact area. The remainder of the expenditures will be captured within the state impact area and the nation. These direct expenditures generate additional economic activity, often called secondary or multiplier effects. The direct and secondary impacts are measured in output, jobs, labor income, and gross regional product (value added) as summarized in the following tables. The regional economic effects are shown for the local, state, and national impact areas. In summary, the expenditures $105,300,000 support a total of 1,762.0 full-time equivalent jobs, $113,948,049 in labor income, $112,249,060 in the gross regional product, and $198,617,584 in economic output in the local impact area. More broadly, these expenditures support 2,395.1 full-time equivalent jobs, $161,935,803 in labor income, $186,897,037 in the gross regional product, and $336,080,301 in economic output in the nation.

**Population and Housing**

As discussed above in Section 3.11.2.4.1, given the current availability of approximately 21,100 housing units within the ROI (USCB 2019c), any small in-migration resulting from construction projects is not expected to substantially affect housing availability for current residents. As such, minor, adverse effects to population and housing would occur under Alternative 4. These effects would occur in the short and medium term and be regional in extent.

**Quality of Life and Recreational Value**

As discussed above in Section 3.11.2.4.1, work-related activities involving heavy equipment would cause visual and auditory disturbance to local residents and recreational users in the vicinity of the project areas, as well as reduce air quality from project-related emissions. Traffic levels would similarly increase during work periods, but would be confined to the immediate vicinity of work sites and would not substantially reduce resident access to community resources or visitor access to reservoirs. Work-related noise, emissions, and congestion would reduce resident quality of life and recreational value during the construction phases only and have local, adverse, moderate effects in the short and medium term. Long-term visual effects from the erection of new structures would be minor.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low-Income Populations**

Low-income populations in Lane, Linn, and Marion counties that are hired to work on these projects would experience minor health benefits through economic pathways in the short and medium term. There may also be minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects, but these effects would not persist beyond the duration of the construction phase. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

*3.11.7.13.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek drawdown;
- Foster Fish Ladder Temperature Improvement (#479);

- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in summer (#721) (GPR);
- Augmentation of instream flows by using the inactive pool (#718) (CTG, DOR, FCR, BLU);
- Augmentation of instream flows by using the power pool (#304) (LOP, HCR, CGR, GPR, DET); and
- Integrated temperature and habitat flow regime (#30a) (All reservoirs).

**Quality of Life**

The Fall Creek Drawdown would continue to adversely affect the quality of life for nearby residents and the recreational value at Fall Creek in the short and long term (recurring). There are no cities directly on the shores of the Fall Creek Reservoir, so therefore effects to the quality of life would be minor and localized.

**Recreational Value**

Increased reservoir levels and alteration of outflows would increase both the quality of recreational opportunities offered at reservoirs and the ability of reservoirs to support increased numbers of visitors over the life of the project. Higher reservoir levels support higher levels of visitation, higher recreational quality, and higher recreational expenditures. These visitors would in turn generate minor, indirect, beneficial, socioeconomic effects through the expenditure of funds in support of their activity of choice for the life of the project. As a result of increased recreational opportunity and quality, average annual NED recreational benefits are expected to increase under Alternative 4 throughout the WVS. Increased recreational revenues attributable to Alternative 4 are also estimated to support 4.3 jobs and $301,000 in total value to the economy of the ROI. Hence, these regional, indirect beneficial effects would be minor and long-term.

**M&I Use and Irrigation**

Under Alternative 4, peak conservation storage would increase 122,000 acre-feet over the NAA and benefit water users throughout the WVS. Increased availability of irrigation water would allow for increases in the amount of irrigated acreage throughout the ROI and reduced prevalence of crop damages for the life of the project, stimulating indirect and induced socioeconomic benefits throughout the ROI as crops are brought to market. M&I users would also likely be able to use the majority of their water allocations, decreasing costs of living and business throughout the ROI for the life of the project. Hence, these beneficial effects would be minor, regional, and long-term.

**Non-Use and Existence Value**

As such, the overall beneficial effect to socioeconomic resources due to recreation and water supply as a result of the alteration of outflows and reservoir levels would be moderate in magnitude, medium in extent, long-term, and significant.

*3.11.7.13.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. For reasons similar to those discussed above as they relate to recreational value; agricultural irrigation and M&I use; and quality of life, effects to socioeconomic resources would range from minor to moderate and adverse in the short term and long term (recurring). Visitation would likely further decrease due to decreased recreational quality of reservoirs and could affect recreational revenues. Costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss of surface water would adversely affect the viewshed for nearby residents for longer than three weeks.

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long-term.

*3.11.7.13.4 Climate change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors would contribute to indirect adverse effects to socioeconomic resources throughout the entirety of the ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I.

Under Alternative 4, construction measures would cause adverse effects to population and housing with an in-migration of workers to the ROI. Increased capital expenditures would benefit labor and earnings and low-income populations. Climate change would not exacerbate these effects and the magnitude, extent, and duration would remain the same. Effects to the recreational value and viewshed (and therefore quality of life) from construction activities and the Fall Creek Drawdown could be exacerbated if wildfires and HABs further affect turbidity and water quality. However, effects from construction activities and the Fall Creek drawdown in combination with climate change would likely remain moderate, localized, and occur in the short, medium, and long term (recurring).

Under Alternative 4, beneficial effects resulting from increased reservoir storage would be minor, regional, and long term. These beneficial effects would offset the adverse effects from climate change on recreational value and water supply described above. As such, the alteration of outflows and reservoir levels in combination with climate change would have long term, regional, negligible to minor, beneficial effects.

#### *3.11.7.14 Alternative 5 – Integrated Water Management and ESA-Listed Fish Alternative (using diversion tunnel at CGR)*

Alternative 5 is nearly identical to Alternative 2B and differs only in its use of a refined integrated temperature and habitat flow regime (#30b). Given their similarity, the socioeconomic effects of the Alternatives are essentially identical to those and are affected by the same mechanisms discussed in Section 3.11.2.6; the use of integrated temperature and habitat flow regime only affect biologic and hydrologic parameters and would not noticeably affect socioeconomic resources differently from Alternative 2B.

Under Alternative 5, beneficial socioeconomic effects to labor and earnings and low-income populations due to construction and maintenance of structural measures would be negligible to minor in magnitude, regional in extent, short-term and medium-term. Adverse effects to population and housing would be negligible to minor, regional in extent, and short- and medium-term in duration. Adverse effects to quality of life and recreational value from construction would be minor in magnitude, regional in extent, and occur in the short and medium term. Long-term visual effects to quality of life from the erection of new structures would be negligible to minor. Beneficial, indirect effects to recreation expenditures from the alteration of outflows and reservoir storage measures under Alternative 5 would be negligible in magnitude, regional in extent, and long-term. Indirect, adverse effects to M&I and agricultural water supply costs from the alteration of outflows and reservoir storage measures under Alternative 5 would be minor in magnitude, regional in extent, and long-term. Preserving the existence value of the UWR Chinook salmon and UWR steelhead would have long-term, minor beneficial effects to society in the state and beyond. Alternative 5 would have nearly identical affects as Alternative 2B, similar effects to socioeconomic resources as Alternatives 2A, and would have effects of substantially lower magnitude than Alternatives 1, 3A, 3B and 4.

##### *3.11.7.14.1 Construction, Operation, Management, Rehabilitation, and Replacement of Structural Measures*

The same measures as those under Alternative 2B would be occur under Alternative 5, resulting in beneficial and adverse socioeconomic effects through the mechanisms discussed in Section 3.11.4.2.1.

- Gravel augmentation below dams (#384) (CGR, BLU, FOS, BCL);
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) (All reservoirs);

- Maintenance of existing and new fish release sites above dams (#726) (DET, BCL, GPR, FOS, CGR, HCR, FCR, LOP);
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Construction of WTC towers (#105) (DET);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in summer (#721) (GPR);
- Construction of AFFs (#722) (GPR);
- Provide Pacific lamprey passage and infrastructure (#52) (GPR);
- Construction of structural downstream fish passage (#392) (LOP, FOS, DET); and
- Operation, Maintenance, Repair, Replacement, and Rehabilitation. (All reservoirs)

**Labor and Earnings**

Given their functional similarity, the socioeconomic effects of Alternatives 5 and 2B are very similar and are affected by the same mechanisms discussed in Section 3.11.2.4. Construction costs would not appreciably differ between these alternatives and it is not likely implementation of either alternative would substantially alter the support of jobs or noticeably increase consumer demand within the ROI. As such, beneficial socioeconomic effects due to increased construction expenditures under Alternative 5 would be negligible to minor in magnitude in the short-term, increasing to major in the medium term while construction is occurring, and regional in extent.

**Population and Housing**

As discussed above in Section 3.11.2.4.1, given the current availability of approximately 21,100 housing units within the ROI (USCB 2019c), any small in-migration resulting from construction activities under Alternative 5 could be measurable and could be noticeable but would not affect housing availability or pricing for current residents. Any adverse effects which may occur would only persist for the short- or medium-term duration of the construction period depending on the scale of the project in question. As such, adverse effects on population and housing would be negligible to minor and regional in extent.

**Quality of Life and Recreational Value**

Quality of life and recreational value of reservoirs would be minorly reduced in the vicinity of project sites during the construction due to the visual disturbance from the presence of heavy equipment and workers, increased air emissions, noise and traffic. Effects would be confined to the immediate vicinity of project sites (reservoirs and towns bordering reservoirs) and would only persist for the duration of construction projects. These effects would be most pronounced in the towns of Detroit and Sweet Home, in particular due to the construction of a WTC tower at Detroit and construction of structural downstream fish passages at Detroit and Foster; both of which are relatively larger projects that would occur in the medium-term. As such, effects to quality of life and recreational value due to construction-related activity under Alternative 5 would be short- and medium-term, localized, and major.

Although these works of improvement have been specifically designed to meet the requirements of ESA-listed species, their populations would not return to a level that would directly affect recreational fishing. However, other species including those within recreational fisheries would also benefit from improved habitat value. Recreational fishing use and visitation within the ROI would likely increase in the long term and have negligible, beneficial, indirect effects on the recreational value of affected reservoirs.

**Low Income Populations**

Low-income populations in Lane, Linn, and Marion counties that are hired to work on these projects would experience negligible to minor health benefits through economic pathways in the short and medium term. There may also be negligible to minor adverse effects to the physical health and well-being of low-income communities (from increased air emissions and noise levels) that are hired to work at the sites for the duration of these projects, but these effects would not persist beyond the duration of the construction phase. Benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. All effects would be regional in extent.

#### *3.11.7.14.2 Alteration of outflows and reservoir levels*

The following measures would affect recreational value and reservoir levels.

- Fall Creek drawdown;
- Foster Fish Ladder Temperature Improvement (#479) (FOS);
- Use of regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) (GPR);
- Use of spillway for surface spill in summer (#721) (GPR);
- Augmentation of instream flows by using the inactive pool (#718) (FCR, BLU);
- Augmentation of instream flows by using the power pool (#304) (LOP, HCR, GPR, DET);
- Refined integrated temperature and habitat flow regime (#30b) (All reservoirs);
- Deeper fall reservoir drawdowns for fish passage (#40) (CGR, GPR);
- Spring reservoir drawdown for downstream fish passage (#720) (CGR); and
- Pass water over spillway in spring for fish passage (#714) (GPR).

**M&I Use and Irrigation**

Similar to Alternative 2B, Alternative 5 would result in a decrease of 64,000 acre-feet of conservation storage from the NAA. Reduced conservation storage would increase water costs and crop damages to M&I and irrigation users throughout the ROI, resulting in general cost of living increases for the life of the project. These regional, indirect, adverse socioeconomic effects would be minor and long-term.

**Recreational Value**

As described under Alternative 2B, deep fall reservoirs draw-downs at Green Peter would likely decrease visitation in the short term but would not likely affect revenues due to seasonally low levels of visitation during this timeframe. Spring drawdowns in particular at Cougar Reservoir would reduce recreational expenditures at this reservoir due to decreased recreational quality during the spring recreation season throughout the life of the project. However, Cougar is one of the least visited reservoirs of the 13 reservoirs; and visitors spend the least amount of dollars per visit at this reservoir (USACE 2019g). Hence, these short- and long-term (recurring) adverse effects from drawdowns at Fall Creek, Green Peter, and Cougar would be negligible and localized.

Conversely, fall and spring reservoir drawdowns would negligibly increase habitat values for recreational fish species throughout the ROI for the life of the project, resulting in increased recreational visitation and expenditures. Average annual NED benefits under Alternative 5 would be slightly higher than the NAA; these benefits would support 5.2 jobs and $356,000 in total economic value. These regional, beneficial effects would ultimately be negligible in magnitude and long-term.

**Quality of Life**

As discussed above in Section 3.11.2.4.2, drawdowns under this alternative would also adversely affect the quality of life for nearby residents at Fall Creek and Green Peter. Additionally, under this alternative, deep fall and spring reservoirs drawdowns at Cougar would similarly affect the quality of life for nearby residents. There are no cities directly on the shores of Fall Creek, Green Peter, or Cougar and therefore effects to the quality of life would be minor and localized. Effects would occur in the short term and recur annually in the long term.

**Non-Use and Existence Values**

As discussed above in Section 3.11.2.4.3, implementation of the measures under Alternative 2A would preserve the existence value of the UWR Chinook salmon and UWR steelhead and therefore have long-term, minor beneficial effects to society.

*3.11.7.14.3 Suite of Near-Term Operations*

Near-term operations that could affect socioeconomic resources include deep drawdowns, extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Visitation would likely further decrease due to decreased recreational quality of reservoirs and could affect recreational revenues. Costs to agricultural and M&I users would further increase due to reduced WVS water availability; and the loss of surface water would adversely affect the viewshed for nearby residents for longer than three weeks. As such, socioeconomic effects as they relate to recreational value; agricultural irrigation and M&I use; and quality of life would range from minor to moderate and adverse in the short term and long term (recurring).

The suite of near-term operations would also further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. As such, the implementation of these near-term operations would have indirect, minor beneficial effects to the recreational value in the long-term.

#### *3.11.7.14.4 Climate Change*

As discussed in Section 3.11.2.3.1, climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors in combination with decreased reservoir storage under Alternative 5 would contribute to indirect adverse effects to socioeconomic resources throughout the entirety of the ROI through decreased recreational revenues resulting from lower recreational quality and visitation as well as increased costs to irrigation and M&I. These adverse effects would be additive, long term, and minor to moderate.

Under Alternative 5, effects to visitation and the viewshed (and therefore quality of life) from construction activities and the Fall Creek, Green Peter, and Cougar drawdowns could be exacerbated if wildfires and HABs further affect turbidity and water quality. However, effects from construction activities and drawdowns in combination with climate change would likely remain minor, localized, and occur in the short, medium, and long term (recurring).

### ***3.11.7.15 Conclusion***

Reservoir drawdowns would be a main component of alternatives 3A and 3B, with a total of 10 drawdowns across seven reservoirs per year. As such, Alternatives 3A and 3B3B would cause the most severe short and long term adverse effects to quality of life, recreational value, and agricultural irrigation and M&I use; followed by alternatives 2A, 2B, and 5. In contrast, Alternatives 1 and 4 would consist largely of the construction structural measures and due to their high construction expenditures, would cause the most beneficial short- and medium-term effects to labor and earnings, as well as the most adverse short-and medium-term effects to population and housing and quality of life to workers. Alternatives 2A, 2B, and 5 consist of a combination of construction and reservoir drawdowns which allow for both beneficial effects due to construction expenditures without compromising the ability of WVS reservoirs to fulfill other authorized purposes.

## 3.12 POWER GENERATION AND TRANSMISSION AFFECTED ENVIRONMENT

The Willamette River Basin (WRB) contains several federal and non-federal hydroelectric facilities used to generate electrical energy for local and regional consumption, as well as high-voltage transmission lines and other facilities that move this energy from the generating facilities to local and regional loads.

The Flood Control Acts of 1948, 1950, 1954 modified the Flood Control Act of 1938 to provide for the installation of hydroelectric power-generating facilities at eight Corps multipurpose projects throughout the Willamette Basin: Detroit, Green Peter, Lookout Point, Cougar, Hills Creek, Big Cliff, Foster, and Dexter dams. These are a subset of the Federal Columbia River Power System (FCRPS) projects. The Corps dictates the parameters for dam operations to meet its statutory requirements, and power generation is subsequently scheduled within these parameters. The Cougar, Hills Creek, Big Cliff, Foster, and Dexter projects run a flat generation schedule each day based on the water available, and the generation schedule is determined solely by the Corps. For the Detroit, Green Peter, and Lookout Point projects, the Bonneville Power Administration (Bonneville) is provided an opportunity to optimize the daily timing of power generation after the Corps determines its statutory requirement needs for other project purposes, such as flood control and fish and water quality operations and identifies how many hours of generation would be available within a day, as well as any constraints (e.g., cannot be more than 10 continuous hours without generation).

Bonneville is a federal power marketing administration designated by statute to sell power and transmission services throughout the Pacific Northwest region. Bonneville sells electric power from FCRPS projects, operated and maintained by other federal agencies (i.e., Corps or Reclamation), to its regional firm power customers (wholesale power customers) across the Pacific Northwest, including municipalities, public utility districts (PUDs), cooperatives, federal agencies, and investor-owned utilities (IOUs) and one direct service industry customer. These wholesale power customers, in turn, serve residential, commercial, and industrial retail customers (i.e., “end users”).

Bonneville also operates and maintains about 15,000 circuit miles of the high-voltage transmission system within the Pacific Northwest region (Bonneville 2013). This system integrates and transmits electric power within the Pacific Northwest region and interconnects with external transmission systems throughout the western United States and parts of Canada and Mexico. Separate from its power sales, Bonneville sells transmission services (for the delivery of electricity from generating resources to end users) and associated ancillary services (for maintaining transmission system reliability) to regional firm power customers, independent power producers, and power marketers.

There are non-federal hydropower generation projects in the Willamette Valley upstream or downstream of the WVS projects, most of which are licensed by the Federal Energy Regulatory Commission (FERC) (Table 3.12-1). The Eugene Water and Electric Board (EWEB) owns and operates two run-of-river hydroelectric projects on the McKenzie River: Carmen-Smith and Leaburg-Walterville (Figure 3.12-1). EWEB's Carmen-Smith project is located close to the origination of the McKenzie River at Clear Lake; its operation is independent of other generation projects in the Willamette Valley. Downstream of the Corps' Cougar and Blue Lake projects, EWEB diverts McKenzie River flows to the Leaburg Power Canal and the Walterville Power Canal for hydropower generation at the Leaburg and Walterville generation facilities, and then returns these flows to the river. The Santiam Water Control District (SWCD) operates a small hydropower project at their facilities at Geren Island (185 kilowatt) in the Santiam River downstream of Detroit Dam, and is in the process of licensing additional generation capacity. In 2013, private developers built a 7.5 MW power house that uses discharges from the Dorena Project. Portland General Electric operates a 15 MW facility at Willamette Falls.

Under section 10(f) of the Federal Power Act, non-federal hydropower projects downstream of federal storage reservoirs are required to pay a portion of the storage costs of the upstream federal projects for the use of improved stream flows which increase their project's generation (referred to as "energy gains"). The payments for these energy gains are known as headwater benefit payments. In the Willamette Valley, this applies to Leaburg/Walterville and Willamette Falls. Both Portland General Electric and Eugene Water and Electric Board make annual payments and their recent 5-year average (2017-2021) energy gains and headwater benefit payments are depicted in Table 3.12-1.

**Table 3.12-1 Non-Federal hydropower projects in the Willamette Valley.**

| Project | Owner | FERC License No. | River Basin | MW | Energy Gains (aMW)[1, 2] | Headwater Benefit Payment[1] |
|---|---|---|---|---|---|---|
| Carmen- Smith | Eugene Water and Electric Board (EWEB) | 2242 | McKenzie | 92.00 | NA[3] | NA[3] |
| Leaburg/ Walterville | EWEB | 2496 | McKenzie | 23.90 | 0.84 | $8,400 |
| Dorena Lake Dam | Dorena Hydro, LLC | 11945 | Row | 7.50 | NA[3] | NA[3] |
| Geren Island | Santiam Water Control District | Exempt | North Santiam | 0.19 | NA[3] | NA[3] |
| Willamette Falls | Portland General | 2233 | Willamette | 16.00 | 2.94 | $26,600 |

1/Annual amount averaged over a five-year period (2017-2021).

2/The aMW for energy gains does not represent an increase in average annual generation. Instead, it is a weighted average to account for differences in critical period generation and average energy with their respective values multiplied by 1 and 2.

3/Energy gains and headwater benefit payments do not apply to projects that are upstream of federal storage projects or are not functionally downstream of federal projects (i.e., Carmen-Smith and Dorena Lake Dam, respectively) or are FERC exempt (Geren Island).

Congress created Bonneville through enactment of the Bonneville Project Act in 1937, Pub. L. No. 75-329, 50 Stat. 731 (codified as amended at 16 U.S.C. §§ 832-832m (2012)) to market and transmit electric power produced by federal hydropower dams in the Pacific Northwest.

Bonneville is statutorily obligated to assure the Pacific Northwest of an adequate, efficient, economical, and reliable power supply consistent with Section 839(3) of the Northwest Power Act. Bonneville's authority to market power generated from the entire FCRPS[19], of which the Willamette Valley System (WVS) hydropower dams are a subset, is codified in Section 8 of the Federal Columbia River Transmission System Act of 1974, Pub. 93-454, 88 Stat. 1376, (codified as amended at 16 USC §§ 838-838l (2012)). The Federal Columbia River Transmission System Act also gave Bonneville express authority to operate and maintain the Federal Transmission System within the Pacific Northwest and to construct improvements, betterments, and additions to and replacements of the system. The terms and rates upon which Bonneville may sell power and transmission services are subject to several statutes, including the Bonneville Project Act, the Flood Control Act of 1944, Pub. L. No. 78-534, 58 Stat. 887 (codified at 16 U.S.C. § 825s (2012)), the Federal Pacific Northwest Consumer Power Preference Act of 1964, Pub. L. No. 88-552, 78 Stat. 756 (codified at 16 U.S.C. §§ 837-837h (2012)), the Federal Columbia River System Transmission Act of 1974, and the Pacific Northwest Electric Power Planning and Conservation Act, 1980, Pub. L. No. 96-501, 94 Stat. 2697 (codified at 16 U.S.C. § 839-839h (2012)).

### 3.12.1 Affected Environment

Sections 3.12.2.1 through 3.12.2.4 describe the federal power and transmission systems, focusing on those elements that could be affected by the alternatives of the Draft WVS EIS.

#### *3.12.1.1 Federal Power*

Bonneville sells firm power at wholesale under long-term contracts to 136 power customers within a 300,000-square-mile service area in the Pacific Northwest. The Bonneville service area is geographically located within the boundary of the Western Interconnection power system. The Western Interconnection is one of four major North American power systems and includes power generation and transmission facilities across 14 U.S. states, two Canadian provinces, and parts of Mexico (WECC 2018). Bonneville imports power and exports surplus power (i.e., power not needed to meet Bonneville's firm power commitments) beyond the Pacific Northwest but within the Western Interconnection.

In understanding power generation, it is important to recognize that "capacity" is distinct from "energy," and that the Alternatives have the potential to affect them in different ways. Capacity is defined as the maximum potential output of a generation unit that can be physically produced at any given instant and is commonly expressed in megawatts (MW). Generators do not operate at full capacity at all times, and output can vary according to a variety of factors such as lower demand, market conditions, and variability in fuel sources. In this context, energy is defined as the amount of electric power generated at a project or power plant over a period of time and is expressed in megawatt-hours (MWh) or average megawatts (aMW). An aMW is a

[19] The FCRPS consists of the Federal transmission system and 31 Federally-owned dams on the Columbia River and its tributaries including eight WVS Projects with hydropower.

unit of energy representing 1 MW of electric power capacity generated continuously over a year. One aMW is equal to 8,760 MWh.

Table 3.12-2 provides a summary of the power-generating capacity within the Western Interconnection, the Pacific Northwest, all of Bonneville's marketable resources, and WVS projects. For each of these areas, the values summarized in Table 3.12-2 are not additive; the smaller areas are a subset of the larger areas (i.e., the Pacific Northwest is a subset of the Western Interconnection, Bonneville's marketable resources are a subset of the Pacific Northwest, and the WVS projects are a subset of Bonneville's marketable resources). In addition, power generating projects typically operate below full capacity primarily because of the variation in available resources (e.g., water, wind, solar, etc.), demand for electric supply, and constraints on project operation to achieve non-power objectives, as well as for any applicable Ancillary Services (e.g., Incremental Capacity, Decremental Capacity, synchronous condensing, etc.). Both capacity and energy existing conditions and trends for these areas are further explained in the discussion below.

- Western Interconnection Resources: The diverse mix of generation resources, referred to as a "resource mix," in the Western Interconnection constitutes roughly 20 percent of all national power generation, with approximately 40 percent of all national hydropower capacity and 35 percent of all wind and solar capacity. Given the geographic, climatic, and consumer (e.g., urban and rural, residential, commercial, and industrial electricity end users) diversity across the Western Interconnection, demand for and generation of power varies greatly. Coordination across the Western Interconnection allows for planning across this diverse power system to ensure cost-effective and reliable power. Overall, across the Western Interconnection for 2016, there were 94,863 aMW generated, of which hydropower generated roughly 26,000 aMW (WECC 2018).
- Pacific Northwest Regional Resources: The Pacific Northwest regional resources are a component of the Western Interconnection resources. Table 3.12-2 illustrates the predominance of hydropower capacity (54 percent) in the resource mix of the Pacific Northwest region. In Figure 3.12-1 total power generation (energy) in the Pacific Northwest fluctuated year to year between 2006 and 2019 (NW Council 2021). Wind energy production has been increasing during this period. The region is experiencing a rapid growth in new renewable generation, primarily wind and solar, largely developed by independent power producers, spurred in part by recent legislative and policy trends.
- Bonneville's Marketable Resources: Bonneville does not own generating resources, rather, Bonneville markets power from a combination of federal resources (31 FCRPS dams), certain non-federal generating resources (e.g., wind, hydro, nuclear, etc.) whose output Bonneville has acquired under contracts, and other contract purchases, as needed. Table 3.12-2 illustrates the predominance of hydropower generation capacity (94 percent) in the mix of all Bonneville's marketable resources.
- WVS Projects: The eight WVS projects with hydropower that are the subject of the WVS EIS are a subset of the 31-project FCRPS. Each of these eight WVS projects has one or more generation units with a specific capacity to produce power. The nameplate capacity (i.e.,

the maximum potential for energy output) for each WVS project ranges from 21 to 138 MW. Table 3.12-3 lists these projects and their generating characteristics. The total combined capacity of these eight WVS projects is 469 MW. This represents about two percent of the 22,441 MW nameplate capacity of the FCRPS. Average generation at these eight projects combined is 171.4 aMW, which constitutes less than two percent of the total energy of the FCRPS.

**Table 3.12-2. Power Generation Capacity in Megawatts (Current as of 2021).**

| Type | Western Interconnection | Pacific Northwest Region | Bonneville[1] | Willamette Valley System |
|---|---|---|---|---|
| Hydropower | 72,000 | 34,650 | 22,441[2] | 469 |
| Wind | 23,000 | 10,710 | 248 | 0 |
| Natural Gas | 102,000 | 9,450 | 0 | 0 |
| Coal | 37,000 | 5,040 | 0 | 0 |
| Solar | 16,000 | 1,260 | 0 | 0 |
| Nuclear | 8,000 | 1,260 | 1,144 | 0 |
| Geothermal | 3,000 | 61 | 0 | 0 |
| Other | 9,000 | 569 | 0 | 0 |
| **Total Capacity** | **270,000** | **63,000** | **23,833** | **469** |

Source: Bonneville (2019), WECC (2018), NW Council (2021)

Note: The estimates across geographic regions are not additive; the Pacific Northwest is geographically within the Western Interconnection. The WVS Projects' capacity is for the eight WVS projects with hydropower facilities that would be affected by the Alternatives, which are a subset of the Bonneville resources.

[1/] This column (Bonneville) represents the generation capacity of all of Bonneville's marketable resources.

[2/] This statistic (Bonneville hydropower) represents the total capacity of the FCRPS' hydropower system, inclusive of the WVS projects, from a total of 196 hydro generating units.

#### *3.12.1.2 Regional Power Supply and Reliability*

"Power system reliability" refers to the ability of the power supply to meet the demand, and demand for power is typically referred to as "load." The flexibility and capacity of the hydropower system is critical to ensuring power system reliability. Power system reliability is measured and discussed in terms of "loss of load probability" (LOLP) of a region's power supply. LOLP reflects the probability that the region's expected supply of power would not be able to meet the region's demand for electricity. The NW Council sets the metric (e.g., LOLP) and target for reliability for the Pacific Northwest. Created by the Northwest Power Act in 1980, the NW Council develops both a regional power plan and the Columbia River Basin Fish and Wildlife Program, which collectively "ensure, with public participation, an affordable and reliable energy system while enhancing fish and wildlife in the Columbia River Basin."[20] The current target for LOLP set by the NW Council in 2011 is five percent, meaning the power supply should have sufficient resources (both capacity and energy) to limit the likelihood of a shortfall to no more than five percent during a future year, taking into account, for example, cold snaps in winter and heat waves in summer. To measure adequacy, LOLP is calculated by dividing the number of simulations with shortfalls by the total number of simulations studied. For the power supply to be deemed adequate, that fraction must be less than 1/20, equating to an LOLP of five percent or less. When the power supply is unable to meet demand, customers could experience blackouts for brief or extended periods of time.

Electricity production at the WVS projects is influenced both by the turbine capacity and the amount of water available for generation. The amount of water available at each hydro project varies from year to year, season to season, day to day, and even hour to hour based on variation in flows and operational constraints. The Corps provides daily operational guidance to Bonneville for scheduling power generation for a specific number of hours each day. The WRB is primarily rain based, and the projects are operated to manage floods fall through spring. Flood risk management in the WRB is accomplished by drafting the reservoirs behind the dams to low levels in the late fall before the rains start to provide storage space to retain inflow during downstream flood events. The release of any retained water during the flood season is regulated by the flow levels at downstream control points such as Albany and Salem whenever possible. After the flood season has passed, the reservoirs are filled with the spring inflows to their maximum conservation season level. Summer is climatically very dry, and the outflows are set for recreation, flow objectives for fish and wildlife, water quality, and irrigation. The eight projects that generate hydropower have minimal capability to shape generation to load. This cycle of drafting and filling is guided by a "Rule Curve" at each storage project that specifies the timing of each of these phases of regulation. The Rule Curve is the pool elevation that the reservoir is managed to stay at or below when possible, with pool levels above the curve when operating for flood risk management, and pool levels below the curve when inflows are low and the stored water is released to meet the various needs of the system. Consequently, the ability

[20] See NW Council, https://www.nwcouncil.org/about/mission-and-strategy. The Council uses the term "standard," but because this is not an enforceable standard, the EIS refers to this as a "target."

to manage the timing of water flow through the WVS projects for power purposes is limited to within each day.

#### *3.12.1.3 Multipurpose System and Economical Power Supply*

As a multipurpose system, the FCRPS produces both power and non-power benefits for the Pacific Northwest and facilities are owned and operated by either the Corps or Reclamation. The Corps and Reclamation operate and maintain their respective FCRPS facilities with a combination of Bonneville direct funding and federal appropriations. Bonneville solely funds activities related to power generation and jointly funds activities that support the shared purposes of the facilities.

As described in Section 3.12.2.1, the FCRPS consists of 196 hydro generating units with a total capacity of 22,441 MW, making it the largest hydro system in the United States (EIA 2014). For decades, it has been an engine of economic prosperity. It provides low-cost, carbon-free electricity, flood risk mitigation, irrigation, navigation, water quality, municipal and industrial water supply, and recreational opportunities throughout the region.

Effective management of FCRPS facilities requires balancing the many uses of these shared resources as efficiently as possible. A joint agency asset management strategy is used to make decisions that maximize the value of the FCRPS as a whole while meeting each agency's various obligations. This means identifying optimal investment timing to mitigate safety, environmental and financial risks, tailoring maintenance programs to the level of service necessary to meet obligations, and efficiently planning and operating the power system.

Congress mandated that Bonneville provide a reliable and economical power supply consistent with its statutory obligations, Bonneville continuously evaluates external factors and risks that affect its ability to bring the benefits of reliable, affordable, and clean electricity to Northwest communities.

In the WVS, the FCRPS facilities are all operated and maintained by the Corps for multiple congressionally authorized purposes, but chiefly for flood risk management. As a subset of the FCRPS and as described in Section 3.12.2.1, the WVS consists of 15 hydro generating units, apportioned to eight dams, with a total capacity of 469 MW. Accordingly, the WVS contributes a small portion, less than 2%, of the total energy of the FCRPS.

In the WVS, using revenues from its electric power rates, Bonneville pays the Corps for its share of operation and maintenance and capital repayment costs based on the power allocation of each project, as determined by congressionally authorized purposes. The FCRPS dams in the WVS have historically operated, and continue to operate, at a higher cost relative to other FCRPS hydroelectric facilities; as such, the Willamette projects as they are operated today are increasingly marginal in their ability to facilitate Bonneville's efforts to provide an economical power supply to the region. Table 3.12-4 shows the three-year average cost of power metrics from 2018-2020 under expected generation from the 2019 Bonneville White Book. The "Cost of Generation" identified in Table 3.12-4 is a measure of the direct-funded capital, and operations and maintenance costs at the facilities. "Fully Loaded Costs" identified in this table include everything in the Cost of Generation plus allocations for all remaining Bonneville power-related costs such as its fish and wildlife program, residential exchange, and other overheads.

**Table 3.12-4. Three-year Average Cost of Power Metrics (Cost of Generation and Fully Loaded Cost) at Average Water Conditions**

| Strategic Class | Cost of Generation[1] ($/MWh) | Fully Loaded Cost[2] ($/MWh) |
|---|---|---|
| Main Stem Columbia | 7.75 | 18.30 |
| Lower Snake | 14.63 | 27.42 |
| Headwater | 13.08 | 23.51 |
| Area Support | 24.80 | 35.53 |
| Area Support - Willamette Valley | 25.28 | 43.16 |
| Local Support | 31.02 | 41.57 |
| **FCRPS Hydro** | **9.48** | **20.70** |

Source: Bonneville 2019 White Book

1/ Cost of Generation represents the Bonneville direct funded costs associated with producing power at a plant. Includes operations, maintenance, administrative, and capital-related costs (interest expense).

2/ Fully Loaded Cost includes the Cost of Generation plus allocations for all remaining Power Services costs attributable to the FCRPS (including Fish and Wildlife). The majority of these costs are system-wide costs that would still be incurred and reapportioned across other Strategic Classes if the power purpose for any individual dam were eliminated.

Given Table 3.12-4 amounts, the current cost-effectiveness of WVS projects is marginal relative to average market prices and other alternative resources. Recent court-ordered changes in operations at several WVS projects are likely to significantly increase the Cost of Generation at several WVS generation facilities while also significantly reducing the amount of electricity generated. Future capital requirements for generating unit modernizations and structural measures are expected to further diminish the cost-effectiveness of WVS projects' power production. Generally, Bonneville does not regard as cost effective measures that would result in a production cost higher than value of electricity generated at individual or group projects.

#### *3.12.1.4 Transmission*

Bonneville's transmission system connects and moves power generated from federal and non-federal dams; nuclear, natural gas, and coal-fired power plants; and solar and wind generation projects to loads throughout the Pacific Northwest and beyond. Bonneville owns and operates about 15,000 circuit miles of high-voltage transmission lines and associated substations in the Pacific Northwest. There are over 260 Bonneville substations that collect power, control its flow, and deliver electricity to Bonneville customers. As shown in Figure 3.12-2, Bonneville's transmission system contains multiple "paths," or routes over which power flowing from one point to another is monitored and managed.[21]

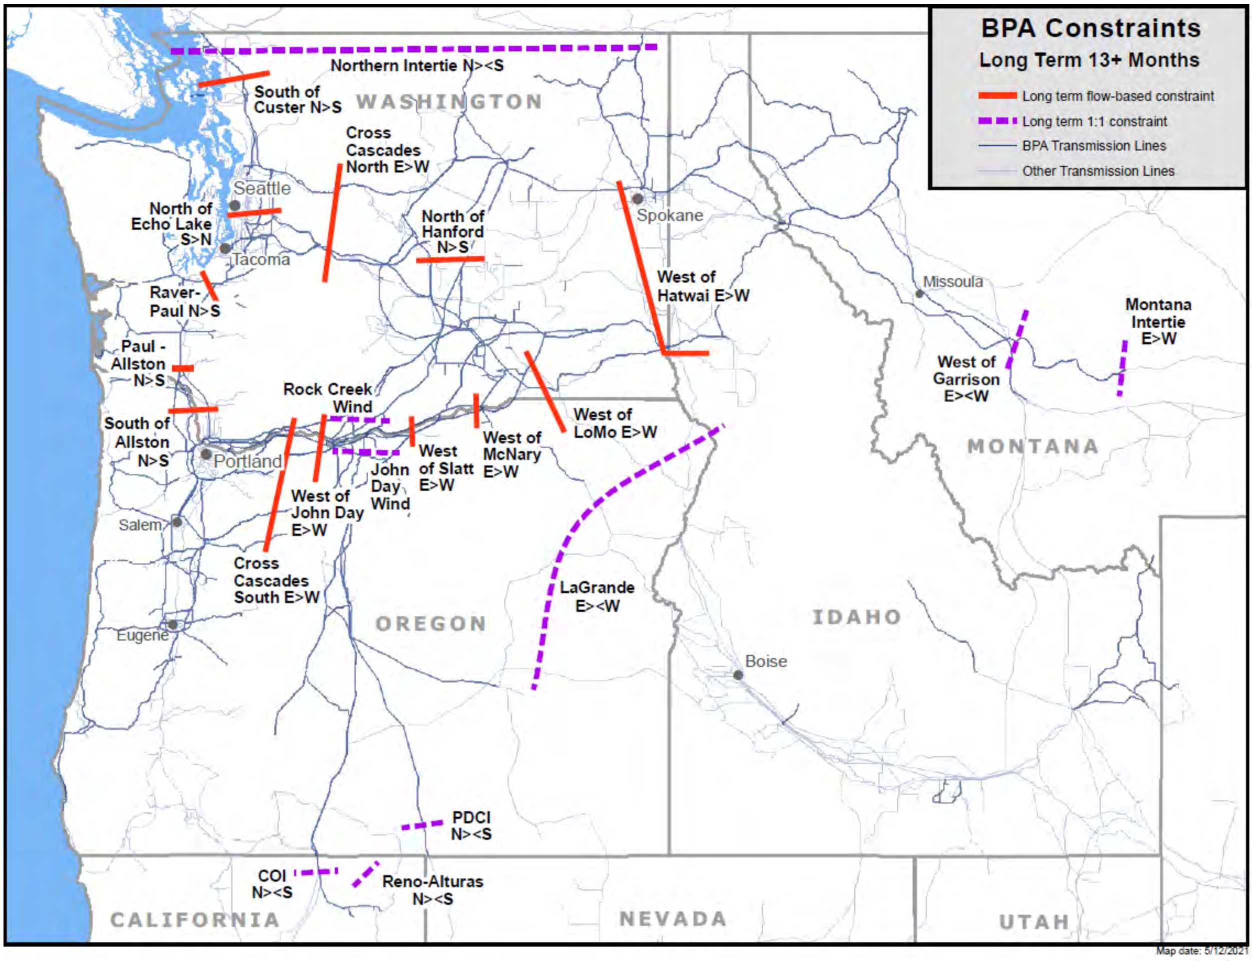

**Figure 3.12-2. Northwest Transmission Paths. Source: Bonneville (2021)**

Note: Blue lines represent Bonneville transmission lines, light gray-blue lines represent non-Bonneville transmission lines, and red and dashed purple lines denote defined paths and interties (locations where power flows are monitored and analyzed).

### *3.12.1.4.1 Bonneville Transmission Flows and Load Areas*

Bonneville's portion of the bulk electric power system (BES) is planned, designed, maintained, and operated to interconnect federal and non-federal generation to the major load centers in both the Pacific Northwest and externally to the major load centers in the WECC region. There is little generation in the Willamette Valley, so power is transmitted from generators located primarily east of the Cascades. The transmission lines that are primarily used for serving loads in the Willamette Valley run approximately from The Dalles, Oregon to substations between Portland and Salem (the "Cross Cascades South" corridor), and then south along the I-5

[21] See glossary for additional definitions of transmission paths and interties.

corridor. This corridor is considered congested,[22] especially in the winter months when loads tend to be highest. There is a notable transmission path that connects thermal generation in the Longview area, and other generators as far north as Olympia, to Portland called "South of Allston" which is also considered congested. A southern transmission path to the Klamath Falls area ties into the Pacific AC intertie, but has limited capacity to serve load in the Willamette Valley.

Changes in generation at the Willamette Valley dams tend to incrementally impact the congested paths of South of Allston and Cross Cascades South as power from generators east of the Cascades is then expected to balance any changes. Seasonal conditions further affect these transmission path capacities; because resulting temperature differences change the line ratings of all transmission paths while changes in generation patterns due to spring runoff and availability of wind and solar impact transmission path flows across the entire network, including paths that serve the Willamette Valley.

###### *3.12.1.4.2 Transmission Local Reliability*

Willamette Valley generators influence local power and transmission reliability in nearby communities. For example, in February of 2019, a severe winter storm caused an outage on the Hills Creek to Lookout Point 115kV line, which isolated the community of Oakridge from February 24 to March 5. Hills Creek generation was critical to providing this community with electric power while the line was repaired. It is expected that under current circumstances, Hills Creek would be needed most years to provide service to Oakridge in the event of a transmission outage. Also of note, in 2020, fires burned through the Thurston to Holden Creek 115kV transmission line, causing a multi-day outage. Cougar was able to generate while isolated ("islanded") from the main power system to provide power to the community of Blue Ridge. Alternatives that compromise the ability for generators at Hills Creek and Cougar to produce power can affect local power supply in those specific communities in such extreme events.

### 3.12.2 Environmental Consequences

This section evaluates effects of the Alternatives in comparison to the No Action Alternative on power generation, power system reliability, power flows across the transmission system, and economic viability of WVS projects power generation.

#### *3.12.2.1 Methodology*

##### *3.12.2.1.1 Area of Analysis*

The areas of analysis for the power and transmission resources are different from each other because of the nature of their services and products. Both the power and transmission analyses are focused on the Bonneville service area shown in Figure 3.12-3. Bonneville's service area is

[22] Congestion occurs on electric transmission systems when flows of electricity across a portion of the system are restricted or constrained below desired levels (DOE 2014).

defined by the Northwest Power Act as the Pacific Northwest, which includes Oregon, Washington, Idaho, the portion of Montana west of the Continental Divide, and the portions of Nevada, Utah, northern California, and Wyoming within the Columbia River drainage basin ("Bonneville's Service Area").[23] However, because Bonneville regularly markets its surplus power both within and outside the Pacific Northwest, the power analysis additionally considers potential effects on the power markets within the larger Western Interconnection area (Figure 3.12-4).

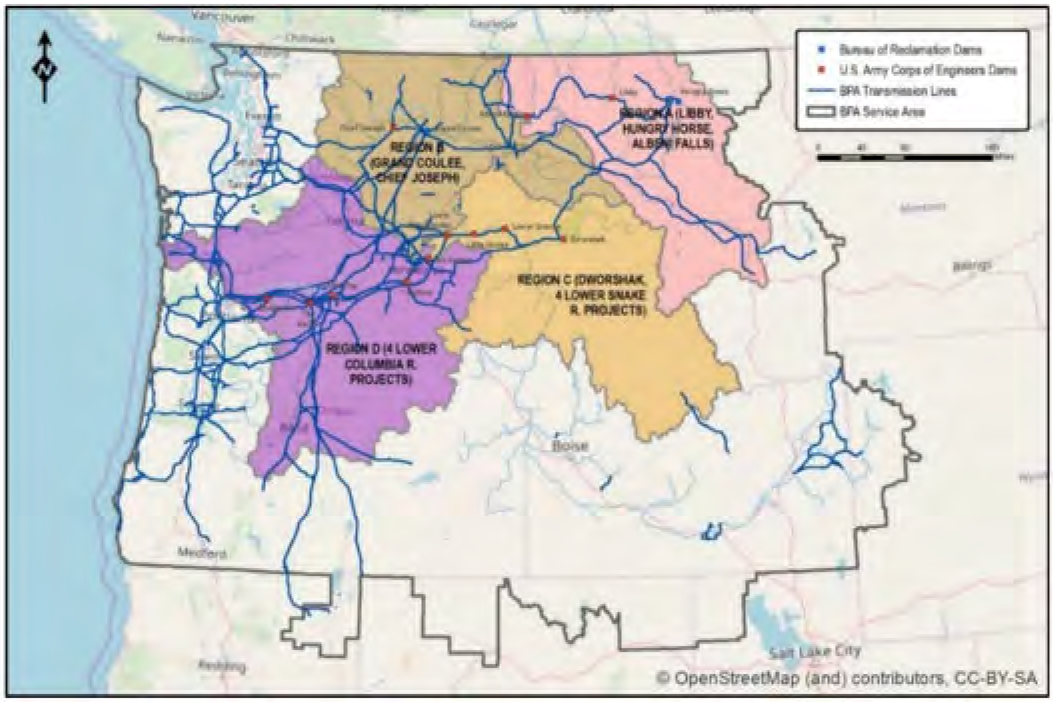

**Figure 3.12-3. Transmission Area of Analysis – the Bonneville Service Area.**

[23] 16 U.S.C. § 839a(14) (2018).

**Figure 3.12-4. Power Area of Analysis – the U.S. Portion of the Western Interconnection and the Bonneville Service Area.**

The future of power generation and transmission across the Pacific Northwest is subject to uncertainty, even under the No Action Alternative, due to evolving policy (e.g., emissions reductions targets), environmental factors (e.g., climate change) and technological growth. To evaluate the potential effects of the Action Alternatives against the No Action Alternative, the power generation and transmission analysis requires a common set of assumptions regarding these factors. These common assumptions, as identified throughout the methodology and results discussion, form the “base case” for the analysis.

### *3.12.2.1.2 Base Case Methodology*

This analysis assesses changes to power generation that would result from the Action Alternatives to inform Bonneville’s ability to assure an adequate and reliable supply of power to meet its firm power obligations under long-term contracts. The analysis considers whether the Action Alternatives require Bonneville or other regional entities (i.e., wholesale customers who might be receiving less power from Bonneville under an alternative) to acquire power from new resources (e.g., new or existing generating plants, wind, solar, etc.[24]) and/or construct new transmission infrastructure to replace lost capability at federal hydropower projects. To the extent that this confirms that this would indeed be the case, and if Bonneville proposes to take such action in the future, Bonneville would do so consistent with its applicable statutes (such as

[24] In the context of power acquired from new resources, “existing” refers to currently operating generating plants or renewables (e.g., wind, solar, etc.) located outside of the Pacific Northwest region.

the Northwest Power Act and Transmission System Act) and would complete additional site-specific planning, analysis, and compliance with environmental laws including NEPA.

The power and transmission analysis characterizes effects as beneficial or adverse (or no effect, where relevant), considering the following:

- Geographic scope of the effect or the size of the population affected. Because of the interconnected nature of the Pacific Northwest electricity system, changes at one or more WVS projects may affect power and transmission more broadly across the Pacific Northwest.
- Relative magnitude of the effect. The intensity of the power and transmission effects refers to the scale of changes in power generation; transmission flows; Net Present Value, and levelized cost of generation.
- How an effect persists over time. An effect may be moderate in the short term (e.g., limited to a construction period), but have negligible or no effect over the long term (e.g., beyond the construction period and within the analyses period). The power and transmission analyses considers the effects of the alternatives over a 30-year and 10-year timeframe, respectively.[25]

Figure 3.12-5 provides a high-level overview and depiction of the analytical framework. Note that multiple components of the analysis occur within each of the boxes depicted in the figure.

[25] Bonneville's standard power generation economic analysis timeframe is 50 years. For consistency with other analyses in the EIS, a 30-year timeframe was used instead. For transmission analysis, WECC produces power flow models for the Western Interconnect power system for different planning horizons and a 10-year case is the furthest case produced.

Additional methodological information is described further in the step descriptions below and in Appendix G, *Power Generation and Transmission*.

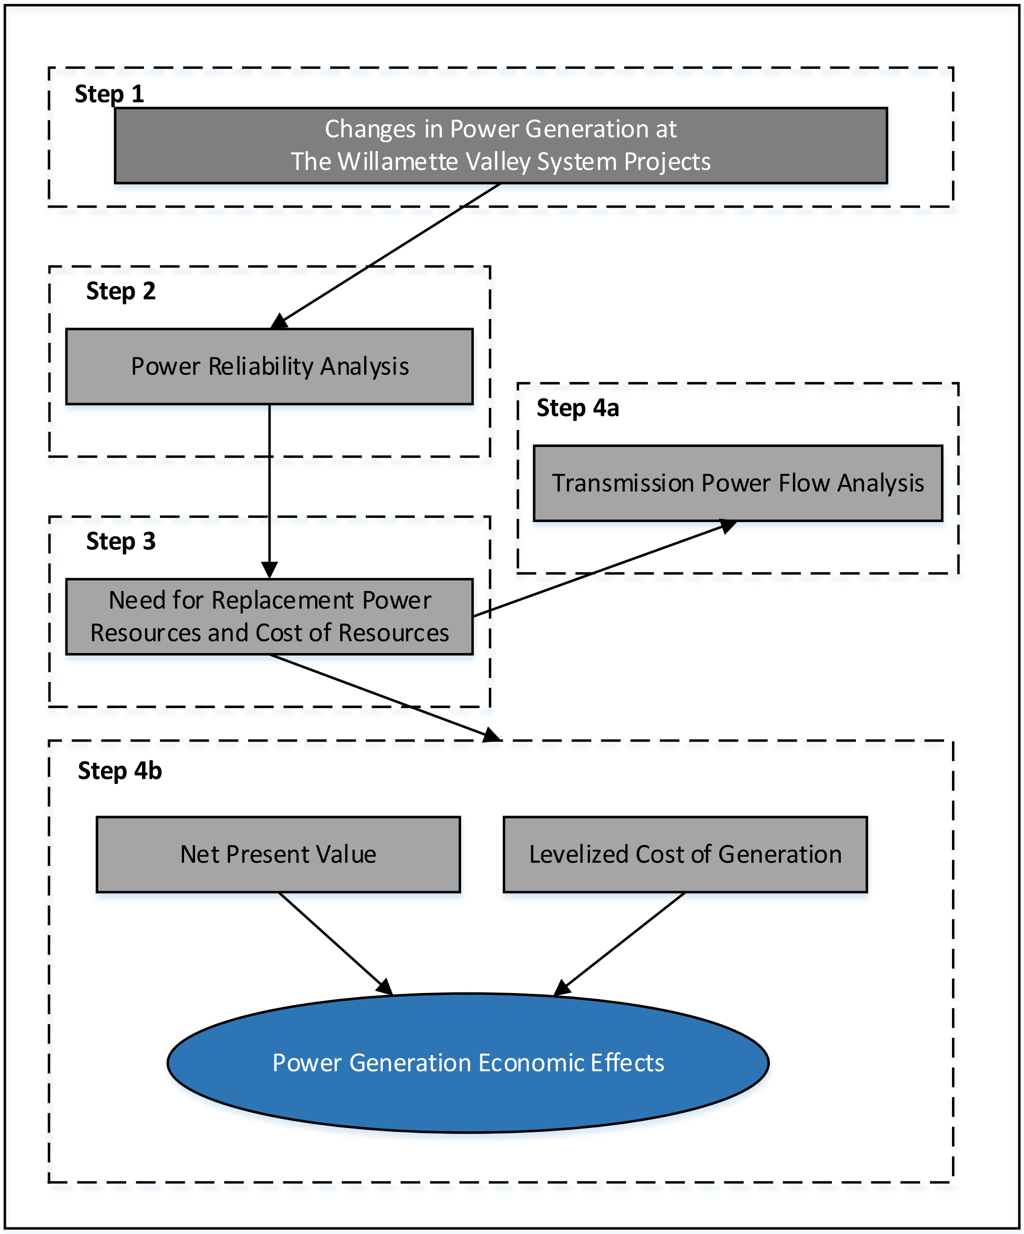

**Figure 3.12-5. Analytical Approach for Evaluating Power and Transmission Effects.**

Note*:* Additional power and transmission analysis occurs within each of the step boxes depicted.

Step 1 of the analysis assesses the effects of the Alternatives on hydropower generation based on average historical water conditions and for critical water conditions.[26] The Bonneville

[26] The "critical water year" or "critical water conditions" represent the historic water year (in this case, 1937) when the capability of the hydropower system produces the least amount of dependable generation to serve the least amount of load while considering power and non-power operating constraints. In June 2022, BPA

hydropower simulation model (HYDSIM) calculates power generation and analyzes that output in 73 different flow years (Water Years 1935/36 through 2007/08) at each of the eight WVS projects. The amount of power generated by the system under each of the alternatives, including the No Action Alternative, determines whether additional changes to, or investments in, the system may be required to maintain Bonneville's ability to supply adequate and reliable power (both energy and capacity) to its firm power customers under 20-year contracts.

Step 2 of the analysis considers whether the region has enough power capacity and energy to meet consumer demand (i.e., load). It evaluates the extent to which the alternatives, including the No Action Alternative, would result in the need for Bonneville or other regional entities to acquire power from other resources (e.g., new or existing generating plants) and construct new transmission infrastructure to replace the lost capability at federal hydropower projects. Synthesizing HYDSIM hydropower generation outputs with NW Council load-and-resource forecasts and power-import assumptions, the GENeration Evaluation SYStem (GENESYS) model simulates regional power generation and demand to determine power system reliability (i.e., LOLP). If an Alternative reduces power system reliability relative to the No Action Alternative, then the analysis continues to Step 3; otherwise, it progresses directly to Step 4a (transmission analysis) and 4b (Net Present Value and levelized costs of generation analyses).

To the extent that Step 2 identifies a potential need to acquire power from new resources or to build transmission infrastructure to meet load, Step 3 would identify potential replacement resources and associated costs[27].

Step 4a, the transmission analysis, estimates the incremental power flow change on Bonneville Network flow paths between the No Action Alternative and each of the other Alternatives during multiple seasons as a result of generation output changes at the Federal WVS projects with hydropower facilities (Detroit, Big Cliff, Cougar, Green Peter, Foster, Hills Creek, Lookout Point, and Dexter dams). The Bonneville transmission system analysis relies on power flow models to assess changes to the flow of electricity on the transmission system under each alternative. Because the transmission system is planned to reliably operate during times of peak loading, performance (and the need to reinforce the system to maintain reliable transmission operation) is analyzed during seasonal peak loading times within the region. Replacement resource assumptions (including quantities and general locations) developed under Step 3 were incorporated into the power flow models. Results of the generation and power flow models were used, along with individual WVS projects' transmission grid connections (single or more than one transmission line) and susceptibility of those connections

decided to update its long-term hydropower planning. BPA will only use the last-30-year subset of the most recent (1989 to 2018) flows and will take a statistical approach to establish firm generation. This methodology will first be used in the BP-24 rate case.

[27] If Bonneville proposes to take such action in the future, Bonneville would do so consistent with the Northwest Power Act and would complete additional site-specific planning and analysis in compliance with environmental laws, including the National Environmental Policy Act (NEPA).

to adverse weather/wildfire conditions, to qualitatively assess potential effects on local transmission reliability.

Step 4b of the analysis considers the Net Present Value (NPV) and Levelized Cost of Generation (LCOG) resulting from the increased costs of providing power associated with the inclusion of any new capital investments under each of the Alternatives. The NPV analysis compares the expected revenue produced by each WVS Project with hydropower facilities against their expected costs over a 30-year study period for each of the Alternatives. A positive NPV indicates that power generation is economically justified while a negative NPV indicates that the costs of power production outweigh the benefits. The LCOG analysis evaluates the incremental cost of producing power, in $/MWh, for each project over the 30-year study period. This value provides a relative measure of cost-competitiveness when compared to other generating resources or market purchases.

Direct effects to power and transmission caused by construction activities will not be analyzed as part of this EIS because these will be analyzed later as part of that proposed construction action's tiered NEPA analysis. During the planning process for any construction activity, the Corps would determine to what extent power and transmission may be impacted at that facility.

Additional details on the methodology used to analyze the effects of the Alternatives as well as the results of the analysis are contained in Appendix G, *Power and Transmission*.

Table 3.12-5 provides a summary of Power and Transmission effects for all WVS Programmatic Environmental Impact Statement (PEIS) Alternatives.

**Table 3.12-5. Summary of Power and Transmission Effects for All WVS PEIS Alternatives.**

| Alternative | Regional Power System Reliability Impacts | Replacement Resources Impacts | Transmission System Impacts | Economic Viability of Power Generation Impacts |
|---|---|---|---|---|
| No Action (NAA) | Same or similar to affected environment. WVS Projects 73-Year Average Generation is estimated to be 171 aMW28 (roughly the amount of power used by 136,416 Northwest homes or used by residential customers in a city slightly more populated than Gresham, Oregon). Loss of Load Probability (LOLP) is 6.5%, which is within the range of the Pacific Northwest Power System LOLP in recent years, and the risk of blackouts or power shortages is about once every 15 years. | ——[1] | Same or similar to affected environment. The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires. | Same or similar to affected environment. Power generation for combined WVS projects would continue to be marginally economically viable. Net Present Value for the combined WVS is about $225 million and the median Levelized Cost of Generation is estimated to be $26.70/MWh. |
| Alternative 1 | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would increase by 8 aMW (roughly enough to power 6,371 households annually). LOLP only decreases by 0.1 percent | NA2 | Long-term, minor, adverse effects on the transmission system. Less than 10MW increased loading on congested paths all seasons (CCS and SOA). Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) similar to the NAA. Construction projects at Cougar Dam are not anticipated to impact local | Long-term, major, adverse effects on economic viability of power generation. There would be a $1.159 billion reduction in Net Present Value to -$934 million and a $27.14 increase in the Levelized Cost of Generation to $53.84/MWh. |

[28] An average megawatt is one million watts delivered continuously 24 hours a day for one year.

| Alternative | Regional Power System Reliability Impacts | Replacement Resources Impacts | Transmission System Impacts | Economic Viability of Power Generation Impacts |
|---|---|---|---|---|
| | and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | | transmission services to Blue River provided generation is not affected. | |
| Alternative 2A | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 4 aMW (roughly enough to power 3,185 households annually). LOLP and the risk of blackouts or power shortages remain the same as the NAA. | NA[2] | Long-term, moderate, adverse effects on the transmission system. Increased loading in winter on CCS path (18.4MW) and in spring on both CCS (61.3MW) and SOA (11.8MW) paths. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated), providing transmission services to Oakridge and Blue River, respectively, similar to the NAA. Construction projects at Cougar Dam are not anticipated to impact local transmission services to Blue River provided generation is not affected. | Long-term, major, adverse effects on economic viability of power generation. There would be a $863 million reduction in Net Present Value to -$638 million and a $20.75 increase in the Levelized Cost of Generation to $47.45/MWh. |
| Alternative 2B | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 18 aMW (roughly enough to power 14,334 households annually). LOLP only increases by 0.1 percent and the risk of blackouts or power shortages remains the same resulting in no | NA[2] | Long-term, moderate, adverse effects on the transmission system. Increased loading in winter on CCS path (21.9MW) and in spring on both CCS (25.1MW) and SOA (5.1MW) paths. Generation at Hills Creek Dam would remain able to operate islanded (isolated), providing transmission services to Oakridge, similar to the NAA. There would be adverse effects on transmission services to Blue River. Deep fall and spring drawdowns would compromise Cougar Dam's ability | Long-term, major, adverse effects on economic viability of power generation. There would be a $933 million reduction in Net Present Value to -$708 million and a $23.96 increase in the Levelized Cost of Generation to $50.66/MWh. |

| Alternative | Regional Power System Reliability Impacts | Replacement Resources Impacts | Transmission System Impacts | Economic Viability of Power Generation Impacts |
|---|---|---|---|---|
| | detectable change to regional power system reliability. | | to operate islanded and serve this community under temporary weather or fire related outage conditions. | |
| Alternative 3A | Negligible Impact on power system reliability. Hydropower generation from the WVS projects would decrease by 87 aMW (roughly enough to power 69,283 households annually). LOLP only increases by 0.5 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to regional power system reliability. | NA[2] | Long-term, moderate, adverse effects on the transmission system. Increased loading on CCS and SOA paths in winter (35.9MW and 13.6MW, respectively) and spring (113.7 MW and 22.3 MW, respectively). There would be adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to operate islanded and serve these communities under temporary storm- or fire-related outage conditions. | Long-term, major, adverse effects on economic viability of power generation. There would be a $853 million reduction in Net Present Value to -$628 million and a $37.61 increase in the Levelized Cost of Generation to $64.32/MWh. |
| Alternative 3B | Negligible Impact on power system reliability. Hydropower generation from the WVS projects would decrease by 79 aMW (roughly enough to power 62,912 households annually). LOLP only decreases by 0.5 percent and the risk of blackouts or power shortages remains the same resulting in no detectable change to | NA2 | Long-term, moderate, adverse effects on the transmission system. Increased loading on CCS path all seasons (winter: 41.4MW, spring: 94.8 MW, and summer: 25.6MW) and on SOA path in winter (15.2MW) and spring (18.7 MW). There would be adverse effects on transmission services to Oakridge and Blue River. Deep fall and spring drawdowns would compromise the Hills Creek and Cougar dams' respective abilities to operate islanded and serve these communities | Long-term, major, adverse effects on economic viability of power generation. There would be a $829 million reduction in Net Present Value to -$604 million and a $32.72 increase in the Levelized Cost of Generation to $59.42/MWh. |

| Alternative | Regional Power System Reliability Impacts | Replacement Resources Impacts | Transmission System Impacts | Economic Viability of Power Generation Impacts |
|---|---|---|---|---|
| | regional power system reliability. | | under temporary weather or fire related outage conditions. | |
| Alternative 4 | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would increase by 1 aMW (roughly enough to power 796 households annually). LOLP and the risk of blackouts or power shortages remain the same. | NA2 | Long-term, minor, adverse effects on the transmission system. Less than 10MW increased loading on congested paths (CCS and SOA) all seasons with exception of a slightly greater increase on the CCS path in spring (15MW). Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) similar to the NAA. Construction projects at Hills Creek and Cougar dams are not anticipated to impact local transmission services to Oakridge and Blue River, respectively, provided generation is not affected. | Long-term, major, adverse effects on economic viability of power generation. There would be a $1.162 billion reduction in Net Present Value to -$937 million and a $27.84 increase in the Levelized Cost of Generation to $54.54/MWh. |
| Alternative 5 | Negligible impact on power system reliability. Hydropower generation from the WVS projects would decrease by 18 aMW (roughly the amount of power consumed by 14,334 Northwest homes in a year) relative to the NAA on average under historical water conditions. The WVS projects would lose 12 aMW of firm power production under critical water conditions. LOLP would | NA2 | Alternative 5 was not studied independently of alternative 2B. Transmission impacts should be considered the same as alternative 2B. | Long-term, major, adverse effects on economic viability of power generation. There would be a $939 million reduction in Net Present Value to -$714 million and a $24.11 increase in the Levelized Cost of Generation to $50.81/MWh. |

| Alternative | Regional Power System Reliability Impacts | Replacement Resources Impacts | Transmission System Impacts | Economic Viability of Power Generation Impacts |
|---|---|---|---|---|
| | increase to 6.6 percent associated due to loss in generation and no replacement resources would occur | | | |
| Near term operations measure | Negligible impact on power system reliability. Average annual hydropower generation from the WVS projects would decrease by 52 aMW (roughly enough to power 41,392 households annually). LOLP and the risk of blackouts or power shortages remain the same. | NA2 | Long-term, moderate, adverse effects on the transmission system. Increased loading on CCS path in winter (47.0 MW) and spring (59.8 MW). Generation at Hills Creek would generally remain able to operate islanded (isolated) similar to the NAA, though some decrease in night time capability may occur. Deep fall and spring drawdowns would compromise Cougar Dam ability to operate islanded and serve the Blue River community under temporary weather or fire related outage conditions. | Long-term, major, adverse effects on economic viability of power generation. There would be a $421 million reduction in Net Present Value to -$196 million and a $11.65 increase in the Levelized Cost of Generation to $38.35/MWh. |

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only occurs as a result of implementing the Alternatives (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would occur; LOLP is within the reasonable historical range of the NW Council target.

3/ Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the Levelized Costs of Generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

4/Near-term operations measure effects are only inclusive of near-term operational measures and do not account for structural measures that have been proposed under the court order (e.g., upgrades to the Dexter adult fish facility), nor do they account for operational changes that could occur as a result of structural measure implementation.

### 3.12.2.2 *No Action Alternative*

This section evaluates power and transmission effects under the No Action Alternative. "No Action" represents continued operations, configuration, and maintenance of the system under the operations rules in effect in 2019. The analysis below projects generation and reliability of the regional power system over a 30-year planning period. It accounts for planned maintenance at WVS projects in future years, load and resource forecasts, and planned retirements of coal power plants as of 2017 (i.e., base case assumptions).

#### *3.12.2.2.1 Power Generation*

Under the No Action Alternative, average annual generation for the combined WVS projects over a 73-year study period (Water Years 1935/36 through 2007/08) is estimated at 171 aMW and for the 1937 critical water year is 150 aMW (for reference, according to the NW Council, 1 aMW can power about 796 Northwest homes for a year). Table 3.12-6 presents the results of two hydropower-generation metrics that are useful for making comparisons between the No Action Alternative and the Action Alternatives. The first is average monthly generation for the WVS projects combined across a 73-year study period, which is greatest during the months of November through January and again in May corresponding to high winter/spring run-off and is lowest in the summer. The second is average generation for the WVS projects combined under a critical water year (1937), which is greatest during late April through June and lowest in December through February. Exhibit 2 in Appendix G provides detailed generation results by project and for all water years modeled.

**Table 3.12-6. WVS Projects 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation (aMW): No Action Alternative.**[1]

| Month | No Action Alternative AVG GEN | No Action Alternative CWY GEN |
|---|---|---|
| October | 134 | 119 |
| November | 230 | 156 |
| December | 231 | 80 |
| January | 235 | 47 |
| February | 147 | 67 |
| March | 143 | 121 |
| April I | 177 | 188 |
| April II | 182 | 227 |
| May | 222 | 356 |
| June | 162 | 264 |
| July | 106 | 111 |
| August I | 114 | 115 |

| Month | No Action Alternative AVG GEN | No Action Alternative CWY GEN |
|---|---|---|
| August II | 118 | 124 |
| September | 151 | 155 |
| **Annual Average[2]** | **171** | **150** |

1/ HYDSIM uses a 14-period time step. April and August are split into two half-month periods because these months tend to have substantial natural flow differences between their first and second halves. Estimates are rounded to two significant digits and may not sum to the totals reported due to rounding.

2/ The Annual Average is a weighted average to account for the different number of days in the 14 periods.

Source: HYDSIM modeling results.

##### *3.12.2.2.2 Power System Reliability*

Based on load forecasts, limited coal plant retirements, and changes in power generation, the No Action Alternative would result in an LOLP of 6.5 percent in 2022. This LOLP estimate relies on an assumption about the resources available to serve regional loads over time. The basis for that assumption is the NW Council's resource adequacy dataset developed in 2017. While it accounts for the planned coal plant closures known at that time, it also assumes coal plant generating capacity (4,246 MW) would continue to serve primarily regional IOU loads (Table 3.12.7). Although the No Action Alternative's LOLP exceeds the current NW Council target of five percent, the scope of the WVS EIS analysis does not address the resources that might be needed to achieve the NW Council target under the No Action Alternative.[29]

Energy economics and state and local de-carbonization policies are changing the generation portfolio in the region and across the Western Interconnection that will accelerate coal plant retirements post-2025. Since 2017, the year of the base-case assumptions used in this EIS, additional and accelerated coal plant retirements have been announced and more are being contemplated, mainly impacting the region's IOUs, which use these resources to serve their retail loads. In Washington, the Clean Energy Transformation Act (CETA) (2019) mandates the elimination of coal-generated electricity by all Washington utilities by 2025 (RCW 19.405). The Oregon Clean Energy and Coal Transition Act (2016) mandates the elimination of the cost of coal resources in retail rates of IOUs by 2030 (ORS 757.518). Additionally, deep reductions in greenhouse gas emissions are being mandated by recently enacted legislation, including Washington's CETA, Washington's Climate Commitment Act (2021, RCW 70A.65.260), and Oregon's clean energy standard (2021, HB 2021).

---

[29] Note that LOLP is a probabilistic estimate and does not indicate magnitude or scale of potential power system outages and it is also not linear in effects; however, it is a useful metric of overall power system reliability and stability. Furthermore, the NW Council's target is not an enforceable standard (NW Council 2011). *See* NW Council 2011, Page 4, available at: https://www.nwcouncil.org/sites/default/files/2011_14_1.pdf ("The adequacy standard adopted by the NW Council does not mandate compliance or imply any enforcement mechanisms. It does not apply to individual utilities because each utility faces different circumstances. It is intended to be an early warning should aggregate regional resource development fall short, for whatever reason.").

The loss of dispatchable coal generation is having an impact on regional resource adequacy. According to E3 (March 2019), the retirement of coal power supplied to the Northwest threatens to create an electric power supply shortage of up to 8,000 MW by 2030 (E3 2019). In the Council's 8$^{th}$ Power Plan, they addressed regional reliability in the period from 2022 to 2029 that included additional coal plant retirements. Depending on the scenario, regional energy needs to meet the Council's adequacy standard range from 0 to 2,857 aMW. Regional utilities, including Bonneville, have begun working together to address the issue.

#### *3.12.2.2.3 Potential Replacement Resources and Associated Costs*

Given the key assumptions described above for the base case analysis (including continued coal capacity), the analysis finds that no acquisition of power from new resources (i.e., replacement resources) would occur under the No Action Alternative. Though greater than the NW Council's standard of five percent, the 6.5 percent LOLP is within the reasonable historical range of the NW Council target.

#### *3.12.2.2.4 Transmission*

Under the No Action Alternative, no impacts to the transmission system would be expected. The congested paths of Cross Cascades South and South of Allston remain congested with capacity either a little unsubscribed or oversubscribed, respectively. For local impacts, generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for all alternatives, including the No Action Alternative, are presented in Appendix G, Power and Transmission.

#### *3.12.2.2.5 Economic Viability of Power Generation*

Under the No Action Alternative, power generation from the combined WVS projects would remain marginally economically viable. As shown previously, the three-year (2018-2020) average cost of generation for the WVS projects under expected generation from the 2019 Bonneville White Book (Table 3.12-4) was $25.28/MWh. This cost of generation is currently marginal relative to average market prices and other generation resources and is among the highest costs in the FCRPS. Over the 30-year study period, the median Levelized Cost of Generation for the combined WVS projects is estimated to rise to $26.70/MWh under the No Action Alternative and the median Net Present Value is about $225 million[30]. Despite remaining economically viable, this indicates there is little room for taking on additional costs or operational changes without making WVS projects more costly to operate than their generation is worth.

Under the No Action Alternative, three individual projects[31] have positive median NPVs including Hills Creek ($39 million), Detroit/Big Cliff ($84 million), and Lookout Point/Dexter ($109 million). These same projects are the only ones with a positive Net Present Value in more than 50% of the 1,600 iterations. Levelized costs of individual projects range between $21.85/MWh (Hills Creek) and $33.86/MWh (Green Peter/Foster).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

---

[30] Bonneville's share of basin-wide costs (e.g., research, monitoring, and evaluation [RME]) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher.

[31] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

### *3.12.2.2.6 Summary of Effects*

Table 3.12-8 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative, which would remain similar to recent history.

**Table 3.12-8. Summary of Conditions under the No Action Alternative.[5]**

| Metrics | No Action Alternative |
|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 |
| Loss of Load Probability (LOLP) | 6.5%[1] |
| Resource Replacement | ——[2] |
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5<br>SU 5862.9 |
| South of Allston | W 1183.0<br>SP 4100.5<br>SU 5862.9 |
| Transmission Reliability | Same or similar to affected environment[4] |
| Net Present Value (median) | $225 Million |
| Levelized Cost of Generation ($/MWh) | $26.70 |

1/ Though greater than the NW Council's standard of five percent, LOLP is within the reasonable historical range of the NW Council target.

2/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only occurs as a result of implementing the Alternatives (e.g., the need for new generation and transmission infrastructure and associated costs).

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher.

### *3.12.2.2.7 NAA Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow, which could produce incremental increases in power generation during the winter. However, higher projected air temperatures are likely to result in decreased heating loads. Increases in power generation that may occur in the winter months would incrementally decrease stress on existing congested transmission paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested transmission paths (i.e., South of Allston and Cross Cascades South).

Decreasing summer and fall inflows may lead to more rapid drawdown in the fall to meet downstream minimum flow targets.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation.

These potential climate change impacts to hydropower and transmission are based on the climate change impacts as described in the hydrologic processes section.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

### *3.12.2.3 Alternative 1 – Project Storage Alternative*

#### *3.12.2.3.1 Changes in Power Generation*

Table 3.12-9 and Figure 3.12-6 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 1 and differences by month. Overall, generation from the WVS projects would increase from 171 aMW under the No Action Alternative, on average, over all water years, to 179 aMW under Alternative 1. This represents an increase of 8 aMW, which is a 4.7 percent increase in average annual generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 160 aMW under Alternative 1 represents a 10 aMW (or 6.7 percent) increase.

**Table 3.12-9. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 1 (ALT1) relative to No Action Alternative (NAA), in aMW.[1]**

1/ HYDSIM uses a 14-period time step. April and August are split into two half-month periods because these months tend to have substantial natural flow differences between their first and second halves.

2/ The Annual Average is a weighted average to account for the different number of days in the 14 periods.

Source: HYDSIM modeling results.

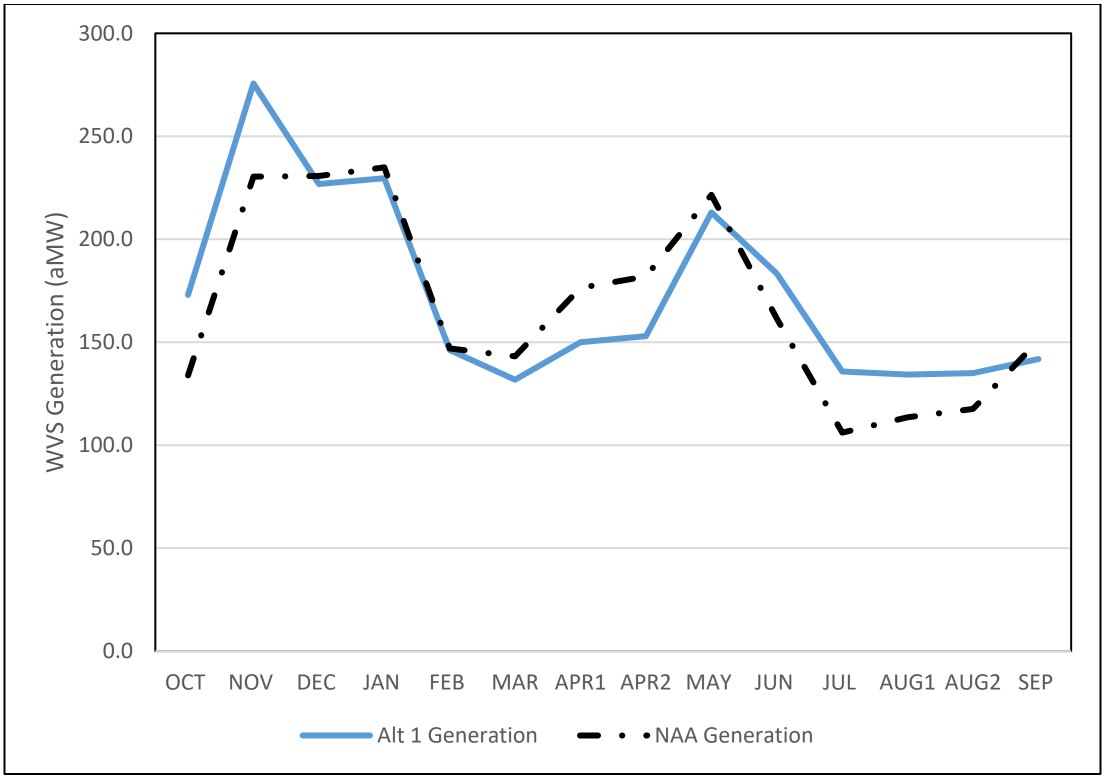

**Figure 3.12-6. Monthly Average Generation (aMW) at the WVS Projects, Alternative 1 and No Action Alternative.**

*3.12.2.3.2 Effects on Power System Reliability*

Due to the slight increase in total hydropower generation under Alternative 1, the LOLP would be 6.4 percent, or 0.1 percentage points lower than the LOLP in the No Action Alternative. The LOLP changes from the No Action Alternative (6.5 percent) to Alternative 1 (6.4 percent) are negligible (i.e., within the +/- 1 percent range of modeling accuracy). A 6.4 percent LOLP under Alternative 1 is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

*3.12.2.3.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 1 and the No Action Alternative, the analysis finds that no acquisition of power from new resources (i.e., replacement resources) would be needed under Alternative 1 to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.4 percent LOLP under Alternative 1 is within the reasonable historical range of the NW Council target.

#### *3.12.2.3.4 Effects on Transmission*

Overall, changes in the patterns of WVS projects generation under Alternative 1 would have minor impacts to the transmission system. The congested paths of Cross Cascades South and South of Allston would remain congested with small (less than 10MW) increases to loading expected. For local impacts, generation at Hills Creek and Cougar dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires. Construction projects at Cougar Dam are not anticipated to impact local transmission services to Blue River provided generation is not affected.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 1 with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### *3.12.2.3.5 Effects on Economic Viability of Power Generation*

Under Alternative 1, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$934 million under Alternative 1[32]. This is a $1.159 billion, or 515 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 0.7 percent resulted in a positive Net Present Value for the combined WVS projects. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $53.84/MWh under Alternative 1, which is a $27.14, or 102 percent, increase. This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

When considering projects individually, all of the WVS projects under Alternative 1, with the exception of Hills Creek, have negative median Net Present Values, ranging from -$22 million (Cougar) to -$351 million (Detroit/Big Cliff) and their levelized costs of generation range from $38.22/MWh (Cougar) to 66.01/MWh (Green Peter/Foster). Hills Creek was the only project with a positive Net Present Value at $45 million and a levelized cost of generation of $21.26/MWh. Across the 1600 iterations from the analysis, Cougar and Hills Creek resulted in a positive Net Present Value in 26% and 92% of the iterations, respectively. Detroit/Big Cliff,

[32] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

Green Peter/Foster, and Lookout Point/Dexter had a positive NPV in less than 0.5% of the iterations.

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, Power and Transmission.

### *3.12.2.3.6 Summary of Effects*

Table 3.12-10 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 1. Under Alternative 1, the average annual hydropower generation from the WVS projects would increase by 8 aMW (roughly the amount of power consumed by 6,371 Northwest homes in a year) relative to the No Action Alternative. The WVS projects would gain 10 aMW of firm power production under critical water conditions. Alternative 1 decreases the LOLP to 6.4 percent associated with the incremental gain in generation and no replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

Under Alternative 1, minor regional and no local transmission impacts are anticipated.

Under Alternative 1, power generation from the combined WVS projects would not be economically viable. There would be a $1,159 billion reduction in Net Present Value and a $27.14 increase in the median Levelized Cost of Generation compared to the No Action Alternative[14]. Under Alternative 1, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-10. Summary of Effects under Alternative 1 (ALT 1).[5]**

| Metrics | No Action Alternative | ALT1 | ALT1 relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 179 | +8 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 160 | +10 |
| Loss of Load Probability (LOLP) | 6.5% | 6.4% | -0.1 |
| Resource Replacement to return LOLP to No Action Alternative level | ——[1] | NA[2] | NA[2] |
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5<br>SU 5862.9 | W 6478.7<br>SP 4105.7<br>SU 5836.6 | W +3.2<br>SP +5.2<br>SU -26.3 |
| South of Allston | W 1183.0<br>SP 732.1 | W 1184.2<br>SP 733.9 | W +1.2<br>SP +1.8 |

| Metrics | No Action Alternative | ALT1 | ALT1 relative to No Action |
|---|---|---|---|
| | SU 2525.1 | SU 2521.9 | SU -3.2 |
| Transmission Reliability | Same/similar to affected environment[4] | No change | No change |
| Net Present Value (median) | $225 Million | -$934 Million | -$1.159 Billion |
| Levelized Cost of Generation ($/MWh) | $26.70 | $53.84 | +$27.14 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.3.7 Alternative 1 Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow which could produce incremental increases in power generation during the winter. However, higher projected air temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Since flow targets are lower under Alternative 1, reservoirs could store more water during conservation season than under the No Action Alternative. However, it is likely this stored water would be needed to meet downstream flow targets due to climate change projected increased variability in the spring, drier, hotter summer months and lower summer base flow. Due to these changes under climate change and the downstream flow requirements under this alternative, reservoirs are projected to have lower water surface elevations compared to the No Action Alternative which would negatively impact power generation. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

##### *3.12.2.5.8 Evaluation of Near-Term Operations Measure*

Please refer to Chapter 2 for descriptions of the Near-Term Operations Measures. The Near-Term Operations Measure cannot occur under Alternative 1, but is detailed under Alternative 2A.

### 3.12.2.4 ***Alternative 2A -- Hybrid Alternative***

##### *3.12.2.4.1 Changes in Power Generation*

Table 3.12-11 and Figure 3.12-8 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 2A and differences by month. Overall, generation from the WVS projects would decrease from 171 aMW under the No Action Alternative, on average, over all water years, to 167 aMW under Alternative 2A. This represents a decrease of 4 aMW, which is a 2.3 percent decrease in annual average generation. There was no difference in generation between the No Action Alternative and the critical water year.

**Table 3.12-11. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 2A (ALT2A) relative to No Action Alternative (NAA), in aMW.[1]**

Source: HYDSIM modeling results.

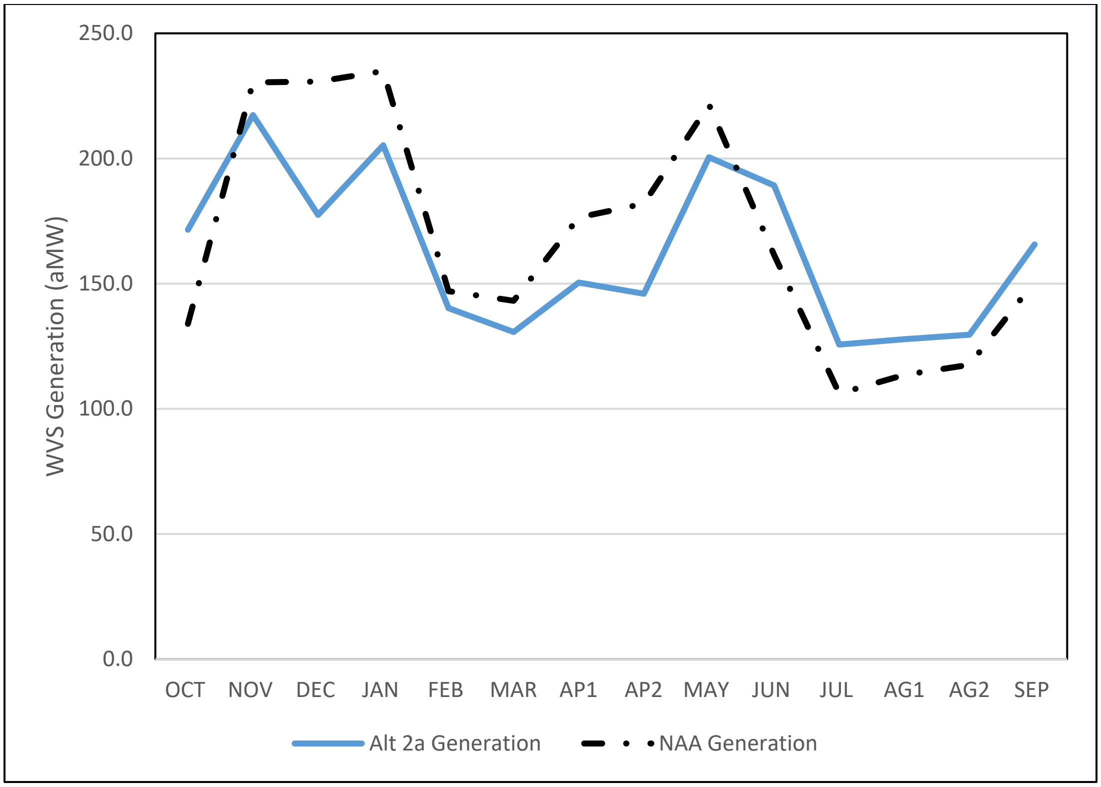

**Figure 3.12-7. Monthly Average Generation (aMW) at the WVS Projects, Alternative 2A and No Action Alternative.**

*3.12.2.4.2 Effects on Power System Reliability*

Due to the minimal decrease in total hydropower generation under Alternative 1, the LOLP would be 6.5 percent, which is the same as the No Action Alternative. A 6.5 percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions).

*3.12.2.4.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 2A and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 2A to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.5 percent LOLP under Alternative 2A is within the reasonable historical range of the NW Council target.

*3.12.2.4.4 Effects on Transmission*

Overall, changes in the patterns of WVS projects generation under Alternative 2A would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. Studies showed the congested path of Cross Cascades South increased 18.4MW in the Winter Peak case. Also, studies showed the congested paths of Cross Cascades South and South of Allston increased 61.3MW and 11.8MW in the Spring Off-peak case, respectively. For local impacts, generation at Hills Creek and Cougar dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due primarily to weather events or fires. Construction projects at Cougar Dam are not anticipated to impact local transmission services to Blue River provided generation is not affected.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 2A with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

### *3.12.2.4.5 Effects on Economic Viability of Power Generation*

Under Alternative 2A, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$638 million under Alternative 2A[33]. This is a $863 million, or 384 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 3.0 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $47.45/MWh under Alternative 2A, which is a $20.75, or 78 percent, increase. This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects[34], Hills Creek is the only WVS project that has a positive median Net Present Value at $43 million under Alternative 2A. It's levelized cost of generation is $21.54/MWh. Hills Creek is the only project that has a positive Net Present Value in more than 50% of the 1600 iterations from the economic analysis. Other projects have negative median Net Present Values ranging from -$28 million (Lookout Point/Dexter) to -$353 million (Detroit/Big Cliff); levelized costs of generation ranging from $34.52/MWh (Lookout Point/Dexter) to $64.74/MWh (Green Peter/Foster); and a proportion of 1,600 iterations resulting in a positive Net Present Value ranging from 0.1 percent (Green Peter/Foster) to 38.81 percent (Lookout Point/Dexter).

[33] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[34] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, Power and Transmission.

#### *3.12.2.4.6 Summary of Effects*

Table 3.12-12 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 2A. Under Alternative 2A, the average annual hydropower generation from the WVS projects would decrease by 4 aMW (roughly the amount of power consumed by 3,185 Northwest homes in a year) relative to the No Action Alternative. There would be no change in the firm power production of the WVS projects under critical water conditions.

There is no change in the LOLP under this alternative and no replacement resources would occur. The LOLP of 6.5 percent is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

Under Alternative 2A, a long-term, moderate impact on Cross Cascades South path and no local transmission impacts are anticipated.

Under Alternative 2A, power generation from the combined WVS projects would not be economically viable. There would be a $863 million reduction in Net Present Value and a $20.75 MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[16]. Under Alternative 2A, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-12. Summary of Effects under Alternative 2A (ALT2A).[5]**

| Metrics | No Action Alternative | ALT2A | ALT2A relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 167 | -4 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 150 | 0 |
| Loss of Load Probability (LOLP) | 6.5% | 6.5% | 0 |
| Resource Replacement | ——[1] | N/A[2] | N/A[2] |
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5<br>SU 5862.9 | W 6493.9<br>SP 4161.8<br>SU 5853.5 | W +18.4<br>SP +61.3<br>SU -9.4 |
| South of Allston | W 1183.0<br>SP 732.1<br>SU 2525.1 | W 1189.9<br>SP 743.9<br>SU 2521.9 | W +6.9<br>SP +11.8<br>SU -9.0 |
| Transmission Reliability | Same/similar to affected environment[4] | No change | No change |

| Metrics | No Action Alternative | ALT2A | ALT2A relative to No Action |
|---|---|---|---|
| Net Present Value (median) | $225 Million | -$638 million | -$863 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $47.45 | +$20.75 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

##### *3.12.2.4.7 Alternative 2A Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow which could produce incremental increases in power generation during the winter. However, higher projected air temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Climate change would affect Alternative 2A similar to the No Action Alternative with regards to hydropower. Under Alternative 2A, there may be the potential to release and store more water in the spring and summer of dry years as compared to the No Action Alternative. The flow targets in Alternative 2A are lower than the current flow requirements, the reservoir may be able to store more water. However, the projects would likely have to use more of the stored water later in the season due to the projected variability in the spring months, hotter, drier summers, and lower summer base flow due to climate change.

Reservoirs in Alternative 2A sometimes drop to minimum elevation during the summer, but less often than the No Action Alternative, meaning storage levels would generally be able to augment summer flow for longer than the No Action Alternative even with projected decline in later spring and summer flows. This may alleviate some of the projected in decrease in power generation in the summer from climate change than would occur under the No Action Alternative.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative, commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

##### *3.12.2.4.8 Evaluation of Near Term Operations Measure*

See Alternative 2A, Section 3.12.2.3.8, for description of effects due to the Near-Term Operations Measure.

##### *3.12.2.4.9 Changes in Power Generation*

Table 3.12-13 and Figure 3.12-7 present the generation results of the combined WVS projects for the No Action Alternative and the Near-term operations measure in differences by month. Overall, generation from the WVS projects would decrease from 171 aMW under the No Action Alternative, on average, over all water years, to 120 aMW under Near-term operations measure. This represents a decrease of approximately 52 aMW, which is a 30.1 percent decrease in average annual generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 108 aMW under Near-term operations measure represents a 42 aMW (or 28 percent) decrease.

**Table 3.12-13. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Near term operations measure (NTOM) relative to No Action Alternative (NAA), in aMW.[1]**

1/ HYDSIM uses a 14-period time step. April and August are split into two half-month periods because these months tend to have substantial natural flow differences between their first and second halves.

2/ The Annual Average is a weighted average to account for the different number of days in the 14 periods.

Source: HYDSIM modeling results.

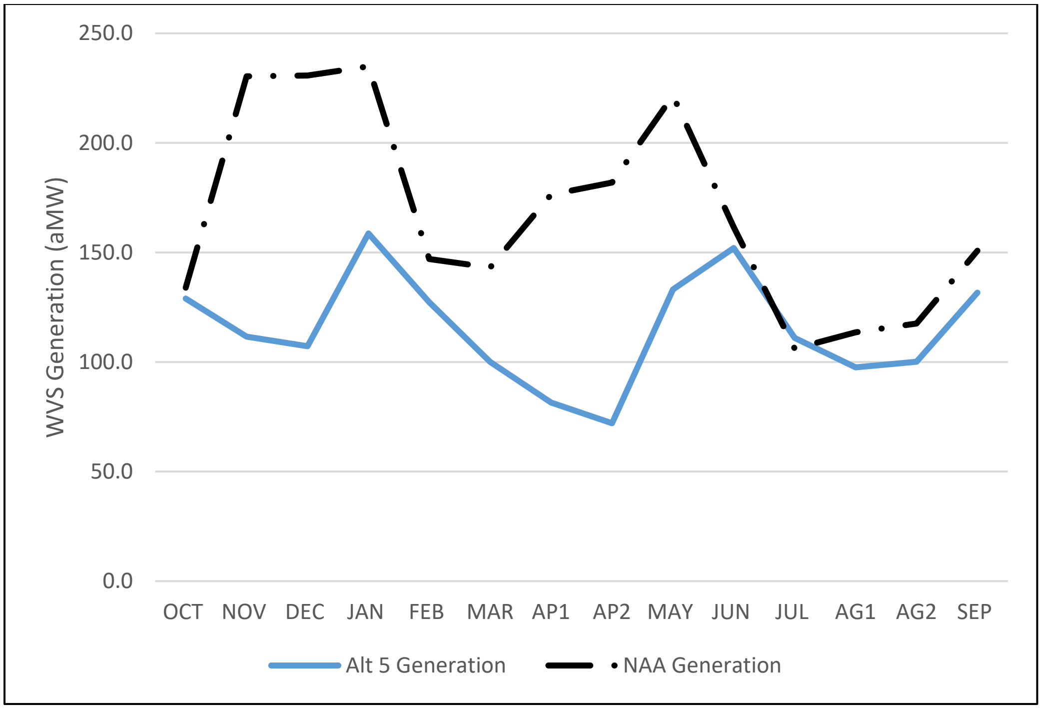

**Figure 3.12-8. Monthly Average Generation (aMW) at the WVS Projects, Near term operations measure and No Action Alternative.**

*3.12.2.4.10 Effects on Power System Reliability*

Due to the decrease in total hydropower generation under Near-term operations measure, the LOLP would be 6.8 percent, or 0.3 percentage points greater than the LOLP in the No Action Alternative. The LOLP change from the No Action Alternative (6.5 percent) to Near term operations measure (6.8 percent) is negligible (i.e., within the +/- 1 percent range of modeling accuracy). A 6.8 percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

*3.12.2.4.11 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Near-term operations measure and the No Action Alternative, the analysis finds that no replacement resources would occur under Near term operations measure to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.8 percent LOLP under Near-term operations measure is within the reasonable historical range of the NW Council target.

*3.12.2.4.12 Effects on Transmission*

Overall, changes in the patterns of WVS projects' generation under Near-term operations measure would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. Studies showed that impacts to the congested paths of Cross Cascades South and South of Allston remain congested with significant (up to 60MW) increases to loading expected, especially in the Spring Off-peak case. For local impacts, generation at Hills Creek would generally continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the community of Oakridge during power system outages primarily due to weather events or fires, though some decrease in capability during night time is anticipated. Deep fall and spring drawdowns of the Cougar reservoir would likely compromise the ability of Cougar Dam to provide power to the community of Blue River in the event of a fire or severe storm causing a transmission outage between Blue River and Thurston substations.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Near term operations measure with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### *3.12.2.4.13 Effects on Economic Viability of Power Generation*

Under the Near-term operations measure, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$196 million under Near term operations measure[35]. This is a $421 million, or 187 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 20.9 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $38.35/MWh under Near term operations measure, which is an $11.65, or 44 percent, increase. This is greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects[36], Detroit/Big Cliff and Hills Creek are the only WVS projects having positive median Net Present Values of $5 million and $49 million, respectively; and their levelized costs of generation are $31.97/MWh and $21.57/MWh, respectively. They are also the only projects having a positive Net Present Value in more than 50% of the iterations. Other projects have negative median Net Present Values ranging from -$32 million (Cougar) to -$123 million (Green Peter/Foster) and levelized costs of generation ranging from $42.76/MWh (Cougar) to $50.40/MWh (Green Peter/Foster); and a proportion of 1,600 iterations resulting in

[35] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, Near term operations measure effects are only inclusive of near term operational measures and do not account for structural measures that have been proposed under the court order (e.g., upgrades to the Dexter adult fish facility), nor do they account for operational changes that could occur as a result of structural measure implementation.

[36] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

a positive Net Present Value ranging from 1.4 percent (Green Peter/Foster) to 14.4 percent (Cougar).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

#### *3.12.2.4.14 Summary of Effects*

Table 3.12-14 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Near term operations measure. Under Near term operations measure, annual average hydropower generation from the WVS projects would decrease by 52 aMW (roughly the amount of power consumed by 41,392 Northwest homes in a year) relative to the No Action Alternative. The WVS projects would lose 42 aMW of firm power production under critical water conditions. Near term operations measure increases the LOLP to 6.8 percent associated with the loss in generation and no replacement resources would occur since this 0.3 percent difference relative to the No Action Alternative is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

A moderate impact on the Cross Cascades South transmission path would be expected. Overall, the ability for Hills Creek and Cougar generation to support the communities of Oakridge and Blue River, respectively, during temporary transmission outages would continue to be available similar to the No Action Alternative, though some decrease in capability is anticipated.

Under Near term operations measure, power generation from the combined WVS projects would not be economically viable. There would be a $421 million reduction in Net Present Value and a $11.65/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative.[27] Under Near term operations measure, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-14. Summary of Effects under Near term operations measure (NTOM).** [1]

| Metrics | No Action Alternative | NTOM | NTOM relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 120 | -52 |

| Net Present Value (median) | $225 Million | -$196 million | -$421 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $38.35 | +$11.65 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, Near term operations measure effects are only inclusive of near term operational measures and do not account for structural measures that have been proposed under the court order (e.g., upgrades to the Dexter adult fish facility), nor do they account for operational changes that could occur as a result of structural measure implementation.

2/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

3/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

4/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

5/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

#### *3.12.2.4.15 Near term operations measure Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected temperatures are likely to result in decreased heating loads.

Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows and potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Projected decreases in summer base flows from climate change combined with expected lower summer reservoir levels from spring drawdowns that last past April under the near-term operations measure would likely result in further reductions of power generation during the summer compared to the No Action Alternative.

After the fall drawdowns under this alternative, there would be additional storage space in the reservoirs compared to the No Action Alternative. Despite increasing winter inflows from climate change, this additional storage capacity would allow these inflows to be stored so that downstream winter flow releases would be similar to existing No Action Alternative conditions. This could mean little negative impact to power generation due to the drawdowns from the existing No Action Alternative condition during these times.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Nighttime regulating outlet prioritization conditions at Hills Creek Dam would incrementally increase the risks that the dam would be unable to provide power during evening hours to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels or nighttime prioritization through regulating outlets.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

#### *3.12.2.5 Alternative 2B -- Hybrid Alternative*

##### *3.12.2.5.1 Changes in Power Generation*

Table 3.12-15 and Figure 3.12-9 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 2B and differences by month. Overall, generation from the WVS projects would decrease from 171 aMW under the No Action Alternative, on average, over all water years, to 153 aMW under Alternative 2B. This represents a decrease of 18 aMW, which is a 10.5 percent decrease in annual average generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 136 aMW under Alternative 2B represents a 14 aMW (or 9.3 percent) decrease.

**Table 3.12-15.-73 Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 2B (ALT2B) relative to No Action Alternative (NAA), in aMW.1**

Source: HYDSIM modeling results.

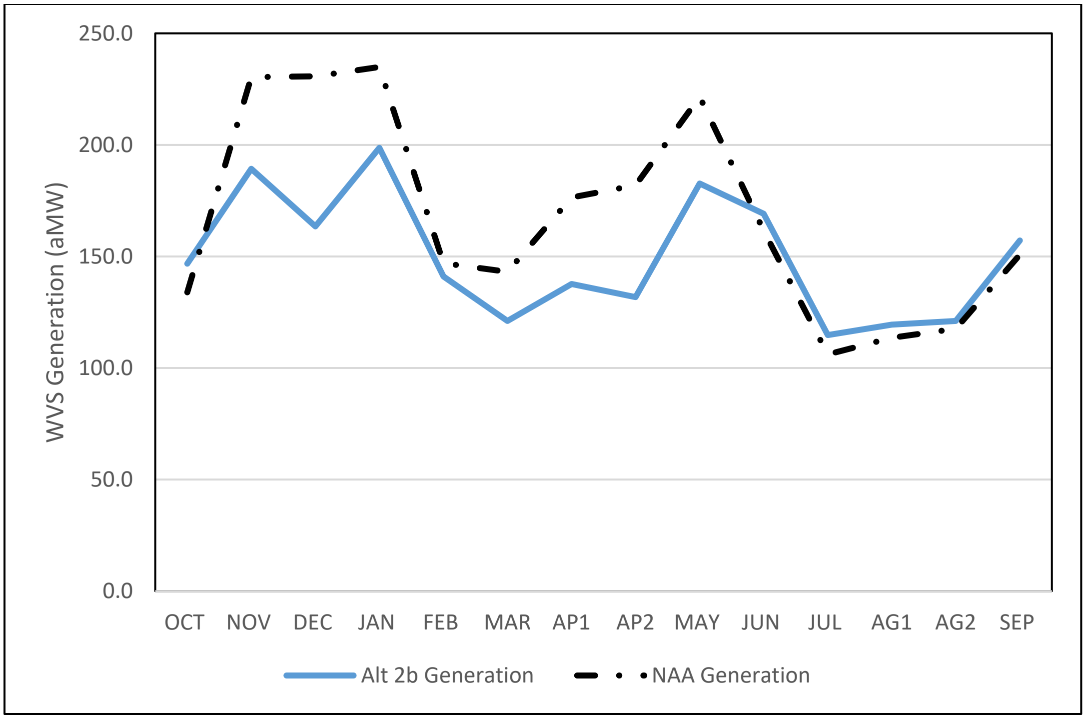

**Figure 3.12-9. Monthly Average Generation (aMW) at the WVS Projects, Alternative 2B and No Action Alternative.**

### *3.12.2.5.2 Effects on Power System Reliability*

Due to the slight decrease in total hydropower generation under Alternative 2B, the LOLP would be 6.6 percent, or 0.1 percentage points greater than the LOLP in the No Action Alternative. The LOLP change from the No Action Alternative (6.5 percent) to Alternative 2B (6.6 percent) are negligible (i.e., within the +/- 1 percent range of modeling accuracy). A 6.6 percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

### *3.12.2.5.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 2B and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 2B to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.6 percent LOLP under Alternative 2B is within the reasonable historical range of the NW Council target.

### *3.12.2.5.4 Effects on Transmission*

Overall, changes in the patterns of WVS project generation under Alternative 2B would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. The congested path of Cross Cascades South and South of Allston would see an increase of 21.9MW and 8.3MW in the Winter Peak case, respectively, and an increase of 25.1MW and 5.1MW in the Spring Off-peak case, respectively. For local impacts, generation at Hills Creek Dam would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the community of Oakridge during temporary power system outages primarily due to weather events or fires. Whereas, deep fall and spring drawdowns of the Cougar reservoir would likely compromise the ability of Cougar Dam to provide power to the community of Blue River in the event of a fire or severe weather event causing a temporary transmission outage between Blue River and Thurston substations.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 2B with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### *3.12.2.5.5 Effects on Economic Viability Of Power Generation*

Under Alternative 2B, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$708 million under Alternative 2B[37]. This is a $933 million, or 415 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 1.31 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $50.66/MWh under Alternative 2B, which is a $23.96, or 90 percent, increase. This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects,[38]Hills Creek is the only WVS project under Alternative 2B that has a positive median Net Present Value at $39 million. Its levelized cost of generation is $21.95/MWh. Hills Creek is the only project that has a positive Net Present Value in more than 50% of the 1600 iterations from the economic analysis. Other projects have negative median Net Present Values ranging from -$30 million (Lookout Point/Dexter) to -$354 million (Detroit/Big Cliff); levelized costs of generation ranging from $34.52/MWh (Lookout

[37] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[38] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

Point/Dexter) to $340.57 MWh (Cougar)and proportion of 1,600 iterations resulting in a positive Net Present Value ranging from 0 percent (Cougar) to 0.2 percent (Detroit/Big Cliff).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

#### *3.12.2.5.6 Summary of Effects*

Table 3.12-16 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 2B. Under Alternative 2B, hydropower generation from the WVS projects would decrease by 18 aMW (roughly the amount of power consumed by 14,334 Northwest homes in a year) relative to the No Action Alternative on average under historical water conditions. The WVS projects would lose 12 aMW of firm power production under critical water conditions. Alternative 2B increases the LOLP to 6.6 percent associated with the loss in generation and no replacement resources would occur since this 0.1 percent difference relative to the No Action Alternative is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

Under Alternative 2B, moderate impacts on the Cross Cascades South transmission path would be expected. There would be an increase of 25.1MW on the Cross Cascades South path. Under fall and spring deep drawdown conditions, the ability for Cougar Dam to serve load to the community of Blue River during temporary transmission outages that may occur is expected to be compromised.

Under Alternative 2B, power generation from the combined WVS projects would not be economically viable. There would be a $933 million reduction in Net Present Value and a $23.96/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[18]. Under Alternative 2B, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-16. Summary of Effects under Alternative 2B (ALT2B).[5]**

| Metrics | No Action Alternative | ALT2B | ALT2B relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 153 | -18 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 136 | -12 |
| Loss of Load Probability (LOLP) | 6.5% | 6.6% | +0.1[2] |
| Resource Replacement | ——[1] | N/A[2] | N/A[2] |
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5 | W 6497.4<br>SP 4125.6 | W +21.9<br>SP +25.1 |

| Metrics | No Action Alternative | ALT2B | ALT2B relative to No Action |
|---|---|---|---|
| | SU 5862.9 | SU 5858.6 | SU -4.3 |
| South of Allston | W 1183.0<br>SP 732.1<br>SU 2525.1 | W 1191.3<br>SP 737.2<br>SU 2523.8 | W +8.3<br>SP +5.1<br>SU -1.3 |
| Transmission Reliability | Same/similar to affected environment4 | Regionally- Same/similar to NAA<br>Locally: unable to operate islanded at Cougar Dam during deep fall and spring drawdowns under certain conditions | No change regionally; comprised ability to meet local transmission services at Blue River during weather or fire related temporary outages |
| Net Present Value (median) | $225 Million | -$708 million | -$863 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $50.66 | +$23.96 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.5.7 Alternative 2B Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected air temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Climate change would affect Alternative 2B similar to the No Action Alternative with regards to hydropower. Under Alternative 2B, there may be the potential to release and store more water in the spring and summer of dry years as compared to the No Action Alternative. The flow targets in Alternative 2B are lower than the current flow requirements, the reservoir may be able to store more water. However, the projects would likely have to use more of the stored water later in the season due to the projected variability in the spring months, hotter, drier summers, and lower summer base flow due to climate change.

Reservoirs in Alternative 2B sometimes drop to minimum elevation during the summer, but less often than the No Action Alternative, meaning storage levels would generally be able to augment summer flow for longer than the No Action Alternative even with projected decline in later spring and summer flows. This may alleviate some of the projected decrease in power generation in the summer from climate change than would occur under the No Action Alternative.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

See Alternative 2A, Section 3.12.2.3.8, for description of effects due to the Near-Term Operations Measure.

### ***3.12.2.6 Alternative 3A – Operations-Focused Fish Passage Alternative***

#### *3.12.2.6.1 Changes in Power Generation*

Table 3.12-17 and Figure 3.12-10 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 3A and differences by month. Overall, generation from the WVS projects would decrease from 171 aMW under the No Action Alternative, on average, over all water years, to 84 aMW under Alternative 3A. This represents a decrease of 87 aMW, which is a 50.9 percent decrease in average annual generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 60 aMW under Alternative 3A represents a 90 aMW (or 60 percent) decrease.

**Table 3.12-17. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 3A (ALT3A) relative to No Action Alternative (NAA), in aMW.[1]**

2/ The Annual Average is a weighted average to account for the different number of days in the 14 periods.

Source: HYDSIM modeling results.

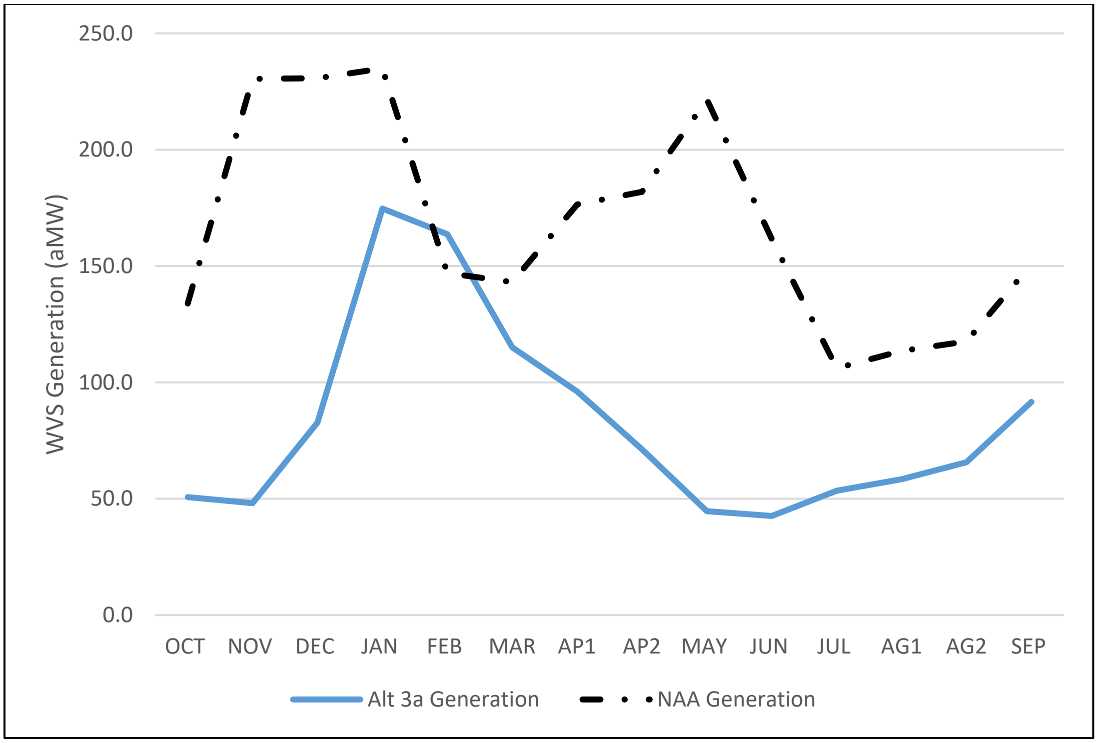

**Figure 3.12-10. Monthly Average Generation (aMW) at the WVS Projects, Alternative 3A and No Action Alternative.**

#### *3.12.2.6.2 Effects on Power System Reliability*

Due to the decrease in total hydropower generation under Alternative 3A, the LOLP would be seven percent, or 0.5 percentage points greater than the LOLP in the No Action Alternative. The LOLP change from the No Action Alternative (6.5 percent) to Alternative 3A (7.0 percent) is negligible (i.e., within the +/- 1 percent range of modeling accuracy). A seven percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

#### *3.12.2.6.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 3A and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 3A to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the seven percent LOLP under Alternative 3A is within the reasonable historical range of the NW Council target.

#### *3.12.2.6.4 Effects on Transmission*

Overall, changes in the patterns of WVS projects generation under Alternative 3A would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. Studies showed the congested path of Cross Cascades South and South of

Allston increased 37.2MW and 13.6MW in the Winter Peak case, respectively. Also, studies showed the congested paths of Cross Cascades South and South of Allston increased 113.7 MW and 22.3 MW in the Spring Off-peak case, respectively. Studies showed an increase of 28.3 MW for Cross Cascades South in the Summer Peak case. Deep fall and spring drawdowns at Hills Creek reservoir may compromise the ability to provide power to Oakridge during transmission system outages. There is little redundancy for Oakridge, and the loss of the Hills Creek – Lookout Point 115kV transmission line would cause a loss of power to Oakridge if Hills Creek Dam generation is not available. Recent weather trends suggest at least one winter storm serious enough to cause an outage of this transmission line could be expected annually. The durations of the recent outages have ranged from approximately two hours to two weeks. Wildfire could have similar or greater impact. Similarly, deep fall and spring drawdowns of the Cougar reservoir would likely compromise the ability of Cougar Dam to provide power to the community of Blue River in the event of a fire or severe storm causing a transmission outage between Blue River and Thurston substations.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 3A with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

###### *3.12.2.6.5 Effects on Economic Viability of Power Generation*

Under Alternative 3A, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$628 million under Alternative 3A[39]. This is an $853 million, or 379 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 0.3 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $64.32/MWh under Alternative 3A, which is a $37.61, or 141 percent, increase. This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects,[40] all of the WVS projects under Alternative 3A have negative median Net Present Values ranging from -$41 million (Hills Creek) to -$189 million (Detroit/Big

[39] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[40] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

Cliff) and levelized costs of generation ranging from $44.79/MWh (Hills Creek) to $81.57/MWh (Detroit/Big Cliff); and a proportion of 1,600 iterations resulting in a positive Net Present Value ranging from 0.25 percent (Cougar) to 6.7 percent (Hills Creek).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

##### *3.12.2.6.6 Summary of Effects*

Table 3.12-18 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 3A. Under Alternative 3A, hydropower generation from the WVS projects would decrease by 87 aMW (roughly the amount of power consumed by 69,283 Northwest homes in a year) relative to the No Action Alternative on average under historical water conditions. The WVS projects would lose 90 aMW of firm power production under critical water conditions.

Alternative 3A increases the LOLP to seven percent associated with the loss in generation and no replacement resources would occur since this 0.5 percent difference relative to the No Action Alternative is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

A moderate impact on the Cross Cascades South transmission path would be expected. The ability for Hills Creek and Cougar to support the communities of Oakridge and Blue River, respectively, during temporary transmission outages that may occur is expected to be compromised.

Under Alternative 3A, power generation from the combined WVS projects would not be economically viable. There would be an $853 million reduction in Net Present Value and a $37.61/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[20]. Under Alternative 3A, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-18. Summary of Effects under Alternative 3A (ALT3A).[5]**

| Metrics | No Action Alternative | ALT3A | ALT3A relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 84 | -87 |

| Net Present Value (median) | $225 Million | -$628 million | -$853 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $64.32 | +$37.61 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.6.7 Alternative 3A Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Projected decreases in summer base flows from climate change combined with expected lower summer reservoir levels from spring drawdowns that last past April under Alternative 3A would likely result in further reductions of power generation during the summer compared to the No Action Alternative.

After the fall drawdowns under this alternative, there would be additional storage space in the reservoirs compared to the No Action Alternative. Despite increasing winter inflows from climate change, this additional storage capacity would allow these inflows to be stored so that downstream winter flow releases would be similar to existing No Action Alternative conditions. This could mean little negative impact to power generation due to the drawdowns from the existing No Action Alternative condition during these times.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

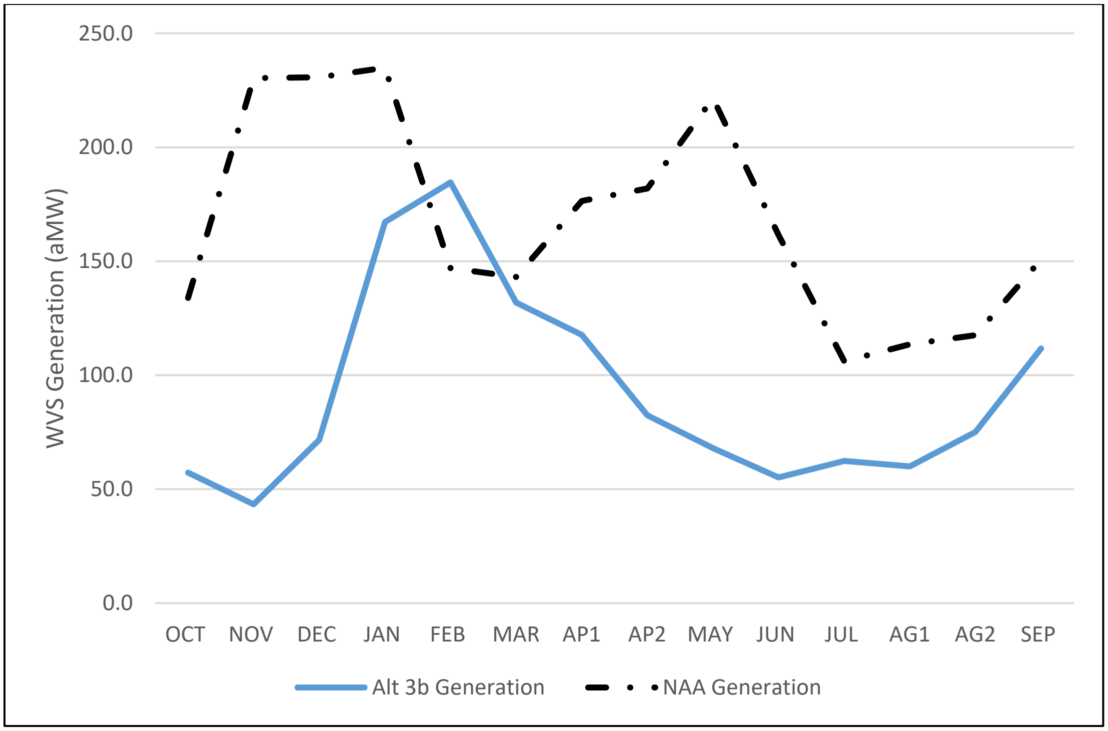

**Figure 3.12-11. Monthly Average Generation (aMW) at the WVS Projects, Alternative 3B and No Action Alternative.**

*3.12.2.7.2 Effects on Power System Reliability*

Due to the decrease in total hydropower generation under Alternative 3B, the LOLP would be seven percent, or 0.5 percentage points greater than the LOLP in the No Action Alternative. The LOLP change from the No Action Alternative (6.5 percent) to Alternative 3B (seven percent) are negligible (i.e., within the +/- 1 percent range of modeling accuracy). A seven percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

*3.12.2.7.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 3B and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 3B to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the seven percent LOLP under Alternative 3B is within the reasonable historical range of the NW Council target.

*3.12.2.7.4 Effects on Transmission*

Overall, changes in the patterns of WVS projects generation under Alternative 3B would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. Studies showed the congested path of Cross Cascades South and South of

Allston increased 41.4MW and 15.2MW in the Winter Peak case, respectively. Also, studies showed the congested paths of Cross Cascades South and South of Allston increased 94.8MW and 18.7MW in the Spring Off-peak case, respectively. Studies showed an increase of 25.6MW for Cross Cascades South in the Summer Peak case. Deep fall and spring drawdowns at Hills Creek reservoir may compromise the ability to serve load to Oakridge during transmission system outages. There is little redundancy for Oakridge, and the loss of the Hills Creek – Lookout Point 115kV transmission line would cause a loss of power to Oakridge if Hills Creek generation is not available. Recent weather trends suggest at least one winter storm serious enough to cause an outage of this transmission line could be expected annually. The durations of the recent outages have ranged from approximately two hours to two weeks. Wildfire could have similar or greater impact. Similarly, deep fall and spring drawdowns of the Cougar reservoir would likely compromise the ability of Cougar Dam to provide power to the community of Blue River in the event of a fire or severe storm causing a transmission outage between Blue River and Thurston substations.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 3B with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### *3.12.2.7.5 Effects on Economic Viability of Power Generation*

Under Alternative 3B, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$604 million under Alternative 3B[41]. This is an $829 million, or 369 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 0.5 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $59.42/MWh under Alternative 3B, which is a $32.72, or 123 percent, increase). This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects[42], all of the WVS projects have negative median Net Present Values ranging from -$68 million (Hills Creek) to -$231 million (Green Peter/Foster) and their

[41] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[42] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

levelized costs of generation range from $41.25/MWh (Detroit/Big Cliff) to $346.18/MWh (Cougar). None of the projects had a positive Net Present Value in more than 50% of the iterations, with the proportion of 1,600 iterations resulting in a positive Net Present Value ranging from 0 percent (Cougar) to 12.69 percent (Detroit/Big Cliff).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

#### *3.12.2.7.6 Summary of Effects*

Table 3.12-20 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 3B. Under Alternative 3B, annual average hydropower generation from the WVS projects would decrease by 79 aMW (roughly the amount of power consumed by 62,912 Northwest homes in a year) relative to the No Action Alternative. The WVS projects would lose 83 aMW of firm power production under critical water conditions. Alternative 3B increases the LOLP to seven percent associated with the loss in generation and no replacement resources would occur since this 0.5 percent difference relative to the No Action Alternative is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

A moderate impact on the Cross Cascades South transmission path would be expected. The ability for Hills Creek and Cougar to support the communities of Oakridge and Blue River, respectively, during transmission outages that may occur is expected to be compromised.

Under Alternative 3B, power generation from the combined WVS projects would not be economically viable. There would be an $829 million reduction in Net Present Value and a $32.72/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[22]. Under Alternative 3B, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-20. Summary of Effects under Alternative 3B (ALT3B).[5]**

| Metrics | No Action Alternative | ALT3B | ALT3B relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 93 | -79 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 67 | -83 |
| Loss of Load Probability (LOLP) | 6.5% | 7.0% | +0.5[a] |
| Resource Replacement | ——[1] | N/A[a] | N/A[a] |

| Metrics | No Action Alternative | ALT3B | ALT3B relative to No Action |
|---|---|---|---|
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5<br>SU 5862.9 | W 6516.9<br>SP 4195.3<br>SU 5888.5 | W +41.4<br>SP +94.8<br>SU +25.6 |
| South of Allston | W 1183.0<br>SP 732.1<br>SU 2525.1 | W 1198.2<br>SP 750.8<br>SU 2534 | W +15.2<br>SP +18.7<br>SU +8.9 |
| Transmission Reliability | Same/similar to affected environment[4] | Regionally- Same/similar to NAA<br>Locally: unable to operate islanded at Hills Creek and Cougar dams during deep fall and spring drawdowns under certain conditions | No change regionally; comprised ability to meet local transmission services at Oakridge and Blue River during weather or fire related temporary outages |
| Net Present Value (median) | $225 Million | -$628 million | -$829 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $59.42 | +$32.72 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.7.7 Alternative 3B Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Projected decreases in summer base flows from climate change combined with expected lower summer reservoir levels from spring drawdowns that last past April under Alternative 3B would likely result in further reductions of power generation during the summer compared to the No Action Alternative.

After the fall drawdowns under this alternative, there would be additional storage space in the reservoirs compared to the No Action Alternative. Despite increasing winter inflows from climate change, this additional storage capacity would allow these inflows to be stored so that downstream winter flow releases would be similar to existing No Action Alternative conditions. This could mean little negative impact to power generation due to the drawdowns from the existing No Action Alternative condition during these times.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

#### *3.12.2.7.8 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.12.2.3.8, for description of effects due to the Near-Term Operations Measure.

### *3.12.2.8 Alternative 4 – Structures-Based Fish Passage Alternative*

#### *3.12.2.8.1 Changes in Power Generation*

Table 3.12-21 and Figure 3.12-12 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 4 and differences by month. Overall, generation from the WVS projects would increase from 171 aMW under the No Action Alternative, on average, over all water years, to 172 aMW under Alternative 4. This represents an increase of 1 aMW, which is a 0.6 percent increase in average annual generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 148 aMW under Alternative 4 represents a 2 aMW (or 1.3 percent) decrease.

**Table 3.12-21. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 4 (ALT4) relative to No Action Alternative (NAA), in aMW.[1]**

2/ The Annual Average is a weighted average to account for the different number of days in the 14 periods.

Source: HYDSIM modeling results.

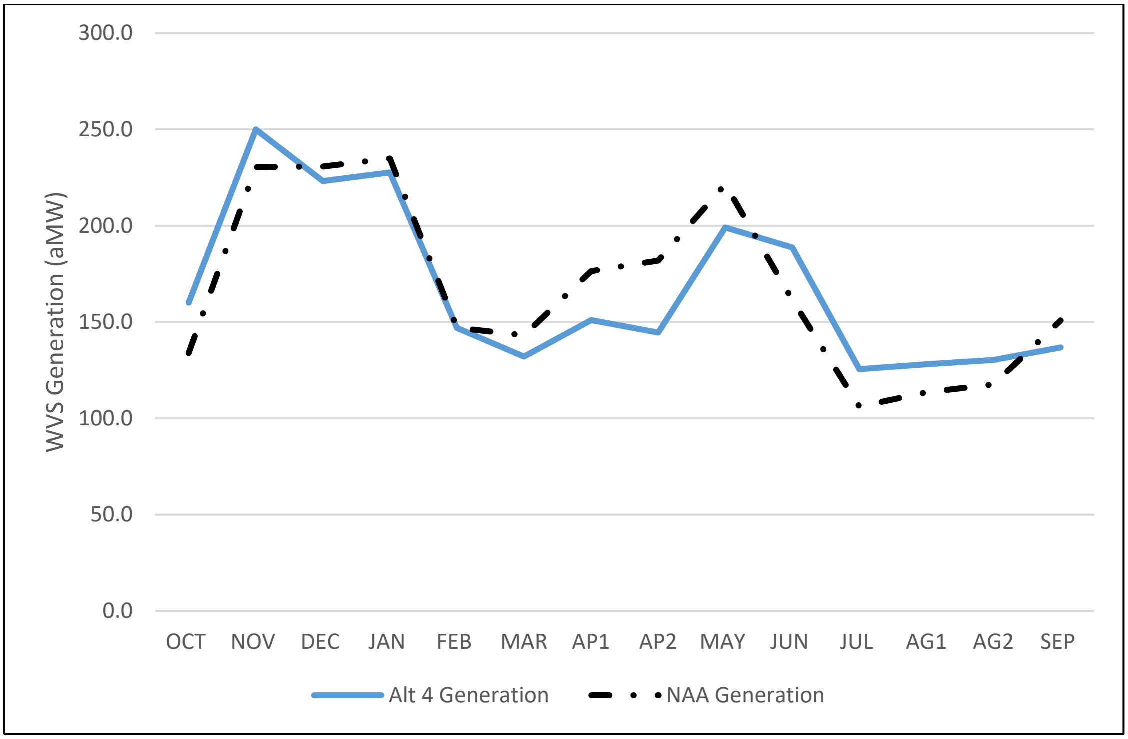

**Figure 3.12-12. Monthly Average Generation (aMW) at the WVS Projects, Alternative 4 and No Action Alternative.**

*3.12.2.8.2 Effects on Power System Reliability*

Due to the minimal decrease in total hydropower generation under Alternative 4, the LOLP would be 6.5 percent, which is the same as the No Action Alternative. A 6.5 percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions).

*3.12.2.8.3 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 4 and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 4 to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.5 percent LOLP under Alternative 4 is within the reasonable historical range of the NW Council target.

*3.12.2.8.4 Effects on Transmission*

Overall, changes in the patterns of WVS projects generation under Alternative 4 would have minor impacts to the transmission system due to the need to replace generation from more distant sources. Studies showed impacts to the congested paths of Cross Cascades South and South of Allston remain congested with small (less than 10MW) increases to loading expected, with the exception that there was a slightly greater increase of 15MW on the Cross Cascades South in the Spring Off-peak case. For local impacts, generation at Hills Creek and Cougar dams would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages primarily due to weather events or fires. Construction projects at Hills Creek and Cougar dams should not have a major impact on transmission services to Oakridge or Blue River, respectively, provided generation is not affected.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 4 with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### 3.12.2.8.5 Effects on *Economic Viability Of Power Generation*

Under Alternative 4, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$937 million under Alternative 4[43]. This is a $1.162 billion, or 517%, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 0.6 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $54.54/MWh under Alternative 4, which is a $27.84, or 104 percent, increase). This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects[44], all of the WVS projects under Alternative 4 have negative median Net Present Values ranging from -$67 million (Hills Creek) to -$356 million (Detroit/Big Cliff) and their levelized costs of generation range from $46.48/MWh (Hills Creek) to $57.71/MWh (Detroit/Big Cliff). None of the projects had a positive Net Present Value in more than 50% of the iterations, with the proportion of 1,600 iterations resulting in a positive Net Present Value ranging from 0.2 percent (Detroit/Big Cliff) to 3.9 percent (Hills Creek).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

[43] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[44] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

#### *3.12.2.8.6 Summary of Effects*

Table 3.12-22 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 4. Under Alternative 4, average annual hydropower generation from the WVS projects would increase by 1 aMW (roughly the amount of power consumed by 796 Northwest homes in a year) relative to the No Action Alternative. The WVS projects would lose 2 aMW of firm power production under critical water conditions.

There is no change in the LOLP under this alternative and no replacement resources would occur. The LOLP of 6.5 percent is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

Minor regional and local transmission impacts would be expected.

Under Alternative 4, power generation from the combined WVS projects would not be economically viable. There would be a $1.162 billion reduction in Net Present Value and a $27.84/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[24]. Under Alternative 4, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-22. Summary of Effects under Alternative 4 (ALT4).[5]**

| Metrics | No Action Alternative | ALT4 | ALT4 relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 172 | +1 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 148 | -2 |
| Loss of Load Probability (LOLP) | 6.5% | 6.5% | 0[a] |
| Resource Replacement | ——[1] | N/A[a] | N/A[a] |

| Net Present Value (median) | $225 Million | -$937 Million | -$1.162 Billion |
| Levelized Cost of Generation ($/MWh) | $26.70 | $54.54 | +$27.84 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/ The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.8.7 Alternative 4 Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate in the and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Since flow targets are lower under Alternative 4, reservoirs could store more water during the conservation season than under the No Action Alternative. However, it is likely this stored water would be needed to meet downstream flow targets due to climate change projected increased variability in the spring, drier, hotter summer months and lower summer base flow. Due to this, reservoirs are projected to have lower water surface elevations compared to the No Action Alternative which would negatively impact power generation.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section.

#### *3.12.2.9 Alternative 5-- Preferred Alternative*

The following sections show the results for Alternative 2B, which was chosen as the preferred alternative with some changes to flow. Models were not run for the preferred alternative; some potential qualitative differences due to the flow changes are described. Otherwise, specific results are shown for Alternative 2B and should be very similar.

##### *3.12.2.9.1 Differences between Alternative 2B and Alternative 5*

At Green Peter and Foster, the minimum outflow target has shifted from 1,000 cfs under Alternative 2B to 700 cfs under Alternative 5. This could potentially lead to slightly lower generation than reported in the summary below.

At Hills Creek, the elevation reaches the top conservation storage less frequently under Alternative 5 than under Alternative 2B. Additionally, the lower minimum elevation is met more frequently. This could potentially lead to slightly lower generation than reported in the summary below.

##### *3.12.2.9.2 Changes in Power Generation*

Table 3.12-23 and Figure 3.12-13 present the generation results of the combined WVS projects for the No Action Alternative and Alternative 5 and differences by month. Overall, generation from the WVS projects would decrease from 171 aMW under the No Action Alternative, on average, over all water years, to 153 aMW under Alternative 5. This represents a decrease of 18 aMW, which is a 10.5 percent decrease in annual average generation. The change in critical water year generation from 150 aMW under the No Action Alternative to 134 aMW under Alternative 5 represents a 16- aMW (or 10.6 percent) decrease.

**Table 3.12-23. 73-Year Average Generation (Water Years 1935/36 through 2007/08) and Critical Water Year (CWY, 1937) Average Generation at the WVS Projects: Alternative 5 relative to No Action Alternative (NAA), in aMW.[1]**

Source: HYDSIM modeling results.

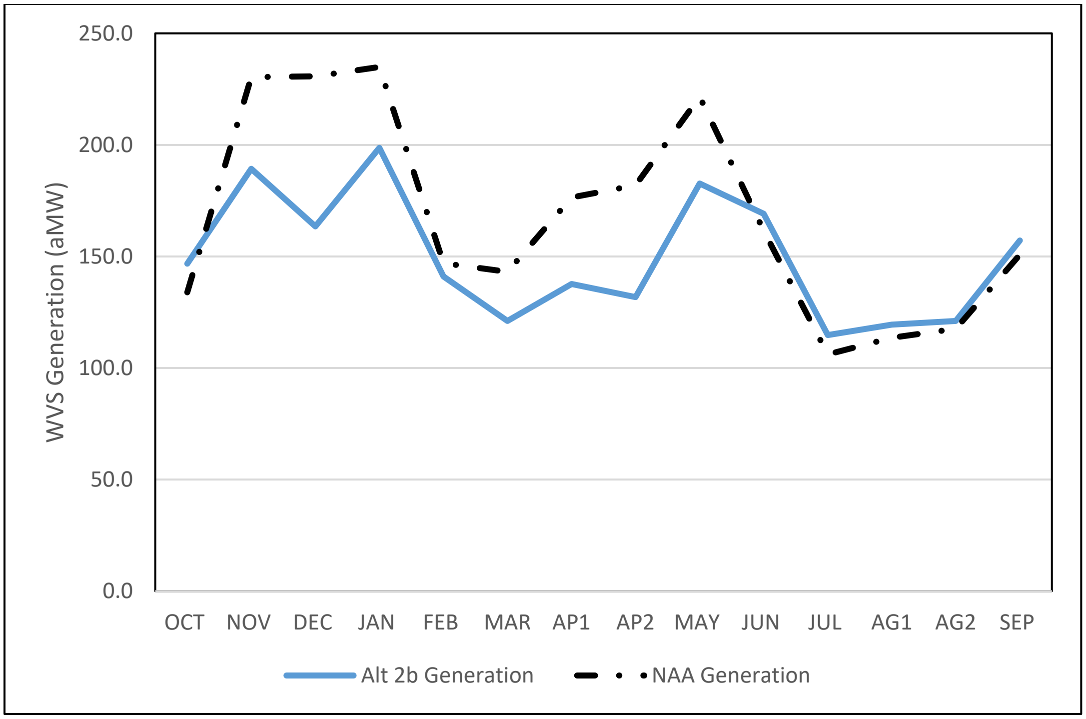

**Figure 3.12-13. Monthly Average Generation (aMW) at the WVS Projects, Alternative 2B and No Action Alternative.**

*3.12.2.9.3 Effects on Power System Reliability*

Due to the slight decrease in total hydropower generation under Alternative 2B, the LOLP would be 6.6 percent, or 0.1 percentage points greater than the LOLP in the No Action Alternative. The LOLP change from the No Action Alternative (6.5 percent) to Alternative 2B (6.6 percent) are negligible (i.e., within the +/- 1 percent range of modeling accuracy). A 6.6 percent LOLP is roughly equivalent to a one-in-fifteen year likelihood of a loss of load event or events (i.e., power shortages resulting in blackouts or emergency actions), which is the same likelihood of an event(s) as the No Action Alternative.

*3.12.2.9.4 Potential Replacement Resources and Associated Costs*

Given that the LOLP is not materially different between Alternative 5 and the No Action Alternative, the analysis finds that no replacement resources would occur under Alternative 5 to return the LOLP to the No Action Alternative level. Though greater than the NW Council's standard of five percent, the 6.6 percent LOLP under Alternative 5 is within the reasonable historical range of the NW Council target.

*3.12.2.9.5 Effects on Transmission*

Overall, changes in the patterns of WVS project generation under Alternative 5 would have moderate impacts to the transmission system due to the need to replace generation from more distant sources. The congested path of Cross Cascades South and South of Allston would see an increase of 21.9MW and 8.3MW in the Winter Peak case, respectively, and an increase of 25.1MW and 5.1MW in the Spring Off-peak case, respectively. For local impacts, generation at Hills Creek Dam would continue to be able to operate islanded (isolated) from the rest of the power system, providing power to the community of Oakridge during temporary power system outages primarily due to weather events or fires. Whereas, deep fall and spring drawdowns of the Cougar reservoir would likely compromise the ability of Cougar Dam to provide power to the community of Blue River in the event of a fire or severe weather event causing a temporary transmission outage between Blue River and Thurston substations.

Tables depicting power flows on Bonneville Transmission Network Paths under different seasonal conditions for Alternative 5 with comparison to the No Action Alternative are presented in Appendix G, Power and Transmission.

#### *3.12.2.9.6 Effects on Economic Viability of Power Generation*

Under Alternative 5, power generation from the combined WVS projects would not be economically viable. Over the 30-year study period, power operations are estimated to have a median Net Present Value of -$714 million under Alternative 2B[45]. This is an $939 million, or 417 percent, reduction in Net Present Value compared to the No Action Alternative. Across the 1,600 iterations that varied energy prices and water conditions, only 1.31 percent resulted in a positive Net Present Value. The median Levelized Cost of Generation for the combined WVS projects is estimated to rise from $26.70/MWh under the No Action Alternative to $50.81/MWh under Alternative 5, which is a $24.11, or 90 percent, increase. This is substantially greater than expected market prices and less competitive compared to other renewable resources that are expected to become more affordable in the future.

Looking at individual projects[46], Hills Creek is the only WVS project under Alternative 5 that has a positive median Net Present Value at $39 million. Its levelized cost of generation is $22.20/MWh. Hills Creek is also the only projects that has a positive Net Present Value in more than 50% of the 1600 iterations from the economic analysis. Other projects have negative median Net Present Values ranging from -$33 million (Lookout Point/Dexter) to -$354 million (Detroit/Big Cliff); levelized costs of generation ranging from $34.52/MWh (Lookout Point/Dexter) to $363.99/MWh (Cougar); and proportion of 1,600 iterations resulting in a

[45] Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

[46] Cougar and Hills Creek dams are operated as individual projects. Additionally, peaking dams and their respective re-regulating dams are functionally operated together as individual projects; therefore, the combined peaking/reregulating dams (Detroit/Big Cliff, Green Peter/Foster, and Lookout Point/Dexter) are treated as individual projects.

positive Net Present Value ranging from 0 percent (Cougar) to 33.63 percent (Lookout Point/Dexter).

Tables depicting 30-year Net Present Value, Percent of Iterations with a Positive Net Present Value, and Levelized Cost of Generation for WVS projects are presented in Appendix G, *Power and Transmission*.

### *3.12.2.9.7 Summary of Effects*

Table 3.12-24 presents generation, power system reliability, transmission flow paths and reliability, and economic conditions under the No Action Alternative with comparison to Alternative 5. Under Alternative 5, hydropower generation from the WVS projects would decrease by 18 aMW (roughly the amount of power consumed by 14,334 Northwest homes in a year) relative to the No Action Alternative on average under historical water conditions. The WVS projects would lose 12 aMW of firm power production under critical water conditions. Alternative 5 increases the LOLP to 6.6 percent associated with the loss in generation and no replacement resources would occur since this 0.1 percent difference relative to the No Action Alternative is within the +/-1 range of the accuracy of the model. The LOLP is within the reasonable historical range of the NW Council target. Therefore, impacts to power system reliability would be negligible.

Under Alternative 5, moderate impacts on the Cross Cascades South transmission path would be expected. There would be an increase of 25.1MW on the Cross Cascades South path. Under fall and spring deep drawdown conditions, the ability for Cougar Dam to serve load to the community of Blue River during temporary transmission outages that may occur is expected to be compromised.

Under Alternative 5, power generation from the combined WVS projects would not be economically viable. There would be an $939 million reduction in Net Present Value and a $24.11/MWh increase in the median Levelized Cost of Generation compared to the No Action Alternative[18]. Under Alternative 5, long-term, major, adverse effects on economic viability of power generation are anticipated.

**Table 3.12-24. Summary of Effects under Alternative 5 (ALT5).[5]**

| Metrics | No Action Alternative | ALT2B | ALT2B relative to No Action |
|---|---|---|---|
| WVS Projects 73-Year Average Generation (aMW) | 171 | 153 | -18 |
| WVS Projects Critical Water year (1937) Average Generation (aMW) | 150 | 136 | -12 |
| Loss of Load Probability (LOLP) | 6.5% | 6.6% | +0.1[2] |
| Resource Replacement | ——[1] | N/A[2] | N/A[2] |
| Transmission Flow Paths[3]<br>Cross Cascades South | W 6475.5<br>SP 4100.5 | W 6497.4<br>SP 4125.6 | W +21.9<br>SP +25.1 |

| **Metrics** | **No Action Alternative** | **ALT2B** | **ALT2B relative to No Action** |
|---|---|---|---|
| | SU 5862.9 | SU 5858.6 | SU -4.3 |
| South of Allston | W 1183.0<br>SP 732.1<br>SU 2525.1 | W 1191.3<br>SP 737.2<br>SU 2523.8 | W +8.3<br>SP +5.1<br>SU -1.3 |
| Transmission Reliability | Same/similar to affected environment4 | Regionally- Same/similar to NAA<br>Locally: unable to operate islanded at Cougar Dam during deep fall and spring drawdowns under certain conditions | No change regionally; comprised ability to meet local transmission services at Blue River during weather or fire related temporary outages |
| Net Present Value (median) | $225 Million | -$714 million | -$939 million |
| Levelized Cost of Generation ($/MWh) | $26.70 | $50.81 | +$24.11 |

Note: The estimated LOLP effect, and resulting transmission and economic viability effects, rely on the best available information regarding planned coal plant retirements as of 2017.

1/ A "——" indicates an effect category that is not relevant to the No Action Alternative because it only has potential to occur as a result of implementing an Action Alternative (e.g., the need for new generation and transmission infrastructure and associated costs).

2/ No replacement resources would be needed to return the LOLP to the No Action Alternative level since this difference of 0.1 percent is within the +/-1 range of the accuracy of the model; LOLP is within the reasonable historical range of the NW Council target.

3/ The amount of loading (in MW) on the congested paths of Cross Cascades South (CCS) and South of Allston (SOA) are depicted during three seasonal cases (W= Winter Peak; SP= Spring Off-peak; SU= Summer Peak).

4/The congested paths of Cross Cascades South (CCS) and South of Allston (SOA) remain congested. Generation at Hills Creek and Cougar dams would remain able to operate islanded (isolated) from the rest of the power system, providing power to the communities of Oakridge and Blue River, respectively, during power system outages due to, especially, weather events or fires.

5/Bonneville's share of basin-wide costs (e.g., RME) were not included in this analysis. With inclusion of those costs, the Net Present Value would be incrementally lower and the levelized costs of generation would be incrementally higher. Additionally, structural cost estimates used in the analysis were at a conceptual design level with a 50% contingency. For other projects of similar size and complexity, the conceptual design cost estimates increased by 137% to 215% upon completion of the detailed design report. Post-construction, the complexity of these systems has typically resulted in further costs to improve performance. Higher implementation costs than currently estimated would result in additional reductions of the Net Present Value and increases in the levelized costs of generation.

#### *3.12.2.9.8 Alternative 5 Climate Change Impacts for Power Generation and Transmission*

Since the WVS will likely experience increasing winter time (December through March) flow volumes due to climate change generally, it is possible that projects may be able to capture some additional flow and produce incremental increases in power generation during the winter. However, higher projected air temperatures are likely to result in decreased heating loads. Increases in power generation would incrementally decrease stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Lower snowpack may reduce springtime and summertime flows, as well as potentially impact refill ability. This could lead to reduced ability to generate power in the spring and summer. Increasing air temperatures are likely to increase demand for power in the summer due to increased cooling loads. Decreases in power generation would incrementally increase stress on existing congested paths (i.e., South of Allston and Cross Cascades South).

Climate change would affect Alternative 5 similar to the No Action Alternative with regards to hydropower. Under Alternative 5, there may be the potential to release and store more water in the spring and summer of dry years as compared to the No Action Alternative. The flow targets in Alternative 5 are lower than the current flow requirements, the reservoir may be able to store more water. However, the projects would likely have to use more of the stored water later in the season due to the projected variability in the spring months, hotter, drier summers, and lower summer base flow due to climate change.

Reservoirs in Alternative 5 sometimes drop to minimum elevation during the summer, but less often than the No Action Alternative, meaning storage levels would generally be able to augment summer flow for longer than the No Action Alternative even with projected decline in later spring and summer flows. This may alleviate some of the projected decrease in power generation in the summer from climate change than would occur under the No Action Alternative.

Reduced reservoir levels associated with decreased refill ability or drawdowns, combined with anticipated increases in the likelihood of extreme wildfire or weather events, would incrementally increase the risks that Cougar Dam would be unable to provide power during periods of reduced reservoir levels to the community of Blue River in the event a fire or severe weather event were to cause a transmission outage between Blue River and Thurston substations. Similarly, these conditions would incrementally increase the risks that Hills Creek Dam would be unable to provide power during periods of reduced reservoir levels to the community of Oakridge if a fire or weather event were to cause a transmission outage between Oakridge and Lookout Point Substation. These risks would be greater than the No Action Alternative and would be commensurate with the duration and timing of reduced reservoir levels.

These potential climate change impacts to hydropower are based on the climate change impacts as described in the hydrologic processes section

#### *3.12.2.9.9 Evaluation of Near-Term Operations Measure*

See Alternative 2A, Section 3.12.2.3.8, for description of effects due to the Near-Term Operations Measure.

## 3.13 WATER SUPPLY

Water is critical for the sustenance and continued growth of the Willamette Valley, which is home to more than 70% of the population of Oregon. The Oregon Water Resources Department is the state entity responsible for managing water in the state, including issuing water rights to use the water, be it for consumptive uses, instream purposes, or storing water for future use. Water users in the Willamette Basin rely on natural river flow, groundwater, and stored water released from reservoirs to satisfy state issued water rights for many types of uses. The two main consumptive uses of water from rivers are municipal and industrial (M&I) water supply and agricultural irrigation. This section focuses on effects to existing natural flow water rights for M&I and irrigation as well as the effects to the use of stored water via the storage allocations as discussed in Section 1.8.2 and detailed in the Willamette Basin Review Feasibility Study Report and Environmental Assessment (WBR), authorized by Congress in 2020 (USACE 2019a).

### 3.13.1 Affected Environment

Agricultural irrigation and municipal and industrial (M&I) water supply were original authorized purposes of the Willamette Valley project.

The study area is defined broadly as the geographic boundaries of the Willamette River Basin (WRB). As noted in Chapter 1, the WRB is located entirely within the state of Oregon, beginning south of Cottage Grove, and extending approximately 187 miles to the north where the Willamette River flows into the Columbia River. For effects to water supply resulting from changes to operations of the Corps' Willamette Valley System of 13 reservoirs, the study area was further refined to include the Willamette River and its tributaries with a Corps' project.

#### *3.13.1.1 Irrigation Water Supply*

The expansion of agricultural irrigation (AI) in the Willamette River Basin was slow until the 1940s. There were about 1,000 irrigated acres of farmland in the WRB in 1911 and 3,000 irrigated acres in 1920. By 1930, the basin contained 5,000 irrigated acres, which increased to 27,000 acres by 1940. A dramatic increase in the number of irrigated acres occurred in the WRB during the postwar decades. In 1964, approximately 194,000 acres were irrigated in the basin (OWRB, 1967). Irrigated acreage increased to about 300,000 acres by 2007, while irrigated acreage reported for 2012 decreased to a level of 250,000 acres (2007 and 2012 reported values from the U.S. Department of Agriculture, Census of Agriculture).

AI was recognized as a project purpose in the Willamette Valley System (WVS) authorizing legislation, and irrigation was thought to be the largest future use of WVS stored water. However, agricultural irrigation water demand in the Willamette Valley has not grown at the rate foreseen in the authorizing documents. Water use and conservation practices employed by the agricultural community also have changed since the WVS was authorized. WVS conservation storage totals approximately 1,590,000 acre-feet. Of this total, only 82,815 acre-feet of stored water (less than 5 percent of the conservation storage volume) is contracted through Reclamation for irrigation use on 43,857 acres. It should be noted that the vast majority of AI is not reliant on Reclamation water service contracts and withdraws water from streams through live flow water rights. At the current low level of use for water service contracts it is typically not necessary for the Corps to increase releases above the minimum flows to meet current contract requirements. The Corps does increase releases at Detroit Dam on the North Santiam River and Fern Ridge Dam on the Long Tom River to satisfy Reclamation's water service contracts.

Oregon's 2015 Statewide Long Term Water Demand Forecast provided a 2015 estimate of 605,700 acre-feet of water per year diverted for AI use within the Willamette River basin, and an estimate of 708,400 acre-feet of water per year by the year 2050 under hotter-drier conditions (a 35-year increase of 102,700 acre-feet of water per year) (OWRD 2015). This study looked only at the amount of water that may be needed under a future climate scenario for existing lands currently covered by irrigation water rights and did not include irrigation use new lands brought into agricultural production.

Irrigation water rights in Oregon identify a season of use, a rate, and a duty of water, which vary by location within the state. The season is the period of the year in which the right can be exercised, which typically corresponds to the growing season and may be extended if requested by the Oregon Department of Agriculture, as outlined in Oregon Revised Statutes (ORS) 537.385. The rate is the maximum amount of water that may be diverted or pumped, which is normally expressed in cfs. Duty is the volume of water that can be applied over the course of the season associated with the water right, which is normally expressed in acre-feet of water applied per acre. The maximum rate cannot typically be sustained on a full-time basis without exceeding the duty; from a practical water-use accounting standpoint, few water rights holders measure their rates, or their duties. All AI water service contracts, as of July 2008, that Reclamation issues from WVS releases include a requirement for flow metering, or measuring.

Based on the forecasted demand for stored water for agricultural irrigation in Corps' affected river reaches as detailed in the WBR, a total of 327,650 acre-feet was reallocated to the specific use of irrigation in the Water Resources Development Act of 2020 (WRDA) (USACE 2019a).

#### *3.13.1.2 Municipal and Industrial Water Supply*

The Willamette River and its tributaries are a major source of water for municipal and industrial needs. As population increases throughout the basin, M&I system needs increase – putting pressure on existing water supplies. To date, M&I systems rely on natural streamflow and groundwater wells in the Willamette Basin, though population growth is leading to a demand for water that exceeds existing supplies for many M&I systems throughout the basin. This need was one of the factors that led to the Willamette Basin Review Feasibility Study project, which resulted in a total of 159,750 acre-feet of conservation storage reallocated to the purpose of municipal and industrial water supply. To date, there are no agreements for using storage from any of the Willamette Project reservoirs for M&I water supply, but interest is significant among water suppliers in the Willamette Basin.

M&I systems must fully incorporate future population growth and peak season water supply demand in their long-term planning. As a result, M&I systems apply for water rights that are in excess of water presently needed so that an adequate supply would be ensured when sufficient numbers of ratepayers live in a community to justify and pay for the construction work on new diversion, conveyance, and treatment facilities. M&I systems are almost never in a position to complete full build-out of their water systems when they apply for a permit, as they lack the immediate need and ratepayer support. Still, the core mission for every M&I supplier is to secure a safe, adequate, and reliable water supply to meet current and future demand. By its nature, then, municipal water supply planning dictates identification of water supplies to meet projected needs decades into the future.

Municipalities are often given preferential treatment under the Oregon water rights system because of the public safety component of municipal water use, which is called the "Growing Communities Doctrine." The following are the components of municipal water use preferences in Oregon, which make up the Growing Communities Doctrine:

- M&I systems are not required to initiate construction of surface water diversion works within one year of being issued a water right permit (systems have up to 20 years to initiate construction plus an opportunity for extension); (FN: ORS 537.230);
- If the water right permit is to store water for municipal use, M&I systems have ten years to begin and complete construction of diversion or storage works; however, systems may apply for extensions in ten-year increments; (FN: ORS 537.248);
- An M&I system can certify a portion of its water right permit without cancellation of the remaining portion of water authorized to be diverted under the right. To do so, the municipality must "perfect", or use, at least 25 percent of the amount authorized on the permit; (FN: ORS 537.260(4));
- An M&I system water right generally is not subject to forfeiture. Although a water right that is unused for five consecutive years is presumed forfeited, the presumption is overcome by showing that the use was for a municipal purpose; (FN: ORS 540.610(2)(a));
- Water rights issued to M&I systems may be used on lands to which the right is not appurtenant, under certain circumstances; and
- Municipal uses for human consumption may take preference over other types of senior instream water rights established through the permitting process (as opposed to conversion or acquisition) if Oregon Water Resources Department (OWRD) determines that this would be in the public interest.

Taken together, this means that there are undeveloped M&I system water rights throughout the basin because use and population for some M&I systems have not yet grown to the extent reflected in their existing water right permits. It is important to note that undeveloped M&I system uses are considered by OWRD when water availability calculations are conducted.

### *3.13.1.3 Summary of Water Use in the Willamette River Basin*

The following sections detail the water rights for municipal and industrial water supply and agricultural irrigation in the Willamette sub-basins with Corps dams and also on the mainstem of the Willamette River.

#### *3.13.1.3.1 Water Rights*

**Error! Reference source not found.**1 and Table 3.13-22 below list the number of diversions and permitted flow of water for withdrawals in tributaries with a Corps dam and reservoir and on the mainstem Willamette River.

The Coast Fork of the Willamette River is a small sub-basin with relatively small levels of consumptive use for M&I water supply and AI.

The Middle Fork of the Willamette River has a moderate level of demand for irrigation water and a small level of demand for M&I water supply. Fall Creek does not have any M&I diversions but does have irrigation withdrawals.

The McKenzie River has the second highest number of M&I and irrigation diversions of the sub-basins but only a third and a quarter, respectively, of the number on the mainstem Willamette River.

The Long Tom River has a very small number of withdrawals for M&I water supply but has a very high number of irrigation diversions relative to the size of the river. The sub-basin is heavily agricultural focused.

The Santiam Basin, comprising the North and South Rivers and the relatively short reach of the Santiam River, is an important area for agricultural use within the Willamette River Basin. The Santiam Basin is second only to the mainstem Willamette River for both M&I and agricultural water use. Large irrigation districts, including the Santiam Water Control District, which provides water to not only irrigation customers, but numerous municipal entities as well, are some of the largest users of water in the Santiam Basin. Irrigators in the Santiam Basin use stored water released from both Detroit and Green Peter dams.

The City of Salem uses water withdrawn from the North Santiam River at Geren Island, near the town of Stayton, as its primary source for drinking water to its citizens as well as industrial customers. The drinking water treatment plant on Geren Island requires a minimum flow in the river of 750 cfs to be operational.

The majority of water withdrawals in the Willamette Basin occurs from the mainstem of the Willamette River, from just south of the City of Eugene to the confluence with the Columbia River. The highest level of use occurs below Salem, in the Portland metropolitan area, home to the majority of the Willamette Basin population.

**Table 3.13-1 . Surface Water Points of Diversion in Select Tributaries to and on the Mainstem Willamette River (OWRD WRIS, July 2021)**

| Reach | Municipal Surface Water Diversions | Industrial Surface Water Diversions | Irrigation Surface Water Diversions |
|---|---|---|---|
| Coast Fork Willamette River | 26 | 15 | 169 |
| Row River | 7 | 0 | 38 |
| Middle Fork Willamette River | 4 | 8 | 71 |
| Fall Creek | 0 | 0 | 27 |
| McKenzie River | 30 | 19 | 309 |
| Long Tom River | 4 | 2 | 250 |
| North Santiam River | 22 | 23 | 359 |
| South Santiam River | 20 | 18 | 205 |
| Santiam River | 7 | 1 | 181 |
| Willamette River | 92 | 53 | 1277 |

**Table 3.13-2. Summary of Water Use in Select Tributaries to the Willamette River (OWRD WRIS, July 2021)**

| Reach | Municipal Surface Water Diversions (cfs) | Industrial Surface Water Diversions (cfs) | Irrigation Surface Water Diversions (cfs) |
|---|---|---|---|
| Coast Fork Willamette River | 3.91 | 4.53 | 94.16 |
| Row River | 10.92 | 0 | 5.23 |
| Middle Fork Willamette River | 6.95 | 4.65 | 13.46 |
| Fall Creek | 0 | 0 | 8.25 |
| McKenzie River | 409.56 | 198.48 | 102.42 |
| Long Tom River | 1.49 | 0.36 | 181.43 |
| North Santiam River | 68.92 | 15.11 | 192.55 |
| South Santiam River | 218.11 | 21.45 | 67.34 |
| Santiam River | 6.51 | 0.67 | 137.51 |

#### *3.13.1.3.2 Forecasted Demand for Stored Water*

The WBR, completed in 2019, estimated the need for water stored in the Corps' reservoirs to supply future M&I water supply and irrigation needs. These demands were spread across the sub-basins, but with a vast majority on the mainstem Willamette River. Table 3.13-3 below lists the distribution of estimated demands for stored water for M&I and irrigation needs by the year 2050.

**Table 3.13-3. Estimated New Demands (annual) for Stored Water by the Year 2050**

| Reach | Waterway | Municipal and Industrial Demand for Stored Water (af) | Agricultural Irrigation Demand for Stored Water (af) |
|---|---|---|---|
| 1 | Willamette River, downstream of Santiam River confluence | 65,358 | 69,483 |
| 2 | Santiam River | 387 | 3,666 |
| 3 | North Santiam River | 1,490 | 5,124 |
| 4 | South Santiam River | 552 | 5,963 |
| 5 | Willamette River, between the Santiam and Long Tom River confluences | 2,018 | 6,433 |
| 6 | Long Tom River | 1 | 6,389 |
| 7 | Willamette River, between the Long Tom and McKenzie River confluences | 808 | 3,870 |
| 8 | McKenzie River | 1,867 | 2,740 |
| 9 | Willamette River, between McKenzie and Coast Fork/Middle Fork confluences | 795 | 29 |
| 10 | Middle Fork Willamette River, below the Fall Creek confluence | 7 | 1,127 |
| 11 | Middle Fork Willamette River | 1 | 4,819 |
| 12 | Fall Creek | 0 | 84 |
| 13 | Coast Fork, below confluence with Row River | 0 | 730 |
| 14 | Row River | 6 | 52 |
| 15 | Coast Fork, above confluence with Row River | 0 | 11 |
| Total | | 73,920 | 110,520 |

### 3.13.2 Methodology

The following section describes the evaluation criteria for determining effects to M&I water supply and irrigation users.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.13-4. Evaluation Criteria for Potential Effects for Water Supply**

| Effect Scale | Criteria (Live Flow Water Rights) | Criteria (Storage Allocations and Stored Water) (1) |
|---|---|---|
| Negligible | Use of water for M&I water supply or irrigation would not be affected because changes to downstream flows would be either nondetectable or, if detected, would have effects that would be slight and localized to a portion of a stream. Effects would be of very limited duration and would not require additional consideration. | More than 90% of available storage space is filled, or more than 1,431,000 acre-feet of water, at least 75% of the time; was stored by May 20. |
| Minor | Changes to downstream flows would be measurable, although the changes would be small and limited to one or two tributaries. The duration of effects would be of limited annual duration, occurring mainly in the spring each year. | More than 75 - 89% of available storage space is filled, or more than 1,192,500 acre-feet but less than 1,431,000 acre-feet of water, at least 75% of the time; was stored by May 20. |
| Moderate | Changes to downstream flows would be measurable and occur on more than two tributaries. The duration of flow changes would occur annually for more than one continuous month during the summer low flow period. | More than 60 - 74% of available storage space is filled, or more than 954,000 acre-feet but less than 1,192,500 acre-feet of water, at least 75% of the time; was stored by May 20. |
| Major | Changes to downstream flows would be measurable and would extend for more than a month during the summer low flow period. | Less than 60% of available storage space is filled, or less than 954,000 acre-feet of water, at least 75% of the time; was stored by May 20. |

[1]Though the model results indicate an increase or decrease to peak May storage volumes, the actual effects to stored water users are unknown at this time because the annual management process in dry years has not been established, as required by WBR BiOp RPA.

Effects to water supply would be both direct and indirect. Based on the recommendation in the WBR Chief's Report, Congress reallocated the conservation storage space in the WVS reservoirs from all joint-use storage to three specific authorized purposes – fish and wildlife (69%), agricultural irrigation (21%), and municipal and industrial water supply (10%) (USACE 2019a). Alternatives that contain measures that intentionally modify operations of the reservoirs such that the ability to refill the conservation storage space is diminished have a direct effect on water supply users relying on the stored water as the water would not be available for them to call on to be released.

Changes to the amount of water released from the dam have a direct effect on downstream water users.

Effects to water supply (M&I and AI) from all the alternatives would be long term. There could be short-term effects to water supply from construction activities associated with structural measures, or where construction or modification of existing facilities is required for an operational measure. These effects will be addressed in site-specific NEPA and are not included in the analysis below.

Beneficial effects result from an increase of water stored in the reservoirs or increases in summer flows when compared to the No Action Alternative (NAA).

Adverse effects result when there is a decrease in the amount of water stored in the reservoirs or a decrease in summer flows when compared to the NAA.

### 3.13.3 Environmental Consequences

The WVS Draft PEIS alternatives include structural and operational measures for fish passage and temperature management and changes to flow regimes downstream of Corps' dams. Structural measures for fish passage and temperature management would not change the flow regimes or ability to refill the reservoirs and would therefore not affect water supply in the long term. Short term and temporary affects due to construction activities would be addressed in site specific NEPA and are not addressed here. Operational fish passage measures may affect the ability to refill the conservation pools within the reservoir and therefore may affect water supply. Minimum flow regimes that change river flows downstream of the Corps' dams may affect downstream water supply users. The water supply analysis below used ResSim modeled flow data to qualitatively evaluate physical effects to water supply.

The Corps analyzed the total maximum volume of water stored in the WVS reservoirs between May 10 – 20 that is expected to occur 75% of the time (P25 on the storage charts shown below) to evaluate effects to storage allocations and use of stored water for consumptive use. This stored water would be released to meet M&I and irrigation consumptive uses and instream to support fish and wildlife. Dexter and Big Cliff dams are re-regulation dams and do not have conservation storage; therefore, these two reservoirs are not considered in this evaluation or in the total volume of stored water.

Assessing effects to live flow water rights on a programmatic level is challenging. The Corps compared the level of flow at the control points on Corps effected tributaries and on the mainstem Willamette River between the NAA and the action alternatives to determine an expected level of impact to these users.

The WBR Biological Opinion (BiOp) Reasonable and Prudent Alternative (RPA) Measure 2 includes a cap on new water storage for M&I use of a total of 11,000 acre-feet and no agreements in the Santiam Basin until National Marine Fisheries Services (NMFS) issues its written agreement to the Corps that instream water rights are in place and providing sufficient protection to flows intended to benefit fish. The Corps determined it is reasonable to assume actions necessary to protect instream flows for fish with instream water rights would occur and this cap would be lifted into the future; therefore, the 2050 M&I demand due to future M&I deficits and new self-supplied industrial (SSI) uses of water, totaling 73,300 ac-ft, for both the NAA and the action alternatives was used for modeling purposes.

While the WBR evaluated effects from the full irrigation allocation volume of 327,650 acre-feet, the WBR BiOp did not address the existing cap on Bureau of Reclamation (BOR) irrigation water service contracts of 95,000 acre-feet. Therefore, the NAA assumes the level of water service contracts of 82,815 acre-feet. It is reasonable to assume that demand for water service contracts for irrigation will increase within the next 30 years. The BOR concurred with using the 2050 increase in demand for stored water for irrigation use calculated as part of the WBR study for modeling effects of increased irrigation use in the system, an additional 110,500 acre-feet plus an additional 62,050 for existing users whose water right would be junior to instream water rights and would therefore need a backup water source. The total agricultural irrigation uses of stored water considered in this analysis is 255,385 acre-feet.

The ResSim model releases the full 2050 demand volumes when there is water above the minimum conservation elevations. Due to limitations with ResSim, the withdrawals and return flows are always active, even when reservoirs are below minimum conservation elevation, and no stored water is released to satisfy the withdrawals. WBR BiOp RPA Measures 3 and 4 require the USACE to determine on an annual basis the amount of water that will be available to satisfy M&I storage agreements and irrigation water service contracts. In dry years when total system storage (amount of water stored in the WVS reservoirs) is low, water may not be available to meet all the stored water demands. This determination will be made based on realized hydrology. ResSim limitations precluded developing complex rules regarding when stored water would be available for consumptive uses and when it would not; therefore, the ResSim model results do not include reductions in use of stored water for M&I and irrigation. Though the model results indicate an increase or decrease to peak May storage volumes, the actual effects to stored water users are unknown at this time because the annual management process in dry years has not been established, as required by RPAs 3 and 4 in the WBR BiOp.

Site-specific project details for each construction measure will be determined during the preconstruction engineering and design phase. While general, qualitative effects from construction are discussed below on a programmatic level, the more detailed, site-specific analysis will be included in future, tiered EAs or EISs.

The geographic scope of effects to water supply can occur at both the local level within a sub-basin and at the larger Willamette River Basin level as the majority of users are on the mainstem Willamette River, downstream of the Corps' projects.

The Coast Fork and Long Tom sub-basins are not discussed in the analysis below as the hydrologic analysis in Section 3.2.3 showed no difference between the NAA and any of the alternatives. Effects to downstream flows in the North Santiam and McKenzie are noted in certain alternatives due to the extent of the operations proposed in those alternatives.

**Table 3.13-5.** **Summary of Effects for Water Supply and Storage Allocations**

| | **No Action Alternative** | **Alternative 1** | **Alternative 2A** | **Alternative 2B** | **Alternative 3A** | **Alternative 3B** | **Alternative 4** | **Alternative 5** |
|---|---|---|---|---|---|---|---|---|
| North Santiam | N/A | Minor adverse | Minor adverse | Minor adverse | Major adverse | Minor adverse | Minor adverse | Minor adverse |
| South Santiam | N/A | Minor adverse | Negligible | Negligible | Negligible | Major adverse | Negligible | Negligible |
| Santiam | N/A | Minor adverse | Negligible | Negligible | Negligible | Minor adverse | Negligible | Negligible |
| Long Tom River | N/A | None | None | None | None | None | None | None |
| McKenzie | N/A | Negligible | Negligible | Negligible | Negligible | Negligible | Negligible | Negligible |
| Middle Fork Willamette | N/A | Negligible | Negligible | Negligible | Moderate adverse | Minor adverse | Negligible | Negligible |
| Coast Fork Willamette | N/A | Negligible | Negligible | Negligible | Negligible | Negligible | Negligible | Negligible |
| Mainstem Willamette | N/A | Minor beneficial | Negligible | Negligible | Negligible | Negligible | Negligible | Negligible |
| Storage Allocations (1) | Moderate beneficial | Moderate beneficial | Minor beneficial | Minor adverse | Major adverse | Major adverse | Minor beneficial | Minor adverse |

(1) These are based on modeled results. The annual management plan for use of available water has not yet been developed per the WBR BiOp RPA.

#### *3.13.3.1 No Action Alternative*

The NAA includes new releases of stored water from the reservoirs and withdrawals in downstream reaches for M&I purposes to satisfy new water storage agreements from the M&I allocation. The volume of M&I water storage agreements was assumed to be 73,300 acre-feet of storage (the 2050 level of demand from the WBR).

The NAA continues the current water management objectives, which attempt to manage reservoir levels to balance the needs of all authorized purposes. Water would be released from the reservoirs to satisfy demands of stored water for municipal and industrial uses at the 2050 demand level and existing, as of April 2019, irrigation water service contracts. See Appendix X for further details. Figure 3.13-1 shows that 75% of the time, the maximum total volume of water stored in the WVS reservoirs would be at least 1.3 million acre-feet, resulting in enough stored water to meet the M&I and irrigation demands in most years. Stored water would not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years. The amount available would be determined on an annual basis based on realized storage volumes across the system.

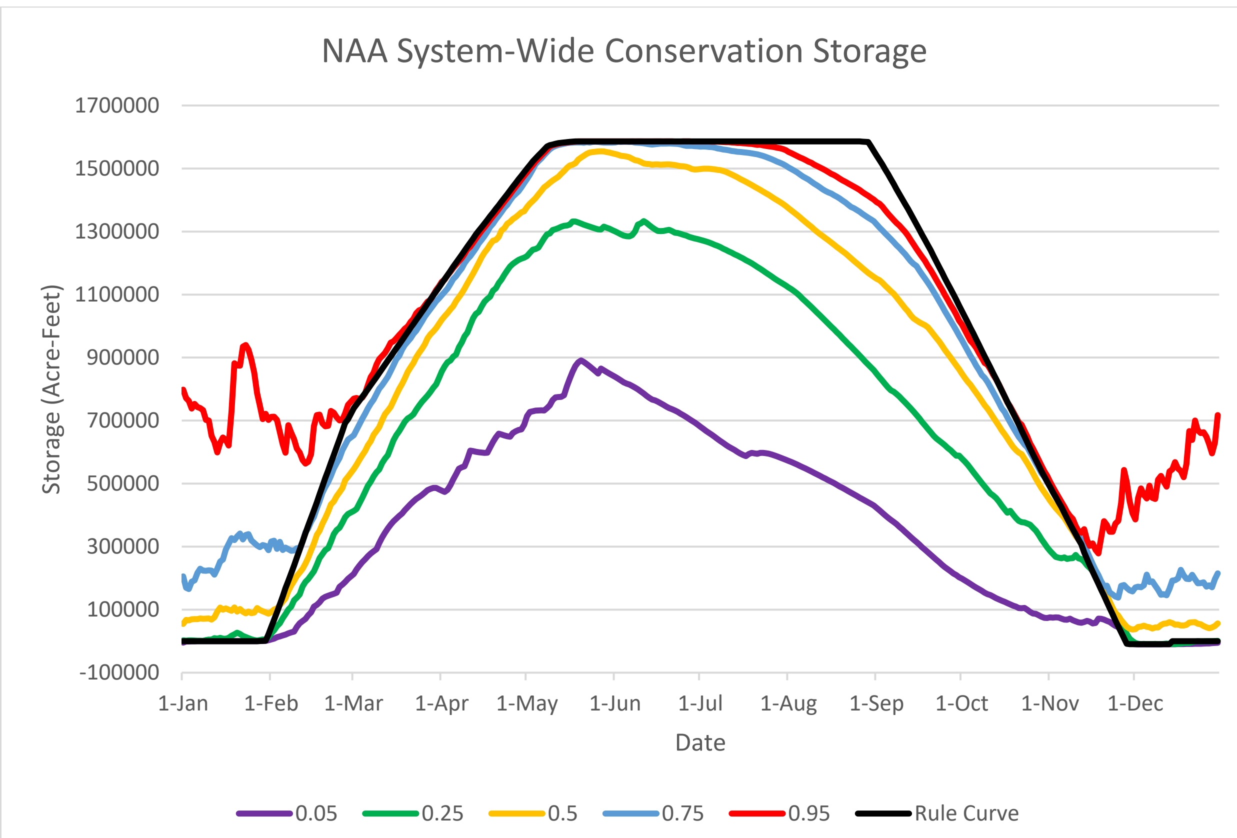

**Figure 3.13-1. System-Wide Conservation Storage Non-Exceedances Under the NAA**

Flows downstream of the WVS dams would continue to support existing water rights in the same frequency as they do today. Not all live flow water rights are fully met in all years and in all months under existing conditions and this would continue under the NAA due to hydrologic conditions beyond the control of the USACE. Figure 3.13-2 shows the modeled flow at Salem for the NAA, which includes increased releases of stored water to satisfy water storage agreements of 73,300 acre-feet, downstream withdrawals, and return flow. Under the NAA conditions, the 2008 BiOp flow target would not be met in all years, which could require a reduction in use of stored water under the storage agreements. As each individual year is different and not reflected in the flow charts, reduction of the use of stored water was not included in the ResSim modeling. Stored water would be available to satisfy M&I water storage agreements at least 80% of the time.

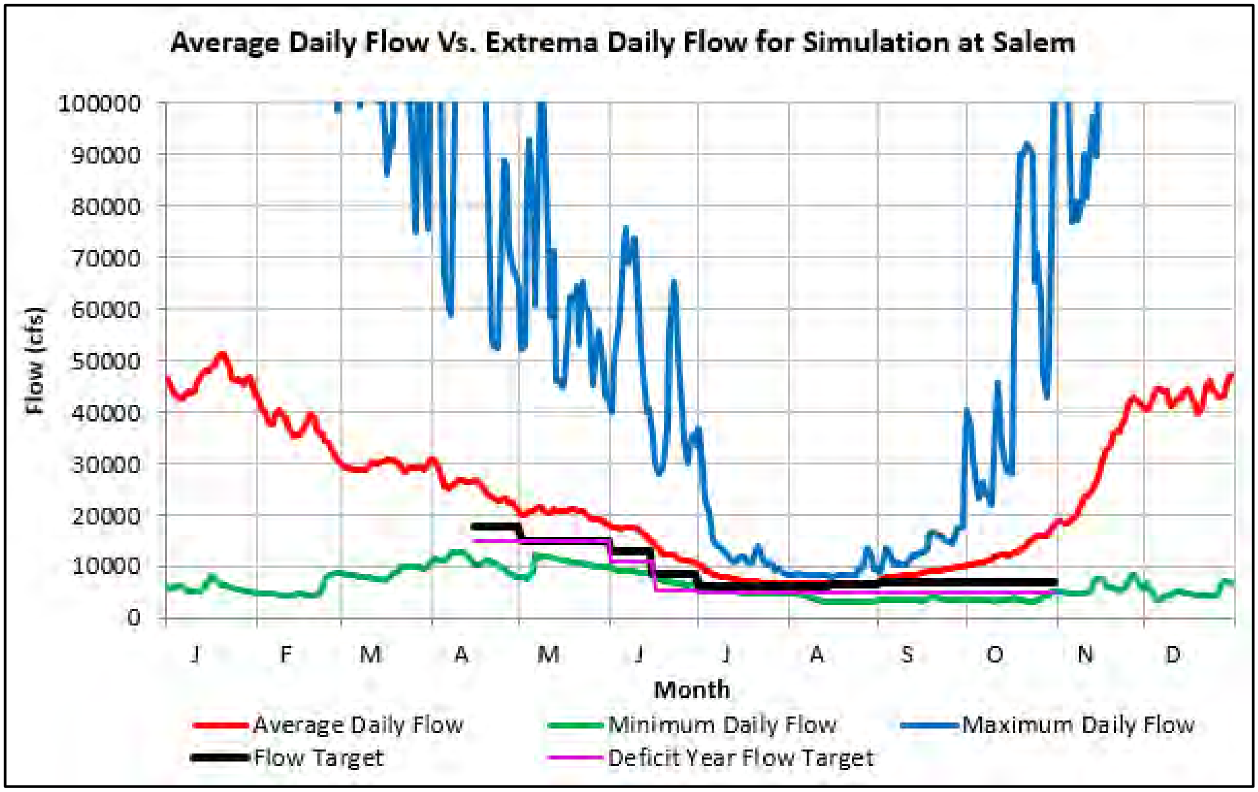

**Figure 3.13-2. Average Daily Flow, Minimum Flow, and Maximum Flow Under the NAA**

Effects from the NAA to water supply would be moderately beneficial and **long term** due to newly accessible source of stored water for M&I uses. Effects would be realized basin-wide.

### *3.13.3.1.1 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under climate change induced hydrology. Climate change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets. Decreased summer baseflows would also adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights. Climate change would have an adverse effect to M&I water supply and irrigation.

#### *3.13.3.2 Alternative 1 – Project Storage Alternative*

Alternative 1 is a storage based alternative that structural downstream fish passage measures and lower minimum flow targets compared to the NAA, particularly in the spring, resulting in increased system-wide conservation storage.

##### *3.13.3.2.1 System-wide Storage*

Figure 3.13-3 shows that peak conservation storage would increase by 168,000 acre-feet in the driest year compared to the NAA, resulting in a moderate beneficial effect to system-wide storage allocations and the municipal and industrial water supply and irrigation users relying on stored water. Stored water would still not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years, but to a lesser extent than in the NAA. The amount available would be determined on an annual basis based on realized storage volumes across the system.

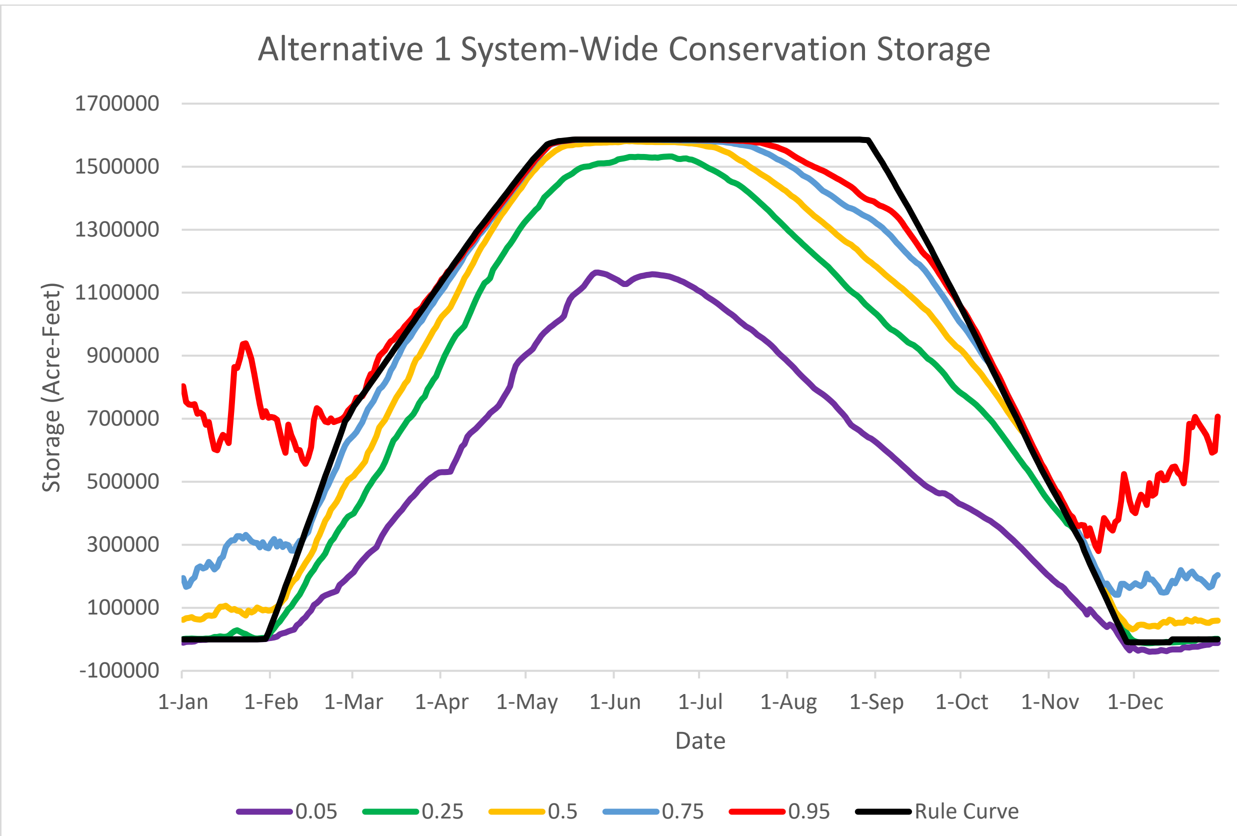

**Figure 3.13-3. System-Wide Conservation Storage Non-Exceedances Under Alternative 1**

##### *3.13.3.2.2 River Flows*

**North Santiam**

Operations affecting water supply in the North Santiam Basin include releasing flow according to the original House Document 531 flow regimes, which are less than the 2008 BiOp flow targets used currently and under the NAA.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is lower in the spring as compared to the NAA, reflecting the lower spring target flows compared to the NAA. Flows drop close to 1000 cfs during parts of the spring and summer during the driest years, resulting in Detroit Reservoir filling higher than in the NAA. The reservoir would reach minimum conservation pool later in the year, following the rule curve. Real time water management of the reservoir would be capable of managing flows in the North Santiam River, as to result in only a minor adverse effect to users relative to existing conditions. This effect would be local and occur only in drier years.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing flow according to the original House Document 531 flow regimes.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March through June in drier years, but nearly equal during the summer most years. As the flows are lower during the spring in drier years, Alternative 1 would have a minor adverse effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are lower than the NAA from mid-March through June and again in September in dry years, and nearly equal in the summer and all years. As the flows are lower during a portion of the spring and summer, but only in dry years, Alternative 1 would have a minor adverse effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam that would effect outflow and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing flow according to the original House Document 531 flow regimes.

Flows at Vida on the McKenzie River are lower than the NAA from April through mid-June but slightly higher mid-June through September in the dry years. As the flows are lower during a portion of the spring but higher during critical summer months in dry years, Alternative 1 would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette Basin include releasing flow according to the original House Document 531 flow regimes.

Flows at Jasper on the Middle Fork Willamette River, downstream of Hills Creek, Lookout Point, and Fall Creek reservoirs, are lower than the NAA from April through mid-June about 50% of the time, but higher than the NAA during the summer months. As the flows are only lower during a portion of the spring but higher during later summer, Alternative 1 would have a negligible effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette Basin include releasing flow according to the original House Document 531 flow regimes.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through mid-June in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 1 would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing flow according to the original House Document 531 flow regimes.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 4000 cfs, and only in the drier years, Alternative 1 would have a negligible effect on water supply in the Willamette River above Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher than in the NAA during the summer months. As are higher during the summer months when water supplies are often at critical limits, Alternative 1 would have a minor beneficial effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As are higher during the summer months when water supplies are often at critical limits, Alternative 1 would have a minor beneficial effect on water supply in the Willamette River near and downstream of Salem.

Overall, Alternative 1 would have a minor adverse effect on water supply in the Santiam Basin, negligible effect on water supply on the McKenzie, Middle Fork, and Coast Fork Willamette, and minor beneficial effect on the mainstem Willamette River. This effect would be long term.

###### *3.13.3.2.3 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under climate change induced hydrology. Climate change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets, but to a lesser degree than in the NAA because the reservoirs would generally retain more water later in the season. Therefore, the likelihood of climate changes constraining stored water supply would be slightly diminished under this Alternative compared to the NAA. Natural river flow in the summer would likely decrease due to climate change and would adversely affect water users as there may not be adequate water in the rivers to satisfy existing live flow water rights.

#### ***3.13.3.3 Alternative 2A - Hybrid Alternative***

Alternative 2A combines structural and operational fish passage measures and includes integrated habitat and temperature minimum tributary flow targets, and reduced mainstem targets. These flow targets vary throughout the year and are dependent on the level of the reservoir relative to the rule curve.

###### *3.13.3.3.1 System Storage*

Figure 3.13-4. System-Wide Conservation Storage Non-Exceedances Under Alternative 2A shows that under Alternative 2A peak conservation storage would increase by 122,000 acre-feet in the dry years, resulting in a minor beneficial effect to system-wide storage allocations and the municipal and industrial water supply and irrigation users of the conservation storage. Stored water would still not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years, but to a lesser extent than in the NAA. The amount available would be determined on an annual basis based on realized storage volumes across the system.

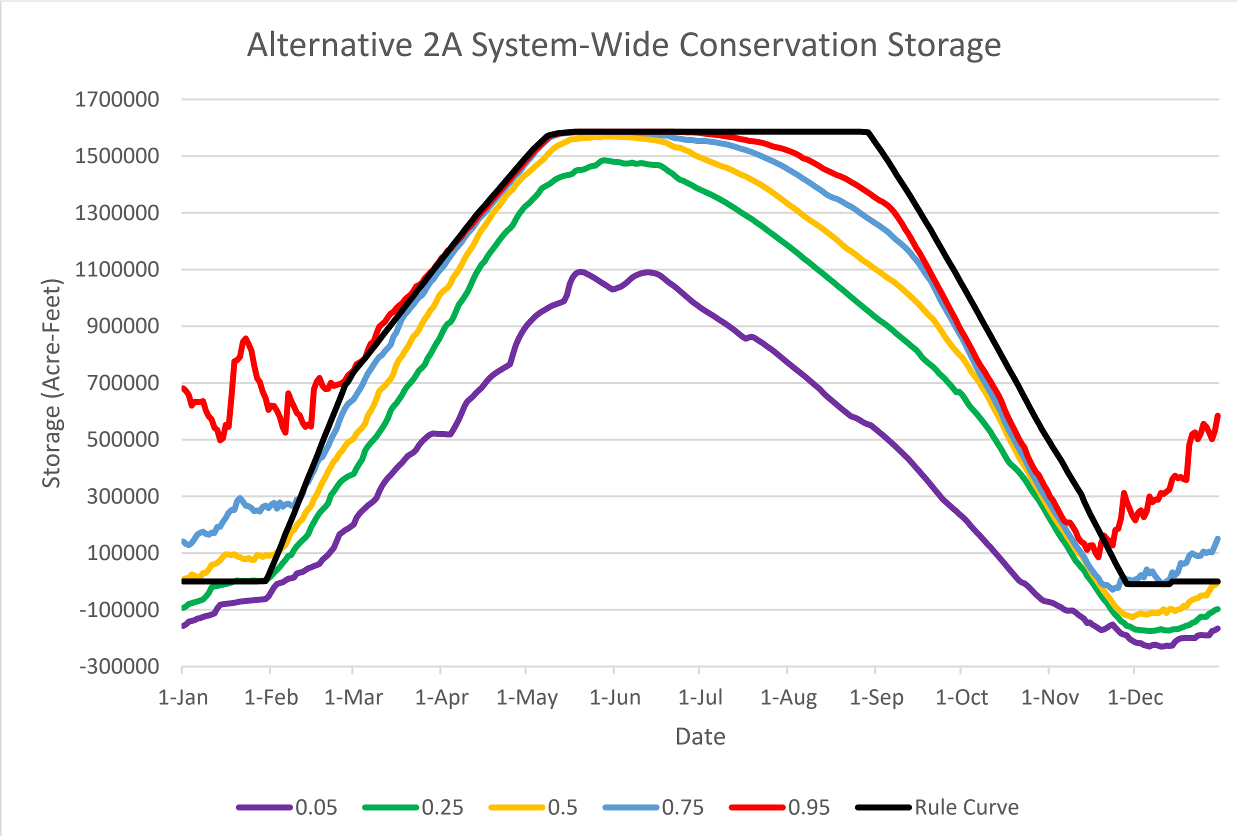

**Figure 3.13-4. System-Wide Conservation Storage Non-Exceedances Under Alternative 2A**

#### *3.13.3.3.2 River Flows*

**North Santiam**

Operations affecting water supply in the North Santiam Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is slightly lower in the spring and late summer, dropping close to 1000 cfs during the late summer during the driest years, as compared to the NAA, reflecting the lower spring target flows from Detroit as compared to the NAA. Detroit Reservoir fills higher in these years and would reach minimum conservation pool later in the year, following the rule curve. Real time water management of the reservoir would be capable of managing flows in the North Santiam River, as to result in only a minor adverse effect to users relative to the NAA. This effect would be local and occur only in the driest years.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and a fall draw down operation for fish passage.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March to early-June in the driest years, but higher in fall in all years due to the fall drawdown operation at Green Peter Dam, as indicated in Appendix B, Figure B-165. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 2A would have a negligible effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are lower than the NAA from mid-March to mid-May in the driest years, but higher in the summer and fall in most years due to the fall drawdown operation at Green Peter Dam, as indicated in Appendix B, Figure B-164. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 2A would have a negligible effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flows at Vida on the McKenzie River would be lower than the NAA from April through mid-June but slightly higher in August and September in the driest years. As the flows would only be lower during a portion of the spring and only in the driest years, Alternative 2A would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary.

Flows at Jasper on the Middle Fork Willamette River, downstream of Hills Creek, Lookout Point, and Fall Creek reservoirs, are lower than the NAA from April through mid-June in most years, but higher than the NAA during the summer months. As the flows are only lower during a portion of the spring and only in drier years, Alternative 2A would have a negligible effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 2A would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the inactive and power pools, as necessary and available, and the fall drawdown at Green Peter for fish passage.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 5000 cfs, and only in the driest years, Alternative 2A would have a negligible effect on water supply in the Willamette River above Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June in the drier years, but higher than in the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 5500 cfs, and only in the driest years, Alternative 2A would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 6000 cfs, and only in the driest years, Alternative 2A would have a negligible effect on water supply in the Willamette River near and downstream of Salem.

Overall, Alternative 2A would have a minor adverse effect on water supply in the North Santiam Basin and negligible effect on water supply on the rest of the tributaries and the mainstem Willamette River. This effect would be long term.

#### *3.13.3.3.3 Near-Term Operations Measure*

**North Santiam**

The near-term operations measure within the North Santiam Basin includes Fall/Winter downstream fish passage through the upper regulating outlets and spring fish passage through strategic use of spillway and turbines at Detroit Dam and spreading spill to reduce total dissolved gas at Big Cliff Dam.

The near-term operations measure would have no effect to water supply (M&I and agricultural irrigation) relative to the NAA as the operations directly affecting Detroit Dam do not reduce the ability of the reservoir to refill, and hence do not affect stored water potential. Due to implementation of the Integrated Flow Regime, Detroit reservoir would be expected to fill more often and higher in dry years, than in the NAA. Flows downstream of the dam would be similar under the near-term operations measure as they would be once Alternative 2A is fully implemented.

**South Santiam**

The near-term operations measure within the South Santiam Subbasin includes outplanting of adult Chinook above Green Peter Reservoir, downstream fish passage at Green Peter Dam via the spillway in the spring and fall, and downstream fish passage at Foster via the spillway in the spring and fall.

There is a potential for minor adverse effects to water supply in the South Santiam due to the near-term operations implemented at Green Peter and Foster dam and reservoirs, but only in the driest years. Green Peter reservoir does not fill as high under the near-term operations measure as it does in the NAA in the driest years. This would affect the ability to provide stored water for M&I and irrigation uses. Flows out of Foster reservoir would be lower in the driest years, due mainly to implementation of the Integrated Flow Regime.

**Mainstem Santiam**

Flows on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are higher under the near-term operations measure than in the NAA, as indicated in Section 3.2.3.3.7. As the flows are higher under all years, there would be a minor beneficial effect to water supply on the mainstem Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the near-term operations measure, as there are no operational changes proposed at Fern Ridge Dam.

**McKenzie River**

The near-term operations measure within the McKenzie Subbasin includes spring and fall drawdown for fish passage at Cougar Reservoir to a target elevation of 1505 feet.

While Blue River Reservoir fills more often, especially in dry years, under the near-term operations measure, Cougar Reservoir refill would be majorly impacted by the operation in the drier years. While the reservoir would refill in average years, the refill could occur later, likely impacting the ability for stored water users to adequately plan for a larger volume use. This would result in a moderate impact to M&I and irrigation stored water users.

As noted in Section 3.2.2.4.7, flow at Vida, the McKenzie River control point downstream of Blue River and Cougar dams, is similar when compared to the NAA. Water users holding live flow water rights would experience negligible impacts from the near-term operations measure.

**Middle Fork of the Willamette River**

The near-term operations measure includes actions at three projects in the Middle Fork sub-basin. Downstream fish passage is provided at Hills Creek by prioritizing the regulating outlets at night during the fall and winter. Hills Creek reservoir is also used in the spring to help fill Lookout Point reservoir for that project's spring spill operation for fish passage. Lookout Point would then be drawn down to near the regulating outlets during the fall to pass fish downstream. Fall Creek would be drawn down to the riverbed in the fall as it is under current conditions, but refill of the reservoir to full conservation pool would be delayed until late spring.

The near-term operations measure would impact the ability of Hills Creek reservoir to refill in the driest years and Lookout Point and Fall Creek reservoirs in all years. This lack of refill would have a major impact to M&I and irrigation users relying on stored water in the Middle Fork of the Willamette River.

As noted in Section 3.2.2.4.7, flows at Jasper would be lower in the summer and fall in all years. This would have moderate, adverse effects to water rights holders, specifically in the dry years.

**Coast Fork of the Willamette River and Row Rivers**

There are no near-term operations for the Coast Fork projects. The near-term operations measure would have negligible effects to water supply on the Coast Fork, as flows during the critical summer months would be similar as compared to the NAA.

**Mainstem Willamette at Salem**

Flows at Salem under implementation of the near-term operations measure would be fairly similar to the NAA; therefore, effects to live flow water rights holders would be negligible. Due to the combined effects of spring delayed refill operations at multiple dams, the near-term operations measure would have a minor, adverse effect to M&I water supply and irrigation users relying on stored water.

##### *3.13.3.3.4 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. Climate change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets, but less so compared to the NAA. Natural river flow in the summer would likely decrease due to climate change and would adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights.

#### ***3.13.3.4 Alternative 2B - Hybrid Alternative***

Alternative 2B combines structural and operational fish passage measures and includes integrated habitat and temperature minimum tributary flow targets, and reduced mainstem targets. These flow targets vary throughout the year and are dependent on the level of the reservoir relative to the rule curve. The difference between Alternative 2A and 2B is the fish passage measure at Cougar dam. Alternative 2A uses a structure that operates with existing reservoir fluctuations to pass fish downstream, whereas Alternative 2B includes an operation where the reservoir is drawdown to elevation 1330 feet to use the diversion tunnel to pass fish.

The combination of actions in Alternative 2B would result in a decrease of 64,000 acre-feet stored water compared to the NAA. The small decrease in system-wide conservation storage would have a minor adverse effect to municipal and industrial water supply and irrigation users of the conservation storage. Due to the expected limited level of demand for stored water on the McKenzie River, Alternative 2B would be expected to have only a minor adverse effect on storage allocations, mostly in the McKenzie sub-basin. Stored water would not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years. The amount available would be determined on an annual basis based on realized storage volumes across the system.

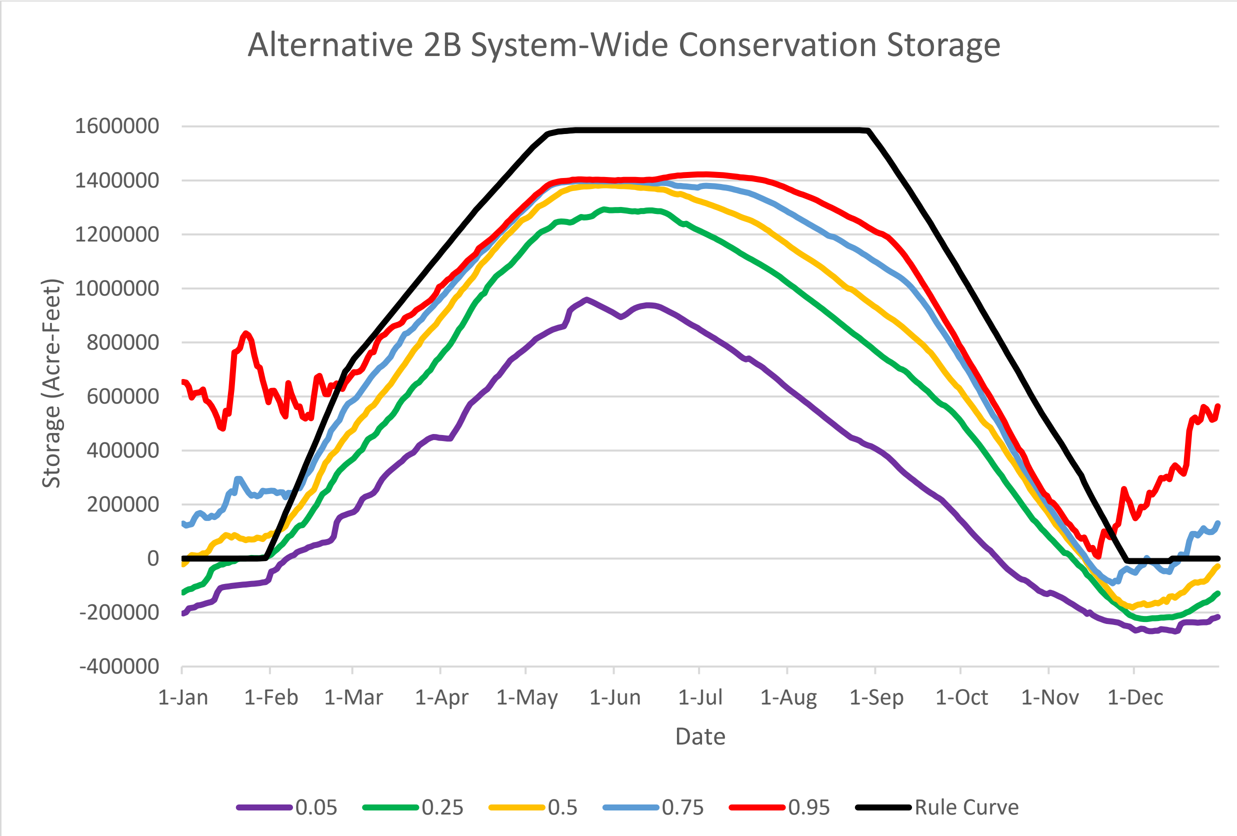

**Figure 3.13-5. System-Wide Conservation Storage Non-Exceedances Under Alternative 2B**

## North Santiam

Operations affecting water supply in the North Santiam Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is slightly lower in the spring and late summer, dropping close to 1000 cfs during the late summer during the driest years, as compared to the NAA, reflecting the lower spring target flows from Detroit as compared to the NAA. Detroit Reservoir fills higher in these years and would reach minimum conservation pool later in the year, following the rule curve. Real time water management of the reservoir would be capable of managing flows in the North Santiam River, as to result in only a minor adverse effect to users relative to the NAA. This effect would be local and occur only in the driest years.

## South Santiam

Operations affecting water supply in the South Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and a fall draw down operation for fish passage.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March to early-June in the driest years, but higher in the summer and fall in all years due to the fall drawdown operation at Green Peter Dam, as indicated in Appendix B, Figure B-165. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 2B would have a negligible effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are lower than the NAA from mid-March to mid-May in the driest years, but higher in the summer and fall in most years due to the fall drawdown operation at Green Peter Dam. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 2B would have a negligible effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the integrated temperature and habitat flow regime and drawing down the reservoir to the diversion tunnel in the spring and fall for fish passage.

The spring drawdown at Cougar affects the flow at Vida on the McKenzie River differently by season and by hydrologic conditions. Flows at Vida in the driest years are lower than the NAA from April through late summer. During wetter years, flows at Vida will be higher than the NAA until late May. As there would be no conservation storage to augment flows, summer flows would be lower than the NAA in the wettest years but nearly equal during most years. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 2B would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary.

Flows at Jasper on the Middle Fork Willamette River, downstream of Hills Creek, Lookout Point, and Fall Creek reservoirs, are lower than the NAA from April through mid-June in most years, but higher than the NAA in the driest years, and nearly equal most years, during the summer months. As the flows are only lower during a portion of the spring and only in drier years, Alternative 2B would have a negligible effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 2B would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the inactive and power pools, as necessary and available, fall drawdown at Green Peter for fish passage, and spring and fall drawdowns at Cougar for fish passage.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June during the driest years, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 5000 cfs, and only in the driest years, Alternative 2B would have a negligible effect on water supply in the Willamette River above Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher than in the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 4500 cfs, and only in the driest years, Alternative 2B would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 6000 cfs, and only in the driest years, Alternative 2B would have a **negligible** effect on water supply in the Willamette River near and downstream of Salem.

Overall, Alternative 2B would have a minor adverse effect on water supply in the North Santiam Basin and negligible effect on water supply on the rest of the tributaries and the mainstem Willamette River. This effect would be long term.

##### *3.13.3.4.1 Near-Term Operations Measure*

See Alternative 2A, Section 3.13.3.3.3, for description of effects due to the Near-Term Operations Measure. The effects of the near-term operations would be the same under this alternative as the near-term operations do not change between alternatives.

#### *3.13.3.4.2 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. As noted in Section 3.2.3.1.7, climate change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets, similar to the NAA. Decreased summer baseflows would result in adverse effects to water users as there may not be adequate water in the rivers to satisfy existing water rights.

### ***3.13.3.5 Alternative 3A – Operations-Focused Fish Passage Alternative***

Alternative 3A is an operational fish passage alternative, combining spring spill and drawdowns with fall drawdowns at 6 of the 11 storage projects. These combined operations significantly affect system-wide conservation storage, resulting in system-wide storage being only 44% of the refill volume in the NAA, or 590,000 acre-feet, as shown below in Figure 3.13-6. System-Wide Conservation Storage Non-Exceedances Under Alternative 3A.

Due to conditions applied to the reallocation of storage from joint-use to specific uses in the WBR BiOp, it is likely that the water that would be stored would be needed to support minimum flows for fish and wildlife, leaving very little available for M&I water supply or irrigation. Therefore, Alternative 3A would have a major adverse effect to the storage allocations and M&I water supply and irrigation users of conservation storage.

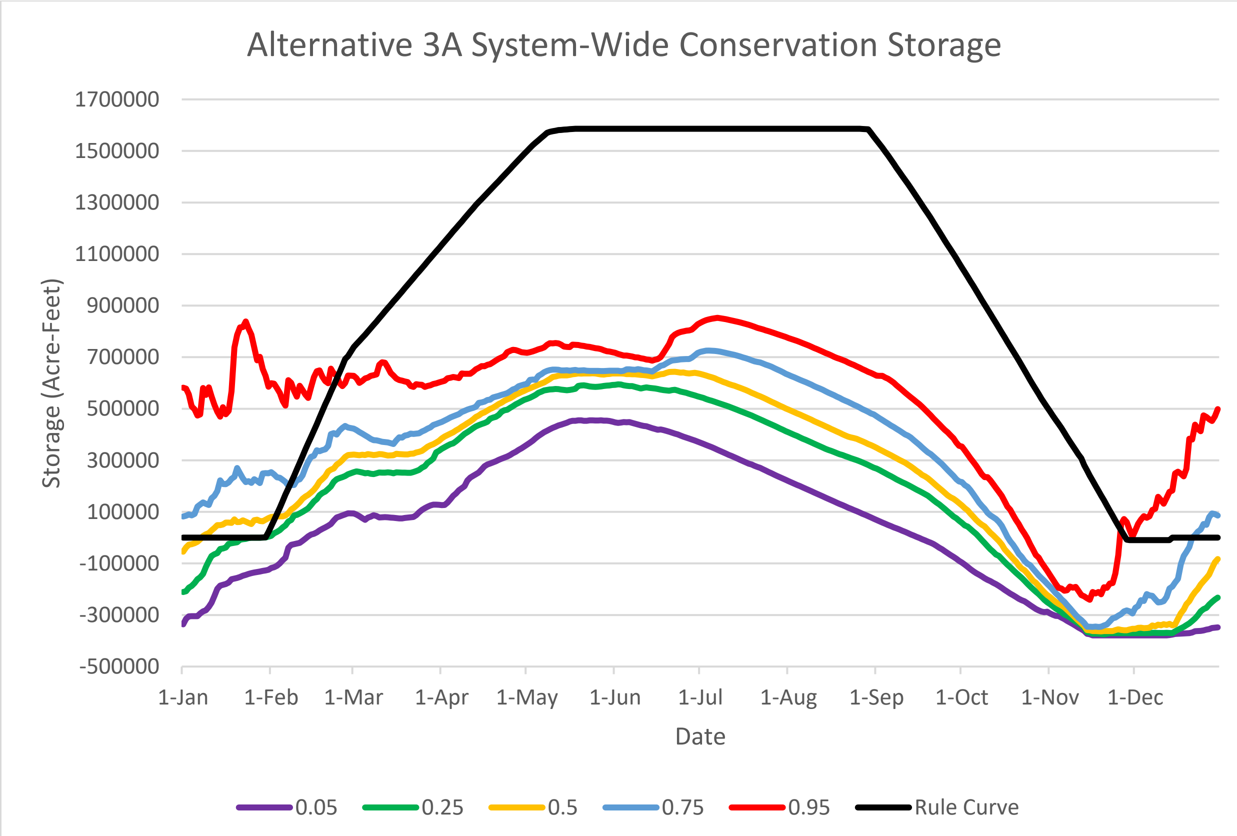

**Figure 3.13-6. System-Wide Conservation Storage Non-Exceedances Under Alternative 3A**

**North Santiam**

Operations affecting water supply in the North Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and drawing down the reservoir in the spring and fall for fish passage.

Under Alternative 3A, Detroit reservoir would be held below minimum conservation pool and as noted in Section 3.2.2.6.1, would very rarely fill into the conservation pool, nearly eliminating the ability to augment naturally low flows. Due to the spring drawdown and need to pass inflows instead of storing water, flows at Mehama in the spring, from March through early to late May, depending on the type of water year, are higher under Alternative 3A as compared to the NAA. Starting in June, flows drop lower than in the NAA as there is little to no water in the conservation pool to augment naturally low flows. Flows at Mehama could drop to less than 750 cfs for extended periods about 50% of the time. This could cause curtailment of water rights for M&I water supply and irrigation and would cause issues at the City of Salem's drinking water intake facility, which requires a minimum flow of 750 cfs for the intake structure to operate. Therefore, Alternative 3A would have a major adverse effect to M&I water supply and irrigation. This effect would be long term in that it would occur in most years and during the critically low flow season.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and a fall draw down operation for fish passage.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March to early-June in the driest years due to reduced flow targets, but higher in the summer and fall in all years due to the fall drawdown operation at Green Peter Dam. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 3A would have a negligible effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, in Alternative 3A are affected by the combination of a spring drawdown operation at Detroit and fall drawdown operations at both Detroit and Green Peter. Flows are slightly higher than the NAA from mid-March to mid-June except in the driest years. Flows in the summer are nearly equal to the NAA. Flows in the fall are lower than the NAA about half the time. As the flows are nearly equal during the critical low flow summer season, Alternative 3A would have a negligible effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and drawing down the reservoir to the regulating outlets in the spring and fall for fish passage.

Flows at Vida are higher in the spring than in the NAA for all but the driest years, as the reservoir needs to pass inflows to keep the pool drawn down for the fish passage operation in both the spring and fall. Flows in the summer are nearly equal to the NAA, but lower in the fall. This is due to not needing to empty the reservoir in preparation for the winter flood management season. As flows are nearly equal, especially for drier years, during the low flow season Alternative 3A would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary and available, and drawing down Lookout Point reservoir in the spring and fall and drawing down Hills Creek reservoir in the fall for fish passage.

Flows at Jasper are higher than in the NAA through mid-May for all years, and through mid-June for wetter years, due to the spring drawdown operation at Lookout Point which prevents storing of water into the conservation pool until mid-June. When the reservoir does start storing water, flows in the Middle Fork Willamette drop drastically most years, closer to what would be realized during dry years in both Alternative 3A and the NAA. Flows during the driest years are nearly equal to the NAA conditions during spring and most of summer, until September when there isn't water in the conservation pools to supplement naturally very low flows. As the flows are lower during the summer, approaching existing dry year conditions, Alternative 3A would have a moderate adverse effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the inactive pools at Dorena and Cottage Grove reservoirs, as necessary and available.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 3A would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the inactive and power pools, as necessary and available, drawing down Detroit, Cougar, and Lookout Point reservoirs in the spring and fall for fish passage, and drawing down Green Peter and Hills Creek reservoir in the fall for fish passage.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June during the driest years, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 5000 cfs, and only in the driest years, Alternative 3A would have a negligible effect on water supply in the Willamette River above Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June during the driest years and nearly equal to the NAA flows during the summer months. As the flows are only lower during a portion of the spring, staying above 3000 cfs, and only in the driest years, Alternative 3A would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June during the driest years and lower during the summer for most years. As the flows would still stay above 6000 cfs most of the time, Alternative 3A would have a negligible effect on water supply in the Willamette River near and downstream of Salem.

Alternative 3A would have a major adverse effect on storage allocations. Alternative 3A would have a major adverse effect on water supply in the North Santiam Basin, moderate adverse effect on the Middle Fork Willamette, and negligible effect on water supply on the rest of the tributaries and the mainstem Willamette River. This effect would be long term.

##### *3.13.3.5.1 Near-Term Operations Measure*

See Alternative 2A for description of effects due to the Near-Term Operations Measure. The effects of the near-term operations would be the same under this alternative as the near-term operations do not change between alternatives.

##### *3.13.3.5.2 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. Climate change would exacerbate the major adverse effects to storage realized due to fish passage operations. Natural river flow in the summer would likely decrease due to climate change and would also adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights.

#### ***3.13.3.6 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)***

Alternative 3B is also an operational fish passage alternative, combining spring spill and drawdowns with fall drawdowns at 6 of the 11 storage projects. These combined operations significantly affect system-wide conservation storage, resulting in system-wide storage being only 50% of the refill volume in the NAA, or 669,000 acre-feet, as indicated in Figure 3.13-7. System-Wide Conservation Storage Non-Exceedances Under Alternative 3B. Due to conditions applied to the reallocation of storage from joint-use to specific uses in the WBR BiOp, it is likely that the water that is stored would be needed to meet minimum flows for fish and wildlife, leaving very little available for water supply or irrigation. This would result in a major adverse effect to the storage allocations and users relying on the stored water for M&I water supply and irrigation.

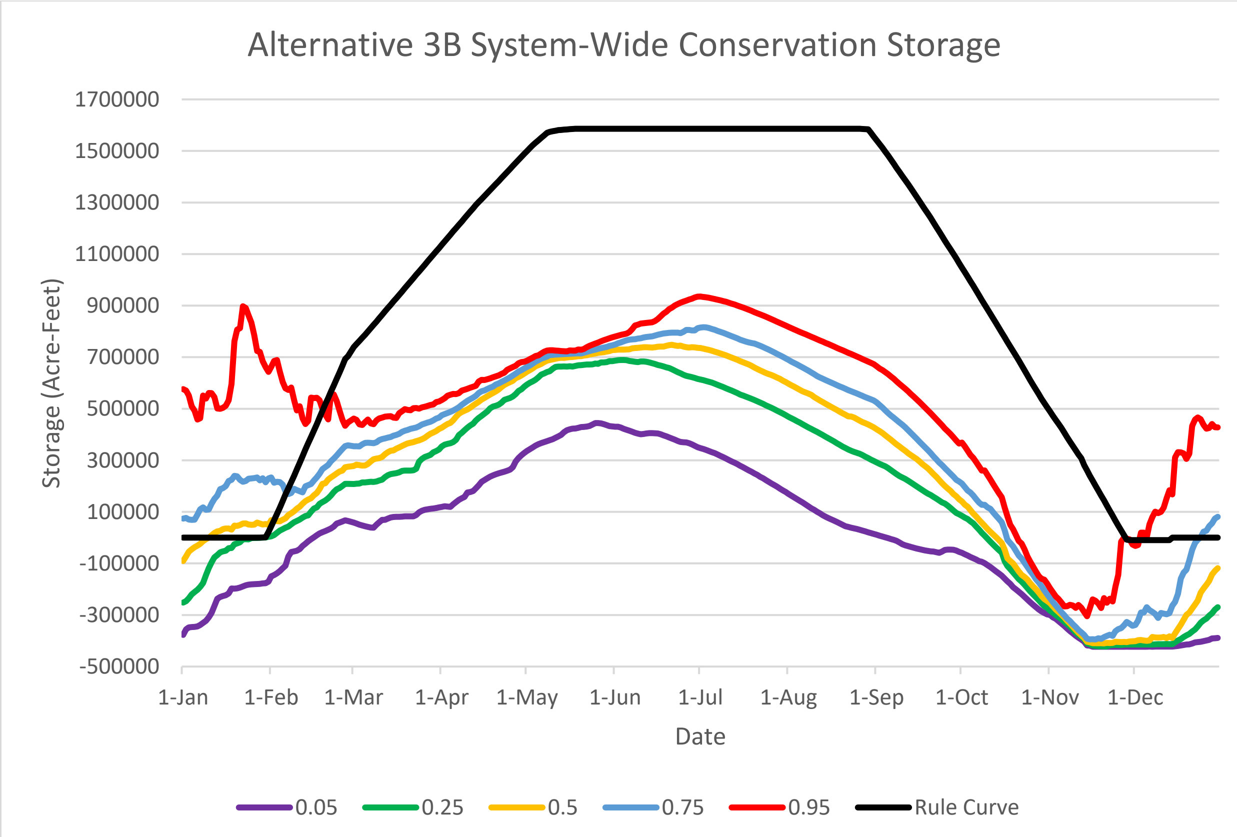

**Figure 3.13-7. System-Wide Conservation Storage Non-Exceedances Under Alternative 3B**

**North Santiam**

Operations affecting water supply in the North Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and drawing down the reservoir in the fall for fish passage.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is slightly lower in the spring and late summer, dropping close to 1000 cfs during the late summer during the driest years, as compared to the NAA, reflecting the lower spring target flows from Detroit as compared to the NAA. Flows in September would be higher in all but the driest years as the reservoir is drafted for the fall drawdown operation for fish passage. Real time water management of the reservoir would be capable of managing flows in the North Santiam River in the driest years to minimize adverse effects; therefore, Alternative 3B would only have a minor adverse effect to users relative to the NAA. This effect would be local and occur only in the driest years.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pool, as necessary, and drawing down the reservoir in the spring and fall for fish passage.

Under Alternative 3B, Green Peter reservoir would be held below minimum conservation pool, rarely filling into the conservation pool, nearly eliminating the ability to augment naturally low flows in the summer. Due to the spring drawdown and need to pass inflows instead of storing water, flows at Waterloo in the spring, from March through early to late May, depending on the type of water year, are higher under Alternative 3B as compared to the NAA. Starting in June (May for driest years), flows drop lower than in the NAA as there is little to no water in the conservation pool to augment naturally low flows. Flows at Waterloo could drop to near 100 cfs for extended periods about 25% of the time. This could cause curtailment of water rights. Therefore, Alternative 3B would have a major adverse effect to M&I water supply and irrigation on the South Santiam River. This effect would be long term in that it would occur in most years and during the critically low flow season.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, in Alternative 3B are affected by the combination of a spring drawdown operation at Green Peter and fall drawdown operations at both Detroit and Green Peter. Flows are very similar to those expected under Alternative 3A: slightly higher than the NAA from mid-March to mid-June except in the driest years when flows would be lower than the NAA starting in late April. Flows in the summer are nearly equal to the NAA. Flows in the fall are lower than the NAA about half the time. As the flows are slightly lower than during the critical low flow summer season, Alternative 3B would have a minor adverse effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the integrated temperature and habitat flow regime and drawing down the reservoir to the diversion tunnel in the spring and fall for fish passage.

Even though Alternative 3B has a more deeper spring drawdown operation at Cougar reservoir, flows at Vida are very similar to those expected to occur under Alternative 3A, i.e., higher in the spring than in the NAA for all but the driest years, as the reservoir needs to pass inflows to keep the pool drawn down for the fish passage operation in both the spring and fall. Flows in the summer are nearly equal to the NAA, but lower in the fall. This is due to not needing to empty the reservoir in preparation for the winter flood management season. As flows are nearly equal, especially for drier years, during the low flow season Alternative 3B would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary and available, and drawing down Lookout Point reservoir in fall and drawing down Hills Creek reservoir in the spring and fall for fish passage.

Flows at Jasper would be higher than in the NAA spring through fall in about 50% of years. For drier years, flows would be slightly less than the NAA April through mid-June, but then slightly higher until late August. During the driest years, flow would again be lower than then NAA, going down close to 1000 cfs at times. As the flows are lower during late summer and early fall, Alternative 3B would have a minor adverse effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the inactive pools at Dorena and Cottage Grove reservoirs, as necessary and available.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 3B would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the integrated temperature and habitat flow regime, augmenting these flows with water from the inactive and power pools at Lookout Point and Hills Creek, as necessary and available, drawing down Detroit and Lookout Point reservoirs in the fall for fish passage, and drawing down Green Peter, Cougar, and Hills Creek reservoirs in the spring and fall for fish passage.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June during the driest years, but higher or equal to the NAA during the summer months for all years. As flows are only lower during a portion of the spring, still staying above 5000 cfs during that time-period, and only in the driest years, Alternative 3B would have a negligible effect on water supply in the Willamette River above and immediately downstream of Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June during drier years. Flows in the summer would be equal to or higher than in the NAA during the summer months, with flows dipping below NAA levels sporadically in late September and early October. As the flows are only lower during a portion of the spring, staying above 6000 cfs during this period, and only in the driest years, Alternative 3B would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June and September during the driest years. As the flows would still stay above 6000 cfs most of the time, Alternative 3B would have a negligible effect on water supply in the Willamette River near and downstream of Salem.

Alternative 3b would have a major adverse effect on storage allocations. Alternative 3B would have a major adverse effect on water supply in the South Santiam Basin, minor adverse effect on the North Santiam, Santiam, and Middle Fork Willamette sub-basins, and negligible effect on water supply on McKenzie and Coast Fork Willamette and mainstem Willamette River. This effect would be long term.

##### *3.13.3.6.1 Near-Term Operations Measure*

See Alternative 2A, Section 3.13.3.3.3, for description of effects due to the Near-Term Operations Measure. The effects of the near-term operations would be the same under this alternative as the near-term operations do not change between alternatives.

##### *3.13.3.6.2 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. Climate change would exacerbate the major adverse effects to storage realized due to fish passage operations. Natural river flow in the summer would likely decrease due to climate change and would also adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights.

#### ***3.13.3.7 Alternative 4 – Structures-Based Fish Passage Alternative***

Alternative 4 is a structural fish passage alternative that includes an integrated habitat and temperature minimum flow regime. As the structures are designed to work with existing levels of reservoir fluctuations, the reservoirs are more likely to refill than they are in Alternative 2B, and especially Alternatives 3A and 3B, due to reservoir drawdowns in the spring for fish passage. As with the reduced minimum flows in Alternative 1, the integrated habitat and temperature flow regime with lower spring mainstem targets results in increased system-wide conservation storage. Figure 3.13-8. System-Wide Conservation Storage Non-Exceedances Under Alternative 4shows system-wide conservation storage would be 1,451,000 acre-feet, an increase of 122,000 acre-feet at the 75% exceedance level compared to the NAA, resulting in more reliable use of stored water, including for municipal and industrial water supply and irrigation than realized in the NAA. Stored water would still not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years, but to a lesser extent than in the NAA. The amount available would be determined on an annual basis based on realized storage volumes across the system. Alternative 4 would have a minor beneficial effect to system-wide storage allocations. This effect would be realized long term and basin-wide.

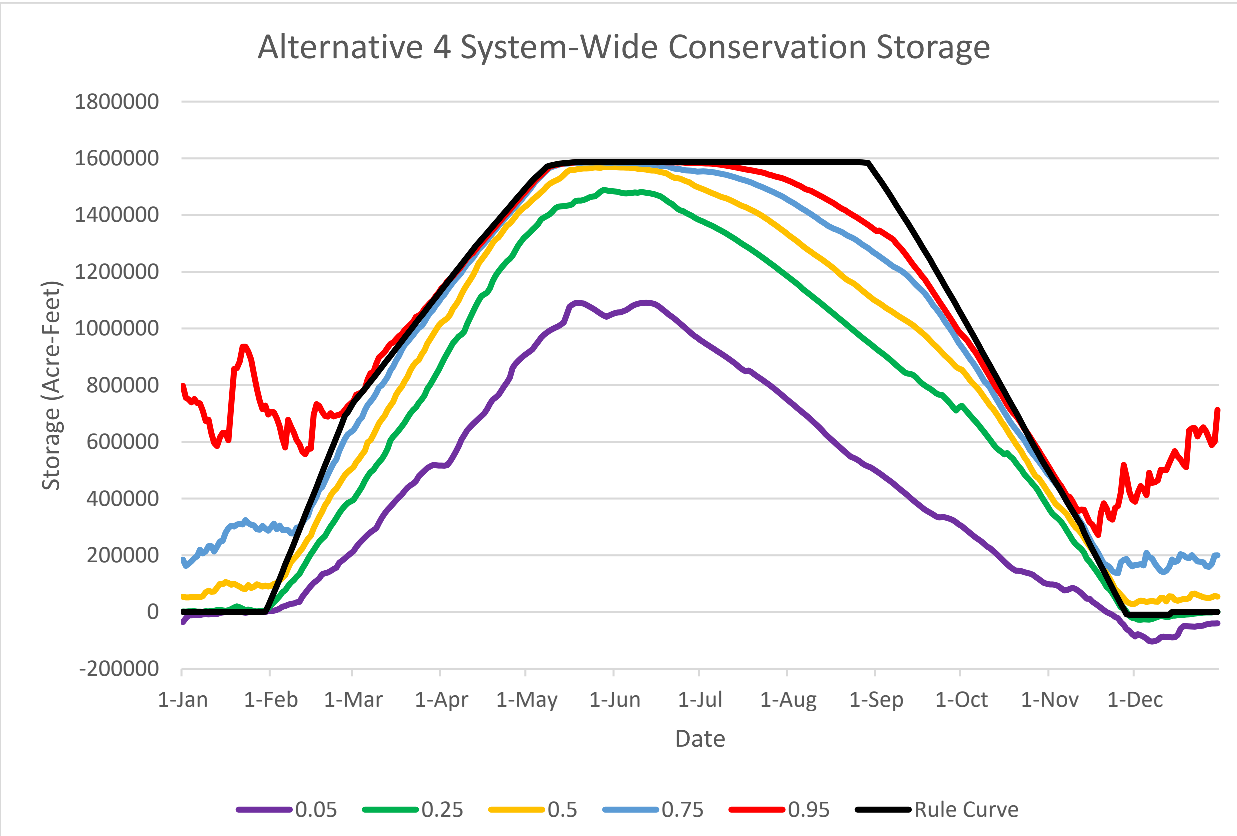

**Figure 3.13-8. System-Wide Conservation Storage Non-Exceedances Under Alternative 4**

**<u>North Santiam</u>**

Operations affecting water supply in the North Santiam Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is slightly lower in the spring and late summer, dropping close to 1000 cfs during the late summer during the driest years, as compared to the NAA, reflecting the lower, dry year target flows from Detroit as compared to the NAA. Detroit Reservoir fills higher in these years and would reach minimum conservation pool later in the year, following the rule curve. Real time water management of the reservoir would be capable of managing flows in the North Santiam River, as to result in only a minor adverse effect to users relative to the NAA. This effect would be local and occur only in the driest years.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March to early-June in the driest years, but higher through the summer during most years. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 4 would have a negligible effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are lower than the NAA from mid-March to mid-May in the driest years, but higher, or nearly equal, in the summer and fall in most years. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 4 would have a negligible effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flows at Vida on the McKenzie River are lower than the NAA from April through mid-June but slightly higher in August and September in the driest years. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 4 would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary.

Flows at Jasper on the Middle Fork Willamette River, downstream of Hills Creek, Lookout Point, and Fall Creek reservoirs, are lower than the NAA from April through mid-June in most years, but higher than the NAA during the summer months. As the flows are only lower during a portion of the spring and only in drier years, Alternative 4 would have a negligible effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the inactive pools at Dorena and Cottage Grove reservoirs, as necessary and available.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in drier years, Alternative 4 would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the integrated temperature and habitat flow regime and augmenting these flows with water from the inactive and power pools, as necessary and available.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 4000 cfs, and only in the driest years, Alternative 4 would have a negligible effect on water supply in the Willamette River above Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher than in the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 4500 cfs, and only in the driest years, Alternative 4 would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 6000 cfs, and only in the driest years, Alternative 4 would have a negligible effect on water supply in the Willamette River near and downstream of Salem.

Alternative 4 would have a moderate beneficial effect on storage allocations and minor adverse effect on water supply in the North Santiam Basin and negligible effect on water supply on the rest of the tributaries and the mainstem Willamette River. This effect would be long term.

##### *3.13.3.7.1 Near-Term Operations Measure*

See Alternative 2A for description of effects due to the Near-Term Operations Measure. The effects of the near-term operations would be the same under this alternative as the near-term operations do not change between alternatives.

##### *3.13.3.7.2 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. Change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets, similar to Alternative 1. Natural river flow in the summer would likely decrease due to climate change and would also adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights.

#### *3.13.3.8 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 has the same measures as Alternative 2B but uses the Revised Integrated Habitat and Temperature Flow Regime (M30b) that includes higher mainstem flow targets than M30. The combination of actions in Alternative 5 would result in a decrease of 98,536 acre-feet of stored water compared to the NAA. Stored water would not be available to meet all M&I storage agreements and irrigation water service contracts in the driest years. The amount available would be determined on an annual basis based on realized storage volumes across the system. The small decrease in system-wide conservation storage would have a minor adverse effect to municipal and industrial water supply and irrigation users of the conservation storage. Due to the expected limited level of demand for stored water on the McKenzie River, Alternative 5 would be expected to have only a minor adverse effect to system-wide storage allocations.

**North Santiam**

Operations affecting water supply in the North Santiam Basin include releasing water for the modified integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flow at Mehama, a key indicator for water supply users on the North Santiam, is slightly lower in the spring and late summer, dropping close to 1000 cfs during the late summer during the drier years, as compared to the NAA, reflecting the lower spring target flows from Detroit as compared to the NAA for dry years. Detroit Reservoir fills higher in these years and would reach minimum conservation pool later in the year, following the rule curve. Real time water management of the reservoir would be capable of managing flows in the North Santiam River, as to result in only a minor adverse effect to users relative to the NAA. This effect would be local and occur only in the driest years.

**South Santiam**

Operations affecting water supply in the South Santiam Basin include releasing water for the modified integrated temperature and habitat flow regime and augmenting these flows with water from the power pool, as necessary.

Flows at Waterloo on the South Santiam are lower than the NAA from mid-March to early-June in the driest years due to reduced tributary flow target, higher in the summer most years due to a higher flow target than in the NAA, and much higher in September and the first half of October in all years due to the fall drawdown operation at Green Peter Dam. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 5 would have a negligible effect on water supply in the South Santiam River.

**Santiam**

Flows at Jefferson on the Santiam, downstream of the confluence of the North and South Santiam Rivers, are lower than the NAA from mid-March to mid-May in the driest years, but higher in the summer due to higher summer flow targets, and higher in fall in most years due to the fall drawdown operation at Green Peter Dam. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 5 would have a negligible effect on water supply in the Santiam River.

**Long Tom River**

There would be no effect to M&I water supply or irrigation from the alternative, as there are no operational changes proposed at Fern Ridge Dam and the reservoir is not used to support mainstem flow targets.

**McKenzie River**

Operations affecting water supply in the McKenzie Basin include releasing water for the modified integrated temperature and habitat flow regime and drawing down the reservoir to the diversion tunnel in the spring and fall for fish passage.

The spring drawdown at Cougar affects the flow at Vida on the McKenzie River differently by season and by hydrologic conditions. Flows at Vida in the driest years are lower than the NAA from April all year except for about the first two weeks of March when the Cougar reservoir is drafted for the spring drawdown operation for fish passage. During wetter years, flows at Vida will be higher than the NAA until early June when Cougar reservoir is nearly empty and there is not stored water available to augment streamflow on the McKenzie nor in the mainstem Willamette River. As there would be no conservation storage to augment flows, summer flows would be lower than the NAA in the wettest years but same as the NAA during most years. As the flows are only lower during a portion of the spring and only in the driest years, Alternative 5 would have a negligible effect on water supply in the McKenzie River.

**Middle Fork of the Willamette River**

Operations affecting water supply in the Middle Fork Willamette sub-basin include releasing water for the modified integrated temperature and habitat flow regime and augmenting these flows with water from the power pools at Lookout Point and Hills Creek, as necessary.

Flows at Jasper on the Middle Fork Willamette River, downstream of Hills Creek, Lookout Point, and Fall Creek reservoirs, are lower than the NAA from April through mid-June in most years, but higher than the NAA in the driest years, and nearly equal most years, during the summer months. As the flows are only lower during a portion of the spring and only in drier years and higher in the summer, Alternative 5 would have a negligible effect on water supply in the Middle Fork Willamette River.

**Coast Fork of the Willamette River and Row River**

Operations affecting water supply in the Coast Fork Willamette sub-basin include releasing water for the modified integrated temperature and habitat flow regime.

Flows at Goshen on the Coast Fork Willamette River, downstream of Dorena and Cottage Grove reservoirs, are only lower than the NAA from April through May in the driest years. As the flows are only lower during a portion of the spring and only in driest years, Alternative 5 would have a negligible effect on water supply in the Coast Fork Willamette River.

**Mainstem Willamette River**

Operations affecting water supply on the mainstem Willamette River include releasing water for the modified integrated temperature and habitat flow regime and augmenting these flows with water from the inactive and power pools, as necessary and available.

Flows at Harrisburg on the Willamette River, downstream of the McKenzie River confluence, are lower than the NAA from April through mid-June during drier years, but higher or equal to the NAA during the summer months, except for the wettest years when the flows in the late summer are slightly less than in the NAA. As the low flows are only lower during a portion of the spring, still staying above 5000 cfs, and only in the driest years, Alternative 5 would have a negligible effect on water supply in the Willamette River above and around Harrisburg.

Flows at Albany on the Willamette River, upstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher than in the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 5000 cfs, and only in the driest years, Alternative 5 would have a negligible effect on water supply in the Willamette River above and immediately downstream of Albany.

Flows at Salem on the Willamette River, downstream of the Santiam River confluence, are lower than the NAA from April through mid-June about 25% of the time, but higher or equal to the NAA during the summer months. As the flows are only lower during a portion of the spring, still staying above 6000 cfs, and only in the driest years, Alternative 5 would have a negligible effect on water supply in the Willamette River near and downstream of Salem.

Alternative 5 would have a moderate beneficial effect on storage allocations and minor adverse effect on water supply in the North Santiam Basin and negligible effect on water supply on the rest of the tributaries and the mainstem Willamette River. This effect would be long term.

###### *3.13.3.8.1 Near-Term Operations Measure*

See Alternative 2A for description of effects due to the Near-Term Operations Measure. The effects of the near-term operations would be the same under this alternative as the near-term operations do not change between alternatives.

###### *3.13.3.8.2 Climate Change*

Water supply, both from water stored in Corps' reservoirs and from natural river flow, may be adversely affected in the future under a climate change induced hydrology. Climate change may result in less reliable refill of the reservoirs and drafting earlier to minimum conservation elevations to support downstream minimum flow targets, similar to Alternative 2B. Natural river flow in the summer would likely decrease due to climate change and would also adversely affect water users as there may not be adequate water in the rivers to satisfy existing water rights.

## 3.14 RECREATION

The analysis of recreational resources identifies recreational facilities, visitation trends, revenue, and the overall recreational experience that may be affected by the Proposed Action and alternatives. The analysis considers how the Proposed Action might affect the recreational resources and its recreational value to individuals and communities within the Willamette River Basin (WRB). Potential impacts would be felt most by residents, communities, and businesses near each of the USACE projects. However, recreationists, businesses, and recreational outfitters throughout the WRB would also be impacted by the proposed alternatives, and therefore, the boundary of the WRB is defined as the area of analysis. This includes the 13 Oregon counties that intersect or lie within the boundary: Benton, Clackamas, Columbia, Douglas, Klamath, Lane, Linn, Marion, Multnomah, Polk, Tillamook, Washington, and Yamhill counties.

Some information in this section (such as the descriptions of state park amenities) comes from the Oregon Parks and Recreation Department’s 2019-2023 Statewide Comprehensive Outdoor Recreation Plan (SCORP). The Oregon SCORP identifies state-wide trends in recreational needs and participation. In addition to information provided by the SCORP and Lake Level Reports, the amenities and activities available at recreation sites managed by Lane County, Linn County, the U.S. Forest Service (USFS), Oregon Parks and Recreation Department (OPRD), Oregon Department of Fish and Wildlife (ODFW), Bureau of Land Management (BLM), and private entities are sourced from the best available online resources maintained by the managing agency. Information on fishing at each of the reservoirs is based on ODFW’s Recreation Report for the “Willamette Zone” (i.e., WRB).

USACE publishes *Value to the Nation Fast Facts Reports* that provide a “Lake Level Report” for each of the reservoirs and include statistics such as type of recreational facilities available and visitation and economic effects of the available activities. However, at some reservoirs, there are non-USACE facilities that have their own associated visitation and economic data (primarily campgrounds) which are not captured in the *Value to the Nation Fast Facts Reports*. As such, USACE used GIS analysis and local, county, and state data to capture visitation and economic effects at these non-USACE campgrounds. The methodology is described in more detail in Section 1.1 of Appendix K - Recreation Technical Report.

### 3.14.1 Willamette Valley System

Within the Willamette Valley System (WVS), USACE cooperates with the USFS, OPRD, ODFW, BLM, Lane and Linn County parks, and private organizations to build and manage more than 50 recreation sites around USACE reservoirs. Recreation is a congressionally authorized project purpose at all of USACE WVS reservoirs. The conservation pool is largely used to fulfill the USACE recreation mission as a number of the reservoirs are heavily used for recreational purposes during the conservation season, which in the WVS is from March to October. Visitation slowly increases from April to May followed by peak visitation between Memorial Day and Labor Day and then a decline after September. The three most important reservoirs for recreational us are Detroit, Fern Ridge, and Foster; these three reservoirs are last to be drained to meet summer instream flow objectives (USACE 2019a).

Recreation within the vicinity of each USACE reservoir is both water- and land-based. Water-based recreation includes activities that are dependent on access to a body of water such as fishing, boating, or swimming and to facilities such as boat ramps, marinas, and docks. In 2017, 40 percent of Oregon's population participated in recreation around lakes, reservoirs, and rivers (OPRD 2019). Land-based recreation includes camping, hiking, or wildlife viewing and relies on access to facilities such as campgrounds, trails, and picnic areas. There were approximately 2,882,010 total annual visitors to USACE reservoirs in the WVS during 2021, resulting in a total annual recreation value of 21,689,601. The following sections describe the estimated total annual visitors and recreational value of each of the USACE reservoirs in the WVS[47]. See Appendix K – Recreation Technical Report for more information.

The area of analysis overlaps with the Willamette National Forest (WNF), Umpqua National Forest, and Mt. Hood National Forest; however, none of the USACE reservoirs are located within the Umpqua National Forest or Mt. Hood National Forest. The recreation sites that are located within the WNF are operated by USFS. The WNF spans 110 miles along the western slopes of the Cascade Mountain Range and offers visitors views of high mountains, narrow canyons, cascading streams, and wooded slopes (USFS 2021). All or portions of Detroit, Big Cliff, Cougar, Blue River, Lookout Point, and Hills Creek reservoirs are located within the WNF. During the 2020 wildfire season, three wildfires (Beachie Creek, Lionshead and Holiday Farm) damaged many recreation sites, forest structures, and road corridors in parts of the WNF (USFS 2020). As of August 2021, USFS is tracking the extent of the Middle Fork Complex Wildfire near Fall Creek and Hills Creek reservoirs as well as the Bruler Fire approximately 8 miles south of Detroit Reservoir (USFS 2021). Closures of any recreation sites due to fires are noted throughout the section.

#### *3.14.1.1 Detroit*

Detroit Dam and Reservoir is located in the rugged mountain forests below Mt. Jefferson at river mile 49 on the North Santiam River, about 45 miles southeast of Salem, Oregon. River miles refer to the distance along a river upstream from the mouth of the river (i.e., where the river empties into another body of water). Recreation sites around Detroit Reservoir are accessible via North Santiam Highway (Oregon Route 22) and local roads. Detroit Reservoir is a popular recreation area for water-based recreation including fishing, boating, water skiing, and swimming and land-based recreation including camping and picnicking. The availability of boating and other water-based recreation is seasonally limited by the planned lower reservoir levels between fall and spring. The reservoir is a designated stop along the Mt. Jefferson Loop of the Oregon Cascades Birding Trail, a self-guided auto tour of nearly 200 prime birding destinations in the Oregon Cascades. The Oregon Cascades Birding Trail is divided into five major loops that run down both sides of the Cascade Mountains covering over 1,000 miles of

[47] Big Cliff Reservoir does not have designated recreational areas with amenities or the associated tracking of recreational value. See Section 3.14.1.2 for more information.

roadways with opportunities to see over 300 species of birds. The Mt. Jefferson Loop is known for its variety in habitat, ranging from dry sagebrush and juniper flats to dense forests and mountain streams. Detroit Reservoir is known for spotting western and horned grebes, common loons, hooded and common mergansers, and gulls with opportunities to see bald eagles and osprey in the spring and summer (The Oregon Birding Trails Working Group No Date). The Detroit Reservoir area provides habitat for songbirds in its hardwood stands and osprey use lakeshore snags and trees as roosts (places to rest or sleep) and nesting sites (USACE 2020e; USACE No Date-e). Visitors to the reservoir can fish for trout and kokanee using shore, motorized boat, float tube, fly, spin, and bait fishing methods. The reservoir is typically stocked with one-pound hatchery trout. Harvesting Chinook in the reservoir is prohibited and any Chinook accidentally caught must be released unharmed (USFS 2021; ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-1. The recreation sites are shown below in Figure 3.14-1. Recreation sites operated by USFS include Upper Arm Day Use, Detroit Flats Day Use, Santiam Flats Campground, Hoover Campground, Piety Island Campground, Cove Creek Campground, and Southshore Campground. The Upper Arm Day Use Area is located in a quiet cove of the Breitenbush Arm of the Detroit Reservoir where visitors can fish along the shoreline trails or from the wooden fishing pier. The Upper Arm Day Use Area is closed for the 2021 season for reconstruction after damage from the Beachie Creek and Lionshead Fire. The Detroit Flats Day Use Area offers picnicking, kayaking, swimming, boating, and water skiing. The Santiam Flats Campground, located at the confluence of the North Santiam River along the shore of the reservoir, consists of 32 campsites with fishing, boating, and hiking at nearby trails. Hoover Campground is located at an elevation of 1,600 feet on the shore of the reservoir. The campground includes an interpretive trail and has campfire rings, picnic tables, and more. Piety Island Campground has boat-in access from the northeast side of the island and sites are available on a walk-in basis. The campground is closed for the 2021 season as a result of damage from the Beachie Creek Fire. Cove Creek Campground, the largest USFS campground on Detroit Reservoir, consists of 63 camp sites. Southshore Campground is located on the south shore, further away from the busier portions of the reservoir, and offers 25 campsites (USFS 2021).

Mongold Day Use and Detroit Lake State Park are operated by OPRD. Mongold Day Use is located along the forested shores of the reservoir and offers year-round boating access, including a paved boat ramp, swim area with a grassy beach, picnic area, and over 80 parking spots. Detroit Lake State Park offers 300 camping sites, some of which are full-hookup sites (sewer, electricity, and water). The state park also has parking, picnic tables, fire rings, showers, and swimming areas (OPRD 2020). Two privately owned marinas, Detroit Lake Marina and Kane's Marina, are located on the reservoir near the town of Detroit. The Detroit Lake Marina includes a food and supply store and rentable boats, canoes, kayaks, and jet skis as well as a food vender, shower, parking, gas dock, and guest tie up dock (Detroit Lake Marina 2021). Kane's Marina is equipped with boat moorage and rentals, an RV park and day use area, fishing licenses and supplies, and a rustic tavern (Kane's Marina No Date).

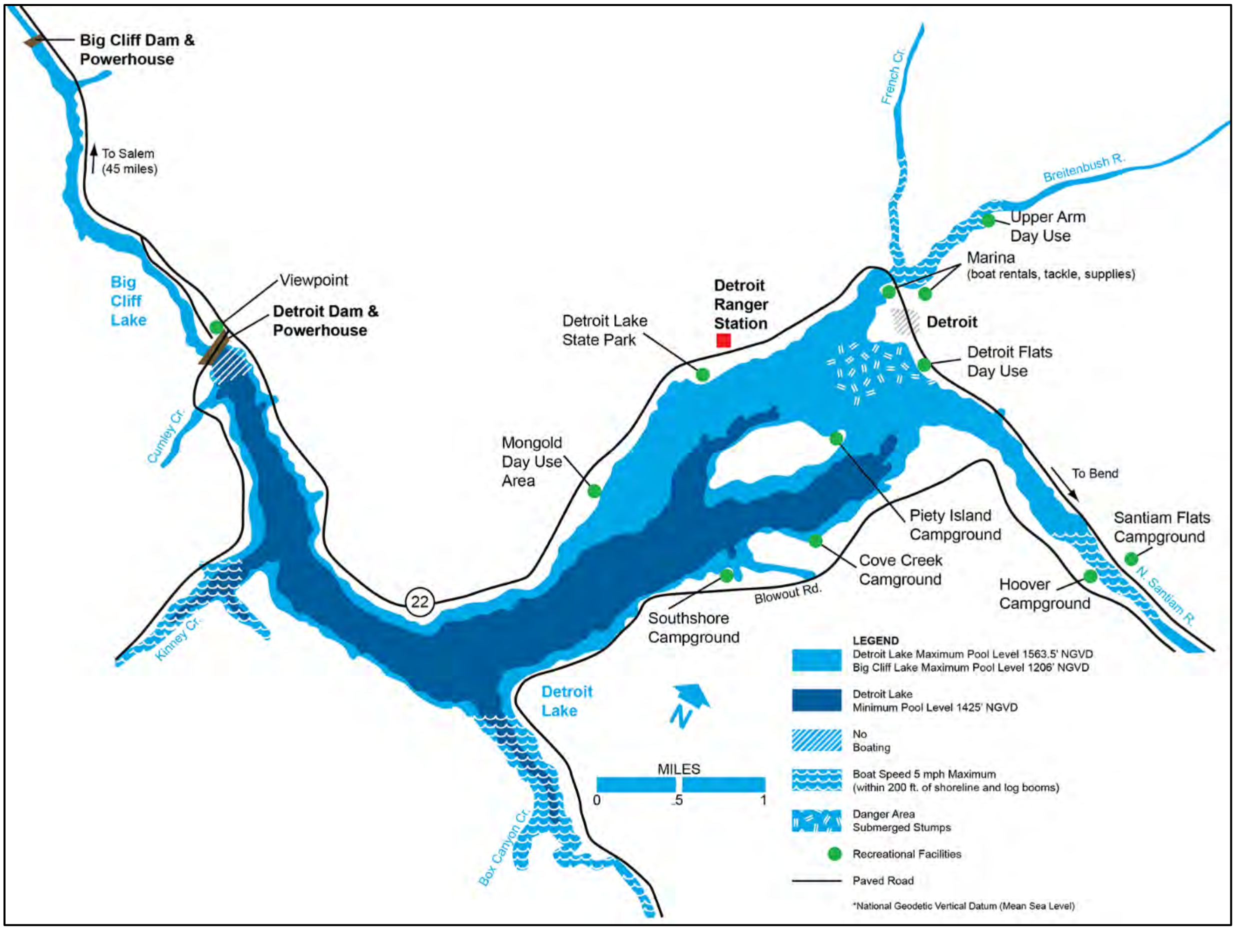

**Figure 3.14-1. Map of Recreation Sites at Detroit and Big Cliff**

Source: USACE No Date-e

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-1.

**Table 3.14-1. Recreation Areas, Activities, and Amenities at Detroit Dam and Reservoir**

| Recreation Area | Managing Agency | Open | Day-Use | Restrooms | Playground | Hiking Trail | Drinking Water | Swimming Area | Camping/Camp Sites | RV Camp/Utilities | Reservable Sites | Fees | Boat Launch | Showers | Marina/Boat Moorage | Dump Station |

OPRD = Oregon Parks and Recreation Department; USFS = U.S. Forest Service

Source: USACE 2020e; USACE 2019h; Kane's Marina No Date; Detroit Lake Marina 2021

USACE collects and manages data on annual visitation to each of its projects through the Natural Resources Management Assessment, Operations and Maintenance Business Information Link (OMBIL), Visitation Estimation & Reporting System (VERS), and National Recreation Reservation System (NRRS). A summary of this data is provided for each reservoir in a Value to the Nation Fast Facts report. The data on the number of visits is collected over the Fiscal Year (FY) which begins July 1 and ends June 30. A "visit" is defined as the entry of one person onto a USACE site to engage in one or more recreational activities regardless of the length of stay.

In 2021, visitors to Detroit Reservoir participated most in camping, sightseeing, and angling. Visitation for specific recreation activities in visits (person-days/nights) to Detroit Reservoir is summarized below in Table 3.14-2. All estimated visits in Section 3.14.1 are provided in the units of person-days/nights, which is calculated by dividing the number of annual visitors by the number of days in the recreation season (124 days from May 15 to September 15).

**Table 3.14-2. Visits to Detroit Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 17,524 |
| Campers[2] | 44,961 |
| Swimmers | 15,707 |
| Water Skiers[3] | 15,442 |
| Boaters[3] | 14,533 |
| Sightseers | 40,243 |
| Anglers | 23,649 |
| Hunters | 5,776 |
| Total | 177,836 |

Source: USACE 2016h; USCB 2016; USCB 2021

[1] Estimated adjusted visits are indexed from 2016 to 2021 using data from U.S. Census Bureau 1-Year American Community Survey County level data.

[2] Number of campers are estimated for 2021 using GIS tools and data as well as local, county, and state data as described in Section 1.1 of Technical Appendix K -Recreation.

[3] Number of boaters are estimated for 2021 using regression analysis as described in Section 1.1 of Technical Appendix K -Recreation.

* Note that numbers may not add up exactly due to rounding.

USACE also estimates the recreational value of each USACE project (see Appendix K – Recreation Technical Report). At Detroit Reservoir in 2021, 177,836 annual visits resulted in approximately $1,149,965 of recreational value as shown in below in Table 3.14-3.

**Table 3.14-3. Recreational Value of Detroit Reservoir, FY 2021**

| Description | U.S. Dollars |
|---|---|
| Total Annual Recreational Value | $1,149,965 |

#### *3.14.1.2 Big Cliff (Reregulating)*

Big Cliff Dam and Reservoir is located at river mile 58.1 on the North Santiam River, three miles downstream of Detroit Dam, and is accessible from North Santiam Highway (Oregon Route 22). Since the dam is used to regulate power-generating water releases from Detroit Dam, the water level of Big Cliff Reservoir fluctuates as much as 24 feet daily. Like the Detroit Dam, Big Cliff Dam is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding

Trail where visitors can see osprey and neotropical migrant songbirds. The boat ramp at Big Cliff Reservoir is permanently closed to vehicle traffic; however, non-motorized boats (i.e., kayaks) are still allowed to launch (USACE No Date-a). Due to its proximity to Detroit Reservoir and the smaller size of Big Cliff Reservoir, recreation at Big Cliff is closely connected to Detroit Reservoir as shown in Figure 3.14-1. As such, Big Cliff Reservoir does not have designated recreational areas with amenities or the associated estimated recreational value.

#### *3.14.1.3 Foster*

Foster Dam is located at river mile 38.5 on the South Santiam River, at the confluence of the South Santiam and Middle Santiam rivers. Recreation sites around Foster Reservoir are accessible via Foster Dam Road off of Santiam Highway (U.S. Highway 20) and other local roads. The 1,800-acre Foster Reservoir area provides habitat for species including the northern spotted owl, steelhead and cutthroat trout, Chinook salmon, the western pond turtle, and several amphibians (USACE No Date-j). Foster Reservoir is typically stocked with trout; however, visitors to the reservoir can also catch smallmouth bass, yellow perch, catfish, bluegill, and crappie (ODFW 2021b)

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-4. The recreation sites are shown below in Figure 3.14-2. USACE operates one day-use park, Andrew S. Wiley Park, which has picnic tables, barbecue grills, and a paved boat ramp with access to the South Santiam River below the dam. Linn County Parks operates several day-use sites, boat ramps, and campgrounds (USACE No Date-j). Lewis Creek Park is an approximately 40-acre day-use area with boarding floats, moorage, picnic areas, and a roped-off swim beach. As of spring 2021, Linn County is conducting public outreach for developing a master plan to upgrade the park and its amenities in response to visitor needs. Shea Point is a viewpoint with a day-use area and access to nearby hiking trails. Calkins Ramp has a two-lane boat ramp and parking for 39 trucks and trailers and 10 additional vehicles. Gedney Creek Ramp has 55 boat parking spaces. Edgewater County Park and Marina has 49 full hookup RV campsites with WiFi connections; 40 boat slips on the reservoir; and boating, fishing and other water-based recreation. Sunnyside Park is a 98-acre campground with picnicking, volleyball, and water-based recreation like water skiing, fishing, and jet skiing. Other amenities include RV hookups, group camping, moorage, group shelters, showers, and a boat ramp, dog park, dump station, and playground. As of spring 2021, Linn County is conducting public outreach for developing a master plan to upgrade the park and its amenities in response to visitor needs (Linn County Parks & Recreation No Date).

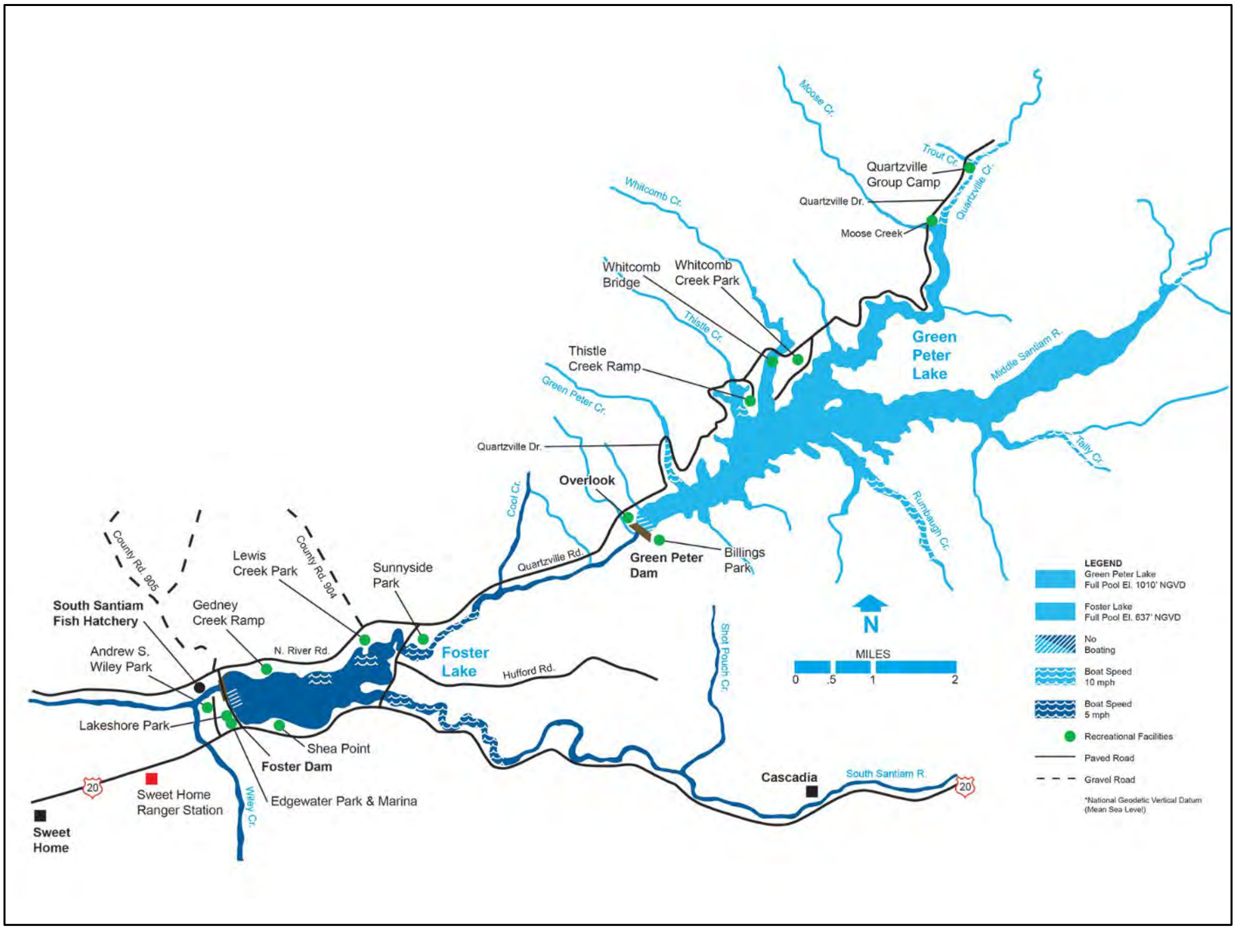

**Figure 3.14-2. Map of Recreation Sites at Foster and Green Peter**

Source: USACE No Date-j

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-4.

**Table-3.14-4. Recreation Areas, Activities, and Amenities at Foster Dam and Reservoir**

In 2021, Foster Reservoir was the second most visited reservoir out of the 13 USACE reservoirs. Visitors to Foster Reservoir participated most in sightseeing, boating, and angling. Visitation for specific recreation activities at Foster Reservoir is summarized below in Table 3.14-5.

**Table 3.14-5. Visits to Foster Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 52,502 |
| Campers | 10,706 |
| Swimmers | 35,886 |
| Water Skiers | 29,397 |
| Boaters | 92,280 |
| Sightseers | 190,554 |
| Anglers | 67,095 |

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Hunters | 0 |
| Total | 478,419 |

Source: USACE 2016m

#### *3.14.1.4 Green Peter*

Green Peter Dam and Reservoir is located at river mile 5.5 on the Middle Santiam River, 7 miles upstream of Foster Dam. Recreation sites around Green Peter Reservoir are accessible via Quartzville Drive off of Santiam Highway (U.S. Highway 20) and other local roads. Along with Foster Reservoir, Green Peter Reservoir is a popular recreation destination for fishing, boating, water skiing, swimming, and picnicking. Similar to the other dams and reservoirs, visitors can see osprey nests along the shorelines of the reservoir. USACE works with the ODFW to support resident game and nongame fisheries within the waters of the Middle Santiam River Basin (USACE 2020f; USACE No Date-k). The Green Peter Reservoir is stocked annually with 20,000 hatchery trout and was stocked with an additional 6,250 trout in July of 2021. Anglers at the reservoir can catch up to 25 kokanee per day, unlimited smallmouth bass, and up to five trout per day (ODFW 2021b). See the Fish, Aquatic Invertebrates, and Habitat Section for more information on how fisheries at Green Peter Reservoir are maintained.

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-7. The recreation sites are shown above in Figure 3.14-2. USACE operates two recreation areas at Green Peter: the Dam Overlook and Billings Park. The Dam Overlook is a day-use area located on the southwest corner of the reservoir, on the northwest side of the dam. Billings Park is a simple day-use area located across the dam from the overlook.

Linn County Parks operates several boat ramps, campgrounds, and day-use areas at Green Peter (USACE No Date-k). Thistle Creek Park is a 9.2-acre boat ramp area located on the north shore of the reservoir. The elevations of the upper and lower ramp are 980 feet and 919 feet, respectively. When the water level drops below an elevation of 982-983 feet, boaters are only able to launch from the lower ramp which is accessible all year. Whitcomb Creek Park consists of 328 acres of forest along the reservoir. Visitors to the park and campground enjoy mountain views, bird-watching, sailing, fishing, hiking, camping, and water skiing. Quartzville Group Camp can accommodate up to 50 people with tents and RVs Linn County Parks & Recreation No Date).

**Table 3.14-7. Recreation Areas, Activities, and Amenities at Green Peter Dam and Reservoir**

| Recreation Area | Managing Agency | Open | Day-Use | Restrooms | Playground | Hiking Trail | Drinking Water | Swimming Area | Camping/Camp Sites | RV Camp/Utilities | Reservable Sites | Fees | Boat Launch | Showers | Marina/Boat Moorage | Dump Station |

#### *3.14.1.5 Cougar*

Cougar Dam and Reservoir is located at river mile 4.4 of the South Fork McKenzie River, about 42 miles east of Eugene. Recreation sites around Cougar Reservoir are accessible via Aufderheide Drive, accessible off of McKenzie Highway (Oregon Route 126) as well as other local roads. The 5,000-acre area provides recreation opportunities for camping, boating, swimming, fishing, and water skiing. All recreation facilities at the reservoir are within the WNF and are managed by USFS. The reservoir is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail where visitors can spot American peregrine falcons around the cliffs above the reservoir (USACE No Date-d). There is a large nesting colony of Cliff Swallows southwest of the dam where visitors can also see Violet-green and Northern Rough-winged Swallows. Visitors may also see Rock Wren, Canyon Wren, Bald Eagle, Belted Kingfisher, and waterfowl such as Bufflehead, goldeneyes, and Common and Hooded Mergansers in the fall (The Oregon Birding Trails Working Group No Date).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-10. The recreation sites are shown below in Figure 3.14-3. All of the recreation sites at Cougar are managed by the USFS. The shaded picnic sites at Echo Park overlook the reservoir. Visitors can hike along the adjacent east fork trail from the lower trailhead. The Slide Creek Campground on the east side of the reservoir near the Slide Creek Day Use Area offers access to fishing, boating, swimming, and water skiing. The 13 campsites at Sunnyside Campground are located amongst a large grove of conifers and have easy access to the nearby creek, river, and lake. French Pete Campground has hiking trails nearby. Delta Campground is a 38-site campground known for its access to rafting and fishing on the McKenzie River. The campground is near nature trails and Terwilliger Hot Springs. As of August 2021, the Delta Campground is closed due to the Holiday Farm Fire wildfire. Cougar Crossing is located on the southern shore of the reservoir and includes a day-use area with camping and a boat launch (USFS 2021).

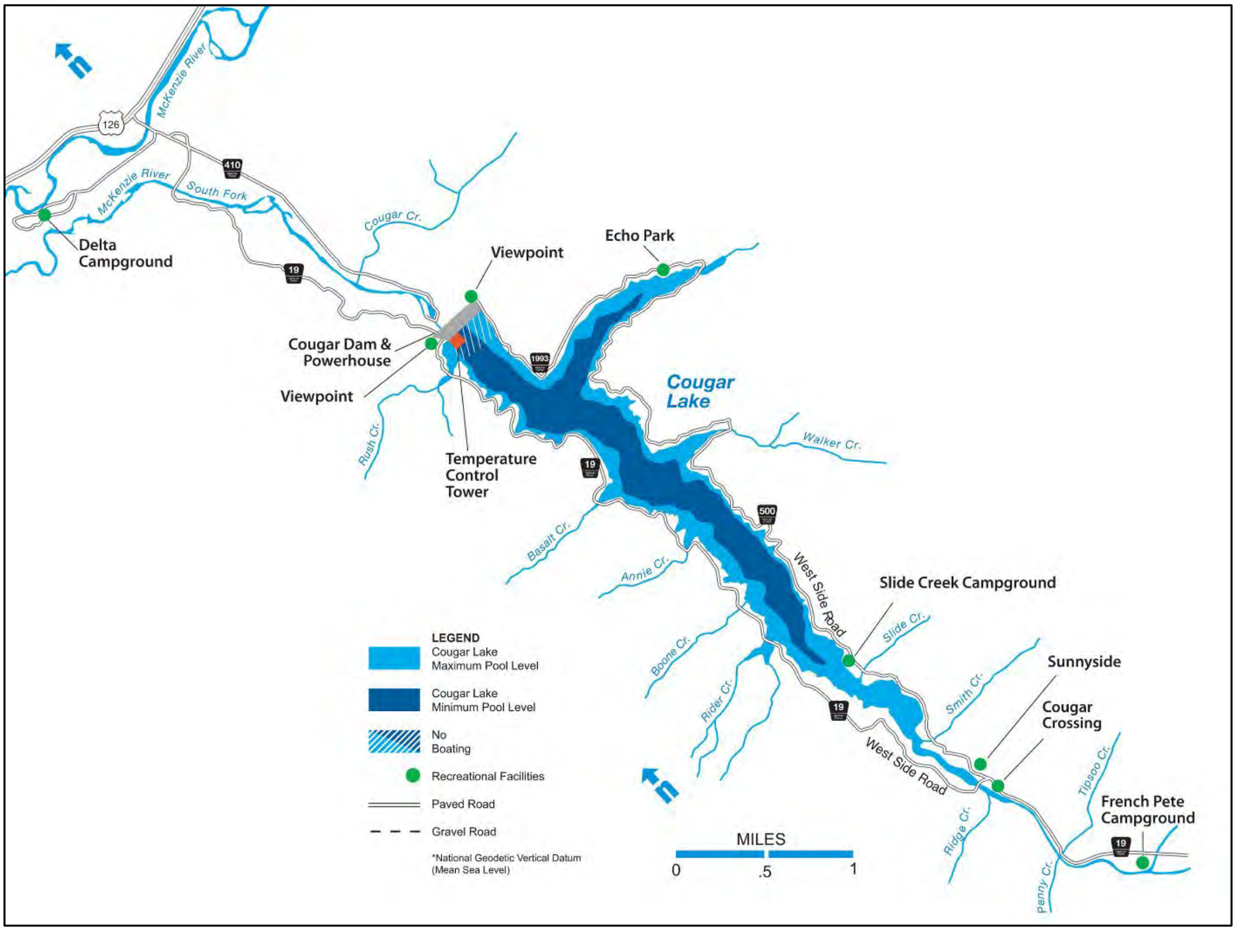

**Figure 3.14-3. Map of Recreation Sites at Cougar**

Source: USACE No Date-d

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-10.

**Table 3.14-10. Recreation Areas, Activities, and Amenities at Cougar Dam and Reservoir**

### *3.14.1.6 Blue River*

Blue River Dam and Reservoir is located at river mile 2 on the Blue River, a tributary of the McKenzie River, about 38 miles east of Eugene, Oregon. Recreation sites around Blue River Reservoir are accessible via Lucky Boy Road, which is accessible off of McKenzie Highway (Oregon Route 126) as well as other local roads. Visitors can see osprey, who use large trees and snags around the reservoir for roosts (places to rest or sleep). The reservoir is also home to several rare species including bull trout, Chinook salmon, and western pond turtles. USACE works with the ODFW to support resident game and nongame fisheries within the waters of the Blue River Reservoir. Anglers at the reservoir can catch warm water species of trout. In May of 2021, the reservoir was stocked with 1,500 legal-size and 50 trophy-size rainbow trout (ODFW 2021b). See the Fish, Aquatic Invertebrates, and Habitat Section for more information on how fisheries at Blue River Reservoir are maintained. The entire 1,600-acre reservoir area is located within the WNF, and the recreational facilities are operated by USFS (USACE No Date-b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-13. The recreation sites are shown below in Figure 3.14-4. USFS operates three recreation sites at Blue River. Mona Campground is located in a long, narrow strip of mixed conifers and is a popular destination for water-based recreation. The campground has 23 sites with tables, fire rings, drinking water, and firewood. Lookout Campground is located on an open meadow and has picnic sites, a boat launch, floating dock, and a day use/overflow parking area. The campground does not have any designated sites, but can accommodate up to 20 single camp sites. The campground has tables, fire rings, drinking water, and firewood. Saddle Dam Ramp is a natural boat ramp on an old access road USACE used when building the Blue River and Saddle Dams. The boat ramp is typically closed from mid-October to mid-March or when the reservoir level dips below 1,295 feet. Open and close dates may be earlier or later depending on water level fluctuation.

In 2021, visitors participated most in sightseeing, camping, and angling. Visitation for specific recreation activities at Blue River Reservoir is summarized below in Table 3.14-14.

**Table 3.14-14. Visits to Blue River Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 1,557 |
| Campers[2] | 4,652 |
| Swimmers | 650 |
| Water Skiers | 676 |
| Boaters | 712 |
| Sightseers | 8,330 |
| Anglers | 3,297 |
| Hunters | 444 |
| Total | 20,318 |

Source: USACE 2016e; USCB 2016; USCB 2021

[1] Estimated adjusted visits are indexed from 2016 to 2021 using data from U.S. Census Bureau 1-Year American Community Survey County level data.

[2] Number of campers are estimated for 2021 using GIS tools and data as well as local, county, and state data as described in Section 1.1 of Technical Appendix K -Recreation.

* Note that numbers may not add up exactly due to rounding.

At Blue River Reservoir in 2021, 20,318 annual visits are estimated to have resulted in $124,055 of recreational value as shown in below in Table 3.14-15.

**Table 3.14-15. Recreational Value of Blue River Reservoir, FY 2021**

### *3.14.1.7 Lookout Point*

Lookout Point Dam and Reservoir is located at river mile 21.3 on the Middle Fork Willamette River, about 22 miles southeast of Eugene, Oregon. Recreation sites around Lookout Point Reservoir are accessible via local roads off of Willamette Highway (Oregon Route 58). The 7,800-acre reservoir area overlaps with the WNF; the surrounding recreational areas are operated by USFS. Lookout Point is a popular recreation destination for fishing, boating, water skiing, swimming, picnicking, and hunting. The reservoir's shoreline provides habitat for rare species, including northern spotted owl, western pond turtles, Chinook salmon, and Oregon chub; most notably, bald eagles winter and regularly nest at Lookout Point (USACE No Date-m).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-16. The recreation sites are shown below in Figure 3.14-5. USACE operates one day-use park (Meridian Park), one day-use boat ramp (Signal Point Ramp), and one campground (Ivan Oakes). Meridian Park includes a gravel road and parking area, picnic tables, and a boat ramp with a courtesy dock; however, access to the ramp is limited by seasonal water levels. Signal Point Ramp has a day-use area, access to nearby hiking trails, and a boat launch. The water southeast of the ramp area is known to be a hazardous stump area (submerged tree stumps pose a collision hazard to boaters). Ivan Oakes campground has direct access to the reservoir for water-based recreation.

USFS operates two campgrounds: Hampton Campground and Black Canyon Campground. Hampton Campground is located in an open area near the reservoir with few trees dotting the shoreline. Camping, boating, and fishing are available; however, the campground is adjacent to a railroad which is active at all hours. Black Canyon Campground is located along the middle Fork Willamette River where visitors can fish and have picnics.

### *3.14.1.8 Hills Creek*

Hills Creek Dam is located at river mile 47.8 on the Middle Fork Willamette River. Recreation sites around Hills Creek Reservoir are accessible via local roads off of Willamette Highway (Oregon Route 58). The 2,735-acre reservoir and its 44 miles of forested shoreline make Hills Creek a popular destination for camping, boating, swimming, fishing, and water skiing. All recreation facilities are within the WNF and as such are operated by USFS (USACE 2009g). Hills Creek is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail (USACE No Date-l). Visitors to Hills Creek Reservoir can catch trout, crappie, and bass. The reservoir is typically stocked with legal-size rainbow trout, 60,000 adipose fin-clipped (clipped between the tail and dorsal fin to enable anglers to identify their catch as a stocked fish) rainbow trout fingerlings, and 100,000 adipose fin-clipped spring Chinook salmon fingerlings annually. Trout and salmon must be adipose-fin clipped to be harvested at the reservoir (ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-19. The recreation sites are shown below in Figure 3.14-6. The boat ramp, picnicking sites, and camping sites at Hills Creek are all operated by USFS. Bingham Boat Ramp is a small, day use only launch located at the south end of the reservoir. The ramp requires higher reservoir levels to be accessible by boat, whereas the Packard boat launch (near the Packard Creek Campground) is usually accessible year- round. Cline-Clark Picnic Area is located on the shore of the reservoir. In addition to picnicking with views of the reservoir, visitors can fish for crappie, largemouth bass, brown bullhead, catfish, and rainbow and cutthroat trout. C.T. Beach Picnic Area has two picnic tables and one fire ring. Sand Prairie Campground has 21 sites. Visitors are able to access the 27-mile Middle Fork Willamette Trail from the Sand Prairie Campground for hiking, horseback riding, and mountain biking. Packard Creek Campground has 37 sites with great views of the reservoir. Each campsite has a picnic table and campfire ring. Visitors can swim, boat, and fish and access the nearby Larison Creek Trail to hike, horseback ride, and mountain bike.

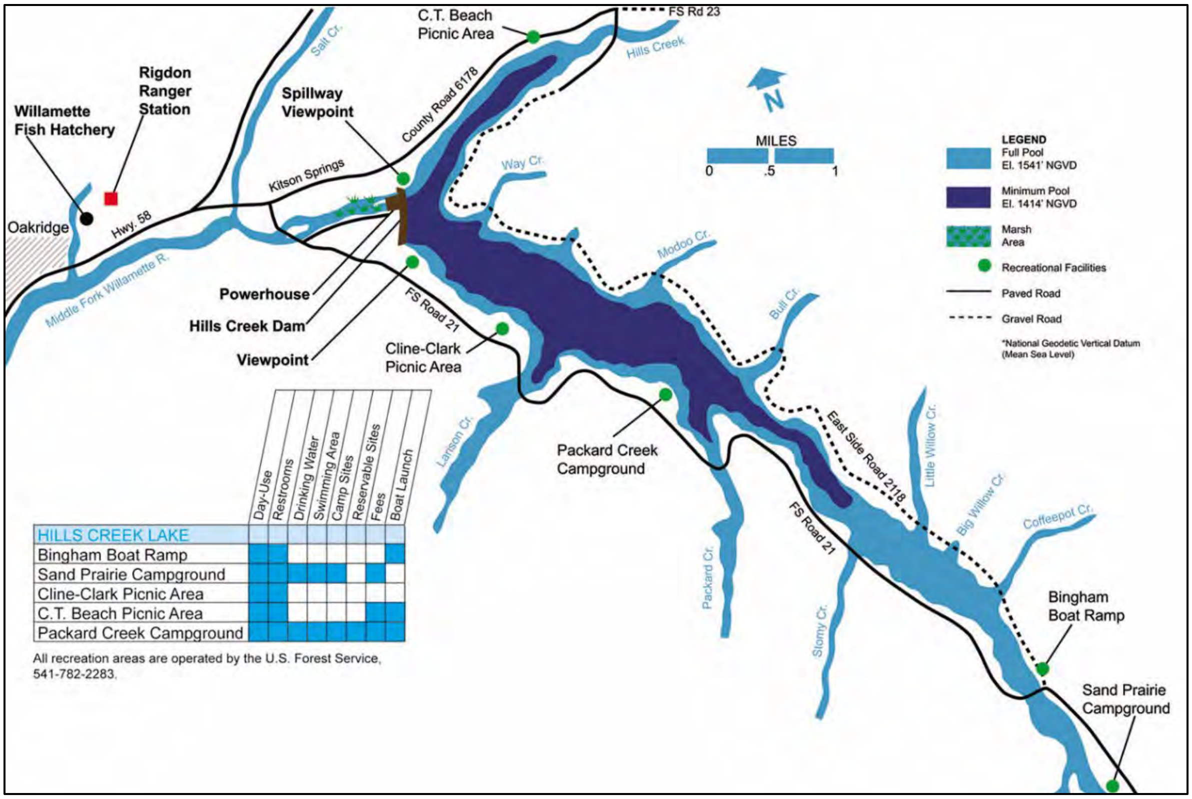

**Figure 3.14-6. Map of Recreation Sites at Hills Creek**

Source: USACE No Date-l

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-19.

**Table 3.14-19. Recreation Areas, Activities, and Amenities at Hills Creek Dam and Reservoir**

In 2021, visitors to Hills Creek Reservoir participated most in camping, water skiing, and boating. Visitation for specific recreation activities at Hills Creek Reservoir is summarized below in Table 3.14-20.

**Table 3.14-20. Visits to Hills Creek Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 55 |
| Campers[2] | 23,015 |
| Swimmers | 8 |
| Water Skiers[3] | 11,554 |
| Boaters[3] | 11,059 |
| Sightseers | 1,070 |
| Anglers | 347 |
| Hunters | 1 |
| Total | 47,110 |

Source: USACE 2016o; USCB 2016; USCB 2021

[1] Estimated adjusted visits are indexed from 2016 to 2021 using data from U.S. Census Bureau 1-Year American Community Survey County level data.

[2] Number of campers are estimated for 2021 using GIS tools and data as well as local, county, and state data as described in Section 1.1 of Technical Appendix K -Recreation.

[3] Number of boaters and water skiers are estimated for 2021 using regression analysis as described in Section 1.1 of Technical Appendix K -Recreation.

* Note that numbers may not add up exactly due to rounding.

At Hills Creek Reservoir in 2021, 47,110 annual visits resulted in approximately $290,933 of recreational value as shown in below in Table 3.14-21.

**Table 3.14-21. Recreational Value of Hills Creek Reservoir, FY 2021**

### *3.14.1.9 Dexter (Reregulating)*

Dexter Dam and Reservoir is located at river mile 18 on the Middle Fork of the Willamette River, about 22 miles southeast of Eugene. Recreation sites around Dexter Reservoir are accessible via local roads off of Willamette Highway (Oregon Route 58). The 1,300 acres of water and shoreline lands provides habitat for waterfowl, upland game birds, song birds, bald eagles, osprey, black-tailed deer, wintering elk, and other species (USACE 2009h; USACE No Date-f). Dexter is a designated stop along the McKenzie Loop of the Willamette Valley Birding Trail where visitors can see migratory and resident songbirds, osprey and eagles along the northeast shoreline (USACE No Date-f). The Willamette Valley Birding Trail is a self-guided driving tour around the Cascade Mountains that is divided into 12 major loops highlighting 138 birding hotspots (Oregon Birding Trails No Date). The reservoir is typically stocked with rainbow trout, but anglers can also catch largemouth and smallmouth bass (ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-22. USACE operates a boat launch (Middle Fork Boat Launch), fishing area (South Side Fishing Area), and a day-use park (Orchard Park). Visitors can catch trout and salmon in the South Side Fishing Area. Orchard Park is located on the north shore of the reservoir between Dexter Dam and Lookout Point Dam. The park's day use area has picnic tables with a view of Lowell Covered Bridge.

OPRD operates two day-use areas at Dexter: Dexter State Park and Lowell State Park. Dexter State Park has docks, a two-lane launch ramp, and a picnic area that overlooks the reservoir. The park is near an 18-hole disc golf course and is connected to Elijah Bristow State Park through a system of trails that follow the Middle Fork of the Willamette River. Lowell State Park has a picnic shelter that overlooks the reservoir, a wooded picnic area, playground, basketball court, a swim beach, a marina with rentable moorage, a large courtesy dock, and a four-lane launch ramp. The Oregon Association of Rowers and the University of Oregon have boathouses at the park, and host Regattas (rowing races) each spring (OPRD No Date). These recreation sites are shown above in Figure 3.14-5.

**Table 3.14-22. Recreation Areas, Activities, and Amenities at Dexter Dam and Reservoir**

#### *3.14.1.10 Fall Creek*

Fall Creek Dam is at river mile 7.2 on the Fall Creek tributary of the Willamette River and is about 20 miles southeast of Eugene, Oregon. Recreation sites around Fall Creek Reservoir are accessible via local roads off of Willamette Highway (Oregon Route 58). The 1,582-acre reservoir and its 22 miles of forested shoreline provide habitat to a wide variety of wildlife including waterfowl, upland game birds, song birds, bald eagles, osprey, black-tailed deer and other species and makes Fall Creek a popular destination for fishing, boating, water skiing, swimming, camping, and picnicking (USACE No Date-h). Fall Creek Reservoir is stocked with legal-size and pound-size rainbow trout which can be caught all year; however, the use of bait, lures, or artificial flies are seasonally restricted. Visitors are permitted to catch five hatchery trout and an additional two wild trout daily. Fishing for salmon upstream of the dam is prohibited, but downstream of the dam, hatchery Chinook, hatchery steelhead, and wild steelhead greater than 24 inches can be harvested all year (ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-25. The recreation sites are shown below in Figure 3.14-7. USACE operates one day-use park (Tufti Park) which includes a minimally developed day use area with a gravel parking lot, access to the Fall Creek below the dam, and a hiking trail. OPRD operates five day-use areas (Winberry Park, North Shore Park, Free Meadow, and Lakeside One and Two) and two campgrounds (Cascara Campground and Fisherman's Pt. Group Campground). Winberry Park has a two-lane boat ramp, parking for more than 100 cars and 150 boat trailers, a swim dock and swim beach, and picnic areas with barbecue grills and fire rings. North Shore Park has high- and low-water ramps and a picnic area overlooking the reservoir. Cascara Campground has 39 campsites, a boat ramp, and a swim area. Fisherman's Pt. Group Campground is a primitive group site with a 64-person capacity along the shore of the reservoir (OPRD No Date). Sky Camp is a 100-acre private campground operated by the Springfield School District and used for educational purposes. It includes a main lodge with a kitchen and cabins with 164 total beds (USACE No Date-h; Sky Camp No Date).

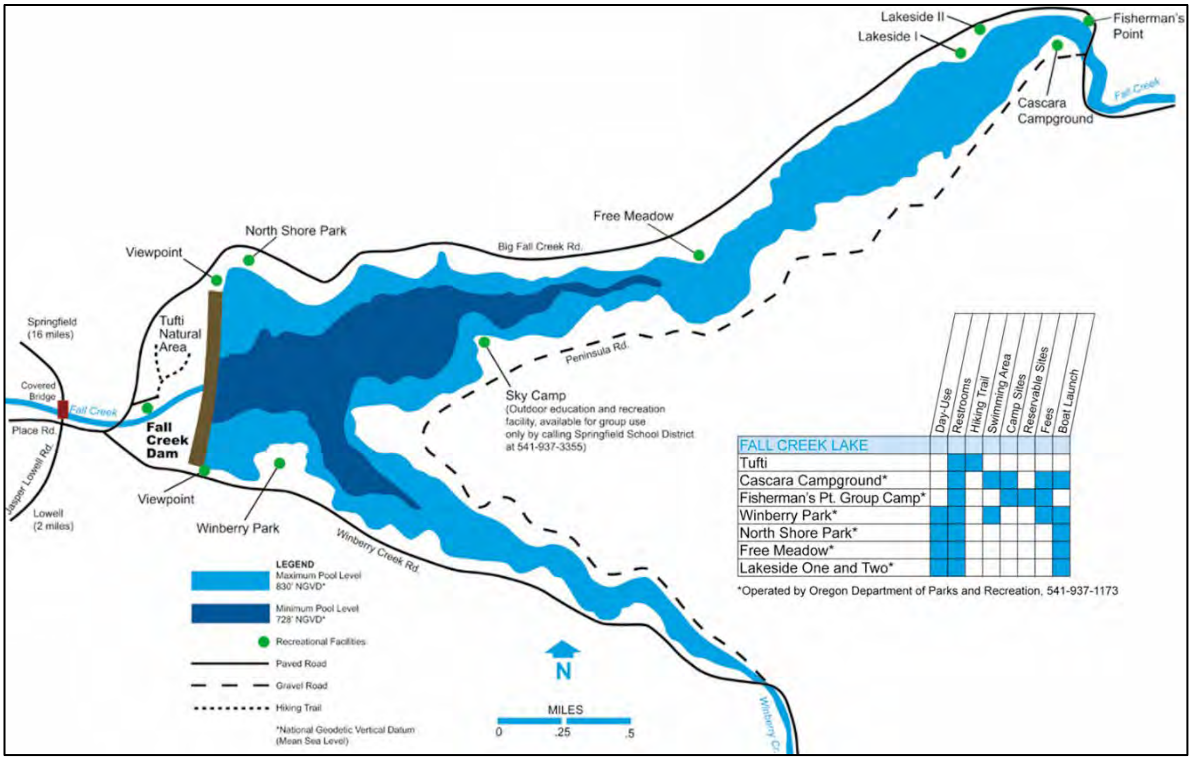

**Figure 3.14-7. Map of Recreation Sites at Fall Creek**

Source: USACE No Date-h

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-25.

**Table 3.14-25. Recreation Areas, Activities, and Amenities at Fall Creek Dam and Reservoir**

#### *3.14.1.11 Dorena*

Dorena Dam is located on the Row River, a tributary of the Willamette River. Recreation sites around Dorena Reservoir are accessible via local roads off of Pacific Highway (Interstate 5). Dorena provides more than 2,400 acres of habitat for a variety of wildlife and plants and is a designated stop along the Big River Loop of the Willamette Valley Birding Trail. Visitors can see rare birds such as the purple martin, the willow flycatcher, and the yellow-breasted chat. Osprey and purple martins nest around the reservoir (USACE No Date-g). Anglers at Dorena Reservoir can catch rainbow trout (which are regularly stocked), largemouth bass, smallmouth bass, yellow perch, crappie, and bluegill (ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-28. The recreation sites are shown below in Figure 3.14-8. USACE operates a campground (Schwarz Campground) located immediately downstream of the dam and two day-use parks (Harms Park and Bake Stewart Park). Schwarz Campground has fishing, boating, swimming, and hiking. The campground has 59 single campsites for RVs, trailers, and tents and six group campsites (Oregon's Best Camping 2021). Harms Park has a boat launch and visitors can hike along the adjacent Row River Trail. BLM operates the paved Row River Trail, which follows Dorena Reservoir’s north shore for over 5 miles with biking, hiking, and horseback riding.

Lane County operates Baker Bay Park which includes a day-use area, boat ramp, marina, campground with group camping and RV camping, dock/pier, hiking, multiuse play fields, a picnic area, children’s play equipment, swimming areas, and showers (Lane County No Date).

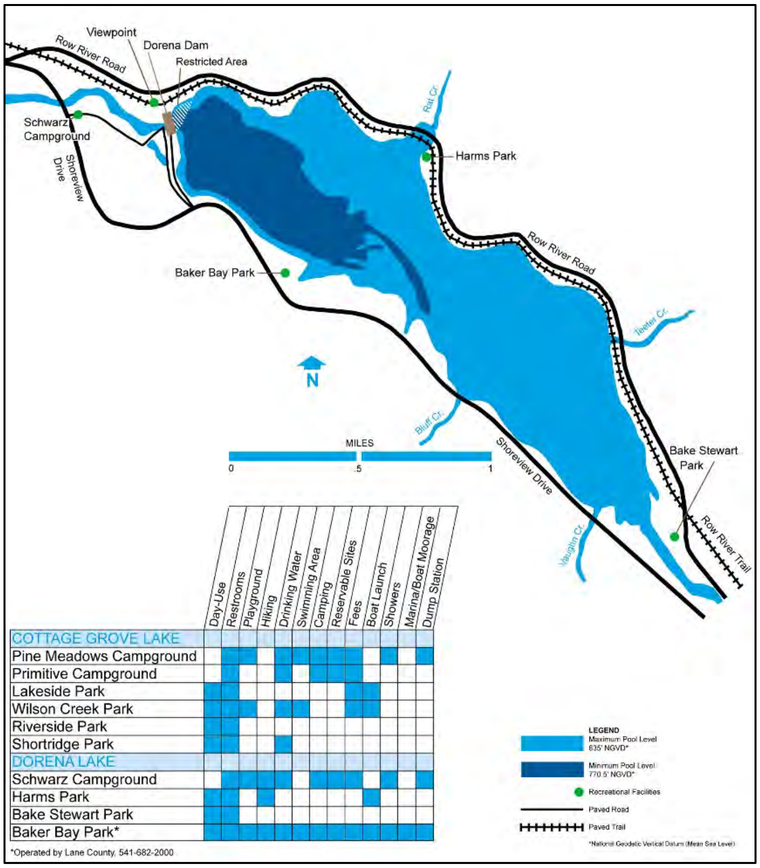

**Figure 3.14-8. Map of Recreation Sites at Dorena**

#### *3.14.1.12 Cottage Grove*

Cottage Grove Dam and Reservoir is located at river mile 29 of the Coast Fork of the Willamette River. Recreation sites around Cottage Grove Reservoir are accessible via local roads off of Pacific Highway (Interstate 5). Cottage Grove is a designated stop along the Big River Loop of the Willamette Valley Birding Trail where visitors can see rare birds such as the purple martin, the willow flycatcher, and the yellow-breasted chat. Similar to Dorena, osprey and purple martins nest along the reservoir (USACE No Date-c). Cottage Grove Reservoir is typically stocked with one-pound rainbow trout; anglers can also catch spotted bass, largemouth bass, crappie, yellow perch, and bluegill (ODFW 2021b).

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-31. The recreation sites are shown below in Figure 3.14-9. USACE operates two campgrounds (Pine Meadows Developed and Primitive campgrounds) and four day-use parks (Lakeside Park, Wilson Creek Park, Riverside Park, and Shortridge Park). Pine Meadows Developed Campground has 85 campsites, paved roads, showers, campfire rings, picnic tables, children's play area, and a marked, but unsupervised swim area with a life jacket loaner station. The primitive campground has 15 individual campsites, drinking water, gravel roads, picnic tables, and fire rings. Neither the developed nor the primitive campgrounds have hookups. Lakeside Park is located on London Road just past the dam and has paved roads and parking lots, picnic tables, fire rings, and a boat launch ramp with a courtesy dock and a life jacket loaner station. Wilson Creek Park has paved roads and parking lots, picnic tables, fire rings, a children's play area, an unsupervised swim area with a life jacket loaner station, and a boat launch ramp with a courtesy dock. Riverside Park is located on the east bank of the river (downstream from the dam) and is a minimally developed area with a gravel road and parking area, two picnic tables, and a paved path with pull-outs suitable for wheelchairs that is close enough to the river for fishing (USACE No Date-c).

In 2021, visitors to Cottage Grove Reservoir participated most in boating, water skiing, and picnicking. Visitation for specific recreation activities at Cottage Grove Reservoir is summarized below in Table 3.14-32.

**Table 3.14-32. Visits to Cottage Grove Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 59,238 |
| Campers | 3,446 |
| Swimmers | 51,839 |
| Water Skiers | 57,586 |
| Boaters[2] | 70,908 |
| Sightseers | 28,011 |
| Anglers | 44,601 |
| Hunters | 9,452 |
| Total | 325,083 |

Source: USACE 2016f; USCB 2016; USCB 2021

[1] Estimated adjusted visits are indexed from 2016 to 2021 using data from U.S. Census Bureau 1-Year American Community Survey County level data.

[2] Number of boaters are estimated for 2021 using regression analysis as described in Section 1.1 of Technical Appendix K -Recreation.

* Note that numbers may not add up exactly due to rounding.

At Cottage Grove Reservoir in 2021, 325,083 annual visits resulted in approximately $2,854,006 of recreational value as shown in below in Table 3.14-33. Cottage Grove is estimated to have the third most annual visits and third largest recreational value of USACE reservoirs in the WVS.

### *3.14.1.13 Fern Ridge*

Fern Ridge Dam and Reservoir is located at river mile 23.6 on the Long Tom River tributary of the Willamette River, about 12 miles west of Eugene, Oregon. Recreation sites around Fern Ridge Reservoir are accessible via local roads off of Florence-Eugene Highway, Territorial Highway, and Oregon Routes 99 and 569. Fern Ridge is a popular destination for fishing, boating, water skiing, swimming, camping, picnicking, hunting, and birding (USACE No Date-i). The large surface area and consistent winds make Fern Ridge one of the best sailing reservoirs in Oregon (USACE 2019a). The thousands of acres of emergent marsh (shallow-water wetlands) support summer breeding habitat for a variety of water-bird species, including Oregon's largest breeding colony of purple martins. USACE works with ODFW to support resident game and non-game fisheries within the Long Tom River Basin (USACE No Date-i). Anglers at Fern Ridge Reservoir can catch largemouth bass, crappie, bluegill, and brown bullhead. Bass and crappie are available throughout the spring and summer (ODFW 2021b). See the Fish, Aquatic Invertebrates, and Habitat Section for more information on how fisheries at Fern Ridge Reservoir are maintained.

The managing agency, the months available, and many of the activities and amenities available at each recreation area are included below in Table 3.14-34. The recreation sites are shown below in Figure 3.14-10. ODFW operates Fern Ridge Wildlife Area and East Kirk Park. The Fern Ridge Wildlife Area covers approximately half of the reservoir and consists of wetlands, wet prairie, oak and mixed woodlands, upland prairie, and freshwater aquatic habitats. It is a popular destination for water-based recreation, hunting, bird watching, hiking, and environmental education. Kirk Park is one of 11 management units within the Fern Ridge Wildlife Area; the eastern two-thirds of the area is designated for wildlife management and consists of woodland, meadow, marsh, and pond habitat. The western third of Kirk Park (West Kirk Park) is managed by USACE (ODFW 2020b).

USACE operates three day-use parks (West Kirk Park, Jeans Park, and Shore Lane Park). West Kirk Park is located below the dam off Clear Lake Road, and provides access to the Long Tom River and ponds and has trails, picnic tables, paved roads, and fire rings. Jeans Park is a wooded park with trails. It is located on Jeans Road on the west side of Fern Ridge Reservoir, and it includes visitor parking. Shore Lane Park is a small and rustic park that is often used for launching paddle craft.

Lane County operates four day-use sites: Richardson Park, Orchard Point Park, Perkins Peninsula Park, and Zumwalt Park. Richardson Park has a boat ramp, campground with group camping, RV camping, concessions, a dock/pier, hiking, a marina, a picnic area with shelter, children's play equipment, swimming areas, and showers. Orchard Point Park has a boat ramp, concessions, a dock/pier, a marina, multiuse play fields, a picnic area, children's play equipment, swimming areas, hiking, and a viewpoint. Perkins Peninsula Park has a boat ramp, a dock/pier, multiuse play field, a picnic area, swimming areas, hiking, and a viewpoint. Zumwalt Park has an interpretive trail, multiuse play fields, a picnic area, swimming areas, hiking, and a wildlife/natural area (Lane County No Date).

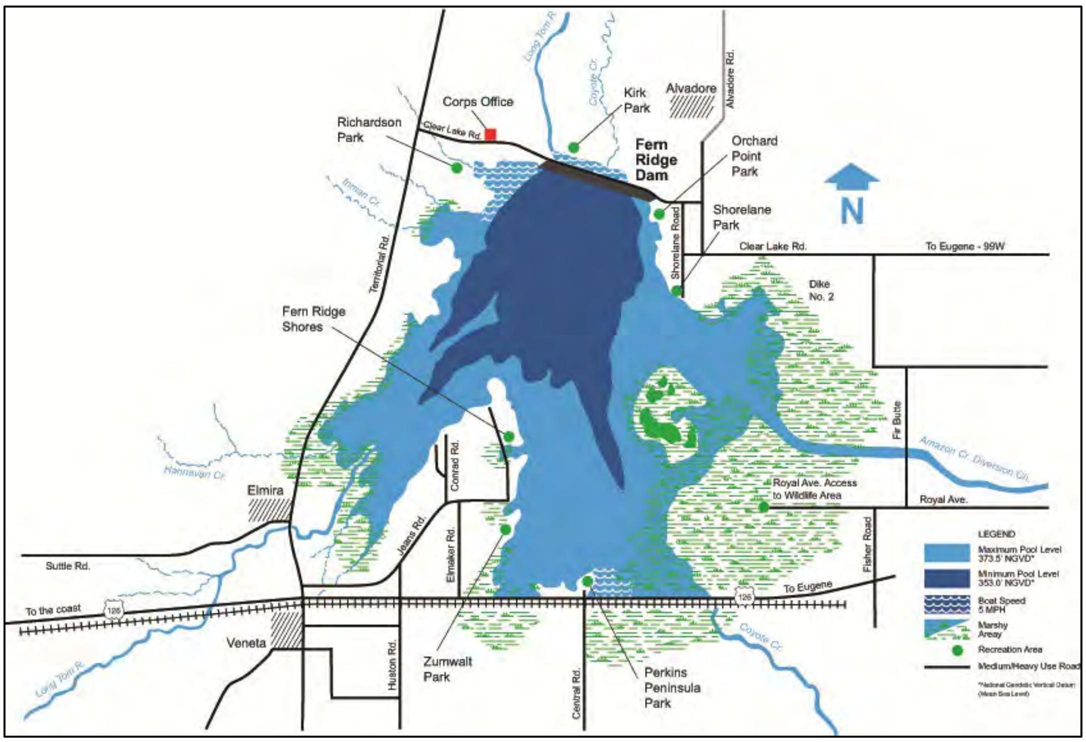

**Figure 3.14-10. Map of Recreation Sites at Fern Ridge**

Source: USACE No Date-i

The activities and amenities available at each of these recreation sites are summarized below in Table 3.14-34.

**Table 3.14-34. Recreation Areas, Activities, and Amenities at Fern Ridge Dam and Reservoir**

In 2021, visitors to Fern Ridge Reservoir participated most in picnicking, boating, and angling. Visitation for specific recreation activities at Fern Ridge Reservoir is summarized below in Table 3.14-35.

**Table 3.14-35. Visits to Fern Ridge Reservoir, FY 2021**

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Picnickers | 184,125 |
| Campers | 15,138 |
| Swimmers | 109,010 |
| Water Skiers | 92,004 |
| Boaters | 180,016 |
| Sightseers | 84,704 |

| Activity | 2021 Estimated Visits[1] |
|---|---|
| Anglers | 123,267 |
| Hunters | 26,115 |
| Total | 814,378 |

[1] Source: USACE 2016l; USCB 2016; USCB 2021

[2] Estimated adjusted visits are indexed from 2016 to 2021 using data from U.S. Census Bureau 1-Year American Community Survey County level data.

* Note that numbers may not add up exactly due to rounding.

At Fern Ridge Reservoir in 2021, 814,378 annual visits resulted in approximately $6,006,087 of recreational value as shown in below in Table 3.14-36. Fern Ridge is estimated to have the most annual visits and largest recreational value of all USACE reservoirs in the WVS.

**Table 3.14-36. Recreational Value of Fern Ridge Reservoir, FY 2021**

### *3.14.1.14 Riverine Recreation*

Similar to recreational opportunities in the vicinity of the dams and reservoirs, riverine recreation includes water-based recreation such as boating, kayaking, fishing, and swimming and land-based activities such as hiking, camping, and picnicking. Though the WVS does not release or regulate water specifically for downstream recreation, the timing and quantity of flows released from the 13 dams and reservoirs can affect downstream recreation opportunities including along the Long Tom River (from Fern Ridge Dam to Willamette River), the Mainstem Willamette River, McKenzie River, and North and South Santiam Rivers. The location of boat ramps along river segments can be used to illustrate which river segments are used for boat-related recreational activities. Figure 3.14-11 shows the location of boat ramps and boat access points throughout the WRB, with the greatest concentration of boat ramps occurring along the McKenzie River and North and South Santiam Rivers (USACE 2019a).

**Figure 3.14-11. Boating Access in the Willamette River Valley**

Source: USACE 2019a

### 3.14.2 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on recreation. The discussion includes the methodology, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis for each alternative.

### *3.14.2.1 Methodology*

Potential effects to recreation were evaluated both quantitatively and qualitatively for reservoir and riverine areas.

1. Quantitative Analysis – Uses HEC-ResSim model[48] outputs and USACE Visitor Estimation & Reporting System (VERS) data to quantify changes in visitation and the associated economic benefit based on the reservoir water surface elevations (WSEs) in relation to boat ramp elevations. This portion of the analysis for reservoirs focuses on visitation and economic benefits. For riverine recreation, HEC-ResSim river flow outputs at river gage locations for the action alternatives were compared to the NAA to quantify effects.

2. Qualitative Analysis – Considers how changes to noise levels, air quality, visual resources, and traffic from construction; and changes to water levels from recurring deep drawdowns would affect the quality of the recreational experience at reservoirs and rivers, as applicable. This portion of the analysis focuses on the recreational experience.

#### *3.14.2.1.1 Quantitative Analysis*

The purpose of the quantitative analysis is to estimate average annual visitation at reservoirs and the associated economic benefits; and how the action alternatives would affect visitation and economic benefits compared to the NAA.

First, to estimate the average annual number of usable days, WSE data from the HEC-ResSim model was compared to boat ramp elevations at each reservoir during the peak recreation season (from May 15 to September 15). WSE data from the HEC-ResSim model was available for 83 full water years. The number of days in each season that the bottom of a given boat ramp elevation was lower than the WSE were counted as usable days, with the remaining days counted as unusable. (The top of a boat ramp should sit above the WSE and the bottom of the ramp should be deep enough for the boat to be backed into the water). Then, reservoir recreational visitor data from the USACE VERS was used to quantify how many people would visit each reservoir annually. A simplifying assumption was made that all people would visit the reservoirs during the peak recreation season from May 15 to September 15, i.e., visitation data was not separated by month or season: all annual visitation was grouped into the peak recreational season. Lastly, USACE Unit-Day-Value data was used to estimate the dollar value of a visit to a reservoir.

Because drawdowns would have a far more substantial effect on WSE compared to some of the other measures (e.g., use spillway for surface spill in summer), and boat ramp availability (which is tied to WSE) was used as the main factor in estimating visitation (as explained above),

[48] The HEC-ResSim model is described in detail in Appendix B, *Hydrology and Hydraulics.*

for each alternative, it is assumed that changes in visitation and riverine flows under each action alternative would occur as a result of deep drawdowns in the fall and spring. Therefore, to calculate changes in visitation and economic benefits for each action alternative, it is assumed that 90% of boaters and fishermen, 100% of water skiers, and 25% of swimmers, campers, sightseers, and picnickers would forego visiting the reservoir if the WSE is below the bottom of the boat ramps and the boat ramps are not usable. Applying these assumptions, the number of people that would visit each reservoir annually were calculated using the above-mentioned recreational visitor data from the USACE VERS. As done under the NAA, USACE Unit-Day-Value data from Economic Guidance Memorandum (EGM-21-02) was used to estimate the dollar value of recreational visits under each action alternative.

Visitation estimates are not made for riverine areas because of the many access points available to recreators, which are not operated by USACE. Therefore, riverine visitation data is not available. Instead, changes in flows for each alternative compared to the NAA are used as an indicator of general effects to riverine recreation. Modeling results indicate that changes in alternative flows could remain essentially unaffected at some reservoirs or rivers; or change up to 55 percent. The full results of visitation estimates are presented in Appendix K — Recreation Technical Report.

###### *3.14.2.1.2 Qualitative Analysis*

It is assumed that during a drawdown, some recreationists would not forego visiting a reservoir even if the WSE is below the bottom of the boat ramp and it is unusable. This is because boat ramps are only required to launch motorized boats. Non-motorized watercraft such as kayaks and paddleboards do not require boat ramps to launch. Additionally, fishing and swimming can be accessed from the shore, and land-based recreation like camping is generally available from mid-May to mid-September regardless of WSE. The *availability* of land-based recreation including but not limited to wildlife viewing (including birding), hiking, cycling, and picnicking are typically unaffected by changes in WSE; however, the *quality* of both land- and water-based recreational experiences would be affected by changes in WSE (e.g., recurring fall and spring drawdowns) regardless of an individual recreationist's location at the reservoir.

Independent of WSE, construction activities would also affect the quality of land- and water-based recreational experiences from increases in noise levels, air emissions, and traffic; as well as visual intrusions. Changes in the quality of recreation would increase proportionally with the proximity of the recreational facility to construction. At each dam and reservoir, effects at recreational facilities were analyzed spatially: facilities adjacent to construction would experience more severe effects, and those over two miles away would experience less adverse effects.

The quality of riverine recreation would also be affected from construction measures, regardless of the presence of USACE-managed recreational facilities. Similar to the quality of recreation at a facility on a reservoir, changes would increase proportionally with the proximity of the recreationist to construction. Riverine recreationists adjacent to construction would experience more severe adverse effects; and those further away would experience less severe adverse effects. Measures affecting recreational fishing in both reservoirs and rivers, whether directly or indirectly, were also considered. The quality of recreational fishing in reservoirs and on rivers for some species could be adversely impacted due to increased turbidity from suspended sediment associated with construction measures and drawdowns. In the long-term, many (most) measures aim to improve fish habitat and increase fish populations and therefore would benefit recreational fishing.

*3.14.2.1.3 Evaluation Criteria*

The magnitude of effects is determined using both the quantitative and qualitative portions of the analysis described above, as appropriate. Most of the proposed measures (e.g., maintain revetments using nature-based methods, install gravel below dams) would not directly affect visitation; in these cases, the effects are qualified. Reservoir drawdowns would drastically change the WSE and would both directly affect visitation and the recreational experience; these effects are described both quantitatively and qualitatively. Table 3.14-37 describes the evaluation criteria for the effect factors (magnitude, duration, and extent), and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.14-37. Evaluation Criteria for Potential Effects to Recreation**

| Effect Factors and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Changes in visitation and economic benefits at reservoirs are not measurable or change less than one percent compared to baseline conditions. Changes in flows at select gage locations in riverine areas are not measurable or change less than one percent compared to baseline conditions. Impacts from changes in noise, air quality, visual resources, traffic, or other conditions would not affect the quality of recreational experiences. |
| Minor | Changes in visitation and economic benefits at reservoirs or flows at select gage locations in riverine areas are between one and five percent compared to baseline conditions. Impacts from changes in noise, air quality, visual resources, traffic, or other conditions would be slightly noticeable and begin to affect the quality of recreational experiences. |
| Moderate | Changes in visitation and economic benefits at reservoirs or flows at select gage locations in riverine areas are between five and twenty percent compared to baseline conditions. Impacts from changes in noise, air quality, visual resources, traffic, or |

| Effect Factors and Scale | Definition |
|---|---|
| | other conditions would be noticeable and affect the quality of recreational experiences. |
| Major | Changes in visitation and economic benefits at reservoirs or flows at select gage locations in riverine areas are more than twenty percent compared to baseline conditions. Impacts from changes in noise, air quality, visual resources, traffic, or other conditions would be very noticeable and significantly affect the quality of recreational experiences. |
| **Duration** | |
| Short-term | Alteration lasts for the duration of small construction project, and is continuous for less than 2 years. |
| Medium-term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long-term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Local | Changes to visitation, economic benefits, or the recreational experience would be confined to the dam/reservoir or river. |
| Regional | Changes to visitation, economic benefits, or the recreational experience would be perceived throughout a single county, multiple counties, or the entire WVS. |
| State-wide | Changes to visitation, economic benefits, or the recreational experience would be perceived throughout the entire state. |

#### *3.14.2.2 Measures Analyzed for Recreation*

All measures under the action alternatives could impact recreation, either directly or indirectly. These measures are:

- Construct water temperature control (WTC) tower (#105)
- Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Structural improvements to reduce total dissolved gas (TDG) (#174)
- Integrated temperature and habitat flow regime (#30a)
- Refined Integrated temperature and habitat flow regime (#30b)
- Augment instream flows by using the power pool (#304)

- Gravel augmentation below dams (#384)
- Construct structural downstream fish passage (#392)
- Deeper fall reservoir drawdowns for fish passage (#40)
- Foster Fish Ladder Temperature Improvement (#479)
- Provide Pacific lamprey passage and infrastructure (#52)
- Restore upstream and downstream passage at drop structures (#639)
- Pass water over spillway in spring for fish passage (#714)
- Augment instream flows by using the inactive pool (#718)
- Adapt Hatchery Program (#719)
- Spring reservoir drawdown for downstream fish passage (#720)
- Use spillway for surface spill in summer (#721)
- Construct adult fish facility (AFF) (#722)
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)
- Maintenance of existing and new fish release sites above dams (#726)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Fall Creek drawdown
- Continued Operation of Existing Adult Fish Facilities
- Operation, Maintenance, Repair, Replacement and Rehabilitation

A summary of the recreation effects discussed in the sections below is provided in Table 3.14-38. Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the lesser beneficial effect does not occur at that reservoir. This follows the approach to present the most conservative conclusions in this table; instead of simply omitting reservoirs where less severe or more beneficial effects would occur. Discussion of all adverse and beneficial effects are included below.

**Table 3.14-38. Summary of Effects to Recreation Under Each Alternative**

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| | **Short-Term** | | | | | | | |
| Magnitude | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse |
| Extent | Local (basin-wide, FCR) | Local (basin-wide; FRN, GPR, BCL, BLU, CGR, FOS, FCR) | Local (basin-wide BCL, BLU, CGR, FOS, GPR, FCR) | Local (basin-wide, BCL, BLU, CGR, FOS, GPR, FCR) | Local (basin-wide, BCL, BLU, CGR, FOS, GPR, HCR, FCR) | Local (basin-wide, BCL, BLU, CGR, FOS, GPR, HCR, FCR) | Local (basin-wide, BCL, BLU, CGR, FOS, FRN, HCR, FCR) | Local (basin-wide, BCL, BLU, CGR, FOS, GPR, FCR) |
| | **Medium-Term** | | | | | | | |
| Magnitude | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse |
| Extent | Local (basin-wide) | Local (basin-wide, DET, LOP, CGR, FOS, GPR) | Local (basin-wide, DET, CGR, DET, LOP, FOS, GPR) | Local (basin-wide, DET, LOP, FOS, GPR, CGR) | Local (basin-wide, BLU, GPR, HCR, FOS) | Local (basin-wide, FOS, BLU, GPR, HCR, CGR) | Local (basin-wide, CGR, DEX, FOS, GPR, DET, HCR, LOP, FOS) | Local (basin-wide, DET, LOP, FOS, GPR, CGR) |
| | **Long-Term (Permanent, Intermittent, and/or Recurring)** | | | | | | | |
| Magnitude | Major adverse | Moderate beneficial; major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse |
| Extent | Local (basin-wide, FCR) | Local (basin-wide, FCR) | Local (basin-wide, GPR, FCR, CGR, GPR, LOP) | Local (basin-wide, CGR, GPR, FCR, LOP, FOS) | Local (basin-wide, CGR, GPR, LOP, FOS, HCR, DET, BLU, FCR) | Local (basin-wide, CGR, GPR, LOP, HCR, FOS, DET, BLU, FCR) | Local (basin-wide, CGR, GPR, LOP, FOS, FCR) | Local (basin-wide, CGR, GPR, FCR, LOP, FOS) |
| Duration Type | Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring |

In the following subsections, the effects are discussed for the No Action Alternative and the measures analyzed in the action alternatives.

#### *3.14.2.3 Discussion of Effects by Measure(s)*

This section applies the methodology described above to each measure analyzed for the resource to determine the potential effects. Where possible, the discussion of the magnitude and duration of effects is grouped by measures that would have similar effects. The effects by measure or measures will then be referenced in the action alternative's analysis that follows. The extent of effects is discussed by dam/reservoir under the appropriate alternative. The following would require construction, as described above in Section 3.1.4.2

- Gravel augmentation below dams (#384)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Maintenance of existing and new fish release sites above dams (#726)
- Operation, maintenance, repair, replacement and rehabilitation
- Foster fish ladder temperature improvement (#479)
- Construct WTC tower (#105)
- Use spillway for surface spill in summer (#721)
- Structural improvements to reduce total dissolved gas (#174)
- Restore upstream and downstream passage at drop structures (#639)
- Construct AFF (#722)
- Provide Pacific lamprey passage and infrastructure (#52)
- Construct structural downstream fish passage (#392)
- Deeper fall reservoir drawdowns for fish passage (#40)

This section will discuss general, qualitative effects on recreation from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects.

#### *3.14.2.3.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), and Use spillway for surface spill in summer (#721)*

The magnitude of effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; and restoring upstream and downstream passage at drop structures would be adverse and negligible to minor in magnitude in the short term, and beneficial, indirect, and minor in magnitude in the long term. At Blue River and Hills Creek only, effects from using the surface spillway for surface spill in the summer would be adverse and negligible to moderate in magnitude in the short term, but would have the same beneficial effects.

Potential effects from these measures are determined below. The effects analyses for augmenting gravel below dams, maintaining or altering revetments for ecosystem restoration, and maintaining existing and new fish release sites above dams is referred back to under all action alternatives; the effects of restoring upstream and downstream passage at drop structures is referred back to under Alternatives 1 and 4; and the effects of using the surface spillway for surface spill in the summer is referred back to under Alternatives 2A, 2B, 3A, 3B, 4, and 5.

Augmenting gravel below dams would add clean round river gravel to areas of wetted streambeds of rivers below dams that have ESA-listed UWR Chinook salmon and UWR steelhead. Augmenting gravel is likely to occur downstream of dams in relatively close proximity to dams themselves because these areas can experience river-substrate issues due to the water flowing out of dam outlets. Maintaining or altering revetments for aquatic ecosystem restoration would decrease hard surfaces (e.g., rock) within the WVS and could occur at any of the 43 miles of USACE-maintained revetment locations (including the mainstem Willamette River) as described in Section 2.4.2.3. Maintaining existing and new fish release sites above dams may require minor grading and tree removal at the proposed Blue River, Cougar, Detroit, Foster, Green Peter, and Lookout Point outplanting sites. The approach and design of restoring upstream and downstream passage at drop structures would be determined during the design phase, but could include the construction of fish ladders, direct modifications to drop structures, bypass channels, or the replacement of drop structures with riffle and pool systems. Kirk Park, the only recreational facility downstream of the Fern Ridge, is approximately six miles away from the nearest drop structure at Cox Butte where fish passage would be restored. Therefore, recreational facilities would be virtually unaffected by construction. However, these measures would occur in or on the rivers downstream of dams at varying levels of proximity to the dams, where there may or may not be an adjacent USACE-managed recreational facility. Any measures that involve construction on a river could affect the quality of the recreational experience for riverine recreators participating in boating, swimming, and fishing – regardless of the presence of USACE-managed recreational facilities.

These measures could all affect the recreational experience at or near construction-project locations with noise and air emissions, traffic from hauling material, and could generally attract attention from changes in visual resources. Additionally, the quality of recreational fishing along rivers for some species could be adversely impacted in the short-term due to the increased turbidity from suspended sediment caused by gravel augmentation or revetment alteration. The severity of short-term construction-related effects on the quality of recreation are considered qualitatively as follows. For areas that may not have a USACE recreational facility, such as at rivers downstream of dams, the severity of effects on the quality of the recreational experience are based on the proximity of a recreator to the construction project (i.e., not limited to a USACE recreational facility, such as a park). Effects would be minor to a recreator passing by the project location, and negligible as the distance from the construction project location increases. Similarly, for areas that do have a USACE recreational facility, effects on the quality of the recreational experience are based on the proximity of the recreational facility to the construction project. Effects would be minor at recreational facilities adjacent to the construction location, and be negligible for facilities more than one or two miles away from the construction.

In summary, changes in the quality of recreation would range from not noticeable to slightly noticeable and increase proportionally with the proximity of the recreator or recreational facility to construction, therefore, adverse effects would range from negligible to minor in magnitude. Changes in the quality of recreation would last the duration of the small construction projects, so effects would be short term.

These measures would not directly benefit recreation, but would improve fish habitat and passage over time, and could increase the population of native fish species available for recreational fishing in the long term. As such, benefits would be indirect because they would be caused by the action but would occur later in time or be farther removed in distance, but still be reasonably foreseeable. Thus, these measures would have indirect, beneficial, and minor effects to recreational fishing in the long term.

Using the surface spillway for surface spill in the summer would require spillway channel modifications at Blue River and Hills Creek only. At Blue River and Hills Creek there would be negligible to moderate in magnitude and short term in duration effects from construction, similar to the measures described above in this section. These effects would be moderate rather than minor because hydraulic excavators would be required to excavate and regrade the spillway, which would have more severe effects on recreation. At all locations, there would be indirect, beneficial, and minor effects to recreational fishing in the long term.

Therefore, potential adverse effects would be negligible to minor in magnitude (negligible to moderate at Blue River and Hills Creek from construction for using the surface spillway for summer spill) and short term in duration; and potential beneficial effects would be indirect, minor in magnitude, and long term in duration.

#### *3.14.2.3.2 Provide Pacific lamprey passage and infrastructure (#52)*

The magnitude of effects from providing pacific lamprey passage and infrastructure would be negligible to minor in the short term. Potential effects from construction of these structures are determined below and referred back to under all action alternatives.

Like the measures described above in Section 3.14.2.3.1, this measure could affect the recreational experience at or near construction-project locations with noise and air emissions, traffic from hauling material, and could generally attract attention from changes in visual resources. Pacific lamprey passage and infrastructure would be located next to the dams, all of which are immediately adjacent to at least one recreation area (primarily viewpoints and parks). Changes in the quality of recreation would range from not noticeable to noticeable, increasing proportionally with the recreational facility's proximity to the construction, therefore, adverse effects would range from negligible to minor in magnitude. Changes in the quality of recreation would last the duration of the small construction projects, so effects would be short term.

Pacific lamprey is only harvested for subsistence purposes in the WVS and cannot be fished recreationally. So, unlike other structural improvement projects, no long-term direct or indirect benefits to recreational fishing would occur as a result of providing pacific lamprey passage and infrastructure.

#### *3.14.2.3.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

The magnitude of effects from operation, maintenance, repair, replacement, and rehabilitation would be adverse and negligible to minor in magnitude in the short and long term for scheduled/routine maintenance, and be adverse and negligible to moderate in the medium and long term for major maintenance and rehabilitation. Potential effects from this measure are determined below and referred back to under each action alternative.

Similar to the measures described above in Sections 3.14.2.3.1 and 3.14.2.3.2, operation, maintenance, repair, replacement, and rehabilitation could affect the recreational experience at or near construction-project locations with noise and air emissions, traffic from hauling material, and could generally attract attention from changes in visual resources. These activities could be located next to the dams, all of which are immediately adjacent to at least one recreation area (primarily viewpoints and parks), but could also occur at any USACE-managed facility in the WVS that requires maintenance. Changes in the quality of recreation would increase proportionally with the recreationist or recreational facility's proximity to the operation, maintenance, repair, replacement, or rehabilitation activity.

For scheduled/routine maintenance, changes in the quality of recreation would range from not noticeable to noticeable, therefore, adverse effects would be negligible to minor in magnitude. Changes in the quality of recreation would last the duration of the small construction projects, so effects would be short term. Effects from major maintenance and rehabilitation projects would generally be greater in magnitude than scheduled/routine maintenance due to the potential use of heavy-duty construction equipment and the projects generally being more intensive. Changes in the quality of recreation would range from negligible to moderate in magnitude and last the duration of the large construction projects, so effects would be medium-term. Major maintenance and rehabilitation projects would undergo additional tiered NEPA analysis where specific actions would be analyzed and detailed effects would be described. Because both scheduled/routine maintenance and major maintenance and rehabilitation would occur throughout the life of the project, effects would also be long term.

*3.14.2.3.4 Integrated temperature and habitat flow regime (#30a), Refined integrated temperature and habitat flow regime (#30b), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), and Continued Operation of Existing AFFs*

The magnitude of indirect effects from these measures would be minor and beneficial in the long term. The integrated temperature and habitat flow regime is referred back to under Alternatives 2A, 2B, 3A, 3B, and 4, and the revised integrated temperature and habitat flow regime is referred back to under Alternative 5. Using regulating outlets to discharge cold water is referred back to under Alternatives 2A, 2B, 3A, 3B, 4, and 5. Using water from the inactive and power pools to increase downstream river flows and continuing operation of existing AFFs are referred back to under all action alternatives. Passing water over the spillway in spring for fish passage is referred back to under Alternatives 2A, 2B, 3A, 3B, and 5.

Flow measures would improve fish habitat, and existing AFFs are operated to protect and enhance anadromous and resident fish species. Similar to the measures discussed above in Section 3.14.2.3.1, these measures would not directly affect recreation, but would improve fish habitat and passage over time, and could increase the population of native fish species available for recreational fishing in the long term. Benefits to fish habitat would primarily be to water temperature, but flow measures could also improve riparian vegetation, which would help reduce bank erosion and provide additional benefits to fish habitat by way of increased spawning areas and improved aquatic insect habitat. The improvement of riparian vegetation would also generally improve aesthetics and subsequently benefit the recreational experience. Further, higher stream flows support higher recreational carrying capacity: the number of anglers that can use the same stretch of river at once could increase (Duffield, Neher, and Brown 1992).

As such, these measures would have indirect, beneficial, minor effects to recreation in the long term.

##### *3.14.2.3.5 Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)*

The magnitude of effects from reducing minimum flows to Congressionally authorized minimum flow requirements would be moderate and beneficial at reservoirs and minor to moderate and adverse at rivers in the long term. These potential effects are determined below and referred back to under Alternative 1.

This measure would allow reservoirs to capture more spring runoff instead of releasing it to meet reservoir refill objectives. As a result of this measure, reservoirs would refill faster in the spring and reach their conservation season pool elevations earlier in the season. A full reservoir during the early parts of the season would improve the experience of both land- and water-based recreation, and it would also extend the recreational season. These beneficial effects would be noticeable, so they would be moderate in magnitude. While benefits would occur at reservoirs, there would be adverse effects to riverine recreation downstream of reservoirs. When dam outflows are reduced, reservoirs would fill faster, but river water levels would be lower. Lower river water levels could range from slightly noticeable to noticeable depending on the river, reach, and season, therefore effects would be minor to moderate in magnitude. Flows would change for the life of the project, making effects at both dams and rivers long term in duration. While exact visitation at rivers is unknown, visitation at reservoirs is higher than in rivers; therefore, the beneficial effects would be felt by more recreators at reservoirs than the adverse effects in rivers.

##### *3.14.2.3.6 Adapt Hatchery Program (#719)*

Adapting the hatchery program would have indirect, adverse, and negligible effects in the long term. Potential effects are determined below and referred back to under all action alternatives.

Hatchery production levels would be adjusted based on the efficacy of fish passage measures. USACE has mitigated the blocking of habitat of migratory fish by carrying out a program to produce and release hatchery UWR Chinook salmon, UWR steelhead, and trout in the WVS. Hatchery production levels would be decreased as the amount of accessible fish habitat resulting from fish passage measures increases. Similar to those discussed above in Section 3.14.2.3.1, this measure would not directly affect recreation, but would affect fish populations. Therefore, the effects would be indirect. Hatchery levels would not be decreased until improved fish passage is observed, so effects would be long term. Changes to recreation would not be noticeable, so adverse effects on recreational fishing would be negligible in magnitude.

##### *3.14.2.3.7 Structural improvements to reduce total dissolved gas (#174), Construct WTC towers (#105), Construct structural downstream fish passage (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFFs (#722)*

The magnitude of effects from improving structures to reduce TDG, constructing WTC towers and downstream passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would be negligible to moderate and adverse in the medium term (negligible to minor and adverse in the short term at Foster from constructing downstream passage infrastructure), and indirect, beneficial, and minor in the long term.

Potential effects from improving TDG structures are determined below and referred back to under Alternatives 1 and 4. Effects from constructing WTC towers, structural downstream fish passage infrastructure, and the Foster fish ladder temperature improvement are referred back to under Alternatives 1, 2A, 2B, 4, and 5. Effects from constructing AFFs are referred back to under all action alternatives.

These measures could involve the use of heavy-duty construction vehicles such as trucks, dozers, backhoes, and/or cranes, and would generally be more intensive projects than those described above in Sections 3.14.2.3.1 and 3.14.2.3.2. Construction could disturb recreators with noise and air emissions, traffic from hauling material, and could generally attract attention from changes in visual resources. Construction would be located next to the dams, all of which are immediately adjacent to at least one recreation area (primarily viewpoints and parks). Changes in the quality of recreation would range from not noticeable to noticeable, and increase proportionally with the proximity of the recreational facility to construction; therefore, adverse effects would range from negligible to moderate in magnitude. Changes in the quality of recreation would last the duration of the large construction project, so effects would be medium term. At Detroit and Lookout Point (as well as at Green Peter, under Alternative 1 only), the WTC towers would be designed to reduce TDG (i.e., no separate TDG structures would be developed). At these locations, there would be no separate construction effects from structural improvements to reduce TDG because these effects would be included with those of constructing the WTC towers themselves. Note that, at Foster under measure #392, improvements to the 'surface route structure' fish weir would be made, which is a modification of one of the dam's spillways. This would be a simpler and shorter construction project than those required for the downstream passage FSSs or FSCs and similar to those described in Section 3.14.2.3.1. Therefore, the effects from constructing downstream passage infrastructure at Foster would be adverse and negligible to minor in magnitude in the short term.

As described above in Section 3.14.2.3.1, these measures would not directly benefit recreation, but would improve fish habitat and passage over time, and could increase the population of native fish species available for recreational fishing in the long term.

Therefore, potential adverse direct effects would be negligible to moderate in magnitude and medium term in duration, and potential beneficial effects would be indirect, minor in magnitude, and long term in duration.

##### *3.14.2.3.8 Deeper fall reservoir drawdowns for downstream fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), and Fall Creek drawdown*

The magnitude of effects from drawing down reservoirs in the fall and spring for fish passage and the Fall Creek drawdown would be major, adverse, short term, and recur in the long term and indirect, beneficial, and minor in the long term. Effects would be negligible to major in magnitude and medium term in duration at Cougar for the construction required to drawdown to the diversion tunnel (DT). Potential effects from deeper fall drawdowns are determined below and referred back to under Alternatives 2A, 2B, 3A, 3B, and 5. Effects from spring reservoir drawdowns are referred back to under Alternatives 2B, 3A, 3B, and 5. Effects from the Fall Creek drawdown are referred back to under all alternatives.

As described in Section 3.14.2.1, the effects of drawdowns on visitation at reservoirs were quantified but the effects on visitation for riverine areas were not quantified. Instead, changes in alternative flows compared to the NAA are used as an indicator of general effects to recreation. It is assumed that changes in visitation and flows under each action alternative would occur as a result of deep drawdowns in the fall and spring; therefore, results of the model by reservoir and river/river reach are included below in the discussion by alternative. The magnitude of effects would range from negligible to major. The timing (season) and release (volumetric flow rate) of river flows downstream of WVS reservoirs would especially affect certain types of water-based riverine recreation, such as white-water rafting and fishing via boat[49]. For the purposes of this analysis, increases in river flows are generally assumed to benefit riverine recreation because of increased water availability. However, depending on the river reach and other factors such as season, substantial increases in river flows could potentially be dangerous for water-based riverine recreationists due to dangerous currents and waterborne hazards such as logs and trees (Chalmers 2019). Riverine recreationists should always check river conditions[50] before recreating, and caution should always be exercised during all recreational activities.

As described in Section 3.14.2.2, drawdowns would also affect the recreational experience. It is assumed that some recreationists will continue to visit the reservoir despite drastic changes in the WSE. In general, spring drawdowns would have a more noticeable effect on WSE and subsequent recreational quality than fall drawdowns. This is because spring inflows are paramount in reservoirs reaching their conservation season elevation (in May, typically. See Section 3.2, Hydrologic Processes, for more information), and these inflows would have to be released in order to draw-down reservoirs. Additionally, spring drawdowns would occur before the peak recreation season begins in May, which could shorten the recreation season. Fall drawdowns would begin during the peak recreation season, which also has the potential to shorten the season, although not as long as with spring drawdowns. After fall drawdowns, reservoirs would still have their typical winter and spring inflows in order to refill to their conservation season elevation. But for any drawdown, changes would be very noticeable due to the visual impact of the drawdown, which would substantially impact the recreational experience for recreationists that continue to visit the reservoir during drawdowns.

Reductions in visitation at some reservoirs and in recreational quality at all reservoirs would cause adverse effects to be major overall. Because drawdowns would last for approximately

[49] Rivers are commonly fished via drift boat, a type of small, non-motorized row boat. Drift boats are especially popular in shallow river reaches that are inaccessible by traditional motorized boats.
[50] Real-time river flow data are available via the USGS National Water Dashboard at https://dashboard.waterdata.usgs.gov/app/nwd/?region=lower48&aoi=default

three weeks out of the year and recur for the life of the project, adverse effects would be long-term recurring in duration. Additionally, drawdowns would improve fish passage, which would have minor and indirect beneficial effects on recreation by enhancing fishing over time. The beneficial effects would be long term in duration.

Note that, at the Cougar Reservoir, drawdowns to the DT would require dam modifications, including the construction of a tower and bridge. The construction would be similar to that described above in Section 3.14.2.3.7: relatively intensive construction could disturb recreators with noise and air emissions, traffic from hauling material, and could generally attract attention from changes in visual resources. The construction would also require an extended deep drawdown so that concrete placement could occur in dry conditions. Potential adverse effects from the construction (i.e., concrete placement) that would require the fall drawdown to Cougar's DT would be negligible to major in magnitude and medium term in duration.

Therefore, potential adverse effects from construction would be negligible to moderate in magnitude and medium term in duration (for Cougar DT drawdowns only), and major in magnitude in the short term and long-term recurring in duration (for all drawdowns). Potential beneficial effects would be indirect, minor in magnitude, and long term in duration.

#### *3.14.2.3.9 Suite of near-term operations*

The suite of near-term operations includes 16 measures at various locations to provide relief for ESA-listed species until they can be replaced with the measures in the Preferred Alternative. The magnitude of effects from the suite of near-term operations would be moderate to major, adverse, and recur in the long term, and be indirect, beneficial, and minor in the long term. Potential effects from the suite of near-term operations are determined below and referred back to under Alternatives 2A, 2B, 3A, 3B, 4, and 5.

Several actions within the suite of near-term operations would have similar effects to recreation as the measures discussed above in Section 3.14.2.3.8. Deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and the delayed refills at Fall Creek and Cougar (which would lengthen the effects of the deep drawdowns), would result in very noticeable visual impacts and could shorten the recreational season. Drawdowns and drawdowns with delayed refills would have major adverse effects on the recreational experience. Additionally, refill would be delayed at Foster despite not including a drawdown. This could have noticeable visual impacts and shorten the recreation season, although not as drastically as the deep drawdowns. The adverse effects at Foster would be moderate.

The other actions in the suite of near-term operations, such as RO prioritization, the outplanting plan, and using spillways to improve TDG, temperature, and fish passage would have indirect benefits as discussed above in Section 3.14.2.3.1. These actions would not directly affect recreation, but would improve fish habitat and passage over time, and could increase the population of native fish species available for recreational fishing in the long term. Thus, these measures would have indirect, beneficial, and minor effects to recreational fishing in the long term.

#### *3.14.2.4 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue with no changes. As discussed under Section 3.14.2.1, the availability of water-based recreation and the quality of both water- and land-based recreation is dependent on WSE. Under the NAA, WSEs would not change from how they are currently maintained. Conservation pool elevations would continue to be maintained high until early September, at which point the reservoirs with lower recreation demand would be used first to meet summer flow requirements (measured at Albany and Salem). Water from the Detroit, Fern Ridge, and Foster reservoirs would continue to be used last because of their recreational importance.

The NAA includes water quality, flow, and upstream and downstream passage operations. Water quality operations include using the spillway to release warm surface water and manage downstream temperatures at Foster and Detroit; strategically using outlets to meet temperature targets (when possible) at Fall Creek; operating the Cougar WTC tower to manage downstream temperatures; spreading spill across the Dexter and Big Cliff spillways to reduce TDG; and discharging water through the powerhouse at power-producing dams to reduce TDG. Flow operations include meeting the 2008 BiOp targets basin-wide and augmenting flows using the inactive or power pool at Green Peter. Flow operations would primarily benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience. Higher stream flows would also increase riverine recreational carrying capacities. Fish passage operations include passing fish over the Foster spillway and through the lowest RO at Fall Creek (Fall Creek drawdown). The recurring drawdown at Fall Creek would have major, adverse, short-term and long-term recurring effects like those discussed above in Section 3.14.2.3.8.

Operation, maintenance, repair, replacement, and rehabilitation would continue to adversely impact the recreational experience at recreation areas immediately adjacent the dams and effects would increase proportionally with the recreational facility’s proximity to these activities. As described above in Section 3.14.2.3.3, effects to the recreational experience would be would be adverse and negligible to minor in magnitude in the short and long term for scheduled/routine maintenance, and be adverse and negligible to moderate in the medium and long term for major maintenance and rehabilitation due to increases in noise, air emissions, visual intrusions, and traffic.

The NAA is the baseline for which visitation estimates are made; therefore, there would be no effects to average annual visits or average annual benefits (Appendix K– Recreation Technical Report). The extent of effects would be local because impacts to the quality of recreation would be confined to the dam/reservoir. Ongoing operation and routine and non-routine maintenance activities would occur in the short, medium, and long term.

##### *3.14.2.4.1 Climate Change*

As discussed in Appendices F1 and F2 (Qualitative Assessment of Climate Change Impacts and Supplemental Climate Change Information, respectively), climate change is expected to result in wetter winters (where more precipitation falls as rain rather than snow), less snowpack, drier summers, increased air and water temperatures, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the O&M of the WVS over the next 30 years. These factors would exacerbate adverse effects to recreation.

Because recreation is largely dependent on water due to activities such as boating, fishing, and swimming, it is affected by both water quantity and quality. Precipitation and temperature trends would decrease water quantity. As discussed in Appendix B, Hydrology and Hydraulics, higher winter reservoir in-flows due to more precipitation falling as rain would not be stored until approximately February 1, when WVS reservoirs begin adhering to their rule curves. This would decrease the chance of reservoirs reaching the pool levels they had in previous years, which could shorten the recreational season and limit recreational availability because water (and boat ramps) could become unavailable sooner in the year. Other trends would contribute to these adverse effects: less snowpack would decrease spring reservoir inflows, and drier, hotter summers (in terms of both air and water temperatures) would increase evaporation rates and further limit water quantity. Increased temperatures, less snowpack, and more winter rain would result in lower summer river flows downstream of WVS projects, which would shorten the recreational season and decrease the quality of riverine recreation. Further, increased occurrence and severity of wildfires would substantially degrade air quality during wildfire season, which would not only decrease the quality of the recreational experience due to adverse visual impacts, but could put recreationists at risk of health effects due to wildfire smoke, which is comprised of gaseous pollutants, hazardous air pollutants (HAPs), water vapor, and particulate matter[51] (PM). PM is a main component of wildfire smoke and the principal public health threat (EPA 2021e). The severity of effects would depend on the size and proximity of the fire(s) (OHA No Date-a). During times when regional air quality from wildfire smoke is poor, the majority of recreationists are likely to forego outdoor recreation; recreational areas or part or all of the reservoir(s) may be closed.

Climate change-driven effects on water quality would also have effects on the quality of the recreational experience, although these effects would be less direct than those that would shorten the recreational season, limit recreational availability, and affect air quality as described above. Higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity, elevated concentrations of contaminants such as mercury, and increased occurrence of harmful algal blooms (HABs). Increased occurrence of HABs would decrease dissolved oxygen (DO) concentrations and could adversely affect recreational fishing. Both elevated turbidity and increased occurrence of HABs would also contribute to adverse effects to the recreational experience through visual impacts.

Because climate change would affect water quantity and both air and water quality, effects to recreation would be direct. The water quality, flow, and upstream and downstream passage

[51] "Particulate matter" also referred to as particles or particle pollution, is a general term for a mixture of solid and liquid droplets suspended in the air.

measures of the NAA would result in negligible to major adverse effects from ongoing operation, maintenance, repair, replacement, and rehabilitation, as well as recurring drawdowns as described above. Climate change would not exacerbate effects from operation, maintenance, repair, replacement, and rehabilitation, but would exacerbate the effects from the Fall Creek drawdowns due to recurring reductions in water quantity. The NAA would also provide indirect benefits to recreational fishing by reducing TDG and normalizing temperatures at dams such as Big Cliff, Cougar, Detroit, Dexter, Fall Creek, Foster, Green Peter; however, the effects would be negligible as they would not be enough to avoid jeopardizing ESA-listed species. Climate change would further reduce these benefits by adversely impacting water quality. Over time, effects would increase in severity as water levels get lower, temperatures get higher, and air and water quality worsen. The effects of the measures under the NAA in combination with climate change on recreation would be regional in extent, minor in magnitude, but could become moderate or more severe over the life of the project; and long term.

#### *3.14.2.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, restoring upstream and downstream passage at drop structures, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from reducing minimum flows to congressionally authorized minimum flows would be minor to moderate in magnitude in the long term and localized in extent at rivers. Adverse effects from improving structures to reduce TDG, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would range from negligible to moderate in the medium term and be local in extent. At Foster Dam only, potential adverse effects from constructing downstream fish passage infrastructure would range from negligible to minor in the short term and be local in extent from the fish weir modifications. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the Fall Creek drawdown would be major, adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, restoring upstream and downstream passage at drop structures, augmenting instream flows using the inactive or power pools, continued operation of AFFs, adapting the hatchery program, improving structures to reduce TDG, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, constructing AFFs, and Fall Creek drawdowns would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent. Direct beneficial effects from reducing minimum flows to congressionally authorized minimum flows would moderate in magnitude and local in extent at reservoirs.

Under Alternative 1, adverse effects would be less severe than alternatives 2A, 2B, 3A, 3B, 4, and 5. This is because Alternative 1 includes only one recurring drawdown and does not include the suite of near-term operations. Additionally, Alternative 1 is the only action alternative that would result in direct benefits to recreation by promoting reservoir storage (i.e., from reducing minimum flows to congressionally authorized minimum flows). All other alternatives would only result in indirect benefits to recreation over time by improving recreational fishing.

###### *3.14.2.5.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Restore upstream and downstream passage at drop structures (#639)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 1, restoring upstream and downstream passage at drop structures would occur at Fern Ridge, but its effects are discussed generally under riverine recreation because recreational facilities at Fern Ridge would be virtually unaffected.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas are discussed below.

**<u>Big Cliff Dam and Reservoir</u>**

Effects would be negligible from the augmentation of gravel below the Big Cliff Dam and Reservoir because it does not have a USACE recreational facility: the only USACE recreational facility nearby is a viewpoint above the lake near the Detroit Dam, more than two miles away. While this viewpoint is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail where visitors can see osprey and neotropical migrant songbirds, construction activities would be far enough away that noise would not scare birds away and decrease the recreational experience for bird watchers. None of these measures would occur near the viewpoint: augmenting gravel below dams would occur in the river below the Big Cliff Dam where there are no adjacent recreational facilities (effects to riverine recreation are discussed below). If minor structural improvements are required for the maintenance of existing or new fish release sites, any adjacent recreational facilities would experience minor effects.

**Blue River Dam and Reservoir**

The Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to its proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from these projects.

**Cougar Dam and Reservoir**

The Cougar Dam is adjacent to two viewpoints (one on either side of the dam), which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. This reservoir is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail where visitors can spot American peregrine falcons around the cliffs above the reservoir. There is also a large nesting colony of Cliff Swallows southwest of the dam, where visitors can also see Violet-green and Northern Rough-winged Swallows. Visitors may also see Rock Wren, Canyon Wren, Bald Eagle, Belted Kingfisher, and waterfowl such as Bufflehead, goldeneyes, and Common and Hooded Mergansers in the fall (The Oregon Birding Trails Working Group No Date). Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be more than one and two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because adding gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

Augmenting gravel below dams, maintaining or altering revetments, and restoring upstream and downstream passage at drop structures would occur in and on rivers, and would affect the experience for recreationists near the construction projects. As discussed above in Section

3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects to fishing would be indirect and minor in magnitude in the long term.

*3.14.2.5.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 1, providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Green Peter. As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The severity of short-term effects on the quality of recreation would depend on the proximity of the recreational facilities to construction. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Fern Ridge Dam and Reservoir**

The Fern Ridge Dam is adjacent to Kirk and Orchard Point Parks, which would experience minor effects due to their proximity to where Pacific lamprey passage infrastructure would be provided. More specifically, increases in noise and visual intrusions would be slightly noticeable to hunters, bird-watchers, and hikers at Kirk Park. Kirk Park is one of 11 management units within the Fern Ridge Wildlife Area, which covers approximately half of the reservoir and consists of wetlands, wet prairie, oak and mixed woodlands, upland prairie, and freshwater aquatic habitats. Effects to sailing (the large surface area and consistent winds make Fern Ridge one of the best sailing reservoirs in Oregon) would not occur; effects would not be visible, audible, or otherwise felt on the reservoir because Pacific lamprey passage infrastructure would be provided on the downstream side of the dam. Effects would likely be negligible at other recreational areas like Perkins and Zumwalt parks, which would be over two miles away from construction.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience minor effects due to their proximity to where Pacific lamprey passage infrastructure would be provided. Other recreational facilities, such as the Thistle Creek Boat Ramp, Whitcomb Creek Park, and Quartzville Group Camp would experience negligible effects as these facilities would be over two miles away from construction.

*3.14.2.5.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above in Section 3.14.2.3.3, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

*3.14.2.5.4 Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), and Continued Operation of Existing AFFs*

Under Alternative 1, augmenting instream flows by using the inactive pool would occur at Blue River, Cottage Grove, Dorena, and Fall Creek; augmenting instream flows by using the power pool would occur at Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point; and continued operation of existing AFFs would occur at Dexter, Cougar, Foster, Fall Creek, and Minto at Big Cliff.

As discussed above in Section 3.14.2.3.4, beneficial effects would be indirect and minor in magnitude in the long term. Effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS.

*3.14.2.5.5 Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)*

Under Alternative 1, reducing minimum flows to Congressionally authorized minimum flow requirements would occur basin-wide. As discussed above in Section 3.14.2.3.5, potential effects would be moderate and beneficial at reservoirs and minor to moderate and adverse at rivers, both in the long term. The effects would be local in extent because they would be limited to the dam/reservoir or river.

*3.14.2.5.6 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above in Section 3.14.2.3.6 (and all action alternatives), potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

*3.14.2.5.7 Structural improvements to reduce total dissolved gas (#174), Construct WTC towers (#105), Construct structural downstream fish passage infrastructure (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFFs (#722)*

Under Alternative 1, improving structures to reduce TDG would occur at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point; constructing WTC towers would occur at Detroit, Green Peter, and Lookout Point; constructing downstream fish passage infrastructure would occur at Detroit, Foster, Green Peter, and Lookout Point; the fish ladder temperature improvement would occur at Foster; and constructing AFFs would occur at Green Peter.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. At Foster Dam, potential adverse effects would range from negligible to minor in the short term from the fish weir modifications. Potential beneficial effects would be indirect and minor in magnitude in the long term. The short- and medium-term effects would be local in extent because they would be limited to the dam/reservoir. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Detroit Dam and Reservoir**

The Detroit Dam is adjacent to one viewpoint, which would experience moderate effects due to its proximity to where downstream fish passage and a WTC tower would be constructed. This dam is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail where visitors can see osprey and neotropical migrant songbirds. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Detroit Reservoir, such as the Mongold Day Use Area and Detroit Lake State Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Lookout Point and Dexter dams and reservoirs**

The Lookout Point Dam is adjacent to Meridian and Orchard parks, which would experience moderate effects due to their proximity to where downstream fish passage and a WTC tower would be constructed. Dexter Reservoir, which is directly below Lookout Point Dam, is a designated stop along the McKenzie Loop of the Willamette Valley Birding Trail where visitors can see migratory and resident songbirds and osprey and eagles along the northeast shoreline. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Lookout Point Reservoir, such as Landax Park and Signal Point Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Cougar, Foster, and Green Peter dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where structures would be improved to reduce TDG at Cougar and Foster, downstream fish passage infrastructure would be constructed and the fish ladder temperature improvement would occur at Foster, and an AFF would be constructed at Green Peter. The recreational experience at recreational facilities directly adjacent to Cougar, Foster, and Green Peter dams would be moderately affected. The effects on specific recreational facilities closest to and farthest from Cougar, Foster, and Green Peter dams (and therefore the construction sites) are noted above under Sections 3.14.2.5.1 and 3.14.2.5.2.

#### *3.14.2.5.8 Fall Creek drawdown*

Under all alternatives, drawdowns would continue to recur at Fall Creek. As discussed under Section 3.14.2.3.8, effects would be major, adverse, short term, and recur in the long term; and be indirect, beneficial, and minor in the long term.

Potential beneficial effects to visitation under this alternative are shown below in Table 3.14-39. Effects would be minor and beneficial at Fall Creek with approximately 4,000 more annual visitors and a 2 percent increase in total annual benefits. Fall Creek is unique from most other WVS reservoirs in that it has an unusually long boat ramp (North Shore), which extends to elevation 689 feet and would not close due to drawdowns under any of the alternatives. Thus, visitation would not decrease. As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), adverse effects to the recreational experience of recreationists that continue to visit the reservoir during drawdowns would be major. Adverse effects on the recreational experience would be short term and recur in the long term. Beneficial effects from improved recreational fishing would be indirect, minor in magnitude and long term at Fall Creek. The full results of visitation estimates are presented in Appendix K — Recreation Technical Report.

**Table 3.14-39. Visitation and Economic Benefits at Fall Creek Under Alternative 1**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Fall Creek | 3,000 | 1.43% | Minor beneficial |

**<u>Riverine Recreation</u>**

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown) drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation (Appendix K — Recreation Technical Report). Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would also benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-40.

**Table 3.14-40. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 1**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | 0.94% | Negligible beneficial |
| | Spring/Summer average | 1.13% | Minor beneficial |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |
| | Spring/Summer average | 0.13% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | 0.77% | Negligible beneficial |
| | Spring/Summer average | -0.05% | Negligible adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | 0.38% | Negligible beneficial |
| | Spring/Summer average | 2.01% | Minor beneficial |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | 1.13% | Minor beneficial |
| | Spring/Summer average | -0.90% | Negligible adverse |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | 2.03% | Minor beneficial |
| | Spring/Summer average | -5.57% | Moderate adverse |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | 4.11% | Minor beneficial |
| | Spring/Summer average | -12.08% | Moderate adverse |
| **Upper Willamette River** | | | |
| Albany, Eugene, and Harrisburg averages | Fall/Winter average | 0.45% | Negligible beneficial |
| | Spring/Summer average | 1.90% | Minor beneficial |

##### *3.14.2.5.9 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 1 would improve reservoir storage (water quantity) and improve water quality by reducing TDG and normalizing temperatures. Therefore, the effects of climate change on recreation would be less severe under Alternative 1 than any other alternative, including the NAA. Climate change in combination with the measures under Alternative 1 would have direct, adverse, negligible to minor, regional effects to recreation in the long term.

#### ***3.14.2.6 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Under Alternative 2A, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would range from negligible to moderate in the medium term and be local in extent. At Foster Dam only, potential adverse effects from constructing downstream fish passage infrastructure would range from negligible to minor in the short term and be local in extent from the fish weir modifications. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the deeper fall reservoir drawdown, Fall Creek drawdown, and suite of near-term operations would be major (moderate at Foster from the near-term operations), adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, augmenting instream flows using the inactive and power pools, continued operation of AFFs, integrated habitat and flow regime, adapting the hatchery program, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, constructing AFFs, deeper fall reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be minor in magnitude. These measures would all occur in the long term and be regional in extent.

Under Alternative 2A, adverse effects would be more severe than Alternative 1 but less severe than Alternatives 2B, 3A, 3B, 4, and 5 due to the number of recurring drawdowns.

##### *3.14.2.6.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), and Maintenance of existing and new fish release sites above dams (#726)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas are discussed below.

**Big Cliff Dam and Reservoir**

As discussed above in Section 3.14.2.3.1, effects would be negligible at Big Cliff Dam and Reservoir because augmenting gravel below dams and maintaining or altering revetments would occur in rivers, and Big Cliff Dam and Reservoir does not have designated recreational facilities within two miles of the river.

**Blue River Dam and Reservoir**

As discussed above in Section 3.14.2.3.1, the Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to its proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from construction.

**Cougar Dam and Reservoir**

As discussed above in Section 3.14.2.3.1, the Cougar Dam is adjacent to two viewpoints, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be over one or two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because augmenting gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

As discussed above in Section 3.14.2.3.1, Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks, and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

As discussed above in Section 3.14.2.3.1, augmenting gravel below dams and maintaining or altering revetments would occur in and on rivers, and would affect the experience for recreationists at or near the construction projects. Potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects would be indirect and minor in magnitude in the long term.

*3.14.2.6.2 Provide Pacific Lamprey Passage and Infrastructure (#52)*

Under Alternative 2A, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The magnitude of effects to specific recreation areas are discussed below at Green Peter.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. Other recreational facilities, such as the Thistle Creek Boat Ramp and Whitcomb Creek Park, would experience negligible effects as these facilities would be over two miles away from construction.

*3.14.2.6.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above in Section 3.14.2.3.3, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

##### *3.14.2.6.4 Integrated temperature and habitat flow regime (#30a), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), and Continued Operation of Existing AFFs*

Under Alternative 2A, the integrated habitat and flow regime would occur basin-wide; using ROs to discharge colder water would occur at Green Peter, augmenting instream flows by using the inactive pool would occur at Blue River and Fall Creek; augmenting instream flows by using the power pool would occur at Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point; passing water over the spillway in the spring for fish passage would occur at Green Peter, and continuing operations of existing AFFs would occur at Dexter, Cougar, Foster, Fall Creek, and Minto at Big Cliff.

As discussed above in Section 3.14.2.3.4, beneficial effects would be indirect and minor in magnitude in the long term. Effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS.

##### *3.14.2.6.5 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above in Section 3.14.2.3.6, potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

##### *3.14.2.6.6 Construct WTC towers (#105), Construct structural downstream fish passage infrastructure (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFFs (#722)*

Under Alternative 2A, constructing a WTC tower would occur at Detroit; constructing structural downstream fish passage infrastructure would occur at Cougar, Detroit, Foster, and Lookout Point; the fish ladder temperature improvement would occur at Foster; and constructing AFFs would occur at Green Peter.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. At Foster Dam, potential adverse effects would range from negligible to minor in the short term from the fish weir modifications. The short- and medium-term effects would be local in extent because they would be limited to the dam/reservoir. Potential beneficial effects would be indirect and minor in magnitude in the long term. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Detroit Dam and Reservoir**

The Detroit Dam is adjacent to one viewpoint, which would experience moderate effects due to its proximity to where downstream fish passage and a WTC tower would be constructed. This dam is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail where visitors can see osprey and neotropical migrant songbirds. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Detroit Reservoir, such as the Mongold Day Use Area and Detroit Lake State Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Lookout Point Dam and Reservoirs**

The Lookout Point Dam is adjacent to Meridian and Orchard parks, which would experience moderate effects due to their proximity to where downstream fish passage and a WTC tower would be constructed. Dexter Reservoir, which is directly below Lookout Point Dam, is a designated stop along the McKenzie Loop of the Willamette Valley Birding Trail where visitors can see migratory and resident songbirds and osprey and eagles along the northeast shoreline. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Lookout Point Reservoir, such as Landax Park and Signal Point Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Cougar, Foster, and Green Peter dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where downstream fish passage infrastructure would be constructed at Cougar, the fish ladder temperature improvement would occur at Foster, and an AFF would be constructed at Green Peter. The recreational experience at recreational facilities directly adjacent to Cougar, Foster, and Green Peter dams would be moderately affected. The specific recreational facilities closest to and farthest from Cougar, Foster, and Green Peter dams (and therefore the construction sites) are noted above under Sections 3.14.2.6.1 and 3.14.2.6.2.

*3.14.2.6.7 Deeper fall reservoir drawdowns for fish passage (#40), Fall Creek drawdown*

Under all action alternatives, the Fall Creek drawdown would continue to recur, and under Alternative 2A, a deeper fall reservoir drawdown would occur at Green Peter. Potential adverse effects to visitation under this alternative are shown below in Table 3.14-41. The full list of effects to visitation are available in Appendix K — Recreation Technical Report. Quantified effects would be minor and adverse at Green Peter with approximately 6,000 fewer annual visitors and a 4 percent decrease in total annual benefits; and minor and beneficial at Fall Creek with approximately 4,000 more annual visitors and a 2 percent increase in total annual benefits. Fall Creek is unique from most other WVS reservoirs in that it has an unusually long boat ramp

(North Shore) that extends to elevation 689 feet, and does not close under any of the alternatives.

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), adverse effects to the experience of recreationists that continue to visit the reservoir during drawdowns would be major. Adverse effects on visitation, benefits, and the recreational experience would be short term and recur in the long term. Beneficial effects from improved recreational fishing would be indirect, minor in magnitude and long term, and regional in extent.

**Table 3.14-41. Visitation and Economic Benefits at Green Peter and Fall Creek Under Alternative 2A**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Green Peter | -6,000 | -3.65% | Minor adverse |
| Fall Creek | 4,000 | 1.80% | Minor beneficial |

<u>**Riverine Recreation**</u>

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown) drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-42. Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience.

**Table 3.14-42. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 2A**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | 0.91% | Negligible beneficial |
| | Spring/Summer average | -1.07% | Minor adverse |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| | Spring/Summer average | 0.14% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | 1.24% | Minor beneficial |
| | Spring/Summer average | -1.17% | Minor adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | 3.36% | Minor beneficial |
| | Spring/Summer average | -4.84% | Minor adverse |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | 0.64% | Negligible beneficial |
| | Spring/Summer average | 1.70% | Minor beneficial |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | -0.93% | Negligible adverse |
| | Spring/Summer average | 6.44% | Moderate beneficial |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | -3.70% | Minor adverse |
| | Spring/Summer average | 18.65% | Moderate beneficial |
| **Upper Willamette River** | | | |
| Albany, Eugene, and Harrisburg averages | Fall/Winter average | 2.09% | Minor beneficial |
| | Spring/Summer average | -2.79% | Minor adverse |

#### *3.14.2.6.8 Suite of near-term operations*

The suite of near-term operations would be included in Alternative 2A. As discussed in Section 3.14.2.3.9, effects from the deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and the delayed refills at Fall Creek and Cougar (which would lengthen the effects of the deep drawdowns) would be major, adverse, short term, and recur in the long term. Effects of the delayed refill (with no deep drawdown) at Foster would be moderate, adverse, and recur in the long term. Effects of all other near-term operations would be indirect, beneficial, and minor in the long term. The adverse effects would be local in extent because they would be limited to the dam/reservoir, and beneficial effects to recreational fishing would be regional in extent because they would be perceived throughout the WVS.

##### *3.14.2.6.9 Climate Change*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 2A would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. In general, climate change would exacerbate effects from deep drawdowns: as temperatures increase and snowpacks decline, reservoirs may struggle to reach their conservation pool elevations over time, which would indirectly and adversely affect recreation in the long term. Climate change in combination with the measures under Alternative 2A would have direct, adverse, minor to moderate, regional effects to recreation in the long term.

#### *3.14.2.7 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (using diversion tunnel at CGR)*

Under Alternative 2B, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would range from negligible to moderate in the medium term and be local in extent. At Foster Dam only, potential adverse effects from constructing downstream fish passage infrastructure would range from negligible to minor in the short term and be local in extent from the fish weir modifications. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be major (moderate at Foster from the near-term operations), adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, augmenting instream flows using the inactive and power pools, integrated habitat and flow regime, continued operation of AFFs, adapting the hatchery program, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, constructing AFFs, deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent.

Under Alternative 2B, adverse effects would be the same as Alternative 5, more severe than Alternatives 1 and 2A, but less severe than Alternatives 3A, 3B, or 4 due to the number of recurring drawdowns.

*3.14.2.7.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), and Maintenance of existing and new fish release sites above dams (#726)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, maintenance of existing and new fish release sites would occur basin-wide.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas are discussed below.

**Big Cliff Dam and Reservoir**

As discussed above under the other action alternatives, effects would be negligible at Big Cliff Dam and Reservoir because augmenting gravel below dams and maintaining or altering revetments would occur in rivers, and Big Cliff Dam and Reservoir does not have designated recreational facilities within two miles of the river.

**Blue River Dam and Reservoir**

As discussed above under the other action alternatives, the Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from construction.

**Cougar Dam and Reservoir**

As discussed above under the other action alternatives, the Cougar Dam is adjacent to two viewpoints, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be over one or two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because augmenting gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

As discussed above under the other action alternatives, Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks, and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

As discussed above under the other action alternatives, augmenting gravel below dams and maintaining or altering revetments would occur in and on rivers, and would affect the experience for recreationists at or near the construction projects. Potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects would be indirect and minor in magnitude in the long term.

##### *3.14.2.7.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 2B, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The magnitude of effects to specific recreation areas at Green Peter are discussed below.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. Other recreational facilities, such as the Thistle Creek Boat Ramp and Whitcomb Creek Park, would experience negligible effects as these facilities would be over two miles away from construction.

##### *3.14.2.7.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above under the other action alternatives, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

*3.14.2.7.4 Integrated temperature and habitat flow regime (#30a), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), and Continued Operation of Existing AFFs*

Under Alternative 2B, the integrated habitat and flow regime would occur basin-wide; using Ros to discharge colder water would occur at Green Peter, augmenting instream flows by using the inactive pool would occur at Blue River and Fall Creek; augmenting instream flows by using the power pool would occur at Detroit, Green Peter, Hills Creek, and Lookout Point; passing water over the spillway in the spring for fish passage would occur at Green Peter, and continuing operations of existing AFFs would occur at Dexter, Cougar, Foster, Fall Creek, and Minto at Big Cliff.

As discussed above in Section 3.14.2.3.4, beneficial effects would be indirect and minor in magnitude in the long term. Effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS.

*3.14.2.7.5 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above under the other action alternatives, potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

*3.14.2.7.6 Construct WTC towers (#105), Construct structural downstream fish passage infrastructure (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFFs (#722)*

Under Alternative 2B, as under Alternative 2A, constructing a WTC tower would occur at Detroit; constructing structural downstream fish passage infrastructure would occur at Detroit, Foster, and Lookout Point (this would also occur at Cougar under Alternative 2A); the fish ladder temperature improvement would occur at Foster; and constructing an AFF would occur at Green Peter.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. At Foster Dam, potential adverse effects would range from negligible to minor in the short term from the fish weir modifications. Potential beneficial effects would be indirect and minor in magnitude in the long term. The short- and medium-term effects would be local in extent because they would be limited to the dam/reservoir. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Detroit Dam and Reservoir**

The Detroit Dam is adjacent to one viewpoint, which would experience moderate effects due to its proximity to where downstream fish passage and a WTC tower would be constructed. This dam is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail where visitors can see osprey and neotropical migrant songbirds. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Detroit Reservoir, such as the Mongold Day Use Area and Detroit Lake State Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Lookout Point Dam and Reservoirs**

The Lookout Point Dam is adjacent to Meridian and Orchard parks, which would experience moderate effects due to their proximity to where downstream fish passage would be constructed. Dexter Reservoir, which is directly below Lookout Point Dam, is a designated stop along the McKenzie Loop of the Willamette Valley Birding Trail where visitors can see migratory and resident songbirds and osprey and eagles along the northeast shoreline. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Lookout Point Reservoir, such as Landax Park and Signal Point Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Foster and Green Peter dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility’s proximity to where downstream fish passage infrastructure would be constructed and the fish ladder temperature improvement would occur at Foster, and where an AFF would be constructed at Green Peter. The recreational experience at recreational facilities directly adjacent to Foster and Green Peter dams would be moderately affected. The specific recreational facilities closest to and farthest from Foster and Green Peter dams (and therefore the construction sites) are noted above under Sections 3.14.2.7.1 and 3.14.2.7.2.

##### *3.14.2.7.7 Deeper fall reservoir drawdowns for fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), and Fall Creek drawdown*

Under all action alternatives, the Fall Creek drawdown would continue to recur, and under Alternative 2B, fall reservoir drawdowns would occur at Cougar (to the DT) and Green Peter and a spring drawdown would occur at Cougar (to the DT). Potential adverse and beneficial effects to visitation under this alternative are shown below in Table 3.14-43. The full list of effects to visitation are available in Appendix K — Recreation Technical Report. Quantified effects would be major and adverse at Cougar with approximately 17,000 fewer annual visitors and a 42 decrease in average annual benefits; minor and adverse at Green Peter with approximately 6,000 fewer annual visitors and a 4 percent decrease in total annual benefits; and minor and beneficial at Fall Creek with 3,000 more annual visitors and a 2 percent increase in total annual benefits. Fall Creek is unique from most other WVS reservoirs in that it has an unusually long boat ramp (North Shore) that extends to elevation 689 feet, and does not close under any of the alternatives.

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), adverse effects to the experience of recreationists that continue to visit the reservoir during drawdowns would be major. Adverse effects on visitation, benefits, and the recreational experience would be short term and recur in the long term. Beneficial effects from improved recreational fishing would be minor in magnitude, long term and regional in extent. Because drawing down Cougar Reservoir to the DT would require the construction of a tower and bridge in-the-dry, Alternative 2B would also have negligible to major effects in the medium term at Cougar from construction. The changes in the quality of recreation would increase proportionally with the recreational facility's proximity to the construction. Effects to the experience at recreational facilities directly adjacent to Cougar Dam would be major. The specific recreational facilities closest to and farthest from Cougar Dam (and therefore the construction sites) are noted above under Section 3.14.2.7.1.

**Table 3.14-43. Visitation and Economic Benefits at Cougar, Green Peter, and Fall Creek Under Alternative 2B**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Cougar | -17,000 | -42.38% | Major adverse |
| Green Peter | -6,000 | -3.65% | Minor adverse |
| Fall Creek | 3,000 | 1.67% | Minor beneficial |

<u>**Riverine Recreation**</u>

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-44. Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience.

**Table 3.14-44. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 2B**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | 0.80% | Negligible beneficial |
| | Spring/Summer average | -0.20% | Negligible adverse |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |
| | Spring/Summer average | 0.14% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | -1.29% | Minor adverse |
| | Spring/Summer average | -1.89% | Minor adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | 1.72% | Minor beneficial |
| | Spring/Summer average | -1.48% | Minor adverse |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | -0.27% | Negligible adverse |
| | Spring/Summer average | 2.00% | Minor beneficial |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | -0.90% | Negligible adverse |
| | Spring/Summer average | 6.40% | Moderate beneficial |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | -3.70% | Minor adverse |
| | Spring/Summer average | 18.65% | Moderate beneficial |
| **Upper Willamette River** | | | |
| Albany, Eugene, and Harrisburg averages | Fall/Winter average | 0.58% | Negligible beneficial |
| | Spring/Summer average | -1.26% | Minor adverse |

##### *3.14.2.7.8 Suite of near-term operations*

The suite of near-term operations would be included in Alternative 2B. As discussed in Section 3.14.2.3.9, effects from the deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and the delayed refills at Fall Creek and Cougar (which would lengthen the effects of the deep drawdowns) would be major, adverse, short term, and recur in the long term. Effects of the delayed refill (with no deep drawdown) at Foster would be moderate, adverse, and recur in the long term. Effects of all other near-term operations would be indirect, beneficial, and minor in the long term. The adverse effects would be local in extent because they would be limited to the dam/reservoir, and beneficial effects would be regional in extent because benefits to recreational fishing would be perceived throughout the WVS.

##### *3.14.2.7.9 Climate Change*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam's DT). As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 2B would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. Due to one more deep drawdown than Alternative 2A, climate change would exacerbate the effects of Alternative 2B more than Alternatives 1 or 2A. But overall, the effects would be the same as under Alternative 2A; climate change in combination with the measures under Alternative 2B would have direct, adverse, minor to moderate, regional effects to recreation in the long term.

#### ***3.14.2.8 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)***

Under Alternative 3A, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from using the spillway for surface spill would range from negligible to moderate in magnitude; be short term in duration; and local in extent at Blue River and Hills Creek only. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from constructing AFFs would range from negligible to moderate in the medium term and be local in extent. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be major (moderate at Foster from the near-term operations), adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, using the spillway for surface spill, augmenting instream flows using the inactive and power pools, integrated habitat and flow regime, continued operation of AFFs, adapting the hatchery program, constructing AFFs, deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent.

Under Alternative 3A, adverse effects would be less severe than Alternative 3B but more severe than Alternatives 1, 2A, 2B, 4, and 5 due to the number of recurring drawdowns.

*3.14.2.8.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Use spillway for surface spill in summer (#721)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, maintenance of existing and new fish release sites would occur basin-wide; and under Alternative 3A, using the spillway for surface spill would occur at Blue River, Detroit, Foster, Green Peter, Hills Creek, and Lookout Point.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude (negligible to moderate at Blue River and Hills Creek when using the surface spillway for summer spill) in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. Under Alternative 3A, there would be adverse effects from using the spillway for surface spill at Blue River and Hills Creek only because using the spillway would require channel modifications.

**Big Cliff Dam and Reservoir**

As discussed above under the other action alternatives, effects would be negligible at Big Cliff Dam and Reservoir because augmenting gravel below dams and maintaining or altering revetments would occur in rivers, and Big Cliff Dam and Reservoir does not have designated recreational facilities within two miles of the river (effects to riverine recreation are discussed below).

**Blue River Dam and Reservoir**

As discussed above under the other action alternatives, the Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to its proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The viewpoint would also experience moderate effects due to its proximity the channel modifications required for using the spillway for surface spill. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from construction.

**Cougar Dam and Reservoir**

As discussed above under the other action alternatives, the Cougar Dam is adjacent to two viewpoints, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be more than one and two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because augmenting gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

As discussed above under the other action alternatives, Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks, and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Hills Creek Dam and Reservoir**

Hills Creek Dam is adjacent to two viewpoints (one on either side of the dam), which would experience moderate effects due to their proximity to where the channel would be modified to use the spillway for surface spill. This reservoir is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail, and noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. The 27-mile Middle Fork Willamette Trail also borders the Hills Creek Reservoir, and construction activities could decrease the experience for recreationists such as hikers, horseback riders, and mountain bikers. Other recreational facilities, such as the Packard Creek Campground and Bingham Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

As discussed above under the other action alternatives, augmenting gravel below dams and maintaining or altering revetments would occur in and on rivers, and would affect the experience for recreationists at or near the construction projects. Potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects would be indirect and minor in magnitude in the long term.

##### *3.14.2.8.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 3A, providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek.

As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. Other recreational facilities, such as the Thistle Creek Boat Ramp and Whitcomb Creek Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Blue River and Hills Creek dams and reservoirs**

As discussed above in Section 3.14.2.3.2, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where Pacific lamprey passage and infrastructure would be provided. The recreational experience at recreational facilities directly adjacent to Blue River and Hills Creek dams would experience minor effects. The specific recreational facilities closest to and farthest from Blue River and Hills Creek dams (and therefore the construction sites) are noted above under Section 3.14.2.8.1.

##### *3.14.2.8.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above under the other action alternatives, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

#### *3.14.2.8.4 Integrated temperature and habitat flow regime (#30a), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), and Continued Operation of Existing AFFs*

Under Alternative 3A, the integrated habitat and flow regime would occur basin-wide; using ROs to discharge colder water would occur at Detroit, Green Peter, and Lookout Point, augmenting instream flows by using the inactive pool would occur at Blue River, Cottage Grove, Dorena, and Fall Creek; augmenting instream flows by using the power pool would occur at Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point; passing water over the spillway in the spring for fish passage would occur at Big Cliff, Dexter, Falls Creek, Green Peter, and Hills Creek, and continuing operations of existing AFFs would occur at Dexter, Cougar, Foster, Fall Creek, and Minto at Big Cliff.

As discussed above in Section 3.14.2.3.4, beneficial effects would be indirect and minor in magnitude in the long term. Effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS.

#### *3.14.2.8.5 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above under the other action alternatives, potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

#### *3.14.2.8.6 Construct AFFs (#722)*

Under Alternative 3A, constructing AFFs would occur at Blue River, Green Peter, and Hills Creek.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. Potential beneficial effects would be indirect and minor in magnitude in the long term. The medium-term effects would be local in extent because they would be limited to the dam/reservoir. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Blue River, Green Peter, and Hills Creek dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where AFFs would be constructed. The recreational experience at recreational facilities directly adjacent to Blue River, Green Peter, and Hills Creek dams would experience moderate effects. The specific recreational facilities closest to and farthest from Blue River, Green Peter, and Hills Creek dams (and therefore the construction sites) are noted above under Sections 3.14.2.8.1 and 3.14.2.8.2.

##### *3.14.2.8.7 Deeper fall reservoir drawdowns for fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), and Fall Creek drawdown*

Under all action alternatives, the Fall Creek drawdown would continue to recur, and under Alternative 3A, fall reservoir drawdowns would occur at Blue River, Cougar (to the RO), Detroit, Green Peter, Hills Creek, and Lookout Point, and spring reservoir drawdowns would occur at Cougar (to the RO), Detroit, and Lookout Point.

Potential adverse and beneficial effects to visitation under this alternative are shown below in Table 3.14-45. The full list of effects to visitation are available in Appendix K — Recreation Technical Report. The quantitative effects would be major and adverse at Cougar, Lookout Point, and Detroit, with approximately 17,000, 40,000, and 63,000 fewer annual visitors and an approximately 42, 48, and 43 percent decrease in total annual benefits (respectively). Effects would be minor and adverse at Green Peter with approximately 6,000 fewer annual visitors and an approximately 4 percent decrease in total annual benefits. Quantified effects would be negligible and beneficial at Hills Creek with no or little change in visitation (due to rounding) and a less than one percent increase in total annual benefits; negligible and adverse at Blue River with no or little change in visitation (due to rounding) and a less than one percent decrease in total annual benefits; and minor and beneficial at Fall Creek with 3,000 more annual visitors and a 2 percent increase in total annual benefits.

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), adverse qualitative effects to the experience of recreationists that continue to visit the reservoir during drawdowns would be major. Adverse effects on visitation, benefits, and the recreational experience would be short term and recur in the long term. Indirect, beneficial effects from improved recreational fishing would be minor in magnitude, long term, and regional in extent.

**Table 3.14-45. Visitation and Economic Benefits at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point Under Alternative 3A**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Cougar | -17,000 | -42.38% | Major adverse |
| Green Peter | -6,000 | -3.65% | Minor adverse |
| Hills Creek[1] | 0 | 0.21% | Negligible beneficial |
| Lookout Point | -40,000 | -48.43% | Major adverse |
| Detroit | -63,000 | -40.11% | Major adverse |
| Blue River[1] | 0 | -0.71% | Negligible adverse |
| Fall Creek | 2,000 | 1.17% | Minor beneficial |

[1] Some locations show no change in the number of average annual visits due to rounding.

**Riverine Recreation**

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-46. Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience.

**Table 3.14-46. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 3A**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | -0.21% | Negligible adverse |
| | Spring/Summer average | 5.35% | Minor beneficial |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |
| | Spring/Summer average | 0.14% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | -1.58% | Minor adverse |

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| | Spring/Summer average | -0.64% | Negligible adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | -1.69% | Minor adverse |
| | Spring/Summer average | -2.87% | Minor adverse |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | -2.76% | Minor adverse |
| | Spring/Summer average | -0.43% | Negligible adverse |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | -4.59% | Minor adverse |
| | Spring/Summer average | 0.97% | Negligible beneficial |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | -3.70% | Minor adverse |
| | Spring/Summer average | 18.65% | Moderate beneficial |
| **Upper Willamette River** | | | |
| Albany, Eugene, and Harrisburg averages | Fall/Winter average | -2.04% | Minor adverse |
| | Spring/Summer average | -3.06% | Minor adverse |

#### *3.14.2.8.8 Suite of near-term operations*

The suite of near-term operations would be included in Alternative 3A. As discussed in Section 3.14.2.3.9, effects from the deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and the delayed refills at Fall Creek and Cougar (which would lengthen the effects of the deep drawdowns) would be major, adverse, short term, and recur in the long term. Effects of the delayed refill (with no deep drawdown) at Foster would be moderate, adverse, and recur in the long term. Effects of all other near-term operations would be indirect, beneficial, and minor in the long term. The adverse effects would be local in extent because they would be limited to the dam/reservoir, and beneficial effects would be regional in extent because benefits to recreational fishing would be perceived throughout the WVS.

#### *3.14.2.8.9 Climate Change*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 3A would improve water quality by normalizing temperatures. It would also provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3A would include the less-deep drawdown to the Cougar RO. Due to the number of deep drawdowns, climate change would exacerbate the effects of Alternative 3A more than under Alternatives 1, 2A, 2B, 4, and 5, and less than Alternative 3B (but not appreciably). Climate change in combination with the measures under Alternative 3A would have direct, adverse, minor to moderate, regional effects to recreation in the long term.

#### *3.14.2.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)*

Under Alternative 3B, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from using the spillway for surface spill would range from negligible to moderate in magnitude; be short term in duration; and local in extent at Blue River and Hills Creek only. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from constructing AFFs (and the deeper fall drawdowns to Cougar's DT from dam modifications) would range from negligible to moderate in the medium term and be local in extent. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be major (moderate at Foster from the near-term operations), adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, using the spillway for surface spill, augmenting instream flows using the inactive and power pools, integrated habitat and flow regime, continued operation of AFFs, adapting the hatchery program, constructing AFFs, deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent.

Under Alternative 3B, adverse effects would be more severe than any other action alternative because it would involve the most recurring drawdowns, including the deeper drawdown to Cougar's DT. Alternative 3B would only be slightly more adverse than Alternative 3A as they would involve the same number of recurring drawdowns, but Alternative 3B would also require the construction of the tower and bridge in order to draw-down Cougar Reservoir to the DT.

##### *3.14.2.9.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Use spillway for surface spill in summer (#721)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, maintenance of existing and new fish release sites would occur basin-wide; and under Alternative 3B, using the spillway for surface spill would occur at Blue River, Detroit, Foster, Green Peter, Hills Creek, and Lookout Point.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude (negligible to moderate at Blue River and Hills Creek when using the surface spillway for summer spill) in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. Under Alternative 3B, there would be adverse effects from using the spillway for surface spill at Blue River and Hills Creek only because using the spillway would require channel modifications.

**Big Cliff Dam and Reservoir**

As discussed above under the other action alternatives, effects would be negligible at Big Cliff Dam and Reservoir because augmenting gravel below dams and maintaining or altering revetments would occur in rivers, and Big Cliff Dam and Reservoir does not have designated recreational facilities within two miles of the river.

**Blue River Dam and Reservoir**

As discussed above under the other action alternatives, the Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to its proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The viewpoint would also experience moderate effects due to its proximity the channel modifications required for using the spillway for surface spill. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from construction.

**Cougar Dam and Reservoir**

As discussed above under the other action alternatives, the Cougar Dam is adjacent to two viewpoints, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be over one or two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because augmenting gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

As discussed above under the other action alternatives, Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks, and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Hills Creek Dam and Reservoir**

Hills Creek Dam is adjacent to two viewpoints (one on either side of the dam), which would experience moderate effects due to their proximity to where the channel would be modified to use the spillway for surface spill. This reservoir is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail, and noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. The 27-mile Middle Fork Willamette Trail also borders the Hills Creek Reservoir, and construction activities could decrease the experience for recreationists such as hikers, horseback riders, and mountain bikers. Other recreational facilities, such as the Packard Creek Campground and Bingham Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

As discussed above under the other action alternatives, augmenting gravel below dams and maintaining or altering revetments would occur in and on rivers, and would affect the recreational experience at or near the construction projects. Potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects would be indirect and minor in magnitude in the long term.

#### *3.14.2.9.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 3B, providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek.

As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. Other recreational facilities, such as the Thistle Creek Boat Ramp and Whitcomb Creek Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Blue River and Hills Creek dams and reservoirs**

As discussed above in Section 3.14.2.3.2, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where Pacific lamprey passage and infrastructure would be provided. The recreational experience at recreational facilities directly adjacent to Blue River and Hills Creek dams would experience minor effects. The specific recreational facilities closest to and farthest from Blue River and Hills Creek dams (and therefore the construction sites) are noted above under Section 3.14.2.9.1.

*3.14.2.9.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above under the other action alternatives, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

*3.14.2.9.4 Integrated temperature and habitat flow regime (#30a), Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166), Augment instream flows by using the inactive pool (#718), Augment instream flows by using the power pool (#304), Pass water over spillway in spring for fish passage (#714), and Continued Operation of Existing AFFs*

Under Alternative 3B, the integrated habitat and flow regime would occur basin-wide; using ROs to discharge colder water would occur at Detroit, Green Peter, and Lookout Point, augmenting instream flows by using the inactive pool would occur at Blue River, Cottage Grove, Dorena, and Fall Creek; augmenting instream flows by using the power pool would occur at Detroit, Green Peter, Hills Creek, and Lookout Point; passing water over the spillway in the spring for fish passage would occur at Big Cliff, Detroit, Dexter, and Lookout Point, and continuing operations of existing AFFs would occur at Dexter, Cougar, Foster, Fall Creek, and Minto at Big Cliff.

As discussed above in Section 3.14.2.3.4, beneficial effects would be indirect and minor in magnitude in the long term. Effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS.

*3.14.2.9.5 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above under the other action alternatives, potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

*3.14.2.9.6 Construct AFFs (#722)*

Under Alternative 3B, constructing AFFs would occur at Blue River, Green Peter, and Hills Creek.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. Potential beneficial effects would be indirect and minor in magnitude in the long term. The medium-term effects would be local in extent because they would be limited to the dam/reservoir. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Blue River Green Peter, and Hills Creek dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where AFFs would be constructed. The recreational experience at recreational facilities directly adjacent to Blue River, Green Peter, and Hills Creek dams would experience moderate effects. The specific recreational facilities closest to and farthest from Blue River, Green Peter, and Hills Creek dams (and therefore the construction sites) are noted above under Sections 3.14.2.9.1 and 3.14.2.9.2.

*3.14.2.9.7 Deeper fall reservoir drawdowns for fish passage (#40), Spring reservoir drawdown for downstream fish passage (#720), and Fall Creek drawdown*

Under all action alternatives, the Fall Creek drawdown would continue to recur, and under Alternative 3B, fall reservoir drawdowns would occur at Blue River, Cougar (to the DT), Detroit, Green Peter, Hills Creek, and Lookout Point, and spring reservoir drawdowns would occur at Cougar (to the DT), Green Peter, and Hills Creek.

Potential adverse and beneficial effects to visitation under this alternative are shown below in Table 3.14-47. The full list of effects to visitation are available in Appendix K — Recreation

Technical Report. Quantified effects would be major and adverse at Blue River, Cougar, Green Peter, and Hills Creek with approximately 6,000, 17,000, 93,000, and 9,000 fewer annual visitors and an approximately 36, 42, 55, and 35 percent decrease in total annual benefits (respectively). Quantified effects would be moderate and adverse at Lookout Point with approximately 7,000 fewer annual visitors and an approximately 8 percent decrease in total annual benefits; minor and adverse at Detroit with approximately 8,000 fewer visitors and an approximately 5 percent decrease in total annual benefits, and minor and beneficial at Fall Creek with 3,000 more annual visitors and a 1.36 percent increase in total annual benefits.

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), adverse effects to the experience of recreationists that continue to visit the reservoir during drawdowns would be major. Adverse effects on visitation, benefits, and the recreational experience would be short term and recur in the long term. Because drawing down Cougar Reservoir to the DT would require the construction of a tower and bridge in-the-dry, Alternative 3B would also have negligible to major effects in the medium term at Cougar. The changes in the quality of recreation would increase proportionally with the recreational facility's proximity to the construction. Effects to the recreational experience at facilities directly adjacent to Cougar Dam would be major. The specific recreational facilities closest to and farthest from Cougar Dam (and therefore the construction sites) are noted above under Section 3.14.2.9.1. Beneficial indirect effects from improved recreational fishing would be minor in magnitude, long term, and regional in extent.

**Table 3.14-47. Visitation and Economic Benefits at Blue River, Cougar, Detroit, Fall Creek, Green Peter, Hills Creek, and Lookout Point Under Alternative 3B**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Cougar | -17,000 | -42.38% | Major adverse |
| Green Peter | -93,000 | -55.45% | Major adverse |
| Hills Creek | -10,000 | -26.17% | Major adverse |
| Lookout Point | -7,000 | -8.26% | Moderate adverse |
| Detroit | -8,000 | -4.99% | Minor adverse |
| Blue River | -6,000 | -36.10% | Major adverse |
| Fall Creek | 3,000 | 1.36% | Minor beneficial |

**<u>Riverine Recreation</u>**

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-48. Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience.

**Table 3.14-48. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 3B**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | -0.67% | Negligible adverse |
| | Spring/Summer average | 1.40% | Minor beneficial |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |
| | Spring/Summer average | 0.14% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | -2.03% | Minor adverse |
| | Spring/Summer average | -3.06% | Minor adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | -3.57% | Minor adverse |
| | Spring/Summer average | 6.06% | Moderate beneficial |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | -2.40% | Minor adverse |
| | Spring/Summer average | -1.24% | Minor adverse |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | -2.79% | Minor adverse |
| | Spring/Summer average | 6.93% | Moderate beneficial |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | -4.41% | Minor adverse |
| | Spring/Summer average | -5.28% | Moderate adverse |
| **Upper Willamette River** | | | |
| | Fall/Winter average | -2.33% | Minor adverse |

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| Albany, Eugene, and Harrisburg averages | Spring/Summer average | -1.96% | Minor adverse |

#### *3.14.2.9.8 Suite of near-term operations*

The suite of near-term operations would be included in Alternative 3B. As discussed in Section 3.14.2.3.9, effects from the deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and the delayed refills at Fall Creek and Cougar (which would lengthen the effects of the deep drawdowns) would be major, adverse, short term, and recur in the long term. Effects of the delayed refill (with no deep drawdown) at Foster would be moderate, adverse, and recur in the long term. Effects of all other near-term operations would be indirect, beneficial, and minor in the long term. The adverse effects would be local in extent because they would be limited to the dam/reservoir, and beneficial effects would be regional in extent because benefits to recreational fishing would be perceived throughout the WVS.

#### *3.14.2.9.9 Climate Change*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 3B would improve water quality by normalizing temperatures and provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3B would include the deeper drawdown to the Cougar DT. Due to the number of deep drawdowns and the deeper drawdown at Cougar, climate change would exacerbate the effects of Alternative 3B more than all other action alternatives. Climate change in combination with the measures under Alternative 3B would have direct, adverse, minor to moderate, regional effects to recreation in the long term.

### ***3.14.2.10 Alternative 4 – Structures-Based Fish Passage Alternative***

Under Alternative 4, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintaining existing and new fish release sites, restoring upstream and downstream passage at drop structures, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration, and local in extent.

Adverse effects from improving structures to reduce TDG, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would range from negligible to moderate in the medium term and be local in extent. At Foster Dam only, potential adverse effects from constructing downstream fish passage infrastructure would range from negligible to minor in the short term and be local in extent from the fish weir modifications. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the Fall Creek drawdown would be major, adverse, short term and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed below.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, restoring upstream and downstream passage at drop structures, augmenting instream flows using the inactive or power pools, continued operation of AFFs, adapting the hatchery program, improving structures to reduce TDG, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, constructing AFFs, and Fall Creek drawdowns would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent. Under Alternative 4, adverse effects would be more severe than Alternatives 1, 2A, 2B and 5, but less severe than Alternatives 3A and 3B due to the number of recurring drawdowns, inclusion of the near-term operations, and number of medium-term construction measures.

###### *3.14.2.10.1 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Restore upstream and downstream passage at drop structures (#639)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 4 (and Alternative 1), restoring upstream and downstream passage at drop structures would occur at Fern Ridge, but its effects are discussed generally under riverine recreation because recreational facilities at Fern Ridge would be virtually unaffected.

As discussed above in Section 3.14.2.3.1, potential adverse effects would range from negligible to minor in magnitude in the short term, and beneficial effects would be indirect and minor in magnitude in the long term. The short-term effects would be local in extent because they would be limited to the dam/reservoir or river. The long-term effects would be regional in extent because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas are discussed below.

**Big Cliff Dam and Reservoir**

As discussed above under the other action alternatives, effects would be negligible at Big Cliff Dam and Reservoir because augmenting gravel below dams and maintaining or altering revetments would occur in rivers, and Big Cliff Dam and Reservoir does not have designated recreational facilities within two miles of the river.

**Blue River Dam and Reservoir**

As discussed above under the other action alternatives, the Blue River Dam and Reservoir is adjacent to one viewpoint, which would experience minor effects due to its proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. The viewpoint would also experience moderate effects due to its proximity to the channel modifications required for using the spillway for surface spill. The Mona and Lookout campgrounds would experience negligible effects as these facilities would be over three miles away from construction.

**Cougar Dam and Reservoir**

As discussed above under the other action alternatives, the Cougar Dam is adjacent to two viewpoints, which would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Other recreational facilities, such as Echo Park and the Slide Creek and Sunnyside campgrounds, would experience negligible effects as these facilities would be over one or two miles away from construction, respectively. The Delta Campground is approximately two miles downstream of the Cougar Dam and is closed indefinitely due to the Holiday Farm wildfire. Because augmenting gravel would occur on and in the rivers below dams, the Delta Campground would experience minor effects if it reopened and construction work occurred in close proximity.

**Foster Dam and Reservoir**

As discussed above under the other action alternatives, Foster Dam is adjacent to Lakeshore and Andrew S. Wiley parks, and Edgewater Park and Marina; and about a half mile from Shea Point. These facilities would experience minor effects due to their proximity to where gravel would be augmented below the dam and potentially from the maintenance of existing and new fish release sites. Lewis Creek and Sunnyside parks would experience negligible effects as these facilities would be over two miles away from construction.

**Riverine Recreation**

Augmenting gravel below dams, maintaining or altering revetments, and restoring upstream and downstream passage at drop structures would occur in and on rivers, and would affect the experience for recreationists at or near the construction projects. As discussed above under the other action alternatives, potential adverse effects would range from negligible to minor in magnitude in the short term: minor to a recreator passing by the project location, and negligible as the distance from the project location increases. Beneficial effects would be indirect and minor in magnitude in the long term.

### *3.14.2.10.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 4, providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Hills Creek. As discussed above in Section 3.14.2.3.2, potential adverse effects would range from negligible to minor in magnitude in the short term. Effects would be local in extent because they would be limited to the dam/reservoir. The severity of short-term effects on the quality of recreation would depend on the proximity of the recreational facilities to construction. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Fern Ridge Dam and Reservoir**

The Fern Ridge Dam is adjacent to Kirk and Orchard Point Parks, which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. More specifically, increases in noise and visual intrusions would be slightly noticeable to hunters, bird-watchers, and hikers at Kirk Park. Kirk Park is one of 11 management units within the Fern Ridge Wildlife Area, which covers approximately half of the reservoir and consists of wetlands, wet prairie, oak and mixed woodlands, upland prairie, and freshwater aquatic habitats. Effects to sailing (the large surface area and consistent winds make Fern Ridge one of the best sailing reservoirs in Oregon) would not occur; effects would not be visible, audible, or otherwise felt on the reservoir because lamprey passage infrastructure would be provided on the downstream side of the dam. Effects would likely be negligible at other recreational areas like Perkins and Zumwalt parks, which would be over two miles away from construction.

**Hills Creek Dam and Reservoir**

Hills Creek Dam is adjacent to two viewpoints (one on either side of the dam), which would experience minor effects due to their proximity to where Pacific lamprey passage and infrastructure would be provided. This reservoir is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail, and noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. The 27-mile Middle Fork Willamette Trail also borders the Hills Creek Reservoir, and construction activities could decrease the experience for recreationists such as hikers, horseback riders, and mountain bikers. Other recreational facilities, such as the Packard Creek Campground and Bingham Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

### *3.14.2.10.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide.

As discussed above under the other action alternatives, potential adverse effects from scheduled/routine maintenance would be negligible to minor in magnitude in the short and long term. Potential adverse effects from major maintenance and rehabilitation would be negligible to moderate in magnitude in the medium and long term. The short-, medium-, and long-term effects would be local in extent because they would be limited to the dam/reservoir or river.

*3.14.2.10.4 Adapt Hatchery Program (#719)*

Under all action alternatives, adapting the hatchery program would occur at all hatcheries (Marion Forks, South Santiam, Leaburg, McKenzie, and Willamette). As discussed above under the other action alternatives, potential effects would be indirect, adverse, and negligible in the long term. Effects would be regional in extent because indirect effects to recreational fishing would occur throughout the WVS.

*3.14.2.10.5 Structural improvements to reduce total dissolved gas (#174), Construct WTC towers (#105), Construct structural downstream fish passage infrastructure (#392), Foster Fish Ladder Temperature Improvement (#479), and Construct AFFs (#722)*

Under Alternative 4, improving structures to reduce TDG would occur at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point; constructing WTC towers would occur at Detroit, Hills Creek, and Lookout Point; constructing structural downstream fish passage infrastructure would occur at Cougar, Detroit, Foster, Hills Creek, and Lookout Point; the fish ladder temperature improvement would occur at Foster; and constructing an AFF would occur at Hills Creek.

As discussed above in Section 3.14.2.3.7, potential adverse effects would range from negligible to moderate in the medium term. At Foster Dam, potential adverse effects would range from negligible to minor in the short term from the fish weir modifications. Potential beneficial effects would be indirect and minor in magnitude in the long term. The short- and medium-term effects would be local in extent because they would be limited to the dam/reservoir. The long-term effects would be regional because indirect benefits to recreational fishing would be perceived throughout the WVS. The magnitude of effects to specific recreation areas are discussed below at each dam and reservoir.

**Detroit Dam and Reservoir**

The Detroit Dam is adjacent to one viewpoint, which would experience moderate effects due to its proximity to where downstream fish passage and a WTC tower would be constructed. This dam is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail where visitors can see osprey and neotropical migrant songbirds. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Detroit Reservoir, such as the Mongold Day Use Area and Detroit Lake State Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Green Peter Dam and Reservoir**

Green Peter Dam is adjacent to Billings Park and a viewpoint, which would experience moderate effects due to their proximity to where structures would be improved to reduce TDG. Other recreational facilities, such as the Thistle Creek Boat Ramp and Whitcomb Creek Park, would experience negligible effects as these facilities would be over two miles away from construction.

**Dexter and Lookout Point dams and reservoirs**

The Dexter Dam is adjacent to Dexter and Lowell Parks, and the Lookout Point Dam is adjacent to Meridian and Orchard parks, which would experience moderate effects due to their proximity to where a WTC tower would be constructed at Lookout Point and structures would be improved to reduce TDG at Dexter. Dexter is a designated stop along the McKenzie Loop of the Willamette Valley Birding Trail where visitors can see migratory and resident songbirds and osprey and eagles along the northeast shoreline. Noise from construction activities could scare birds away and decrease the recreational experience for bird watchers. Recreational facilities on Lookout Point Reservoir, such as Landax Park and Signal Point Boat Ramp, would experience negligible effects as these facilities would be over two miles away from construction.

**Cougar, Foster, and Hills Creek dams and reservoirs**

As discussed above in Section 3.14.2.3.7, changes in the quality of recreation would increase proportionally with the recreational facility's proximity to where structures would be improved to reduce TDG at Cougar and Foster; downstream fish passage would be constructed at Cougar, Foster, and Hills Creek; WTC towers would be constructed at Hills Creek; the fish ladder temperature improvement would occur at Foster; and an AFF would be constructed at Green Peter. The recreational experience at recreational facilities directly adjacent to Cougar, Foster, and Hills Creek dams would be moderately affected. The specific recreational facilities closest to and farthest from Cougar, Foster, and Hills Creek dams (and therefore the construction sites) are noted above under Sections 3.14.2.10.1 and 3.14.2.10.2.

### *3.14.2.10.6 Fall Creek drawdown*

Under all action alternatives, drawdowns would continue to recur at Fall Creek. As discussed under Section 3.14.2.3.8, effects would be major, adverse, and recur in the long term, and be indirect, beneficial, and minor in the long term.

Potential beneficial effects to visitation under this alternative are shown below in Table 3.14-49. Effects would be minor and beneficial at Fall Creek with approximately 4,000 more annual visitors and a 2 percent increase in total annual benefits. As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown), qualitative adverse effects to the recreational experience for those that continue to visit the reservoir during drawdowns would be major. Adverse effects on the recreational experience would be short-term and long-term recurring. Beneficial effects from improved recreational fishing would be indirect, minor in magnitude and long term at Fall Creek. The full list of effects to visitation are available in Appendix K — Recreation Technical Report.

[Note to USACE: Why would Fall Creek experience benefits to visitation during drawdowns under this alternatives and all other action alternatives? Said otherwise, why would there be an increase of 4,000 annual visits and a 1.95 percent increase in annual benefits, corresponding to minor beneficial effects? Drawdowns to all other reservoirs besides Hills Creek would have adverse effects on visitation.]

**Table 3.14-49. Visitation and Economic Benefits at Fall Creek Under Alternative 4**

| Dam/Reservoir | Change in Average Annual Visits | Percent Change in Total Annual Benefits | Magnitude of effects |
|---|---|---|---|
| Fall Creek | 4,000 | 1.95% | Minor beneficial |

**<u>Riverine Recreation</u>**

As discussed above in Section 3.14.2.3.8 (Deeper fall reservoir drawdowns for downstream fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and Fall Creek drawdown) drawing down reservoirs would have effects on river flows downstream of WVS reservoirs. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation (Appendix K — Recreation Technical Report). Higher stream flows would increase riverine recreational carrying capacities and benefit activities such as white-water rafting. Increases in water flows would also benefit fish habitat through water temperature, but could also improve riparian vegetation which would generally improve aesthetics and subsequently benefit the riverine recreational experience. Visitation estimates are not made for riverine areas because of the many access points available to recreators. Instead, changes in alternative flows compared to the NAA at eleven gage locations throughout the study area are used as an indicator of general effects to recreation. The magnitude of effects to specific rivers or river reaches are shown below in Table 3.14-50.

**Table 3.14-50. Percent Change in Flows and Magnitude of Effects on the Coast Fork Willamette, Long Tom, McKenzie, Middle Fork Willamette, Middle Willamette, North Santiam, South Santiam, and Upper Willamette rivers Under Alternative 4**

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| **Coast Fork Willamette River** | | | |
| Goshen | Fall/Winter average | 0.86% | Negligible beneficial |
| | Spring/Summer average | -0.45% | Negligible adverse |
| **Long Tom River** | | | |
| Monroe | Fall/Winter average | -0.02% | Negligible adverse |

| River Gage | Season | Percent Change in Flows from No Action | Magnitude of effects |
|---|---|---|---|
| | Spring/Summer average | 0.14% | Negligible beneficial |
| **McKenzie River** | | | |
| Vida | Fall/Winter average | 1.26% | Minor beneficial |
| | Spring/Summer average | -1.20% | Minor adverse |
| **Middle Fork Willamette River** | | | |
| Jasper | Fall/Winter average | 3.42% | Minor beneficial |
| | Spring/Summer average | -4.97% | Minor adverse |
| **Middle Willamette River** | | | |
| Salem | Fall/Winter average | 0.36% | Negligible beneficial |
| | Spring/Summer average | 0.87% | Negligible beneficial |
| **North Santiam River** | | | |
| Jefferson and Mehama average | Fall/Winter average | -1.07% | Minor adverse |
| | Spring/Summer average | 4.81% | Minor beneficial |
| **South Santiam River** | | | |
| Waterloo | Fall/Winter average | -3.57% | Minor adverse |
| | Spring/Summer average | 11.87% | Moderate beneficial |
| **Upper Willamette River** | | | |
| Albany, Eugene, and Harrisburg averages | Fall/Winter average | 2.11% | Minor beneficial |
| | Spring/Summer average | -2.82% | Minor adverse |

##### *3.14.2.10.7 Suite of near-term operations*

The suite of near-term operations would be included in Alternative 4. As discussed in Section 3.14.2.3.9, effects from the deep drawdowns at Cougar, Lookout Point, and Fall Creek, and the delayed refills at Foster and Cougar would be major, adverse, and recur in the long term, and be indirect, beneficial, and minor in the long term. The effects would be local in extent because they would be limited to the dam/reservoir.

##### *3.14.2.10.8 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 4 would improve water quality by reducing TDG and normalizing temperatures. Alternative 4 would not improve reservoir storage like Alternative 1, but it would feature fewer drawdowns than under all other action alternatives. Therefore, climate change would exacerbate the effects of Alternative 4 more than Alternative 1, but less than Alternatives 2A, 2B, 3A, 3B, and 5. Climate change in combination with the measures under Alternative 4 would have direct, adverse, negligible to minor, regional effects to recreation in the long term.

#### *3.14.2.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 is similar to Alternative 2B but includes the *refined* integrated habitat and flow regime (#30b), rather than the integrated habitat and flow regime (#30a). This measure would not have adverse effects to the quality of the recreational experience. The inclusion of measure #30b would result in less than 0.5 percent changes in total annual benefits for reservoirs with recurring drawdowns between Alternatives 2B and 5. The full results of visitation estimates are presented in Appendix K — Recreation Technical Report. Therefore, the magnitude of adverse effects of Alternative 5 would be identical to those of Alternative 2B. Due to inclusion of the *refined* integrated habitat and flow regime, indirect benefits to recreation would be greater than Alternative 2B, but not appreciably. Differences in benefits would likely be unnoticeable.

Under Alternative 5, adverse effects from augmenting gravel below dams, maintaining or altering revetments, maintenance of existing and new fish release sites, and providing Pacific lamprey passage and infrastructure would range from negligible to minor in magnitude; be short term in duration; and local in extent. Adverse effects from operation, maintenance, repair, replacement, and rehabilitation would range from negligible to moderate in magnitude; be short, medium, and long term in duration and local in extent. Adverse effects from constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, and constructing AFFs would range from negligible to moderate in the medium term and be local in extent. At Foster Dam only, potential adverse effects from constructing downstream fish passage infrastructure would range from negligible to minor in the short term and be local in extent from the fish weir modifications. Adverse effects from adapting the hatchery program would be negligible in magnitude in the long term and regional in extent. Adverse effects from the deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be major (moderate at Foster from the near-term operations), adverse, short term, and recur in the long term. The severity of short- and medium-term effects from construction on the quality of recreation (due to increases in noise levels, air emissions, and traffic as well as visual intrusions) would be dependent on the proximity of the recreator or recreational facilities to the project area. The magnitude of effects to specific recreation areas at each dam and reservoir and riverine areas in general due to construction projects are discussed under Alternative 2B.

Indirect beneficial effects from augmenting gravel below dams, maintaining or altering revetments, augmenting instream flows using the inactive and power pools, refined integrated habitat and flow regime, continued operation of AFFs, adapting the hatchery program, constructing WTC towers and downstream fish passage infrastructure, the Foster fish ladder temperature improvement, constructing AFFs, deeper fall reservoir drawdowns, spring reservoir drawdowns, Fall Creek drawdowns, and suite of near-term operations would be minor in magnitude. The effects of these measures would all occur in the long term and be regional in extent.

Under Alternative 5, adverse effects would be the same as Alternative 2B, more severe than Alternatives 1, and 2A, but less severe than Alternatives 3A, 3B, or 4 due to the number of recurring drawdowns. Alternative 5's climate resilience would be the same as Alternative 2B.

##### *3.14.2.11.1 Climate Change*

Alternative 5 is essentially the same as 2B. As discussed above in Section 3.14.2.4.1, climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 5 would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. Due to one more deep drawdown than Alternative 2A, climate change would exacerbate the effects of Alternative 5 more than Alternatives 1 or 2A. But overall, the effects would be the same as under Alternative 2A and 2B; climate change in combination with the measures under Alternative 5 would have direct, adverse, minor to moderate, regional effects to recreation in the long term.

#### ***3.14.2.12 Conclusion***

The action alternatives in order of least to most severe adverse effects to recreation would be: 1, 2A, 2B/5, 4, 3A, and 3B.

Severity of adverse effects to recreation is primarily driven by the number of recurring drawdowns that would occur under each measure, and secondarily, by the number of construction projects, particularly those that are medium-term and of moderate magnitude. All recurring drawdowns would have short and long term, major, adverse effects from the visual impacts to both water- and land-based recreationists. Further, recurring drawdowns would make boat ramps unusable sooner in the season for launching motorized boats, and depending on whether drawdowns began in the fall or spring, would shorten the overall recreational season. The near-term operations include recurring drawdowns and delayed refills, which would lengthen the effects of the drawdowns.

Alternative 1 would be the least severe because it would include only one recurring drawdown and would not include the suite of near-term operations. Alternative 1 is the only action alternative that would result in direct benefits to recreation by promoting reservoir storage (i.e., from reducing minimum flows to congressionally authorized minimum flows). All other alternatives would only result in indirect benefits to recreation over time by improving recreational fishing. Alternative 2A would be more severe than Alternative 1, followed by Alternative 2B/5, due to the number of recurring drawdowns. While Alternative 4 would only include one recurring drawdown (like Alternative 1), it contains the most medium-term construction projects. Alternative 3A and 3B would be the most severe, but Alternative 3B would be slightly more severe than Alternative 3A due to the construction of the tower and bridge in order to draw-down Cougar Reservoir to the DT.

## 3.15 LAND USE

The area of analysis for land use is the entire Willamette River Basin (WRB) including all 12 of its sub-basins, even those that do not include a USACE dam. This section uses land *cover* as a surrogate for land *use* due to the large area of analysis and the availability of land cover data via National Land Cover Database (NLCD) satellite imagery. This section provides an overview of land use planning and land use in the WRB; a basin-wide comparison of land use in the 1970s and today; a summary of planned, current, and future development; and an overview of current land use by sub-basin.

Oregon's Department of Land Conservation and Development (DLCD) established a statewide land use planning program to conserve important natural resources; encourage efficient development; coordinate planning activities between governments; enhance the state's economy; and reduce public costs from poorly planned development (OSOS No Date). The statewide land use planning program protects land for farming, forestry, and wildlife habitat while discouraging development outside of urban growth boundaries, lines drawn on planning maps that limit further development. Oregon's land use planning is achieved through a set of 19 goals that include topics such as urbanization, recreational needs, natural resources, and agricultural lands. The statewide goals are implemented through local comprehensive planning; each city and county are required to have comprehensive plans consistent with the statewide goals (DLCD No Date).

The total land area of the WRB is approximately 11,200 square miles, or 7.2 million acres, making it Oregon's largest river basin. Developed land covers approximately 9 percent of the basin, primarily along the Interstate 5 (I-5) corridor, which runs north-south through the western third of the basin and roughly parallel to the Willamette River. A majority of the 3 million residents of the basin inhabit the cities of Portland, Salem, Corvallis, and Eugene along this corridor (NLCD 2019). Forest and agriculture are the most extensive land covers, making up roughly 59 percent and 21 percent of the basin, respectively (NLCD 2019). The WRB is considered the most agriculturally diverse region in Oregon with over 170 varieties of crops and livestock grown in the area. The most abundant crops are hay and pasture, tree fruits and nuts, berries including wine grapes, and an assortment of traditional vegetables such as beets and broccoli (ODA 2020).

### 3.15.1 Basin-wide Land Cover

In the 1930s, WRB prairies began to be converted to agriculture for growing forage and seed crops, mainly common rye grass (Robbins 2021). By the 1970s, approximately 22 percent of the basin had been converted to agriculture, with the remaining cover consisting of forest (70 percent), urban (5 percent), and other uses (3 percent). At this time, the most extensive crop coverages were grass seed (34 percent), wheat (20 percent), and other hay (18 percent), which were primarily grown in areas along the main stem Willamette River in the southern portion of the basin, or dispersed throughout the northern valley (Wentz et al., 1998).

Table 3.15-1 compares basin-wide land cover from the 1970s and 2019. Since the 1970s, developed land has increased by 50 percent, though this still accounts for less than 10 percent of the total land cover in the basin. About 11 percent of previously forested land in the WRB has been logged or burned by wildfires and replaced with shrub/scrub, grassland/herbaceous, and other land cover, though forest cover still accounts for over half of the basin (OFRI, 2014; Oregon Wild; 2019; NLCD, 2019). Agricultural cover has remained fairly constant at about 20 percent of the basin. Note that land cover classified as “other“ includes open water, barren land, woody wetlands, and emergent herbaceous wetlands. Developed - open space, - low intensity, and - high intensity were summed in order to achieve a single number for developed land cover. Deciduous, Evergreen, and mixed forests were summed to achieve a single number for forest land cover.

**Table 3.15-1. Willamette River Basin Land Cover**

| Coverage Type | 1970s | 2019 |
|---|---|---|
| Forest | 70% | 59% |
| Agriculture | 22% | 21% |
| Developed | 6% | 9% |
| Other | 2% | 11% |

### 3.15.2 Basin-wide Future Urban Development

Oregon’s statewide land use planning program minimizes urban sprawl by discouraging development outside of urban growth boundaries. Table 3.15-2 indicates that, according to 2017 zoning and urban growth boundary data, approximately 94 percent of Oregon’s planned urban space has already been developed, leaving 15,409 acres left for future development[52].

**Table 3.15-2. Willamette River Basin Planned, Current[53], and Future Development**

| Category | Area (acres) |
|---|---|
| Urban Growth Boundary[54] | 473,941 |
| Total Current Urban Development[2, 55, 5] | 445,548 |
| Future Urban Development [3, 4, 56] | 15,409 |

Source: DLCD 2017

[52] The availability of more detailed future land use information is limited by the workload required to analyze each municipality’s comprehensive plan for land use plans, goals, and zoning ordinances, which was deemed unnecessary for a programmatic O&M EIS.
[53] 2017 data was the most recent available data for both urban growth boundaries and zoning.
[54] Area calculated from the 2017 Oregon Department of Land Conservation and Development Urban Growth Boundaries GIS dataset.
[55] Includes Urban Residential, Urban Industrial, Urban Commercial, Mixed-Used Commercial and Residential, Public and Semi-Public Spaces, and Open Spaces.
[56] Area calculated from the 2017 Oregon Department of Land Conservation and Development Zoning GIS dataset.

### 3.15.3 Sub-basin Land Cover

This section describes current (2019) land cover in the WRB distinguished by sub-basin. Table 3.15-3 presents percentages of the dominant land cover types followed by discussion of each.

**Table 3.15-3. Willamette River Sub-Basin Land Cover**

| Basin/Sub-Basin[1] | Forest | Agriculture | Developed | Other[2] |
|---|---|---|---|---|
| WRB | 59% | 21% | 9% | 11% |
| Clackamas | 82% | 7% | 5% | 7% |
| Coast Fork Willamette | 74% | 9% | 4% | 14% |
| Lower Willamette[3] | 28% | 11% | 46% | 14% |
| McKenzie | 81% | 2% | 2% | 15% |
| Middle Fork Willamette | 87% | 2% | 1% | 10% |
| Middle Willamette[4] | 17% | 55% | 21% | 8% |
| Molalla-Pudding | 44% | 37% | 8% | 11% |
| North Santiam | 74% | 10% | 3% | 14% |
| South Santiam | 70% | 14% | 2% | 13% |
| Tualatin[5] | 39% | 27% | 24% | 9% |
| Upper Willamette | 38% | 41% | 11% | 11% |
| Yamhill | 46% | 36% | 7% | 10% |

[1] Note that subbasins may not total to 100% as values have been rounded to the nearest percent.

[2] Land cover classified as ‘other’ includes but is not limited to shrub/scrub, grassland/herbaceous, and wetland.

[3]Contains the majority of the Portland Metropolitan Area.

[4]Contains the Salem Metropolitan Area.

[5]Contains the other notable portion of the Portland Metropolitan Area, which includes the cities of Beaverton and Hillsboro.

Source: NLCD, 2019

Forest is the dominant land cover in the WRB; half of the sub-basins have 70 percent or greater forest cover and only one sub-basin has less than 25 percent forest cover. Forest cover is greatest in the eastern two-thirds of the WRB and along its western fringe. The Willamette River and I-5 corridor in the western third of the basin exhibits relatively less forest cover, as agriculture, urban development, and other uses are more evident in this part of the basin. The Middle Fork and Coast Fork Willamette, North Santiam, Clackamas, and McKenzie sub-basins have the largest amounts of forest coverage (74-87 percent), the least amount of agriculture (2-10 percent), and the least amount of developed land (1-5 percent).

Agricultural land cover is highest in the Middle Willamette sub-basin at 55 percent, followed by the Upper Willamette with 41 percent and the Molalla-Pudding with 37 percent. The Middle Willamette has a wide variety of crops such as grass seed, small grains, fruits and nuts, broccoli, and wine grapes (ODA 2020) and is also the least forested, at only 17 percent coverage.

Development is greatest in the Lower Willamette sub basin at 46 percent, followed by the Tualatin at 24 percent and the Middle Willamette at 21 percent. The Lower Willamette contains Oregon's largest city, Portland, while the Middle Willamette and Tualatin sub-basins are home to Oregon's capital, Salem, and the cities of Beaverton and Hillsboro.

Other land cover is primarily a combination of shrub/scrub, grassland/herbaceous, and wetland, which individually are typically responsible for <1- 8 percent coverage. Land cover categories within 'other' that are generally <1 percent include barren land, open water, and perennial ice/snow. Sub-basins with the largest amounts of 'other' land cover include North and South Santiam, Coast Fork Willamette, Lower Willamette, and McKenzie, with a range of other land cover from 13-15 percent, dominated by shrub/scrub and grassland/herbaceous cover (NLCD 2019).

### 3.15.4 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on land use. The discussion includes the methodology used to assess effects, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis of effects under each alternative.

#### *3.15.4.1 Methodology*

As discussed in Section 3.15.1, this section uses land *cover* as a surrogate for land *use* due to the large areal extent of the area of analysis (the entire WRB) and the availability of land cover data via National Land Cover Database (NLCD) satellite imagery. The potential effects to land use were assessed by first evaluating which measures could result in changes to land cover. Then, the magnitude, duration, and extent of effects were qualitatively determined using information about each measure from USACE by considering how noticeable land cover changes could be to the public (i.e., in terms of areal extent or general appearance) or how theoretically detectable changes would be at the resolution used by the NLCD. The NLCD uses a 30-meter resolution (i.e., each satellite-image pixel represents an approximately 30-by-30-meter square on the earth's surface). Changes to land cover from each measure would likely be substantially less than 1 percent of the entire WRB, and in some cases, not even detectable at the resolution used by the NLCD. Therefore, the PDT determined that a qualitative analysis would be appropriate for the PEIS.

Although land *use* (the *classification* of how an area is used) changes were not analyzed at the programmatic level, land cover changes could alter the way the public perceives or uses an area. Note that, effects to land *use* are still a possibility from the proposed action and alternatives; however, these effects would be incorporated by future NEPA documents such as master plans. Due to the subjective nature of categorizing changes to land cover as "adverse" or "beneficial", effects are instead discussed generally as changes.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

Table 3.15-4 lists the evaluation criteria for the magnitude, duration, and extent and provides a definition for each factor.

**Table 3.15-4. Evaluation Criteria for Potential Effects to Land Use**

| Term | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Changes in land cover would not be noticeable or be barely noticeable in terms of areal extent or general appearance. Changes would not be detectable at the resolution used by the NLCD. |
| Minor | Changes to land cover would be noticeable but small in terms of areal extent or general appearance. Changes would be detectable at the resolution used by the NLCD, but would be very small on a basin-wide scale. |
| Moderate | Changes to land cover would be very noticeable in terms of areal extent or general appearance. Changes would be detectable at the resolution used by the NLCD, but relatively small on a basin-wide scale. |
| Major | Changes to land cover would be highly conspicuous in terms of areal extent or general appearance. Changes would be detectable at the resolution used by the NLCD and notable on a basin-wide scale. |
| **Duration** | |
| Short term | Alteration lasts for the duration of small construction projects, and is continuous for less than 2 years. |
| Medium term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (i.e., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Effects would be confined to the project area. |
| Medium | Effects would be perceived throughout a single county, multiple counties, or the entire WVS. |
| Large | Effects would be perceived throughout the entire state. |

### *3.15.4.2 Measures Analyzed for Land Use*

Measures that could affect land cover are: Construct adult fish facilities (#722), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720), maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), and restore upstream and downstream passage at drop structures (#639). The following measures would have no effect on land cover and are therefore not discussed further.

- Adapt hatchery program (#719)
- Gravel augmentation below dams (#384)
- Construct structural downstream fish passage (#392)
- Construct water temperature control tower (#105)
- Foster fish ladder temperature improvement (#479)
- Structural improvements to reduce total dissolved gas (#174)
- Maintenance of existing and new fish release sites above dams (#726)
- Provide Pacific lamprey passage and infrastructure (#52)
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)
- Integrated temperature and habitat flow regime (#30a)
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Use spillway for surface spill in summer (#721)
- Pass water over spillway in spring for fish passage (#714)
- Augment instream flows by using the inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Operation, Maintenance, Repair, Replacement and Rehabilitation
- Continued Operation of Existing Adult Fish Facilities

A summary of the effects to land use discussed in the following sections is provided in Table 3.15-5. Note that where a range of potential effects would occur, the most severe magnitude of effects for each alternative was listed in this table. For example, if there is a range of minor to moderate effects, moderate effects are included in the table Said otherwise, the most conservative conclusions of potential effects are presented in the table below. Discussion of all effects are included in the discussion below.

**Table 3.15-5. Summary of Effects to Land Use**

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | **NAA** | **1** | **2A** | **2B** | **3A** | **3B** | **4** | **5** |
| **Short-Term** | | | | | | | | |
| Magnitude | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate | Moderate |
| Extent | Local (FCR) | Local (FCR) | Local (FCR, GPR) | Local (CGR, FCR, GPR) | Local (BLU, CGR, DET, GPR, FCR, HCR, LOP) | Local (BLU, CGR, DET, GPR, FCR, HCR, LOP) | Local (FCR) | Local (CGR, FCR, GPR) |
| **Medium-Term** | | | | | | | | |
| Magnitude | None | None | None | None | None | None | None | None |
| Extent | None | None | None | None | None | None | None | None |
| **Long-Term (Permanent, Intermittent, and/or Recurring)** | | | | | | | | |
| Magnitude | Major | Major | Major | Major | Major | Major | Major; | Major |
| Extent | Local (FCR); regional (basin-wide) | Local (FCR, GPR); regional (FRN, basin-wide) | Local (FCR, CGR, GPR, LOP); regional (basin-wide) | Local (FCR, CGR, GPR, LOP); regional (basin-wide) | Local (BLU, GPR, HCR, CGR, DET, HCR, LOP, FCR); regional (basin-wide) | Local (BLU, GPR, HCR, CGR, DET, HCR, LOP, FCR); regional (basin-wide) | Local (FCR, HCR); regional (FRN, basin-wide) | Local (FCR, CGR, GPR, LOP); regional (basin-wide) |
| Duration Type | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring | Permanent; Recurring |

### *3.15.4.3 Discussion of Effects by Measures*

This section applies the methodology described above to each measure analyzed for the resource to determine the potential effects. The discussion is grouped by measures that would have similar effects where possible. Construct adult fish facilities (#722), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720), maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), and restore upstream and downstream passage at drop structures (#639) would require construction as described in Section 3.1.2.1. The Draft PEIS discusses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents will discuss detailed site-specific effects during the implementation phase. As stated above in Section 3.15.4.1, effects to land *use* are still a possibility from the proposed action and alternatives; however, these effects would be incorporated by future NEPA documents such as master plans.

#### *3.15.4.3.1 Restore Upstream and Downstream Passage at Drop Structures (#639)*

The effects of restoring upstream and downstream passage at drop structures would be minor in magnitude, local in extent, and long term in duration.

Drop structures are small dams built within the river to passively reduce the velocity of water, and can be found at several locations below Fern Ridge. The design of the restoration could include the construction of fish ladders, direct modifications to drop structures, bypass channels, or the replacement of drop structures with riffle and pool systems. Construction of fish ladders, bypass channels, or small modifications to the drop structures without removing the drop structures or changing water levels would have no effect on land cover. However, if the drop structures were removed and replaced with, for example, riffle and pool systems to provide fish passage, land cover would change along a several-mile stretch of the Long Tom River near the project due to the release of impounded water. Open water cover above the drop structures would become noticeably barren and could become vegetated with shrub/scrub cover over time. River banks below the drop structures that had barren or mildly vegetated shrub/scrub cover would be replaced with open water cover. Land cover changes above and below the drop structures would be locally noticeable in terms of general appearance. If changes were detectable at the resolution used by the NLCD, the differences in land cover would be very small on a basin-wide scale. Therefore, the effects would be minor in magnitude and local in extent. These effects would be long term because the land cover changes would last for the life of the project. This measure would be considered an ecological restoration.

#### *3.15.4.3.2 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

The effects of maintaining or altering revetments would be minor in magnitude, regional in extent, and long term.

Maintaining revetments could involve using a hydraulic excavator to recondition the revetment with natural materials and would have no effect on land cover. However, if revetments were altered for aquatic ecosystem restoration, previously barren land cover (revetments are often constructed of concrete, large rocks, or other hard materials) would be replaced with vegetative shrub/scrub cover to benefit aquatic ecosystems. Changes to land cover would be locally noticeable in terms of general appearance, but would likely not be detectable at the resolution used by the NLCD because revetments were not clearly shown in 2019 NLCD data. If revetment alterations were detectable at the resolution used by the NLCD, changes would be very small on a basin-wide scale. Although not all revetments would be altered, revetments are found basin-wide and changes to land cover would be locally noticeable at each project area. Alterations would be designed to last for the life of the project; therefore, effects would be regional in extent and long term.

###### *3.15.4.3.3 Construct Adult Fish Facilities (#722)*

The effects of constructing AFFs would be minor in magnitude, local in extent, and long term.

AFF footprints vary depending on a variety of factors, such as the location, estimated throughput, and the method of fish collection. Facilities could require space for parking lots for workers, fish ladders, holding pools, and covered buildings where facilities are monitored. Developed areas associated with AFFs in the WVS range from approximately half of an acre at the Cougar Dam to just under three acres at the Foster Dam, so constructing AFFs could develop up to three acres of land per location. Constructing AFFs would be locally noticeable in terms of both areal extent and general appearance. The developed land would be detectable at the resolution used by the NLCD; however, changes in land cover would be very small on a basin-wide scale. Therefore, effects would be minor in magnitude. Land cover changes would be confined to the project area, so effects would be local in extent. The AFFs would be designed for the life of the project, so the effects would be long term.

###### *3.15.4.3.4 Deeper Fall Reservoir Drawdown for Fish Passage (#40); Drawdown Reservoir in the Spring for Fish Passage (#720); Fall Creek drawdown; Suite of near-term operations*

The effects of drawing-down reservoirs in the fall and spring for fish passage and the suite of near-term operations would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Reservoir drawdowns would result in recurring open-water-to-barren land cover changes. Although land *use* (the *classification* of how an area is used) changes were not analyzed at the programmatic level, recurring drawdowns would substantially alter the way the public uses the area, be very locally noticeable in terms of areal extent and general appearance, and would be detectable at the resolution used by the NLCD. Effects to land *use* are a possibility from the proposed action and alternatives; however, these effects would be incorporated in future NEPA documents. For example, deep drawdowns could lead to OPRD terminating park leases, and USACE would change land classification(s) within the master plan and analyze these effects in the associated NEPA document accordingly; but it is also possible that some boat ramps could eventually be extended in order to mitigate the effects of drawdowns at affected parks. More information about how public use of reservoirs would change due to drawdowns can be found in the Recreation resource under Section 3.14.2.3.8.

The recurring changes would be relatively small on a basin-wide scale. The suite of near-term operations also includes deep drawdowns at Cougar, Green Peter, Lookout Point, and Fall Creek, and delayed refills at Fall Creek and Cougar (which would lengthen the effects of deep drawdowns). Effects on land cover from of each drawdown would be local at a single reservoir and recur annually between approximately three weeks and four months throughout the life of the project, so effects would be local in extent and occur in the short term but recur in the long term.

### *3.15.4.4 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue. The NAA includes water quality, flow, downstream passage, and upstream passage operations. Because the WVS has been fully constructed and operating for over 50 years, its continued O&M would have no additional effects on land use. The only action in the NAA that would contribute to effects from land cover is the Fall Creek drawdown, which recurs annually to pass fish through the lowest outlet. As discussed above in Section 3.15.4.3.4, the recurring open-water-to-barren land cover changes would be very noticeable on a local level and would be detectable at the resolution used by the NLCD (although still relatively small on a basin-wide scale). Therefore, effects would be moderate in magnitude. The effects on land cover would be confined to the project area; thus, local in extent. The drawdowns would last for approximately three weeks per year but recur for the life of the project, so effects would be short term but recur in the long term.

#### *3.15.4.4.1 Climate Change*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. These factors would contribute to changes in basin-wide land cover; however, they may also result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to land cover types such as barren due to the decreasing availability of water and increasing air and water temperatures. Effects from droughts would become more severe over time. While average summer river flows and reservoir water levels would decrease, high rainfall events would become more intense and unpredictable. High rainfall events could lead to severe flooding in some areas, primarily along the mainstem Willamette River, where the WVS project dams cannot provide FRM for immediately adjacent runoff areas. Flooding would temporarily turn the coverage of affected areas into open water, but could have longer-term effects on vegetation. Flooding could destroy vegetation and even buildings in some areas and make them barren, but over time, vegetation would re-establish itself, and buildings (especially near urban areas) could be rebuilt. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire. The effects on land cover from wildfires would be more severe than those from recurring drawdowns because they could be notable on a basin-wide scale.

Wildfires and floods in particular would also result in changes to land use (classifications). High rainfall events, especially after a wildfire, can also result in landslides. These natural disasters destroy communities and result in land use changes through expanding development (from housing relocation) and may include rerouting roads and making changes to county or local land use plans as applicable. Floodplains may be re-mapped in order to restrict development. Therefore, the effects of climate change on land cover and land use would be major in magnitude, statewide in extent, and long term.

#### *3.15.4.5 Alternative 1 – Storage-Based Fish Passage*

Under Alternative 1, effects from restoring upstream and downstream passage at drop structures would occur at Fern Ridge and be minor in magnitude, local in extent, and long term in duration. Effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing an AFF would occur at Green Peter and be minor in magnitude, local in extent, and long term. Effects from continuing the Fall Creek drawdown would be identical to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 1 would be less than under all other action alternatives because it would have the fewest recurring drawdowns and does not include the suite of near-term operations. The effects of ecological restorations would be the same as under Alternative 4 but less than under Alternatives 2A, 2B, 3A, 2B, and 5 due to restoring upstream and downstream passage at drop structures.

##### *3.15.4.5.1 Restore Upstream and Downstream Passage at Drop Structures (#639)*

Under Alternative 1, restoring upstream and downstream passage at drop structures would occur at Fern Ridge. As discussed above in Section 3.15.4.3.1, the potential effects would be minor in magnitude, local in extent, and long term in duration.

##### *3.15.4.5.2 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

##### *3.15.4.5.3 Construct Adult Fish Facilities (#722)*

Under Alternative 1, constructing an AFF would occur at Green Peter. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

##### *3.15.4.5.4 Fall Creek drawdown*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

##### *3.15.4.5.5 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 1 would be have the least effects from climate change with respect to land cover than any other action alternative because it includes the fewest recurring drawdowns and is the only alternative that would benefit reservoir storage. As discussed above in Section 3.15.4.4.1, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 1 (and all alternatives) would be major in magnitude, statewide in extent, and long term.

#### ***3.15.4.6 Alternative 2A – Integrated Water Management Flexibility and ESA Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)***

Under Alternative 2A, effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing an AFF would occur at Green Peter and be minor in magnitude, local in extent, and long term. Effects from the deeper fall reservoir drawdowns at Green Peter, continuing the Fall Creek drawdown, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek would be similar to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 2A would be greater than under Alternatives 1 and 4, but less than under Alternatives 2B, 3A, 3B, and 5. The effects of ecological restorations would be less than under Alternatives 1 and 4 and the same as under all other action alternatives due to restoring or altering revetments.

##### *3.15.4.6.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

##### *3.15.4.6.2 Construct Adult Fish Facilities (#722)*

Under Alternative 2A, constructing an AFF would occur at Green Peter. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

##### *3.15.4.6.3 Deeper Fall Reservoir Drawdown for Fish Passage (#40); Fall Creek drawdown; Suite of near-term operations*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue, and under Alternative 2A, deeper fall reservoir drawdowns would occur at Green Peter and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

##### *3.15.4.6.4 Climate Change*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 2A would have more recurring drawdowns than under Alternatives 1 and 4, but less than under Alternatives 2B, 3A, 3B, and 5. As discussed above in Section 3.15.4.3, the NAA, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 2A (and all alternatives) would be major in magnitude, statewide in extent, and long term.

#### ***3.15.4.7 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 2B, effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing an AFF would occur at Green Peter and be minor in magnitude, local in extent, and long term. Effects from the deeper fall reservoir drawdowns at Cougar and Green Peter, spring reservoir drawdowns at Cougar, continuing the Fall Creek drawdown, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek would be similar to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 2B would be greater than under Alternatives 1, 2A, and 4, the same as under Alternative 5, and less than under Alternatives 3A and 3B.

###### *3.15.4.7.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

###### *3.15.4.7.2 Construct Adult Fish Facilities (#722)*

Under Alternative 2B, constructing an AFF would occur at Green Peter. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

###### *3.15.4.7.3 Deeper Fall Reservoir Drawdown for Fish Passage (#40); Drawdown Reservoir in the Spring for Fish Passage (#720); Fall Creek drawdown; Suite of near-term operations*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue, and under Alternative 2B, deeper fall reservoir drawdowns would occur at Cougar and Green Peter, spring reservoir drawdowns would occur at Cougar, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

###### *3.15.4.7.4 Climate Change*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam’s DT). These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 2B would have more recurring drawdowns than under Alternatives 1, 2A, 4, and 5, but less than under Alternatives 3A and 3B. As discussed above in Section 3.15.4.4.1, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 2B (and all alternatives) would be major in magnitude, statewide in extent, and long term.

### *3.15.4.8 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Under Alternative 3A, effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing AFFs would occur at Blue River, Green Peter, and Hills Creek and be minor in magnitude, local in extent, and long term. Effects from the deeper fall reservoir drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point, spring reservoir drawdowns at Cougar, Detroit, and Lookout Point, continuing the Fall Creek drawdown, and the suite of near-term operations at Cougar, Green Peter, Lookout Point, and Fall Creek would be similar to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 3A would be the same as under Alternative 3B, which would be more severe than under any other action alternatives due to the number of recurring drawdowns and AFFs. The effects of ecological restorations would be less than under Alternatives 1 and 4 and the same as under all other action alternatives due to restoring or altering revetments.

#### *3.15.4.8.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

#### *3.15.4.8.2 Construct Adult Fish Facilities (#722)*

Under Alternative 3A, constructing AFFs would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

#### *3.15.4.8.3 Deeper Fall Reservoir Drawdown for Fish Passage (#40); Drawdown Reservoir in the Spring for Fish Passage (#720); Fall Creek drawdown; Suite of near-term operations*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue, and under Alternative 3A, deeper fall reservoir drawdowns would occur at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point, spring reservoir drawdowns would occur at Cougar, Detroit, and Lookout Point, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

##### *3.15.4.8.4 Climate Change*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 3A would have more recurring drawdowns than under Alternatives 1, 2A, 2B, 4, and 5, but fewer than under Alternative 3B. As discussed above in Section 3.15.4.4.1, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 3A (and all alternatives) would be major in magnitude, statewide in extent, and long term.

#### ***3.15.4.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Under Alternative 3B, effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing AFFs would occur at Blue River, Green Peter, and Hills Creek and be minor in magnitude, local in extent, and long term. Effects from the deeper fall reservoir drawdowns at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point, spring reservoir drawdowns at Cougar, Green Peter, and Hills Creek, continuing the Fall Creek drawdown, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek would be similar to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 3B would be the same as under Alternative 3A, which would be more severe than under any other action alternatives due to the number of recurring drawdowns and AFFs.

##### *3.15.4.9.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

##### *3.15.4.9.2 Construct Adult Fish Facilities (#722)*

Under Alternative 3B, constructing an AFF would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

##### *3.15.4.9.3 Deeper Fall Reservoir Drawdown for Fish Passage (#40); Drawdown Reservoir in the Spring for Fish Passage (#720); Fall Creek drawdown; Suite of near-term operations*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue, and under Alternative 3B, drawing-down reservoirs in the fall for fish passage would occur at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point, drawing-down reservoirs in the spring for fish passage would occur at Cougar, Green Peter, and Hills Creek, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

##### *3.15.4.9.4 Climate Change*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 3B would have more recurring drawdowns than under any other action alternative; therefore, it would have the most effects from climate change with respect to land cover. As discussed above in Section 3.15.4.4.1, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 3B (and all alternatives) would be major in magnitude, statewide in extent, and long term.

#### ***3.15.4.10 Alternative 4 – Structures-Based Fish Passage Alternative***

Under Alternative 4, effects from restoring upstream and downstream passage at drop structures would occur at Fern Ridge and be minor in magnitude, local in extent, and long term in duration. Effects from maintaining revetments using nature-based engineering methods would occur basin-wide and be minor in magnitude, regional in extent, and long term. Effects from constructing an AFF would occur at Hills Creek and be minor in magnitude, local in extent, and long term. Effects from continuing the Fall Creek drawdown and the suite of near-term operations at Cougar, Green Peter, Lookout Point, and Fall Creek would be similar to those discussed under the NAA: moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

Effects under Alternative 4 would be greater than under Alternative 1 due to the suite of near-term operations and would be less than under all other action alternatives due to the relatively few recurring drawdowns. The effects of ecological restorations would be the same as under Alternative 1 and greater than under all other action alternatives due to restoring upstream and downstream passage at drop structures.

##### *3.15.4.10.1 Restore Upstream and Downstream Passage at Drop Structures (#639)*

Under Alternative 4, restoring upstream and downstream passage at drop structures would occur at Fern Ridge. As discussed above in Section 3.15.4.3.1, the potential effects would be minor in magnitude, local in extent, and long term in duration.

##### *3.15.4.10.2 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Under all action alternatives, maintaining revetments using nature-based engineering methods would occur basin-wide. As discussed above in Section 3.15.4.3.2, the potential effects would be minor in magnitude, regional in extent, and long term.

##### *3.15.4.10.3 Construct Adult Fish Facilities (#722)*

Under Alternative 4, constructing an AFF would occur at Hills Creek. As discussed above in Section 3.15.4.3.3, the potential effects would be minor in magnitude, local in extent, and long term.

##### *3.15.4.10.4 Fall Creek drawdown; Suite of near-term operations*

Under all action alternatives, the Fall Creek Reservoir drawdown would continue, and the suite of near-term operations would occur at Cougar, Green Peter, Lookout Point, and Fall Creek. As discussed above in Section 3.15.4.3.4, potential effects would be moderate in magnitude, local in extent, and occur in the short term but recur in the long term.

##### *3.15.4.10.5 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. These measures would have moderate effects on land cover, but would only result in minor contributions from climate change due to the recurring drawdowns. Alternative 4 would have fewer recurring drawdowns than Alternatives 2A, 2B, 3A, 3B, and 5, and would have the same number of drawdowns as Alternative 1; however, it would not benefit reservoir storage, so it would have greater effects from climate change with respect to land cover as Alternative 1. As discussed above in Section 3.15.4.4.1, climate change is expected to increase the intensity and severity of wildfires, floods, and landslides independent of the USACE O&M of the WVS. Therefore, the effects from climate change under Alternative 4 (and all alternatives) would be major in magnitude, statewide in extent, and long term.

#### ***3.15.4.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Alternative 5 would only differ from Alternative 2B by way of the refined integrated temperature management and habitat flow regime measure (#30b), which would not have effects on land cover. Therefore, the effects of Alternative 5 would be identical to those under

Alternative 2B: effects would be greater than under Alternatives 1, 2A, and 4, and less than under Alternatives 3A, and 3B. Land cover effects from ecological restorations would be less than under Alternatives 1 and 4 and the same as under all other action alternatives due to maintaining or altering revetments.

#### *3.15.4.12 Conclusion*

Severity of effects on land use is primarily driven by the number of recurring drawdowns, and secondarily by the number of construction projects that would require land to be developed (construction of AFFs). The action alternatives organized in order of least to greatest effects on land use would be: 1, 4, 2A, 2B and 5, and 3A and 3B. Land cover effects would also occur from ecological restoration projects, which would be the greatest under Alternatives 1 and 4 (equal) and less than Alternatives 2A, 2B, 3A, 3B, and 5 (equal).

## 3.16 HAZARDOUS MATERIALS

Hazardous materials are defined by the EPA and Occupational Safety and Health Administration (OSHA) as substances that are hazardous to the health of people, plants, or animals. These include materials that are stored and used for O&M activities in the WVS, such as corrosives, flammables, and toxic agents that can cause harm to human health and the environment.

### 3.16.1 Affected Environment

The area of analysis for hazardous materials is the WVS. Hazardous materials are primarily used in the WVS at dams, fish collection and hatchery facilities, and construction sites for O&M activities. This section begins with a discussion of hazard communication and training, and is then organized by hazardous materials and hazardous material-using activities. Hazardous waste is considered in Section 3.24, Public Health – Hazardous, Toxic, and Radioactive Waste.

#### *3.16.1.1 Hazard Communication and Training*

OSHA's 29 CFR 1900.1200 requires workers to be informed of and able to identify hazardous chemicals, as well as protect themselves from hazardous chemical exposures. In order to accomplish this, USACE implements a written Hazard Communication plan that is revised regularly as needed. This plan includes but is not limited to information on: employee training, safety data sheets (SDSs), container labeling, chemical inventory lists, personal protective equipment (PPE) spills, chemicals in pipes, and methods to reduce or prevent exposure. Physical copies of the Hazard Communication Plan are provided at the Cougar, Cottage Grove, Detroit, Dexter, Fern Ridge, Foster, and Lookout Point projects as well as at the pre-work meetings for all contractors. Electronic copies are available on all desktop computers.

Health and safety training occurs to provide employees with proper information before new employees start their initial assignments, and whenever a new chemical is introduced into a work area. This training begins with a general hazard communication training video followed by a quiz. Next, chemical exposure specific to that employee's job is discussed with a supervisor. This includes where the Hazard Communication Plan is stored, hazards associated with chemicals, techniques and observations used to detect the presence or release of a chemical, procedures to prevent exposure, and emergency procedures.

USACE also performs regular personnel training to keep current employees up to date on equipment, procedures, regulations, facility operations, and site-specific protocols as applicable. Annual oil spill training for hydroelectric dam employees is conducted in accordance with 40 CFR 112.7(f). Employees who handle petroleum products are additionally trained in areas of drum handling, petroleum transfers, methods of identifying oil levels on all oil-filled operating equipment, incident command, and the operation of pumps and/or sumps within the Safe Clearance Procedure, USACE's hazardous energy control program. Hazardous energy is defined by OSHA as "any electrical, mechanical, hydraulic, pneumatic, chemical, nuclear, thermal, gravitational, or other energy that can harm personnel", and is typically discussed in the context of lockout/tagout procedures, where dangerous equipment is properly shut off and unable to be started up again prior to the completion of maintenance or repair work. Additionally, designated first responders are trained and authorized to safely respond to a spill emergency and execute the Spill Response Plan.

#### *3.16.1.2 Construction*

Construction activities, such as dam and building maintenance and repairs, as well as the building of new structures, can potentially introduce hazardous materials into the environment without protective measures. Workers, the public, and wildlife might be exposed to this contamination, which could cause a wide range of health issues depending on the contaminant type, concentration, and exposure duration, as well as the receptor's characteristics, such as age.

Accidental releases from construction, typically associated with improper chemical management, are also sources of possible impacts to public health and safety. Spills can cause soil and water contamination and create exposure pathways to workers, the public, and wildlife. The severity of risks and effects from a spill are determined by its composition and quantity. For example, a common material used for construction that could be spilled at a project site is diesel fuel, which is an irritant of the lungs and skin. High levels of diesel exposure can cause nervous system damage or death (HHS 1995). Other common hazardous chemicals around construction sites include aerosols, solvents, and adhesives.

#### *3.16.1.3 Compressed Gases*

Compressed gases are stored and used at dams, fish facilities, and construction sites around the WVS for controlling valves, oxygenating water and anesthetizing fish, and performing repairs and maintenance that require welding, cutting, and brazing. Hazards associated with compressed gases include oxygen displacement, fires, explosions, and toxic gas exposures, as well as the physical hazards associated with high pressure systems (OSHA No Date). Compressed nitrogen is used in transformers and emergency valves, and oxygen and $CO_2$ are used for fish operations. Acetylene, argon mixture, helium mixture, and oxygen are used for welding, cutting, and brazing. USACE mitigates hazards by adhering to the general requirements for compressed gasses in 29 CFR part 1910.101 and the welding, cutting, and brazing requirements found in 29 CFR part 1910.253. Additionally, BMPs are used, which includes securing cylinders and keeping them away from heat sources.

#### *3.16.1.4 Lead-Based Paint and Asbestos-Containing Materials*

Facilities within the WVS were built between 1945 and 1970, and contain some amount of lead-based paint (LBP) and asbestos-containing materials (ACM) from both original construction and O&M activities. More information is known about the extent of ACM in the WVS than LBP due to the cost-effectiveness of testing. In the 1990s, efforts were made to remove ACM throughout the WVS, but some materials remain. Some areas and materials that were reported to still contain ACM during a 2014 survey include components of electrical wiring and electrical control cabinets, glues and sealants, insulation, and gaskets, although more could exist. LBP is assumed to be present on old building and equipment parts that may need to be removed or replaced as part of O&M activities; therefore, all paint is treated as LBP until it can be verified. Before any materials are removed as part of operations and maintenance, suspected areas would be tested for asbestos. Any ACM identified would be removed and collected by a contractor who follows all OSHA regulations when working with asbestos, and ensures waste is disposed of at an approved facility that follows all applicable environmental laws and regulations.

Although an inconclusive survey for LBP has occurred, LBP is expected on old parts being removed or replaced as part of regular O&M. Before any paint is removed, paint is first tested with lead check swabs. Any contractors removing paint must treat the paint as if it is lead containing, and use an LBP stabilizer to reduce hazardous waste generation. After removal, the debris is tested using the EPA's Toxicity Characteristic Leachate Procedure to determine its waste status. BMPs are also used where applicable, which include paint removal gels or the use of hooded needle guns that mechanically remove and vacuum up paint residue. All wastes would be removed, handled, and disposed of by complying with applicable OSHA and environmental laws and regulations.

#### *3.16.1.5 Underground Storage Tanks*

Only one underground storage tank (UST) exists in the WVS. This UST is located at the Cougar Dam and formerly stored heating oil, but was closed in place in 2008. This UST is scheduled to be removed during a building demolition scheduled for 2024.

#### *3.16.1.6 Oil Spills and Above-ground Storage Tanks*

Oil spills are a public health, safety, and environmental concern at dams, especially the eight USACE dams in the WVS that produce hydropower. Dams rely on a variety of oil-filled equipment to operate. The area that has the highest risk for large spills is the powerhouse, as it typically contains large oil and fuel-filled equipment such as transformers, turbines, generators, and their above-ground storage tanks. Smaller equipment and containers of oil less than 55 gallons are also common around the powerhouse. Each USACE project dam within the WVS has an associated spill prevention, control, and countermeasure (SPCC) plan that details sources, types, volumes, locations, and spill prevention systems and responses specific for that location.

Powerhouse transformers and their oil storage tanks typically contain the largest volumes of oil on site, upwards of several thousand gallons in some cases (Figure 3.16-1). All oil-containing equipment and storage containers in the powerhouse are regularly maintained and inspected in accordance with the preventative maintenance schedule established for each piece of equipment. Operational procedures are also in place to minimize spills related to human error and equipment failure. Additionally, oil-filled equipment and storage containers are constructed of steel and stored at ambient temperature and pressure, which is compatible with petroleum products, thereby minimizing the potential of a release.

Above-ground oil storage tanks and equipment located in or around the powerhouses generally have multiple levels of containment. Drain covers and plugs have been placed near all floor drains in the vicinity of oil reservoirs at the powerhouses, which can be deployed in the event of a spill to allow rooms with oil-containing equipment and storage containers to act as secondary containment. Smaller containers of oil such as drums are stored over mobile pallets capable of containing minor spills.

**Figure 3.16-1.Primary transformer insulating oil being stored in the oil treatment and storage room of the Detroit Dam powerhouse**

Powerhouse combined dewatering and drainage sumps are another possible source of oil releases. All drains adjacent to oil-filled equipment in the powerhouse lead to the sump, which is automatically pumped to an oil-water separator (OWS) and out to the river below the dam by a floating pump activation mechanism. Because powerhouse drainage water is inherently oily, while dewatering water is generally clean, the Project Delivery Team has recommended separating these two sources: discharging clean water beneath the dam and oily water to the currently existing OWS equipment that treats transformer and sump drainages. Currently, Foster and Green Peter are the only dams out of the eight that produce power that do not have separated sumps. These facilities have ongoing oil spill prevention system projects that will address this once completed.

One current technique to mitigate potential sump oil discharge to the rivers aside from the OWS involves leaving a column of water in the sump, which keeps the floating oil away from pump intakes. Alarms are present on all substantial oil-containing equipment in the powerhouses that would alert operators to a potential release. If a large amount of oil accumulates in the sump, the operator can disable the drainage pump, allowing the sump to act as secondary containment for the oil spill. Then, designated personnel can access the sump and begin the cleanup process using absorbent materials or an oil skimmer.

An individual turbine may contain upwards of a thousand gallons of oil, which has the potential to leak into river water via the oil cooling system, though this is considered unlikely. It was determined to be cost prohibitive to install measures to address oil cooler system leaks, as it would require a significant alteration to the facility that could compromise system safety. Regular replacement of the cooling coils is performed to reduce the risk of such a release.

The final places that oil releases could happen are dam intake towers. Sources of oil include emergency diesel generator fuel tanks and the hydraulic fluid reservoirs that support adjusting the flow of the regulating outlets (ROs). However, both oil sources can be contained with nearby containment berms and modified drain plugs.

#### *3.16.1.7 Fish Collection and Hatchery Chemicals*

USACE operates five adult fish collection facilities and five hatcheries that anesthetize fish with chemicals to minimize stress and damage during handling. These facilities also use a variety of chemicals to control microorganisms and prevent diseases. The majority of these chemicals are not hazardous. The hazardous chemical names, uses, and hazards are shown below in Table 3.16-1.

**Table 3.16-1. Hazardous Chemical Names, Uses, and Hazards at WVS Fish Collection and Hatchery Facilities**

| Chemical trade name | Use | Hazard |
|---|---|---|
| Formalin | Controls parasites, fungi, and protozoa | Flammable; acute oral and inhalation toxicity |
| Ovadine | Disinfects fish eggs | Eye irritant |
| Chloramine-T | Controls fish gill bacterial outbreaks | Skin and eye irritant |
| Diquat | Controls general bacteria | Eye and respiratory system irritant |
| Tricaine-S | Immobilizes and sedates fish | Skin, eye, and respiratory system irritant |

Source: ODFW 2021c; ODFW 2021d; Sigma Aldrich 2021; Syndel 2015; Syndel 2017; Syngenta 2002; Thermofisher 2010

All chemicals are stored in secure locations according to their SDSs and product labels. Chemical storage rooms have containment systems built into their floors and have eyewash and shower stations available.

#### *3.16.1.8 Pesticides*

Herbicides and insecticides are types of pesticides. These chemicals are applied as spot treatments on a small scale as part of routine maintenance in order to prevent the establishment of new invasive species, manage/control existing populations, and enhance habitat for native species.

Species of exotic blackberries, grasses, and weeds are controlled around the Blue River, Cottage Grove, Dexter, Dorena, Fall Creek, Fern Ridge, Foster, Hills Creek, and Lookout Point reservoirs. The most commonly used chemicals are triclopyr choline and glyphosate (USACE 2021a). Triclopyr choline is considered hazardous under 29 CFR 1910.1200 due to acute toxicity and eye irritation (Dow, 2016). Glyphosate is not considered hazardous (Bayer 2020). Flying insects such as hornets and wasps are controlled around structures as needed using a spray containing tetramethrin, which is not considered hazardous (ARI 2014). These chemicals are stored in a secure cabinet in the Fern Ridge office warehouse.

The majority of applications are away from water. When necessary, aquatic-labeled herbicides are applied at least six and a half feet from bodies of water, and extra caution is used when water bodies are bearing anadromous fish. All pesticide use complies with the ESA consultation between the EPA and the NMFS and the National Pollutant Discharge Elimination System (NPDES) Pesticide General Permit issued by the ODEQ. No chemicals are used that are listed on the EPA's Restricted Use Products Report.

### 3.16.2 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives to hazardous materials. The discussion includes the methodology used to assess effects, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis of effects under each alternative.

#### *3.16.2.1 Methodology*

The potential effects to hazardous materials were assessed by examining ongoing trends in the presence and use of hazardous materials (fuel, oil, pesticides, compressed gasses, LBP, ACM) in the WVS, and the subsequent presence of the materials in soil, sediment, air, and water (exposure pathways). Scientific literature, news releases, and documents such as inventories, reports, and SDSs were used to predict the severity of the threat that hazardous materials pose to natural resources and the public over the life of the project. Table 3.16-2 describes the evaluation criteria for the magnitude, duration, and extent, and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.16-2. Evaluation Criteria for Potential Effects to Hazardous Materials**

| Term | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Emission, discharge, or deposition of hazardous materials in soil, sediment, air, and/or water and the environmental effects from such would not be measurable. |
| Minor | Emission, discharge, or deposition of hazardous materials in soil, sediment, air, and/or water and the environmental effects from such would be measurable but near the detection limit. |
| Moderate | Emission, discharge, or deposition of hazardous materials in soil, sediment, air, and/or water and the environmental effects from such would be measurable and moderately above the detection limit. Mitigation measures would be required to offset adverse effects, but long-term changes to the environment would be expected. |
| Major | Emission, discharge, or deposition of hazardous materials in soil, sediment, air, and/or water and the environmental effects from such would be readily measurable and clearly above the detection limit. Mitigation measures would be required to offset adverse effects, but long-term changes to the environment would be expected. |
| **Duration** | |
| Short term | Alteration lasts for the duration of small construction projects, and is continuous for less than 2 years. |
| Medium term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (i.e., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Local | Effects would be confined to the project area. |
| Regional | Effects would be perceived throughout a single county, multiple counties, or the entire WVS. |
| State-wide | Effects would be perceived throughout the entire state. |

#### *3.16.2.2 Measures Analyzed for Hazardous Materials*

Measures under the action alternatives that could affect hazardous materials include: adapt hatchery program (#719); continued operation of existing adult fish facilities; construct adult fish facility (#722); operation, maintenance, repair, replacement and rehabilitation; gravel augmentation below dams (#384); maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9); maintenance of existing and new fish release sites above dams (#726); restore upstream and downstream passage at drop structures

(#639); use spillway for surface spill in summer (#721); provide Pacific lamprey passage and infrastructure (#52); structural improvements to reduce total dissolved gas (#174); Foster fish ladder temperature improvement (#479); construct water temperature control tower (#105); and deeper fall reservoir drawdowns for fish passage (#40). The following measures would not have effects from hazardous materials, and are therefore not discussed further.

- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b);
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Augment instream flows by using the inactive pool (#718);
- Augment instream flows by using the power pool (#304);
- Pass water over spillway in spring for fish passage (#714);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Spring reservoir drawdown for downstream fish passage (#720); and
- Fall Creek Drawdown.

A summary of the effects from hazardous materials discussed in the following sections is provided in Table 3.16-3.

Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the lesser beneficial effect does not occur at that reservoir. This follows the approach to present the most conservative conclusions in this table; instead of simply omitting reservoirs where less severe or more beneficial effects would occur. Discussions of all adverse and beneficial effects are included below.

**Table 3.16-3. Summary of Effects from Hazardous Materials**

| Effect Factor | | Alternative | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| | Short-Term | | | | | | | |
| Magnitude | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse |
| Extent | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) |
| | Medium-Term | | | | | | | |
| Magnitude | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Minor adverse |
| Extent | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) |
| | Long-Term (Permanent, Intermittent, and/or Recurring) | | | | | | | |
| Magnitude | Minor adverse | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial | Minor adverse; negligible beneficial |
| Extent | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) | Local (basin-wide) |
| Duration Type | Permanent | Permanent | Permanent | Permanent | Permanent | Permanent | Permanent | Permanent |

### *3.16.2.3 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue, which includes water quality, flow, downstream passage, and upstream passage operations. These actions, aside from the continued O&M of existing AFFs, would have no effects from hazardous materials. With respect to hazardous materials, and as stated above in Section 3.16.1, the O&M of the WVS includes construction, demolition, and maintenance (which requires the storage and use of compressed gasses, management of LBP and ACM, and other hazardous materials); fish collection and hatchery chemicals; pesticides; and the operation of oil-filled equipment.

#### *3.16.2.3.1 Fish Collection and Hatchery Chemicals and Pesticides*

Under the NAA, chemicals would continue to be stored and used at the five fish collection and five hatchery facilities. Fish facilities and hatcheries may use hazardous chemicals to clean equipment and anesthetize fish. These facilities are operated in accordance with their NPDES permits as applicable, and the majority of the chemicals are not hazardous as discussed above in Section 3.16.1.6. Pesticides are used basin-wide on an as-needed basis. The chemicals are securely-stored and the majority are also not considered hazardous as discussed above in Section 3.16.1.7. Personnel would adhere to the USACE Hazard Communication Plan, which includes training and wearing PPE as applicable, and as such, the small hazards presented by these chemicals would be adverse and negligible. The fish facilities and hatcheries would continue to discharge in accordance with their NPDES permits as applicable. The effects of pesticide use would be confined to the project area. Therefore, the effects would be local in extent. These activities would occur for the life of the project, so effects would be long term.

#### *3.16.2.3.2 Construction, Demolition, and Maintenance*

Construction and demolition would occur basin-wide under the NAA as a part of routine and non-routine maintenance activities. For example, the removal of a closed underground storage tank is scheduled to occur at the Cougar Project around 2024. Basin-wide maintenance activities, particularly those involving demolition, could potentially release ACM and/or LBP into the air. All maintenance and renovation activities would follow applicable BMPs and environmental regulations to avoid disturbing ACM and LBP. Before removing any materials, suspected areas would be tested for asbestos or LBP as applicable. If ACM is identified, it would be removed and collected by a certified asbestos-abatement contractor. Any contractors removing paint would treat the paint as if it is lead-containing and use a LBP stabilizer to reduce potential hazardous waste generation. After removal, the debris would be tested using the EPA’s Toxicity Characteristic Leachate (TCLP) procedure to determine its waste status. If determined to be hazardous, it would be disposed of in accordance with RCRA. BMPs would also be used where applicable, which may include paint removal gels (to reduce LBP dust) or the use of hooded needle guns that mechanically remove and vacuum up paint residue.

Construction, demolition, and maintenance could require hazardous materials such as diesel and gasoline for fueling equipment; aerosols, solvents, and adhesives for interior decorating; and compressed gasses for welding, cutting, and brazing, depending on the project. USACE mitigates the hazards posed by compressed gasses by adhering to the general requirements for compressed gasses in 29 CFR part 1910.101 and the welding, cutting, and brazing requirements found in 29 CFR part 1910.253. Additionally, BMPs are used, which includes securing cylinders and keeping them away from heat sources. Typically, effects to the environment from hazardous materials used in construction are associated with accidental spills resulting from improper chemical management. Spills could have a wide range of effects depending on the chemical type, quantity, and location of the spill. Some contaminants may affect soil, surface water, groundwater, or any combination thereof. For example, high levels of acute diesel exposure can cause nervous system damage or death in humans and animals (HHS 1995). Toluene, a common solvent and component of fuels, paints, and adhesives, has a moderate chronic toxicity to aquatic life and can cause a range of upper respiratory, cardiac, and reproductive issues (EPA 2016a; NPI No date a; NPI No date b).

Despite these effects, a 2015 study that considered the environmental impacts of construction activities did not rank hazardous material spills to soil or water in the top 20 most important issues (Ansah 2015). This is because the environmental effects from spills at construction sites can be readily mitigated by following BMPs like maintaining a clean working environment and adhering to proper storage and fueling guidelines. Therefore, effects would be adverse and negligible to minor in magnitude. If a spill did occur, it would be limited to the immediate area because the following actions would be taken: stop the source, contain the spill, apply absorbents, and remove affected soil in accordance with applicable BMPs. Therefore, effects would be local in extent. Small maintenance projects could last on the scale of a week, whereas construction and demolition projects may take up to two years or more, so effects would range from short to medium term. These projects would continue to occur for the life of the project, so effects would also be long term.

#### *3.16.2.3.3 Oil-filled Systems*

The greatest concern from hazardous material release into the environment in the WVS comes from the operation of oil-filled systems, which are primarily at hydropower generating facilities. Oil-filled systems are the largest threat due to the volume of stored oil and its proximity to surface water. Oil spills are a possibility when equipment malfunctions or accidents occur. Although other oil-filled equipment exists at hydropower dams, the equipment that presents the greatest oil-spill hazards are electrical transformers and turbines, as well as their auxiliary equipment such as pumps and above-ground storage tanks. However, both risk and severity of oil spills would be reduced through a variety of measures. Engineering and administrative controls are used to prevent and mitigate oil spills in accordance with each facility's SPCC plan. Applicable oil-filled equipment has alarm systems and multiple levels of containment, is regularly inspected and maintained, and operators are trained to detect and respond to oil spills as discussed above in Sections 3.16.1.1 and 3.16.1.5.

The environmental effects of oil spills can vary depending on the amount and type spilled and the water body in question. Effects on vertebrates can range from minor to major nervous system and reproductive damage to individual birds, mammals, and humans, to broader effects such as the decline or loss of key organisms and/or habitats in an ecosystem (EPA 1999; ITOPF No Date).

While no oil discharges have occurred at USACE WVS dams, several have occurred at nearby USACE dams. At the Dalles and John Day dams on the Columbia River, it was estimated that up to several hundred gallons of oil have been spilled into the Columbia River within the past three years. In all cases, USACE responded swiftly by isolating the source of the leak, deploying absorbent pads, booms, and skimmers, and notifying NGOs and partner agencies such as the National Response Center, regional emergency management offices, and the Columbia River Intertribal Fish Commission (USACE 2018d; USACE 2020; USACE 2021b). The eight USACE power-producing dams in the WVS are currently undergoing National Pollutant Discharge Elimination System (NPDES) permit processing, and it is anticipated that they will be permitted to discharge up to 10 parts per million (ppm) of oil and grease per day under Section 402 of the CWA. Because the dams would be permitted to discharge small amounts of oil, effects would be adverse and minor in magnitude. Effects could range from moderate or greater in magnitude if a large spill occurred, however, the likelihood of a large spill is historically low in the WVS. Although NPDES permits typically last for five years, dams would continue to discharge oil for the life of the project, so effects would be long term. Most spills would be contained by berms and drains and applicable equipment would be managed under SPCC plans. Therefore, effects from oil-filled systems would be local in extent because they would be confined to the project area. However, due to the nature of hydroelectric power generation, oil has the potential to enter the nearby water and travel downstream. Therefore, effects could potentially be regional in extent in some situations, such as if a berm overflowed, a drain was clogged, or there was a malfunction in the turbine cooling system (although these situations are unlikely).

#### *3.16.2.3.4 Climate Change*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M over the next 30 years. Climate change would have no effects on hazardous materials through construction, demolition, and repair of buildings and structures, storage and use of compressed gasses, fish collection and hatchery chemicals, management of LBP and ACM, or operation of oil-filled equipment at hydroelectric dams.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become more predominant and invasive plants potentially encroach further into communities of native species, as discussed in Section 3.06, Vegetation. Pest species, including those that are invasive, are managed using a variety of pesticides basin-wide. As invasive species proliferate throughout the WVS over time as a result of climate change, the quantity of pesticides used to control them would be expected to increase proportionally. As discussed above in Section 3.16.1.1 and detailed in the Hazard Communication Plan, USACE personnel are informed of and able to identify hazardous chemicals, as well as protect themselves from hazardous chemical exposures using PPE. Further, pesticides are securely stored, many are considered non-hazardous, and the majority of applications are away from water. Therefore, the effects of climate change in combination with the measures under the NAA from hazardous materials would be negligible in magnitude, local in extent, and long-term.

#### *3.16.2.4 Discussion of Effects by Measures*

This section applies the methodology described above to each measure analyzed for the resource to determine the potential effects. Where possible, the discussion of the magnitude and duration of effects is grouped by measures that would have similar effects. The effects by measure or measures will then be referenced in the action alternative's analysis that follows. Gravel augmentation below dams (#384); maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9); maintenance of existing and new fish release sites above dams (#726); operation, maintenance, repair, replacement and rehabilitation; Foster fish ladder temperature improvement (#479); construct water temperature control tower (#105); use spillway for surface spill in summer (#721); structural improvements to reduce total dissolved gas (#174); restore upstream and downstream passage at drop structures (#639); construct adult fish facility (#722); provide Pacific lamprey passage and infrastructure (#52); construct structural downstream fish passage (#392); and deeper fall reservoir drawdowns for fish passage (#40) would require construction as described above in Section 3.1.2.1. The PEIS discuses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents will discuss detailed site-specific effects.

##### *3.16.2.4.1 Continued Operation of Existing AFFs*

The effects of continuing the operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term.

Existing AFFs use hazardous chemicals for O&M activities such as cleaning equipment and anesthetizing fish. The hazardous chemicals are primarily skin, eye, and/or respiratory irritants, although formalin is also flammable and has acute oral and inhalation toxicity. However, the risk of USACE personnel experiencing effects from these chemicals is very low because employees are briefed and trained on how to identify and avoid chemical hazards and provided with PPE, as discussed above in Section 3.16.1.1. Further, the majority of the chemicals are not hazardous and the facilities would continue to discharge in accordance with their NPDES permits as applicable. Therefore, the effects would be adverse and negligible in magnitude and local in extent. Because the facilities would operate for the lifetime of the project, effects would be long term.

#### *3.16.2.4.2 Adapt Hatchery Program (#719)*

The effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term.

Similar to AFFs, hatcheries also use hazardous chemicals for O&M activities such as cleaning equipment and anesthetizing fish, as discussed above in Section 3.16.2.4.2. Under this measure, hatchery production levels would be adjusted based on the efficacy of fish passage measures: production levels would be decreased as the amount of accessible fish habitat resulting from fish passage measures increases. Therefore, the amount of hazardous chemicals used at hatcheries would decrease proportionally with the production levels, so the effects would be beneficial. The decrease in chemical usage would have a nondetectable effect on the environment because facilities would continue to be operated in accordance with their NPDES permits as applicable, the majority of chemicals are not hazardous, and USACE personnel are briefed and trained on hazards and use PPE as appropriate. Thus, the effects would be negligible in magnitude and local in extent. The changes would last for the duration of the project, so effects would be long term.

Therefore, the potential effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term.

#### *3.16.2.4.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

The effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

Operation, maintenance, repair, replacement, and rehabilitation can be categorized into scheduled/routine maintenance, and major maintenance and rehabilitation. These actions would have identical effects to those discussed above in Section 3.16.2.3.2 from construction, demolition, and maintenance. Therefore, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

#### *3.16.2.4.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), Provide Pacific lamprey passage and infrastructure (#52), and Use spillway for surface spill in summer (#721)*

The effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; restoring upstream and downstream passage at drop structures; using the spillway for surface spill in summer (only at Blue River and Hills Creek); and providing Pacific lamprey passage and infrastructure would be negligible to minor in magnitude, local in extent, adverse, and short term.

These measures include short-term construction activities, and hazardous materials could be present, such as gasoline and diesel for fueling equipment and compressed gasses for welding, cutting, and brazing. These activities would have similar effects to those discussed above in Section 3.16.2.3.2 because the environmental effects from spills at construction sites can be minimized by following BMPs like maintaining a clean working environment and adhering to proper storage and fueling guidelines. Therefore, effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

##### *3.16.2.4.5 Structural improvements to reduce total dissolved gas (#174), Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), Construct water temperature control tower (#105), Deeper fall reservoir drawdowns for fish passage (#40), and Construct structural downstream fish passage (#392)*

The effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing AFFs, WTC towers and structural downstream fish passage; and deeper fall drawdowns would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Additionally, deeper fall drawdowns (only at Detroit, Green Peter, and Lookout Point) and constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also have negligible in magnitude, local in extent, long-term effects from operation after construction. Construction effects from the deeper fall drawdown would only occur at Cougar when the reservoir is drawn down to the DT, as this would require the construction of an intake and access tower. Drawdowns would only have medium-term effects when there would be construction associated with it (Cougar in Alternatives 2B and 3B). Similar to the measures discussed above in Sections 3.16.2.3.2 and 3.16.2.4.4, these measures include medium-term construction activities and could require hazardous materials for fueling equipment and cutting, welding, and brazing. Therefore, effects would be negligible to minor in magnitude, local in extent, adverse, and medium term.

WTC towers effectively serve as hydropower turbine intakes and would require oil-filled systems to adjust the gates that control water flows. WTC towers, AFFs, structural downstream fish passage (excluding Foster), and deep fall drawdowns at Detroit, Green Peter, and Lookout Point would require the installation of emergency diesel generators (EDGs) to provide power during an emergency. The EDGs at Detroit, Green Peter, and Lookout Point would be required for deep drawdowns as the current EDG cooling water intakes are located too high to be used during deep drawdowns. These oil-filled systems would provide new, additional sources for potential oil spills during operation. However, construction of these facilities would include berms and drains to prevent spills from reaching the water, and EDGs and any supporting equipment would be added to and managed under facility SPCC plans as applicable. Therefore, effects from oil-filled systems would be adverse and negligible in magnitude as discussed above in Section 3.16.2.3.3. If a spill did occur, it would be limited to the immediate area, so effects would be local in extent. Operations would continue for the life of the project, so the effects would be long term. AFFs would also require hazardous chemicals for fish facility operations as discussed above in Section 3.16.2.3.1, so effects would be negligible in magnitude, local in extent, adverse, and long term.

Therefore, potential adverse effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing AFFs, WTC towers and structural downstream fish passage; and deeper fall drawdowns would be negligible to minor in magnitude, local in extent, and adverse in the medium-term, and deeper fall drawdowns and constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also have negligible in magnitude, local in extent, long-term effects from operation after construction.

##### *3.16.2.4.6 Suite of near-term operations*

The majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns at Green Peter and Lookout Point dams would require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

#### ***3.16.2.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures***

Under Alternative 1, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; restoring upstream and downstream passage at drop structures; and providing Pacific lamprey passage and infrastructure would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing AFFs, WTC towers and structural downstream fish passage would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also have negligible in magnitude, local in extent, long-term effects from operations.

Overall, these effects would be greater than alternatives 2A, 2B, 3A, and 3B due to the number of medium-term construction projects.

##### *3.16.2.5.1 Continued operation of existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue at Dexter, Cougar, Foster, Fall Creek, and Minto. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.5.2 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

#### *3.16.2.5.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

#### *3.16.2.5.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), and Provide Pacific lamprey passage and infrastructure (#52)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 1, restoring upstream and downstream passage at drop structures would occur at Fern Ridge, and providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Green Peter. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

#### *3.16.2.5.5 Structural improvements to reduce total dissolved gas (#174), Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), Construct water temperature control tower (#105); and Construct structural downstream fish passage (#392)*

Under Alternative 1, improving structures to reduce TDG would have effects at Cougar, Dexter, and Foster; the fish ladder temperature improvement would occur at Foster, constructing an AFF would occur at Green Peter, constructing a WTC tower would occur at Detroit, Green Peter, and Lookout Point; and constructing downstream fish passage infrastructure would occur at Detroit, Foster, Green Peter, and Lookout Point. Due to the construction of WTC towers, there would be no separate structural improvement projects to reduce TDG at Detroit, Green Peter, or Lookout Point. Because EDGs would only be required for structural downstream passage using FSSs or FSCs, no EDG would be installed at Foster and thus, there would be no long-term operational effects.

As discussed in Section 3.16.2.4.5, the effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing an AFF, WTC towers, and structural downstream fish passage would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from constructing an AFF, WTC towers, and structural downstream fish passage (excluding Foster) would also be negligible in magnitude, local in extent, long-term from operation.

##### *3.16.2.5.6 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 1 (and all action alternatives) would result in the same effects from climate change on hazardous materials. As discussed above in Section 3.16.2.3.4, climate change could result in the proliferation of pest species, which may require the increased use of pesticides to control. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

#### ***3.16.2.6 Alternative 2A – Integrated Water Management Flexibility and ESA Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)***

Under Alternative 2A, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; and providing Pacific lamprey passage and infrastructure would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; and constructing AFFs, WTC towers and structural downstream fish passage would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Deeper fall drawdowns and constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also have negligible in magnitude, local in extent, long-term effects from operations.

Overall, these effects would be the same as Alternative 3A, greater than Alternatives 2B and 5, but less than Alternatives 3B and 4 due to the number of medium-term construction projects.

##### *3.16.2.6.1 Continued operation of existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue at Dexter, Cougar, Foster, Fall Creek, and Minto. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.6.2 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

#### *3.16.2.6.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

#### *3.16.2.6.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Provide Pacific lamprey passage and infrastructure (#52)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 2A, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

#### *3.16.2.6.5 Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), Construct water temperature control tower (#105); Deeper fall reservoir drawdowns for fish passage (#40), and Construct structural downstream fish passage (#392)*

Under Alternative 2A, the fish ladder temperature improvement would occur at Foster; constructing an AFF would occur at Green Peter, constructing a WTC tower would occur at Detroit; deeper fall drawdowns would have effects at Green Peter (long term); and constructing structural downstream fish passage infrastructure would occur at Cougar, Detroit, Foster, and Lookout Point. Because EDGs would only be required for structural downstream passage using FSSs or FSCs, no EDG would be installed at Foster and thus, there would be no long-term operational effects.

As discussed above in Section 3.16.2.5.5 effects from the Foster fish ladder temperature improvement; constructing an AFF, WTC tower, and structural downstream passage would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from the deeper fall drawdown and constructing an AFF, WTC towers, and structural downstream fish passage (excluding Foster) would also be negligible in magnitude, local in extent, and long-term from operations.

#### *3.16.2.6.6 Suite of near-term operations*

As discussed above in Section 3.16.2.4.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns Green Peter and Lookout Point dams would each require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.6.7 Climate Change*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 2A (and all action alternatives) would result in the same effects from climate change on hazardous materials. As discussed above in Section 3.16.2.3.4, climate change could result in the proliferation of pest species, which may require the increased use of pesticides to control. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

### ***3.16.2.7 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 2B, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; and providing Pacific lamprey passage and infrastructure would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing AFFs, WTC towers and structural downstream fish passage; and deeper fall drawdowns (at Cougar only) would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Deeper fall drawdowns and constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also be negligible in magnitude, local in extent, long-term effects from operations.

Overall, these effects would be the same as Alternative 5 and less than all other action alternatives because Alternatives 2B and 5 include the fewest short- and medium-term construction projects due to the number of medium-term construction projects that would also result in long-term effects from operations.

##### *3.16.2.7.1 Continued operation of existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue at Dexter, Cougar, Foster, Fall Creek, and Minto. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

##### *3.16.2.7.2 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

##### *3.16.2.7.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

##### *3.16.2.7.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), and Provide Pacific lamprey passage and infrastructure (#52)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 2B, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

##### *3.16.2.7.5 Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), Construct water temperature control tower (#105), Deeper fall reservoir drawdowns for fish passage (#40), and Construct structural downstream fish passage (#392)*

Under Alternative 2B, the fish ladder temperature improvement would occur at Foster, constructing an AFF would occur at Green Peter, constructing a WTC tower would occur at Detroit; deeper fall drawdowns would have effects at Cougar (medium and long term) and Green Peter (long term); and constructing downstream fish passage infrastructure would occur at Detroit, Foster, and Lookout Point. Because EDGs would only be required for structural downstream passage using FSSs or FSCs, no EDG would be installed at Foster and thus, there would be no long-term operational effects.

As discussed above in Section 3.16.2.5.5 effects from the Foster fish ladder temperature improvement, deeper fall reservoir drawdown (only at Cougar due to construction of the intake and access tower required to use the DT), and constructing an AFF, WTC tower, and structural downstream passage would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from the deeper fall drawdown and constructing an AFF, WTC towers, and structural downstream fish passage (excluding Foster) would also be negligible in magnitude, local in extent, and long-term from operations.

##### *3.16.2.7.6 Suite of near-term operations*

As discussed above in Section 3.16.2.4.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns Green Peter and Lookout Point dams would each require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

##### *3.16.2.7.7 Climate Change*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam's DT). These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 2B (and all action alternatives) would result in the same effects from climate change on hazardous materials. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

#### ***3.16.2.8 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)***

Under Alternative 3A, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; providing Pacific lamprey passage and infrastructure; and using the spillway for summer surface spill (at Blue River and Hills Creek) would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from the Foster fish ladder temperature improvement and constructing AFFs would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Deeper fall drawdowns (at Detroit, Green peter, and Lookout Point) and constructing AFFs would also be negligible in magnitude, local in extent, and long-term.

Overall, these effects would be the same as Alternative 2A, greater than Alternatives 2B and 5, and less than Alternatives 1, 3B, and 4 due to the number of medium-term construction projects that would also result in long-term effects from operations.

###### *3.16.2.8.1 Continued Operation of Existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

###### *3.16.2.8.2 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

###### *3.16.2.8.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

###### *3.16.2.8.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Use spillway for surface spill in summer (#721), and Provide Pacific lamprey passage and infrastructure (#52)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 3A, providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek, and using the spillway for surface spill in the summer would have effects at Blue River and Hills Creek. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

###### *3.16.2.8.5 Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), and Deeper fall reservoir drawdown for fish passage (#40)*

Under Alternative 3A, the fish ladder temperature improvement would occur at Foster; constructing an AFF would occur at Blue River, Green Peter, and Hills Creek and deeper fall drawdowns would have effects at Detroit, Green Peter, and Lookout Point (long term).

As discussed above in Section 3.16.2.5.5 effects from the Foster fish ladder temperature improvement and constructing AFFs would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from the deeper fall drawdown and constructing AFFs would be negligible in magnitude, local in extent, and long-term.

#### *3.16.2.8.6 Suite of near-term operations*

As discussed above in Section 3.16.2.4.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns Green Peter and Lookout Point dams would each require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.8.7 Climate Change*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 3A (and all action alternatives) would result in the same effects from climate change on hazardous materials. As discussed above in Section 3.16.2.3.4, climate change could result in the proliferation of pest species, which may require the increased use of pesticides to control. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

### ***3.16.2.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Under Alternative 3B, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; providing Pacific lamprey passage and infrastructure; and using the spillway for summer surface spill (at Blue River and Hills Creek) would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from the Foster fish ladder temperature improvement, constructing AFFs and deeper fall drawdowns (at Cougar only) would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Effects from deeper fall drawdowns and constructing AFFs would also be negligible in magnitude, local in extent, and long-term.

Overall, these effects would be greater than Alternatives 2A, 2B, and 5, but less than Alternatives 1 and 4 due to the number of medium-term construction projects that would also result in long-term effects from operations.

##### *3.16.2.9.1 Continued Operation of Existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

##### *3.16.2.9.2 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

##### *3.16.2.9.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

##### *3.16.2.9.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Provide Pacific lamprey passage and infrastructure (#52), and Use spillway for surface spill in summer (#721);*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 3B, providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek, and using the spillway for surface spill in the summer would have effects at Blue River and Hills Creek. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

##### *3.16.2.9.5 Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), and Deeper fall reservoir drawdowns for fish passage (#40)*

Under Alternative 3B, the fish ladder temperature improvement would occur at Foster; constructing AFFs would occur at Blue River, Green Peter, and Hills Creek; and deeper fall drawdowns would have effects at Cougar (medium and long term), Detroit, Green Peter, and Lookout Point (long term).

As discussed above in Section 3.16.2.5.5 effects from the Foster fish ladder temperature improvement; deeper fall reservoir drawdown (only at Cougar due to construction of the intake and access tower required to use the DT), and constructing AFFs would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from the deeper fall drawdown and constructing AFFs would also be negligible in magnitude, local in extent, and long-term.

#### *3.16.2.9.6 Suite of near-term operations*

As discussed above in Section 3.16.2.4.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns Green Peter and Lookout Point dams would each require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.9.7 Climate Change*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougar Dam's RO). These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 3B (and all action alternatives) would result in the same effects from climate change on hazardous materials. As discussed above in Section 3.16.2.3.4, climate change could result in the proliferation of pest species, which may require the increased use of pesticides to control. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

### ***3.16.2.10 Alternative 4 – Structures-Based Fish Passage Alternative***

Under Alternative 4, effects of continued operation of existing AFFs would be negligible in magnitude, local in extent, adverse, and long term. Effects of adapting the hatchery program would be negligible in magnitude, local in extent, beneficial, and long term. Effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term. Effects from augmenting gravel below dams; maintaining or altering revetments; maintaining existing and new fish release sites above dams; restoring upstream and downstream passage at drop structures; and providing Pacific lamprey passage and infrastructure would be negligible to minor in magnitude, local in extent, adverse, and short term. Effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement and constructing AFFs, WTC towers and structural downstream fish passage would be negligible to minor in magnitude, local in extent, adverse, and medium term from construction. Constructing AFFs, WTC towers, and structural downstream fish passage (excluding Foster) would also have negligible in magnitude, local in extent, long-term effects from operations.

Overall, these effects would be greater than all other action alternatives due to the number of medium-term construction projects that would occur.

*3.16.2.10.1 Adapt Hatchery Program (#719)*

Under all action alternatives the hatchery programs would be adapted in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins. As discussed above in Section 3.16.2.4.2, the effects would be negligible in magnitude, local in extent, beneficial, and long term.

*3.16.2.10.2 Continued Operation of Existing AFFs*

Under all action alternatives, the operation of existing AFFs would continue at Dexter, Cougar, Foster, Fall Creek, and Minto. As discussed above in Section 3.16.2.4.1, the effects would be negligible in magnitude, local in extent, adverse, and long term.

*3.16.2.10.3 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.16.2.4.3, the effects would be negligible to minor in magnitude, adverse, and local in extent in the short, medium, and long term.

*3.16.2.10.4 Gravel augmentation below dams (#384), Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9), Maintenance of existing and new fish release sites above dams (#726), Restore upstream and downstream passage at drop structures (#639), and Provide Pacific lamprey passage and infrastructure (#52)*

Under all action alternatives, augmenting gravel below dams would occur below Big Cliff, Blue River, Cougar, and Foster, maintaining or altering revetments would occur basin-wide in rivers, and maintenance of existing and new fish release sites would occur basin-wide. Under Alternative 4, restoring upstream and downstream passage at drop structures would occur at Fern Ridge, and providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Hills Creek. As discussed above in Section 3.16.2.4.4, the effects would be negligible to minor in magnitude, local in extent, adverse, and short term.

*3.16.2.10.5 Structural improvements to reduce total dissolved gas (#174), Foster Fish Ladder Temperature Improvement (#479), Construct adult fish facility (#722), Construct water temperature control tower (#105), and Construct structural downstream fish passage (#392)*

Under Alternative 4, improving structures to reduce TDG would have effects at Cougar, Dexter, Green Peter, and Foster; the fish ladder temperature improvement would occur at Foster, constructing an AFF would occur at Hills Creek, constructing WTC towers would occur at Detroit, Hills Creek, and Lookout Point; and constructing downstream fish passage infrastructure would occur at Cougar, Detroit, Foster, Hills Creek, and Lookout Point. Due to the construction of WTC towers, there would be no separate structural improvement projects to reduce TDG at Detroit or Lookout Point. Because EDGs would only be required for structural downstream passage using FSSs or FSCs, no EDG would be installed at Foster and thus, there would be no long-term operational effects.

As discussed in Section 3.16.2.4.5, the effects from improving structures to reduce TDG; the Foster fish ladder temperature improvement; constructing an AFF, WTC towers, and structural downstream fish passage would be negligible to minor in magnitude, local in extent, and adverse in the medium-term. The effects from constructing an AFF, WTC towers, and structural downstream fish passage (excluding Foster) would also be negligible in magnitude, local in extent, long-term from operation.

#### *3.16.2.10.6 Suite of near-term operations*

As discussed above in Section 3.16.2.4.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects from hazardous materials. The deep drawdowns Green Peter and Lookout Point dams would each require the installation of an EDG and would provide new, additional sources for potential oil spills during operation as discussed above in Section 3.16.2.4.5. Therefore, the potential adverse effects would be negligible in magnitude, local in extent, adverse, and long term.

#### *3.16.2.10.7 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. These measures would have negligible to minor, adverse and beneficial effects from hazardous materials, but would not contribute to effects from climate change. Therefore, Alternative 4 (and all action alternatives) would result in the same effects from climate change on hazardous materials. As discussed above in Section 3.16.2.3.4, climate change could result in the proliferation of pest species, which may require the increased use of pesticides to control. Because pesticides are securely stored, most are considered non-hazardous, and the majority of applications are away from water, the effects of climate change from hazardous materials would be adverse and negligible in magnitude, local in extent, and long-term.

### ***3.16.2.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Alternative 5 would only differ from Alternative 2B by way of the refined integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would have effects from hazardous materials. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2B and less than all other action alternatives because Alternatives 2B and 5 include the fewest short- and medium-term construction projects that would also result in long-term effects from operations.

#### *3.16.2.12 Conclusion*

Severity of adverse effects on hazardous materials is primarily driven by the number of medium-term construction projects, particularly, those that would require the installation of oil-filled equipment and subsequently also result in long-term effects. The action alternatives organized in order of least-severe to most-severe adverse effects on hazardous materials would be: 2B/5, 2A and 3A, 3B, 1, and 4, although there would only be small differences in the level of adverse effects between Alternatives 2B/5, 2A, 3A, and 3B (i.e., Alternatives 1 and 4 would be markedly more severe than the other action alternatives). Differences between the action alternatives would not contribute to effects from climate change on hazardous materials. Therefore, all action alternatives would result in equal effects from climate change with respect to hazardous materials.

## 3.17 PUBLIC HEALTH AND SAFETY – HARMFUL ALGAL BLOOMS

### 3.17.1 Affected Environment

This section describes the existing conditions and occurrences of harmful algal blooms (HABs) within the waters of the WVS. For more information on HABs see section 3.5.

#### *3.17.1.1 What are HABs?*

HABs occur when colonies of algae — simple plants that can be found in freshwater sources such as rivers, lakes, and streams — grow out of control and produce toxic or harmful effects on people, fish, shellfish, marine mammals and birds. Algae and algal blooms are a natural occurrence in marine ecosystems and brackish waters (mixtures of fresh and salt water). Algae cycle nutrients and support the aquatic food web (Burford et al. 2019). However, there are a few forms of algae that are harmful to humans and animals. These include benthic algae, macroalgae, phytoplankton, and cyanobacteria.

Cyanobacteria, also known as blue-green algae, are a form of algae that can produce toxins, which often cause HAB occurrences in freshwater (NOAA 2021). Cyanobacteria HABs can be harmful to humans, pets, wildlife, and livestock if consumed in water and are also responsible for mass fish kills (Gilbert et al. 2005). HAB "events" can last for a short duration and then subside, potentially recurring again the following year. HAB events cannot be predicted as each event is dependent on certain physical and biological conditions discussed below (NOAA 2021).

HAB events have the potential to occur in surface waters used for recreation and those which supply public drinking water such as reservoirs, lakes, and rivers, posing a threat to public health and drinking water supplies (see section 3.19 on Public Health and Safety – Drinking Water). For example, in 2011, the Great Lakes had a record-setting HAB event in Lake Erie with an algal bloom that covered 5,000 square kilometers ($km^2$), shutting down the water supply for over half a million people for several days (Burford et al, 2019). Water treatment facilities implemented additional filtration steps in order to treat the algae and public warnings were issued (NASA 2021).

The number of HAB events have been observed by the scientific community to be increasing nationally and globally. This is largely due to increased levels of human activities such as agriculture and aquaculture, overfishing of top predatory fish causing disruption in the food chain, and ballast water discharge, as these can all lead to an increase in nutrients discharged to water (Gilbert et al. 2005). Global climate change also increases the incidence of HABs. Warmer temperatures, declining pH due to increased $CO_2$, and limitation of light are also conducive to the rapid growth of cyanobacteria blooms, causing HABs to dominate the water surface (Gilbert 2020).

Domestic and industrial waste are also known contributors to eutrophication (or excess nutrients in water bodies) and subsequent increased HAB growth. The increase in the amount of nutrients in a water body is not as critical to HAB growth as the proportion of nitrogen to phosphorus in the water. Changes in nutrient limitation of either nitrogen or phosphorus can change the composition of some algae, resulting in HABs (King County 2003).

### 3.17.2 HABs in the WVS

Natural seasonal algal blooms occur in the WVS reservoirs; however, as discussed in Section 3.6, Water Quality, HABs have been detected in 10 of the 13 WVS reservoirs in the past 16 years. These include the Detroit, Big Cliff, Cougar, Blue River, Dexter, Falls Creek, Hills Creek, Lookout Point, Dorena, and Fern Ridge reservoirs. The Oregon Health Authority (OHA) runs a HABs surveillance program and lists reservoirs for public advisory on the OHA website. The advisory is based on World Health Organization (WHO) guidelines for monitoring visible scum, toxicity levels, or cyanobacteria cell counts (ODEQ, 2011). Currently, observed algal blooms are reported to the District water quality staff. The District water quality staff will take samples when possible and report the results to OHA. Figure 3.5-53 indicates the number of days that the reservoirs have been listed for public advisory since 2005.

Both nutrients from fertilizers used in rural watersheds and runoff from streets in the urban areas near the reservoirs can contribute to excess nutrient loads in the reservoirs. Compared to natural lakes, reservoirs have a different assimilative capacity (i.e., the ability for the reservoir to cleanse itself from pollutants). The reservoir size relative to the drainage area, the typically elongated shape of reservoirs and outlet structures, and mixing processes within the reservoir can all affect nutrient loading. These factors could explain why HABs are more common in reservoirs than in natural lakes (ODEQ 2011).

Common cyanobacteria occurring in lakes and reservoirs in Oregon include *Microcystis*, *Aphanizomenon*, *Gloeotrichia*, *Anabaena*, *Lyngbya*, and *Phormidium* (ODEQ 2011). Section 3.6, Water Quality, discusses the history of HABs in the ten WVS reservoirs where they have been detected. The species of cyanobacteria contributing to the HAB events in WVS reservoirs are listed Table 3.17-1 below.

**Table 3.17-1. Species of Cyanobacteria Contributing to HABs events in WVS Reservoirs.**

| Sub-basin | Reservoir | Species |
|---|---|---|
| North Santiam | Detroit, Big Cliff | *Dolichospermum spp.* (previously *Anabaena spp.*) |
| McKenzie | Cougar, Blue River | *Anabaena spp.* and *Aphanizomenon spp.* |
| Middle Fork | Dexter, Fall Creek, Hill Creek, Lookout Point | *Gloeotrichia spp*., *Dolichospermum spp*., and *Aphanizomenon spp.* |
| Coast Fork and Long Tom | Dorena, Fern Ridge | *Gloeotrichia spp*., *Aphanizomenon spp*., *Dolichospermum spp*., and *Microcystis spp*. |

Source: See Section 3.6, Water Quality

### 3.17.3 Public Health Concerns

The Harmful Algal Bloom and Hypoxia Research and Control Amendments Act (HABHRCA) was enacted by Congress in 2014. It requires the National Oceanic and Atmospheric Administration

(NOAA) and the U.S. Environmental Protection Agency (EPA) to advance the science and research of HABs to control and mitigate their occurrences (EPA 2021f). The EPA has the statutory authority to determine if a HABs event is an "event of national significance". The EPA's national 10-day health advisory levels are provided in Table 3.17-2 below. If cyanotoxins occur in tap water above these levels over 10-day exposure durations, people are at risk of adverse health effects.

**Table 3.17-2. EPA 10-Day Health Advisories**

| 10-Day Health Advisories | Level |
|---|---|
| **Microcystins** | |
| Children pre-school age and younger (under 6 years old) | 0.3 µg/L |
| School-age children (6 years and older) | 1.6 µg/L |
| **Cylindrospermopsin** | |
| Children pre-school age and younger (under 6 years old) | 0.7 µg/L |
| School-age children (6 years and older) | 3.0 µg/L |

Source: EPA Harmful Algal Blooms and Drinking Water Factsheet (EPA 2016b)
µg/L = micrograms per liter

Certain cyanobacteria can produce toxins which can affect the nervous system, liver, or skin and can cause eye or ear irritation. Diarrhea and vomiting can also occur if cyanobacteria are ingested (ODEQ 2011). Microcystins are the most common cyanobacterial HAB toxins that can cause liver toxins resulting in gastrointestinal illnesses for humans. These illnesses can be debilitating and in rare cases fatal (NOAA 2021).

Low levels of cyanotoxins can be removed with conventional water treatment. However, during severe HABs events drinking water requires additional treatment which can be challenging. The properties of the cyanotoxins (intracellular versus extracellular), growth patterns, species, and available types of treatment must be understood in order to control the levels of cyanotoxins in drinking water. To prevent health risks during severe HAB events, water system managers and decisionmakers must take certain steps including adjusting filtration and treatment, monitoring algal blooms, and issuing public health warnings (EPA 2016b). OHA posts public recreational advisories warning the public to avoid water contact. Groundwater and surface water sources that communities rely on for public drinking water are located downstream of the WVS reservoirs. Water is drawn directly from Dexter Reservoir by the City of Lowell for drinking water.

### 3.17.4 HABS Control Methods

The management of cyanobacteria HABs requires monitoring, mitigation, and prediction. The most effective management measure is mitigation through nutrient reduction. Nutrient reduction in the watershed through methods such as stormwater management, sewage treatment facility upgrades, control of erosion in the watershed, and reduction of nutrients from cattle farms and agriculture is the best long-term strategy, but it can take decades for this to be effective. (Burford et al. 2019).

There are common physical and chemical control methods for waterbody management that can be implemented to control cyanobacterial HABs. The EPA recommends physical water control methods such as aeration, hydrologic manipulations of inflow and outflow, mechanical mixing (i.e., circulation), reservoir drawdown/desiccation, surface skimming, and ultrasound devices that emit ultrasonic waves that destroy the cellular structure of cyanobacteria. Chemical control methods include the use of algaecides, barley straw, coagulation, and flocculation (EPA 2020b).

In 2017, the Corps evaluated several other physical methods to control HABs including hypolimnetic withdrawals and horizontal flushing (USACE 2017h). Hypolimnetic withdrawals release cooler water from the lower layers of a reservoir and allow the warmer layers of the surface to reach lower depths. This mixing action can decrease temperatures and create less suitable conditions for HABs to develop. With this method, however, the reservoir withdrawals can limit mixing to localized areas next to the area of withdrawal. This could increase turbidity, which could in turn affect beneficial phytoplankton, and loss of the cooler water could affect downstream temperature targets.

Horizontal flushing is another HAB control method reviewed by the Corps in 2017 (USACE 2017h). This method requires the upper layer of the reservoir to be flushed using high-velocity water jets to allow mixing. However, the turnover created by this mixing could allow nutrients from the lower level to reach the upper water column where the HAB species occur. This method is also disadvantageous as it is difficult to implement over a large area.

Another HAB control method evaluated by the Corps involved blocking sunlight using floating artificial covers and floating balls to reduce the growth of algae in drinking water reservoirs (USACE 2017h). This method, used by the Los Angeles Department of Water and Power, was effective in reducing evaporation and limiting algal growth. Disadvantages that may result from using this method include the costs to maintain the artificial covers and floating balls in areas with winter ice cover and the potential for sunlight blocking to impact the ecosystem due to decreased dissolved oxygen.

### 3.17.5 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on Public Health and Safety – Harmful Algal Blooms. The discussion includes the methodology, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis for each alternative.

#### *3.17.5.1 Methodology*

The methodology below is used to assess the No Action Alternative (NAA) and the action alternatives' effects on the formation of HABs within the WVS with respect to public health and safety. The formation of HABs is dependent on several environmental factors as described in Section 3.17.1 and can be difficult to predict. The measures for the NAA and action alternatives may enhance the accumulation of HABs or may be beneficial towards the reduction and prevention of HABs. Measures that would contribute to eutrophication including increased sedimentation and nutrients in a water body would have adverse effects because the likelihood of a HABs event would increase. Measures that would prevent HABs events would have beneficial effects and include those in which the continual flow of water would prevent stagnant waters. HABs can last for several days or up to one year or more in a given location and can occur over a small localized area or the entire reservoir and the downstream reaches. Table 3.17-3 describes the evaluation criteria for the effect factors (magnitude, duration, and extent), and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.17-3. Evaluation Criteria for Potential Effects to Public Health and Safety – HABs**

| Effect Factors and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Public health and safety would not be affected, or changes or benefits would be either nondetectable or, if detected by monitoring or exposure to unsafe conditions from a HAB event, would have effects that would be slight and temporary. Chemical or physical changes to water quality would be temporary and within regulatory standards for water quality conditions for recreation or drinking water supply. No mitigation measures would be necessary. |
| Minor | Changes to public health and safety would be measurable if detected by monitoring or exposure to unsafe conditions from a HAB event, although the changes would be small. Chemical or physical changes to water quality would be detectable by monitoring or exposure to unsafe conditions, but would be within regulatory standards for water quality conditions for recreation or drinking water supply. No mitigation measures would be necessary. |
| Moderate | Changes to public health and safety would be measurable by monitoring or exposure to unsafe conditions from a HAB event and would have adverse or beneficial effects on the affected water body and any affected local downstream receiving waters for recreation or drinking water supply. Chemical or physical changes to water quality would be below regulatory standards for water conditions suitable for recreation and drinking water supply. Mitigation measures would be necessary |

| Effect Factors and Scale | Definition |
|---|---|
| | if the affected water body and local downstream receiving waters are used for recreation or drinking water. |
| Major or Significant | Changes to public health and safety would be readily apparent, either severely adverse or exceptionally beneficial, and result in substantial, noticeable effects on the affected water body and any affected local downstream receiving waters for recreation or drinking water supply. The effects would be detectable by monitoring or exposure to unsafe conditions from a HAB event. Chemical or physical changes to water quality would be well below regulatory standards for water quality conditions suitable for recreation and drinking water supply. Adverse effects could not be reduced using mitigation measures for treating the HAB. |
| **Duration** | |
| Short-term | Effects last for the duration of small construction projects and are continuous for less than 2 years. |
| Medium-term | Effects are limited to the duration of large construction projects and is continuous for a period of 2-5 years. |
| Long-term | Effects are permanent or last continuously beyond operational changes or the completion of all construction projects; effects recur at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or effects occur intermittently. |
| **Extent** | |
| Small | Effects would be confined to a small area (e.g., the inflow to the dam, the area surrounding the principal inlet, along the shoreline of the reservoir, downstream of the dam, or the project area). |
| Medium | Effects occur in the entire reservoir. |
| Large | Effects occur in the entire reservoir and downstream receiving water body. |

#### *3.17.5.2 Measures Analyzed for Public Health and Safety – HABs*

Measures under the action alternatives that could impact Public Health and Safety – HABs include:

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9);
- Foster fish ladder temperature improvement (#479);
- Construct water temperature control (WTC) towers (#105);
- Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Use spillway for surface spill in summer (#721);
- Structural improvements to reduce total dissolved gas (#174);
- Augment instream flows by using the inactive pool (#718);
- Augment instream flows by using the power pool (#304);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b)
- Restore upstream and downstream passage at drop structures (#639);
- Construct adult fish facility (AFF) (#722);
- Provide Pacific lamprey passage and infrastructure (#52);
- Construct structural downstream fish passage (#392);
- Deeper fall reservoir drawdowns for fish passage (#40);
- Spring reservoir drawdown for fish downstream fish passage (#720); and
- Pass water over spillway in spring for fish passage (#714).
- Fall Creek drawdown;
- Continued operation of existing adult fish facilities;
- Operation, maintenance, repair, replacement, and rehabilitation;
- Near-term Operations Measure

The following measures would have no effect on Public Health and Safety – HABs and are therefore not discussed further.

- Gravel augmentation below dams (#384);

- Adapt hatchery program (#719);
- Maintenance of existing and new fish release sites above dams (#726).

A summary of the Public Health and Safety – HABs effects discussed in the sections below is provided in Table 3.17-4.

Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the lesser beneficial effect does not occur at that reservoir. This follows the approach to present the most conservative conclusions in this table; instead of simply omitting reservoirs where less severe or more beneficial effects would occur. Discussion of all adverse and beneficial effects are included below.

**Table 3.17-4. Summary of Effects to Public Health and Safety – HABs Under Each Alternative**

| Effect Factor | NAA | Alternative 1 | 2A | 2B | 3A | 3B | 4 | 5 |
|---|---|---|---|---|---|---|---|---|
| | **Short-Term** | | | | | | | |
| Magnitude | Beneficial minor; beneficial and adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor |
| Extent | Small, large (basin-wide, FOS, DET, FCR, CGR, DEX, BCL, LOP, HCR, CGR) | Small, large (basin-wide, FOS, DET, FRN, GPR, CGR, DEX, LOP, BLU, CTG, DOR, FCR, HCR) | Small, large (basin-wide, FOS, DET, GPR, CGR, LOP, BCL, DEX, GPR) | Small, large (basin-wide, FOS, DET, LOP, BCL, DEX, GPR, BLUE, FCR, CGR, HCR) | Small, large (basin-wide, BLU, GPR, HCR, DET, LOP, FOS, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide, BLU, GPR, HCR, DET, LOP, FOS, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide, FOS, FRN, HCR, CGR, DET, DEX, GPR, LOP, BLU, CTG, DOR, FCR, BLU) | Small, large (basin-wide, FOS, DET, GPR, LOP, BCL, DEX, BLU, FCR, HCR, CGR) |
| | **Medium-Term** | | | | | | | |
| Magnitude | Adverse negligible | Adverse negligible | Adverse negligible | Adverse negligible | Adverse negligible | Adverse negligible | Adverse negligible | Negligible adverse |
| Extent | Small (basin-wide) | Small (basin-wide, FOS, DET, FRN, CGR, GPR, LOP, BCL, DEX, FRN, CGR, DEX) | Small (basin-wide, FOS, DET, CGR, LOP, BCL, DEX, GPR) | Small (basin-wide, FOS, DET, GPR, LOP, BCL, DEX) | Small (basin-wide, BLU, GPR, HCR, DET, FOS, LOP, CGR, FCR, BCL) | Small (basin-wide, BLU, GPR, HCR, DET, FOS, LOP, CGR, FCR, BCL) | Small (basin-wide, FOS, FRN, HCR, CGR, DET, DEX, GPR, LOP) | Small (basin-wide, FOS, DET, GPR, LOP, BCL, DEX) |
| | **Long-Term (Permanent, Intermittent, or Recurring)** | | | | | | | |
| Magnitude | Beneficial minor; beneficial | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor | Beneficial and/or adverse minor |

| Effect Factor | | Alternative | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| | and adverse minor | | | | | | | |
| Extent | Small, large (basin-wide, FOS, DET, FCR, CGR, DEX, BCL, LOP, HCR, CGR) | Small, large (basin-wide, FOS, DET, FRN, GPR, CGR, DEX, LOP, BLU, CTG, DOR, FCR, HCR) | Small, large (basin-wide, FOS, DET, GPR, CGR, LOP, BCL, DEX, GPR) | Small, large (basin-wide, FOS, DET, LOP, BCL, DEX, GPR, BLUE, FCR, CGR, HCR) | Small, large (basin-wide, BLU, GPR, HCR, DET, LOP, FOS, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide, BLU, GPR, HCR, DET, LOP, FOS, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide, FOS, FRN, HCR, CGR, DET, DEX, GPR, LOP, BLU, CTG, DOR, FCR, BLU) | Small, large (basin-wide, FOS, DET, GPR, LOP, BCL, DEX, BLU, FCR, HCR, CGR) |
| Duration Type | Recurring | Permanent and/or recurring | Recurring | Recurring | Recurring | Recurring | Permanent and/or recurring | Permanent and/or recurring |

In the following subsections, effects are discussed by measure(s) and subsequently for the (NAA), for each proposed measure that could have an impact, and for each of the action alternatives.

#### *3.17.5.3 Discussion of Effects by Measure(s)*

This section applies the methodology described above to each measure analyzed for the resource to determine the potential effects. Where possible, the discussion of the magnitude and duration of effects is grouped by measures that would have similar effects. The effects by measure or measures will then be referenced in the action alternative's analysis that follows. The extent of effects is discussed by dam/reservoir under the appropriate alternative.

Site-specific project details for each construction measure would be determined during the preconstruction engineering and design phase. While general, qualitative effects from construction are discussed below on a programmatic level, a more detailed, site-specific analysis will be included in a tiered EA or EIS.

##### *3.17.5.3.1 Construction and/or Modification of Structural Measures*

The construction of structural measures would require the use of large equipment which could lead to erosion and sedimentation from exposed soils causing sediment to discharge into the reservoirs. Discharges associated with construction activities could affect public health and safety as sediment-laden runoff could contribute to a HABs event locally. However, construction activities are required to meet NPDES permit requirements for stormwater discharges, and as such adverse, short- and medium-term effects would be negligible as measures to prevent erosion and sedimentation would be implemented during construction. These measures could include the stabilization of exposed soils using measures such erosion control blankets on slopes, temporary sediment storage basins, and silt fencing (USACE 2011).

This section discusses the potential impacts to drinking water from the construction and/or modification of the structural measures shown below.

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Construct water temperature control tower (#105)
- Structural improvements to reduce TDG (#174)
- Restore upstream and downstream passage at drop structures (#639)
- Construct AFF (#722)
- Provide Pacific lamprey passage and infrastructure (#52)
- Construct structural downstream fish passage (#392)
- Operation, Maintenance, Repair, Replacement and Rehabilitation

**<u>Foster fish ladder temperature improvement (#479); Construct WTC towers (#105); Structural improvements to reduce total dissolved gas (#174)</u>**

Construction activities associated with the Foster fish ladder temperature improvement (#479), construction of WTC towers (#105), and structural improvements to reduce TDG (#174) would have adverse negligible effects in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Foster fish ladder temperature improvement (#479) would provide enhanced temperature control and normative (i.e., the standards of temperature needed for fish passage) water temperatures downstream for fish passage during regular operations. A new Forebay Warm Water Supply (FWWS) would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The release of warmer water at the surface would have beneficial effects on the formation of HABs and public health and safety as it would allow mixing of the surface waters. Inadequate mixing and lack of rainfall during summer months can lead to stagnant waters and stratification of the reservoir (i.e., the formation of thermal layers). Temporal stratification has adverse effects on water quality, including the trapping of nutrients in the water column which can lead to eutrophication (see Section 3.17.1 Affected Environment which discusses eutrophication). Therefore, the enhanced temperature controls that reduce stratification would be beneficial towards reducing HABs formation within the water column and on the water surface of the reservoir. The effects would be beneficial, minor, short and long term recurring during reservoir releases.

Construction of WTC towers (#105) would have long-term beneficial effects on the prevention of HABs. During the conservation months, there is a higher potential for HABs formation due to the inflow of water from the watershed, which carries high concentrations of nutrients. Along with the reduction of outflow from the reservoir, this can lead to the accumulation of nutrients in the reservoir. HABs can form when residence time in the reservoir is long and the flushing rate or outflow from the reservoir is reduced. Also, temperature stratification in the reservoir, where warm waters are usually located at the surface and cooler waters at the bottom, can promote HAB growth (Linkov et al. 2009). Mixing and blending cooler water with warmer surface water can reduce HAB accumulation having a beneficial effect; however, this technique may not be possible on a large scale within the entire reservoir. Reservoir releases can reduce the accumulation of HABs and dilute toxins, which can prevent a HABs occurrence. The water temperature control towers would allow blending of warm water with cooler water and would reduce stagnant waters which are conducive to HAB growth. The flowing water and turbulence within the reservoir would also inhibit HAB growth. Also, the release of water from the reservoir would discharge concentrated nutrients from the middle to lower portions of the reservoir downstream, further reducing HAB growth within the reservoir itself. However, water from the middle to lower portions of the reservoir can have high concentrations of nutrients and metals from the sediment accumulated at the bottom of the reservoir (Kennedy and Gaugush, 1988). The discharged concentrated nutrients from the middle to lower portions of the reservoir could also cause adverse impacts, leading to the buildup of nutrients downstream which could cause HABs formation. Therefore effects would be beneficial and adverse minor, short and long term recurring during reservoir releases.

Structural improvements to reduce TDG (#174) would have beneficial effects on HABs and public health and safety. When water flows over the spillway air dissolves into the water which cause nitrogen to increase dramatically (EPA 1971). Excess nutrients can lead to HAB occurrence through the process of eutrophication (or the enrichment of algae growth due to excess nutrients; see Affected Environment Section 3.17.1). Therefore, reducing TDG would be beneficial towards the prevention of HABs. The reduction of TDG is accomplished by discharge through the powerhouse to reduce the TDG from spillways and outlets, or by distributing flows through as many spillways as possible. The reduction in TDG would improve water quality as it would reduce the amount of nitrogen in downstream waters. The effects would be beneficial minor, short and long term permanent in duration.

**Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)**

Maintaining revetments using nature-based engineering or altering revetments for aquatic ecosystem restoration (#9) would occur basin-wide. Increases in sedimentation associated with construction and maintenance work could contribute to a HAB event, which would affect public health and safety. However, measures to prevent erosion and sedimentation would be implemented during construction. Therefore, the effects would be adverse negligible, short term during construction. In the long term, the maintenance revetments would have no effects on public health and safety – HABs.

**Restore upstream and downstream passage at drop structures (#639), construct AFF (#722), provide Pacific lamprey passage and infrastructure (#52), construct structural downstream fish passage infrastructure (#392)**

These four fish infrastructure measures would have similar effects. The construction effects would be adverse and negligible as measures to prevent erosion and sedimentation would be implemented. The effects of restoring upstream and downstream passage at drop structures (#639) would be short term in duration. For the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), construction effects would be medium term in duration.

The construction of structural downstream fish passage infrastructure (#392) would have beneficial effects on the prevention of HABs as minimum flows would be required to allow fish passage operations. The use of Floating Screen Structures (FSS) would require minimum flow rates (see the flow required minimum flow rates in Table 2-10), and modification of the fish weir would require flow rates of 600 cfs per year. Continual flow of water would reduce stagnancy of waters near the location of the fish passage structures, thus preventing HAB growth locally. The effects would be beneficial, minor, short and long term recurring. The construction of AFFs (#722) would have no effects on the formation of HABs in the long term as effluent discharge from the flushing of fish facilities would be required to meet water quality permit requirements (see the discussion under 3.17.5.4.1 under OMRRR). Restoring upstream and downstream passage at drop structure (#639) and the construction of fish passage infrastructure for Pacific lamprey (#52) would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, short and long term recurring.

##### *3.17.5.3.2 Implementation of Water Management Measures*

This section discusses the potential impacts to EJ communities from the implementation of the following water management measures:

- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Augment instream flows by using the inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Integrated temperature and habitat flow regime (#30a)
- Refined integrated temperature and habitat flow regime (#30b)
- Deeper fall reservoir drawdowns for fish passage (#40)
- Spring reservoir drawdown for downstream fish passage (#720)
- Pass water over spillway in spring for fish passage (#714)
- Near-term Operations Measure
- Fall Creek Drawdown
- Existing Operations Continued Forward

**Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166); Deeper fall reservoir drawdowns for fish passage (#40); Spring reservoir drawdown for downstream fish passage (#720)**

Using ROs to discharge cold water (#166) would have adverse effects on downstream waters which may be used for drinking water. Discharging cold water would allow the reservoir to ‘turnover’ as described in Section 2.2.2.2. However, the discharge of the cold water from the reservoir would release concentrated nutrients upward due to mixing in the water column from the lower depths of the reservoir where sediment and heavy metals accumulate in low oxygen conditions; the decreased quality of water would also be released downstream reducing the quality of water used for drinking. The effects would be adverse, minor, short and long term recurring when reservoir releases occur.

The reservoir drawdowns would have adverse effects on water quality downstream. Nutrients at the bottom of the reservoir flow would be released downstream, reducing water quality and would have effects similar to using ROs to discharge cold water (#166). The effects would be adverse minor, short and long term recurring in the fall and spring.

**Use spillway for summer surface spill (#721); Pass water over spillway in spring for fish passage (#714)**

Using the spillway for summer surface spill (#721) would have minor, beneficial effects to HABs and public health and safety as it would promote mixing of the reservoirs' surface waters which could reduce stratification locally as described for Foster fish ladder temperature improvement (#479) in Section 3.17.5.3.1. The release of warmer water at the surface would have adverse minor, short- and long-term recurring effects during summer spillway releases.

Spring spillway fish passage (#714) would have the same effects as using the spillway for summer surface spill (#721). The release of water from the surface spillway reduces stratification which would have beneficial and minor, short- and long-term recurring effects during spillway releases.

**Augment instream flows by using the inactive pool (#718); Augment instream flows by using the power pool (#304); Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)**

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released (see Figure 2 Reservoir storage layers in the Glossary). The downstream waters would be adversely affected by deep reservoir releases, due to the influx of concentrated nutrients resulting in reduced quality of water which could lead to HABs. The effects would be adverse, minor, short and long term recurring during reservoir releases.

Minimizing stream flows to Congressionally authorized minimum flows (#723) would have beneficial effects for HABs. Reducing outflows to the Congressionally authorized minimum flows would allow reservoirs to capture more spring runoff rather than releasing it. The minimum flows would maintain water quality standards by preventing stagnant water. Flowing water and turbulence reduce the potential for HAB growth. Effects would be beneficial minor, short and long term recurring when flows are reduced.

**Integrated temperature and habitat flow regime (#30a); Refined integrated temperature and habitat flow regime (#30b)**

Integrated temperature and habitat flow regime (#30a) and refined integrated temperature and habitat flow regime (#30b) would also have similar beneficial effects on reducing HABs formation and public health and safety. Measure #30b has slight changes to the mainstem and tributary flows than measure #30a. The adaptive fish flows would prevent stagnancy of the water, thereby maintaining water quality. The effects would be beneficial, minor, short and long term recurring annually. Operation of the WVS follows a four-season cycle, winter flood risk management (FRM) season and summer conservation season with spring refill and fall release periods as described in Section 1.10.

**Near-term Operations Measure**

The Near-term Operations Measure are a suite of 16 operations described in Chapter 2. The operations measures are analyzed by grouping measures by where water is released from the dam, either through the regulating outlets or surface spillway releases. The depth in the reservoir from where water is released would have different effects on HABs occurrence. Water released from the surface spillway would have less adverse and more beneficial effects than water released from the lower depths of the reservoir such as from the regulating outlets which is explained below.

***RO Release***

- Nighttime RO prioritization for improved downstream fish passage at Detroit Dam;
- Deep drawdown and RO prioritization for improved downstream fish passage at Cougar Dam;
- Delayed reservoir refill and RO prioritization for improved downstream fish passage at Cougar Dam;
- Nighttime RO prioritization for improved downstream fish passage (downstream fish passage) at Hills Creek Dam;
- Deep drawdown and RO prioritization for improved downstream fish passage at Lookout Point Dam;
- Extended deep drawdown and RO prioritization for improved downstream fish passage at Falls Creek Dam and delayed reservoir refill and RO prioritization for improved downstream fish passage at Falls Creek Dam

Using ROs to discharge cold water would have adverse effects on downstream waters where HABs formation could occur. Discharging cold water would allow the reservoir to ‘turnover’ as described in Section 2.2.2.2. However, the discharge from the ROs of the reservoir would also release concentrated nutrients upward due to mixing in the water column from the lower depths of the reservoir where sediment and heavy metals accumulate in low oxygen conditions. The decreased quality of water would also be released downstream leading to the potential for a HABs event. The effects on HABs formation and public health and safety would be adverse minor, short and long term and recurring during reservoir releases.

***Spillway release***

- Spread spill across spillways to reduce downstream TDG exceedances at Big Cliff Dam;
- Utilize spillway for improved downstream fish passage in the spring; perform spill operation until 01 May or for 30 days, whichever is longer at Green Peter Dam;

- Delay refill and utilize spillway in the spring for improved downstream fish passage; use the fish weir in the summer for improved downstream temperature management and upstream fish migration/passage at Green Peter Dam;
- Utilize the spillway for improved downstream fish passage in the fall at Foster Dam

Using the spillway would have beneficial effects to HABs and public health and safety as it would promote mixing of the reservoirs' surface waters which could reduce stratification locally as described for the Foster fish ladder temperature improvement measure (#479) in Section 3.17.5.3.1 above. The release of warmer water at the surface would have beneficial minor effects in the short and long term recurring during summer spillway releases.

***Combined RO and Spillway release***

- Spring downstream fish passage and operational downstream temperature management at Detroit dam
- Utilize spillway for improved downstream fish passage in the spring at Lookout Point Dam; RO use in the fall for downstream temperature management at Lookout Point Dam

These measures use a combination of using both the RO and the spillway which would result in adverse and beneficial, minor, large and long-term recurring effects similar to the effects analyzed under the RO release and Spillway release measures above. The effects of downstream temperature management at Detroit Dam would be similar to the integrated temperature and habitat flow regime (#30a); the effects would be beneficial, minor, short and long term recurring.

**<u>Existing Operations Continued Forward</u>**

***Fall Creek Drawdown***

Reservoir releases or drawdowns can reduce the accumulation of HABs and dilute toxins within the reservoir itself, which can prevent a HABs occurrence. However, nutrients could be released downstream, causing HABs to occur downstream. The drawdowns would continue to have adverse effects on downstream reaches under the NAA, but would be beneficial for preventing HABs in the reservoir. Overall effects would be beneficial and adverse minor, short and long term recurring throughout the year as the pool volumes are adjusted.

***Continued Operation of Existing Adult Fish Facilities***

O&M activities associated with existing AFFs would continue to have little or no effects on public health and safety – HABs. Water from maintenance for flushing of fish facilities or effluent water may be high in pollutants. However, hatcheries are required to meet water quality standards for their waste/effluent water (EPA 2021j). These discharges from fish facilities are required to meet the NPDES permit requirements. Thresholds are set for total suspended solids (TSS), settleable solids, temperature, and pH and must not be exceeded during routine monitoring. Thus, any effects would be adverse, negligible, short and long term recurring during regular maintenance.

***Operation, Maintenance, Repair, Replacement and Rehabilitation (OMRRR)***

Routine and non-routine maintenance activities, repair, replacement and rehabilitation under the NAA overall would have adverse minor, short term effects on public health and safety as sediment-laden discharges from construction activities could affect drinking water quality. However, construction activities would require measures to prevent erosion and sedimentation to be implemented during construction. Effects would be adverse minor, small in the vicinity of the maintenance site, medium and long term recurring.

### *3.17.5.4 No Action Alternative*

This analysis addresses the effects if the existing O&M of the WVS system would continue. The current operations which could have either beneficial or adverse effects on the growth of HABs and public health and safety.

This analysis addresses the effects if the existing O&M of the WVS system would continue. The current operations which could have either beneficial or adverse effects on the drinking water and public health and safety. Effects of temperature control and TDG reduction measures would be beneficial and adverse minor, large, short and long term recurring. The effects of maintaining flow targets would have beneficial, minor, large effects in the short and long term recurring and augmenting flows would have adverse minor, small, short- and long-term recurring effects. Passing water over the spillway has beneficial, minor, large, short- and long-term recurring effects. For the existing operations continued forward, the effects would be beneficial and adverse minor, large, short and long term recurring due to the Fall Creek drawdown; adverse, negligible, small, short and long term recurring for continued operation of adult fish facilities; adverse, negligible, small, short and long term recurring for routine maintenance; and adverse negligible, small, effects in the short- long-term recurring for routine and non-routine, and medium- and long term recurring for major maintenance.

The NAA includes water quality, flow, and upstream and downstream passage operations. Water quality operations include using the spillway to release warm surface water and manage downstream temperatures at Foster and Detroit; strategically using outlets to meet temperature targets (when possible) at Fall Creek; operating the Cougar WTC tower to manage downstream temperatures; spreading spill across the Dexter and Big Cliff spillways to reduce TDG; and discharging water through the powerhouse at power-producing dams to reduce TDG.

These water quality operations to control temperature and reduce TDG would continue to be beneficial and adverse for drinking water. The release of warmer water at the surface would have beneficial effects on the prevention of HABs of the reservoir as it would allow mixing of the surface waters and would reduce stratification of the reservoir as discussed under the Foster fish ladder temperature improvement (#479) in Section 3.19.5.3.1. Reducing TDG would also be beneficial towards the prevention of HABs as it would reduce the amount of nitrogen in the water as discussed under the construction of WTC towers (#479) in Section 3.19.5.3.1. However, the reduction of TDG is accomplished by discharge through the powerhouse to reduce the TDG from spillways and outlets, or by distributing flows through as many spillways as possible which could release sediment and nutrients downstream. Therefore, effects of temperature control and TDG reduction measures would be beneficial and adverse minor, large, short and long term recurring.

Flow operations include meeting the 2008 BiOp targets basin-wide and augmenting flows using the inactive or power pool at Green Peter. Maintaining operational flow targets for fish and wildlife conservation require reservoir releases which are beneficial to the prevention of HAB accumulation because they reduce residence time and allow blending of cooler water with warm water. Reservoir releases would also continue to dilute concentrated nutrients in the reservoir. Therefore, maintaining operational flow targets for fish and wildlife conservation would continue to have beneficial, minor, large effects in the short and long term recurring. As discussed above in Sections 3.19.6.3.2, augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse, minor, large effects in the short and long term recurring during reservoir releases.

Fish passage operations include passing fish over the Foster spillway and through the lowest RO at Fall Creek (Fall Creek drawdown). Passing water over the spillway has beneficial, minor, large, short- and long- term recurring effects. The Fall Creek drawdown is discussed below under existing operations continued forward.

#### *3.17.5.4.1 Existing operations continued forward*

**Fall Creek Drawdown**

As discussed in Section 3.17.5.3.1, reservoir releases or drawdowns can reduce the accumulation of HABs and dilute toxins within the reservoir itself, which can prevent a HABs occurrence. However, nutrients could be released downstream, causing HABs to occur downstream. The drawdowns would continue to have adverse effects on downstream reaches under the NAA, but would be beneficial for preventing HABs within the reservoir. Effects would be beneficial and adverse minor, large, short and long term recurring throughout the year as the pool volumes are adjusted.

**Continued Operation of Existing Adult Fish Facilities**

O&M activities associated with existing AFFs would continue to have little or no effects on public health and safety – HABs. Discharges from fish facilities are required to meet the water quality standards for effluent as discussed previously in Section 3.17.5.3.2. Thus, any effects would be adverse, negligible, small in extent localized to the area of discharge, short and long term recurring.

**<u>Operation, Maintenance, Repair, Replacement and Rehabilitation</u>**

Scheduled/routine maintenance and non-routine maintenance activities would be adverse as effects of sediment-laden discharges from construction activities could affect drinking water quality. Effects would be negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Therefore, effects are adverse and negligible in the short term. Similarly, effects of major maintenance and repairs would be adverse and negligible however the duration of major maintenance is medium term and long term recurring.

##### *3.17.5.4.2 Climate Change*

The impact on public health and safety – HABs due to environmental conditions which may change as a result of climate change is analyzed in this section. The climate change projected trend information is based on the hydrologic trends discussed in Appendix F.

Increased temperatures due to climate change can cause inflow, stored water, and reservoir release water to be warmer. Warmer water temperatures can increase stratification of the reservoir, restricting the ability of the reservoir to mix and move oxygen and water vertically, which is a favorable condition for HAB growth as well as promoting the toxin producing cyanobacteria to grow faster (EPA 2013a).

Increased precipitation and streamflow events have the potential to draw more nutrient laden sediment into the reservoirs, leading to increased frequency of flood risk storage for prolonged periods. This has the potential to increase nutrients within the reservoirs, leading to greater HABs occurrences. Effects of increased precipitation would be adverse moderate due to the potential for unsafe conditions due to increased occurrence of HABs events, large affecting the reservoir and downstream reaches, and long-term permanent and intermittent on public health and safety.

Prolonged periods between rainfall events (or drought periods) could cause decreases in streamflow, leading to less water entering the reservoirs. The stream inflow to the reservoir allows warmer water to blend and cool down. With less cool water blending with the warm water in reservoir, this could lead to an increase in HABs. Decreased baseflows would have adverse moderate effects due to the potential for unsafe conditions due to increased occurrence of HABs events, large, and long-term permanent and intermittent effects basin wide on public health and safety.

Warmer temperatures from climate change could also provide favorable conditions for the propagation of HABs. which can discolor, cloud, or cover the water's surface and affect drinking water. Wildfire ash can land in reservoirs, streams, and rivers, increasing turbidity and adversely affecting the water quality of those water bodies which communities rely on for drinking water.

#### *3.17.5.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, fish passage would be improved through storage-focused measures by maximizing refill volumes of conservation pools and tapping into the power pool, augmenting flow to the congressionally authorized minimum flows. This would increase the likelihood of refilling to the maximum conservation pool levels. The effects of the measures proposed under Alternative 1 are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Effects are the similar to the effects described under the Discussion of Effects by Measure(s). Alternative 1 effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Operation, maintenance, repair, replacement and rehabilitation; Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); structural improvements to reduce total dissolved gas (#174); restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392).

In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects. Foster fish ladder temperature improvement (#479), the construction of WTC towers (#105), and structural improvements to reduce total dissolved gas (#174) would have beneficial and/or adverse, minor, large, short and long-term recurring effects. The effects of structural improvements to reduce total dissolved gas (#174) would be beneficial, minor, large in the short and long term.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Effects on reducing minimum flows to Congressionally authorized minimum flow requirements (#723) basin-wide would have beneficial minor, large, short and long term recurring when flows are reduced.

Restoring upstream and downstream passage at drop structure (#639), the construction of fish passage infrastructure (#392) and provide Pacific lamprey passage and infrastructure (#52) would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.17.5.5.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.5.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC Towers (#105) at Detroit, Green Peter and Lookout Point dams; Structural improvements to reduce total dissolved gas (#174) at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point dams;*

Foster fish ladder temperature improvement (#479) would have beneficial effects. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large, short and long term recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse minor, large, short and long term recurring when reservoir releases occur.

Structural improvements to reduce total dissolved gas (#174) would have beneficial minor, large effects. The effects would be short and long term and permanent in duration.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.5.3 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove, Dorena, and Falls Creek dams; Augment instream flows by using the power pool (#304) Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point dams; Reduce minimum flows to Congressionally authorized minimum flow requirements (#723) basin-wide; Fall Creek drawdown*

Augmenting instream flows by using the inactive pool (#718), augmenting instream flows by using the power pool (#304), and the Fall Creek drawdown would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

Reducing minimum flows to Congressional authorized minimum flow requirements (#723) would be beneficial minor, large, short and long term recurring when flows are reduced.

##### *3.17.5.5.4 Restore upstream and downstream passage at drop structures at Fern Ridge Dam (#639); construct AFFs at Green Peter Dam (#722); provide Pacific lamprey passage and infrastructure at Fern Ridge and Green Peter dams (#52); and construct structural fish passage infrastructure at (#392) Detroit, Foster, Green Peter, Lookout Point, Big Cliff, and Dexter dams; Continued operation of existing adult fish facilities*

Restoring upstream and downstream passage at drop structure (#639), providing Pacific lamprey passage and infrastructure (#52), and the construction of fish passage infrastructure (#392) would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be adverse, negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.5.5 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. The measures in Alternative 1 would improve reservoir storage and improve water quality by reducing TDG and normalizing temperatures. Therefore, the effects of climate change on drinking water would be less severe under Alternative 1 than any other alternative, including the NAA. Climate change in combination with the measures under Alternative 1 would have adverse, moderate, large, long-term intermittent and /or permanent effects to HABs.

#### ***3.17.5.6 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Under Alternative 2A, integrated temperature and habitat flow regimes would be utilized as well as using the power pool to augment flows. Structural and operational measures are proposed to address water quality as well as the Near-Term Operations Measure(s) as discussed under Section 2.2.5. The effects of the measures proposed under Alternative 2A are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 2A effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); deeper fall reservoir drawdowns for fish passage (#40); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392).

In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects. Foster fish ladder temperature improvement (#479) and the construction of WTC towers (#105) would have beneficial and or adverse, minor, large, short and long-term recurring effects.

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Integrated temperature and habitat flow regime (#30a) would have beneficial minor, small effects in the short and long term recurring annually.

Providing Pacific lamprey passage and infrastructure (#52) and the construction of fish passage infrastructure (#392) and would have beneficial, minor, small effects in the short and long term recurring. The effects of the construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

##### *3.17.5.6.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.6.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC tower (#105) at Detroit Dam*

Foster fish ladder temperature improvement (#479) would have beneficial effects. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large, short and long term recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse minor, large, short and long term recurring when reservoir releases occur.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.17.5.6.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Deeper fall reservoir drawdowns for fish passage (#40) at Green Peter Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

Construction effects of associated with the deeper fall reservoir drawdowns for fish passage (#40) would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.17.5.6.4 Use spillway for surface spill in summer (#721) at Green Peter Dam; Pass water over spillway in spring for fish passage (#714) at Green Peter Dam*

Use spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

*3.17.5.6.5 Augment instream flows by using the inactive pool (#718) at Blue River and Falls Creek dams; Augment instream flows by using the power pool (#304) at Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

*3.17.5.6.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually.

##### *3.17.5.6.7 Construct adult fish facilities (#722) at Green Peter Dam; Pacific lamprey passage and infrastructure at Green Peter Dam (#52); construct structural downstream fish passage (#392) at Cougar, Detroit, Foster, Lookout Point, Big Cliff, and Dexter dams; Continued operation of existing adult fish facilities*

Providing Pacific lamprey passage and infrastructure (#52) and the construction of fish passage infrastructure (#392) and would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be adverse negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.6.8 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.3.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

##### *3.17.5.6.9 Climate Change*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). The measures in Alternative 2A would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. In general, climate change would exacerbate effects from deep drawdowns: as temperatures increase and snowpacks decline, reservoirs may struggle to reach their conservation pool elevations over time, which would directly affect drinking water. Climate change in combination with the measures under Alternative 2A would have adverse, moderate, large, long-term intermittent and /or permanent effects to HABs.

#### ***3.17.5.7 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Under Alternative 2B, the effects to public health and safety - HABs would be the same as those described under Alternative 2A. The difference is that the downstream passage measure at Cougar Dam is changed from a structural fish passage structure under 2A to changing of operations to a deep fall and spring drawdown with the construction of a diversion tunnel under 2B. The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 2B are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 2B effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); deeper fall reservoir drawdowns for fish passage (#40)construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392).

In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects. Foster fish ladder temperature improvement (#479) and the construction of WTC towers (#105) would have beneficial and or adverse, minor, large, short and long-term recurring effects.

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Integrated temperature and habitat flow regime (#30a) would have beneficial minor, small effects in the short and long term recurring annually.

Providing Pacific lamprey passage and infrastructure (#52) and the construction of fish passage infrastructure (#392) and would have beneficial, minor, small effects in the short and long term recurring. The effects of the construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.17.5.7.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.7.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC tower (#105) at Detroit Dam*

Foster fish ladder temperature improvement (#479) would have beneficial effects. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large, short and long term recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse minor, large, short and long term recurring when reservoir releases occur.

##### *3.17.5.7.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Deeper fall reservoir drawdowns for fish passage (#40) at Cougar, and Green Peter dams and spring reservoir drawdown for downstream fish passage (#720) at Cougar Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

Construction effects of associated with the deeper fall reservoir drawdowns for fish passage (#40) would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.7.4 Use spillway for surface spill in summer (#721) at Green Peter Dam; Pass water over spillway in spring for fish passage (#714) at Green Peter Dam*

Use spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

##### *3.17.5.7.5 Augment instream flows by using the inactive pool (#718) at Blue River and Falls Creek dams; Augment instream flows by using the power pool (#304) at Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be minor, large, short and long term recurring during reservoir releases.

##### *3.17.5.7.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually.

##### *3.17.5.7.7 Construct AFF (#722) at Green Peter Dam; Pacific lamprey passage and infrastructure (#52) at Green Peter Dam; construct structural downstream fish passage (#392) at Detroit, Foster, Lookout Point, Big Cliff, and Dexter dams; Continued operation of existing adult fish facilities*

Providing Pacific lamprey passage and infrastructure (#52) and the construction of fish passage infrastructure (#392) and would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.7.8 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.3.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

##### *3.17.5.7.9 Climate Change*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam’s DT). Climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 2B would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. However overall, the effects would be the same as under Alternative 2A; climate change in combination with the measures under Alternative 2B would have adverse, moderate, large, long-term intermittent and/or permanent effects to HABs.

#### ***3.17.5.8 Alternative 3A – Operations-Focused Fish Passage Alternative***

Under Alternative 3A, improved fish passage is proposed through the modifying of operations instead rather than focusing on storage (Alternative 1) or structural measures (Alternative 4). The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 3A are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 3A effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); deeper fall reservoir drawdowns for fish passage (#40) construction of AFFs (#722); and providing Pacific lamprey passage and infrastructure (#52). In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Integrated temperature and habitat flow regime (#30a) would have beneficial minor, small effects in the short and long term recurring annually. Providing Pacific lamprey passage and infrastructure (#52) would be beneficial, minor, small, short and long term recurring. The effects of the construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

#### *3.17.5.8.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

#### *3.17.5.8.2 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Detroit; Green Peter; and Lookout Point dams; Deeper fall reservoir drawdowns for fish passage*

*(#40) at Blue River; Cougar; Detroit; Green Peter; Hills Creek; Lookout Point; Spring reservoir drawdown for downstream fish passage (#720) at Cougar; Detroit; and Lookout Point dams; Fall Creek drawdown*

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

Construction effects of associated with the deeper fall reservoir drawdowns for fish passage (#40) would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.17.5.8.3 Use spillway for surface spill in summer (#721) at Blue River; Detroit; Foster; Green Peter; Hills Creek; and Lookout Point dams; Pass water over spillway in spring for fish passage (#714) at Big Cliff, Dexter, Falls Creek, Green Peter, and Hills Creek dams*

Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

*3.17.5.8.4 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove; Dorena; and Falls Creek dams; Augment instream flows by using the power pool (#304) at Cougar, Detroit, Green Peter; Hills Creek; and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be minor, large, short and long term recurring during reservoir releases.

*3.17.5.8.5 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually.

*3.17.5.8.6 Construct adult fish facilities (#722) at Blue River; Green Peter; and Hills Creek dams; Pacific lamprey passage and infrastructure (#52) at Blue River; Green Peter; and Hills Creek dams; Continued operation of existing adult fish facilities*

Providing Pacific lamprey passage and infrastructure (#52) would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.8.7 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.3.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

##### *3.17.5.8.8 Climate Change*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). The measures in Alternative 3A would improve water quality by normalizing temperatures. It would also provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3A would include the less-deep drawdown to the Cougar RO. Climate change in combination with the measures under Alternative 3A would have adverse, moderate, large, long-term intermittent and/or permanent effects to HABs.

#### *3.17.5.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)*

Under Alternative 3B, the effects to public health and safety - HABs would be the same as those described under Alternative 3A. Alternative 3B proposes the slightly different combination of operations for the downstream passage. 3A proposes the drawdown to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures and 3B proposes drawdown utilizing the diversion tunnel at Cougar. The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 3B are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Overall, Alternative 3B effects would be similar to Alternatives 1, 2A, 2B, and 3A. Alternative 3A effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); deeper fall reservoir drawdowns for fish passage (#40); construction of AFFs (#722); and providing Pacific lamprey passage and infrastructure (#52). In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720); and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Integrated temperature and habitat flow regime (#30a) would have beneficial minor, small effects in the short and long term recurring annually. Providing Pacific lamprey passage and infrastructure (#52) would be beneficial, minor, small, short and long term recurring. The effects of the construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

*3.17.5.9.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.17.5.9.2 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Detroit; Green Peter; and Lookout Point dams; Deeper fall reservoir drawdowns for fish passage (#40) at Blue River; Cougar; Detroit; Green Peter; Hills Creek; Lookout Point and Spring reservoir drawdown for downstream fish passage (#720) at Cougar; Detroit; and Lookout Point dams; Fall Creek drawdown*

Using ROs to discharge cold water (#166), deeper fall reservoir drawdowns for fish passage (#40), spring reservoir drawdown for downstream fish passage (#720), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

Construction effects of associated with the deeper fall reservoir drawdowns for fish passage (#40) would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.9.3 Use spillway for surface spill in summer (#721) at Blue River; Detroit; Foster; Green Peter; Hills Creek; and Lookout Point dams; Pass water over spillway in spring for fish passage (#714) at Big Cliff, Detroit, Dexter, Lookout Point dams*

Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

###### *3.17.5.9.4 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove; Dorena; and Falls Creek dams; Augment instream flows by using the power pool (#304) at Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be minor, large, short and long term recurring during reservoir releases.

###### *3.17.5.9.5 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually.

###### *3.17.5.9.6 Construct adult fish facilities (#722) at Blue River; Green Peter; and Hills Creek dams; Pacific lamprey passage and infrastructure (#52) at Blue River; Green Peter; and Hills Creek dams; Continued operation of existing adult fish facilities*

Providing Pacific lamprey passage and infrastructure (#52) would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.9.7 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.3.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

###### *3.17.5.9.8 Climate Change*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). The measures in Alternative 3B would improve water quality by normalizing temperatures and provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3B would include the deeper drawdown to the Cougar DT. Climate change in combination with the measures under Alternative 3B would have adverse, moderate, large intermittent and/or permanent effects to drinking water in the long term.

##### *3.17.5.10 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, a structures-based approach is proposed to improve fish passage. Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 4 are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Overall, Alternative 4 effects would be similar to Alternatives 1, 2A, 2B, 3A, and 3B. Alternative 4 effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); Foster Fish Ladder Temperature Improvement (#479); construct WTC towers (#105); structural improvements to reduce TDG (#174), restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construct structural downstream fish passage (#392).

In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects. Foster fish ladder temperature improvement (#479); the construction of WTC towers (#105); and structural improvements to reduce TDG (#174) would have beneficial and or adverse, minor, large, short and long-term recurring effects.

Using ROs to discharge cold water (#166) and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Integrated temperature and habitat flow regime (#30a) would have beneficial minor, small effects in the short and long term recurring annually.

Restoring upstream and downstream passage at drop structure (#639), the construction of fish passage infrastructure (#392) and provide Pacific lamprey passage and infrastructure (#52) would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

##### *3.17.5.10.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.10.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC towers (#105) at Detroit; Hills Creek; and Lookout Point dams; Structural improvements to reduce TDG (#174) at Cougar; Detroit; Dexter; Foster; Green Peter; and Lookout Point dams*

Foster fish ladder temperature improvement (#479) would have beneficial effects. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large, short and long term recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse minor, large, short and long term recurring when reservoir releases occur.

Structural improvements to reduce total dissolved gas (#174) would have beneficial minor, large effects. The effects would be short and long term and permanent in duration.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.10.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

##### *3.17.5.10.4 Use spillway for surface spill in summer (#721) at Green Peter Dam*

Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

##### *3.17.5.10.5 Augment instream flows by using the inactive pool (#718) at Cottage Grove; Dorena; Falls Creek; and Blue River dams; Augment instream flows by using the power pool (#304) at Cougar; Detroit; Green Peter; Hills Creek; and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be minor, large, short and long term recurring during reservoir releases.

##### *3.17.5.10.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually.

##### *3.17.5.10.7 Restore upstream and downstream passage at drop structures (#639) at Fern Ridge Dam; construct AFF (#722) at Hills Creek Dam; provide Pacific lamprey passage and infrastructure (#52) at Fern Ridge and Hills Creek dams; construct structural downstream fish passage (#392) at Cougar; Detroit; Foster; Hills Creek; Lookout Point, Big Cliff and Dexter dams; Continued operation of existing adult fish facilities*

Restoring upstream and downstream passage at drop structure (#639), providing Pacific lamprey passage and infrastructure (#52), and the construction of fish passage infrastructure (#392) would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.10.8 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.3.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

##### *3.17.5.10.9 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. The measures in Alternative 4 would improve water quality by reducing TDG and normalizing temperatures. Alternative 4 would have fewer drawdowns than under all other action alternatives. Therefore, climate change would exacerbate the effects of Alternative 4 more than Alternative 1, but less than Alternatives 2A, 2B, 3A, 3B, and 5. Climate change in combination with the measures under Alternative 4 would have direct, adverse, moderate, large, long-term intermittent and/or permanent effects to drinking water.

#### ***3.17.5.11 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 5 – the Preferred Alternative, fish passage would be improved through a combination of modified operations and structural improvements. Alternative 5 is exactly the same as Alternative 2B except the integrated temperature and habitat flow regime (Measure #30a) is replaced with refined integrated temperature and habitat flow regime (Measure #30b). The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 3A are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 5 effects would be adverse negligible, small, in the short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); Foster fish ladder temperature improvement (#479); Construct WTC towers (#105); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construct structural downstream fish passage (#392). In the long term, the maintenance or alteration of revetments (#9) would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects. Foster fish ladder temperature improvement (#479) and the construction of WTC towers (#105) would have beneficial and or adverse, minor, large, short and long-term recurring effects.

Using ROs to discharge cold water (#166) and the Fall Creek drawdown would have adverse minor, large, short- and long-term recurring effects. Using the spillway for surface spill in summer (#721) would have beneficial, minor, large, short- and long-term recurring effects. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse minor, large, short- and long-term recurring effects. Refine integrated temperature and habitat flow regime (#30b) would have beneficial minor, small effects in the short and long term recurring annually.

The construction of fish passage infrastructure (#392) and provide Pacific lamprey passage and infrastructure (#52) would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.17.5.11.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments is a measure common to all alternatives and would occur basin-wide. The effects would be adverse negligible, small, and short term. In the long term, the revetments would have no effects on HABs formation and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.11.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC towers (#105) at Detroit Dam*

Foster fish ladder temperature improvement (#479) would have beneficial effects. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large, short and long term recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse minor, large, short and long term recurring when reservoir releases occur.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.17.5.11.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166), and the Fall Creek drawdown would have adverse effects on downstream waters where HABs formation could occur. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

###### *3.17.5.11.4 Use spillway for surface spill in summer (#721) at Green Peter Dam; Pass water over spillway in spring for fish passage (#714) at Green Peter Dam*

Using the spillway for surface spill in summer (#721) and spring spillway fish passage (#714) would have beneficial effects on HABs formation. The effects would be beneficial, minor, large, short and long term recurring during summer spillway releases.

###### *3.17.5.11.5 Augment instream flows by using the inactive pool (#718) at Blue River and Falls Creek dams; Augment instream flows by using the power pool (#304) at Detroit; Green Peter; Hills Creek; and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse effects on HABs and public health and safety as water from the deeper portions of the pool would be released. The effects would be minor, large, short and long term recurring during reservoir releases.

###### *3.17.5.11.6 Refine integrated temperature and habitat flow regime (#30b) basin-wide*

Refine integrated temperature and habitat flow regime (#30b) would have beneficial effects on reducing HABs formation and public health and safety. The effects would be beneficial, minor, small affecting the downstream waters only, in the short and long term recurring annually. .

###### *3.17.5.11.7 Construct AFF (#722) at Green Peter Dam; provide Pacific lamprey passage and infrastructure (#52) at Green Peter Dam; and construct structural downstream fish passage (#392) at Detroit; Foster; Lookout Point, Big Cliff and Dexter dams; Continued operation of adult fish facilities*

Providing Pacific lamprey passage and infrastructure (#52) and construction of structural downstream fish passage would reduce stagnancy of waters near the location of the fish passage structures due to continual flow of water, thus preventing HAB growth locally. The effects would be beneficial, minor, small, short and long term recurring. The construction of AFFs (#722) and the continued operation of existing adult fish facilities would be negligible, small, in the short and long term recurring.

Construction effects of these measures would be adverse negligible, small, in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.17.5.11.8 Near-term Operations Measures*

The effects of the Near-term Operations Measures are analyzed under Section 3.17.2.5.2. They are a suite of operations measures in which the impacts were analyzed by grouping measures which utilize the ROs or releasing water via the spillway. For both approaches the impacts would result in either adverse and/or beneficial, minor, large, short and long-term recurring effects.

##### *3.17.5.11.9 Climate Change*

Alternative 5 is essentially the same as 2B. The measures in Alternative 5 would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. Due to one more deep drawdown than Alternative 2A, climate change would exacerbate the effects of Alternative 5 more than Alternatives 1 or 2A. But overall, the effects would be the same as under Alternative 2A and 2B; climate change in combination with the measures under Alternative 5 would have direct, adverse, moderate, large, long-term intermittent and/or permanent effects to drinking water.

#### ***3.17.5.12 Summary of Effects***

Alternatives 2A, 2B, 3A, 3B, 4, and 5 promote improving water quality by allowing the continual flow of water from the surface spillways, reduce TDGs and normalize temperatures prevent the formation of HABs thereby reducing effects on public health and safety. Alternative 1 has an emphasis on improving reservoir storage, which can cause sediment, metals and nutrients to accumulate increasing the potential for causing a HABs event within the reservoirs. Alternatives with greater drawdowns or use of the regulating outlets such as Alternatives 2A, 2B, 3A and 3B would also improve water quality within the reservoir itself by reducing sediment buildup and nutrients within the reservoir itself, however the drawdowns would release the sediment downstream where a HABs event could occur. Alternatives 4 and 5 have the least number of drawdowns while also improving water quality and overall would have less severe and more beneficial impacts compared to the other alternatives.

## 3.18 PUBLIC HEALTH AND SAFETY – HAZARDOUS, TOXIC, AND RADIOACTIVE WASTE

This section addresses hazardous, toxic and radioactive waste (HTRW) in the WVS and WRB. The term "HTRW" is used generally by USACE to describe hazardous waste, but radioactive waste does not apply to this project because USACE does not manage radioactive waste in the WVS.

### 3.18.1 Affected Environment

Hazardous waste is generated currently and exists in the WVS from historic activities, ongoing and routine operations and maintenance, and initial construction. The area of analysis for HTRW is the WVS, but also includes some nearby facilities on private property within the WRB such as mines, from which contamination has migrated onto USACE property. Rather than being organized by geographic area (sub-basins), this section begins with a regulatory overview, is then organized by activity, and concludes with legacy environmental contamination.

#### *3.18.1.1 Regulatory Overview*

As noted above, the term "HTRW" is used generally by USACE, but radioactive waste does not apply to this project because USACE does not manage radioactive waste in the WVS. This section primarily focuses on hazardous waste, which is defined and regulated by the Resource Conservation and Recovery Act (RCRA) see Chapter 7 for additional information. RCRA defines hazardous waste as a waste that exhibits ignitability, corrosivity, reactivity, or toxicity, or is listed on one of the EPA's lists of wastes from non-specific sources, specific sources, or discarded commercial chemical products. RCRA establishes the framework to manage hazardous waste from the "cradle-to-the-grave" and stipulates requirements for waste generators, amongst other categories such as transporters and treatment, storage, and disposal facilities. Waste generators are generally grouped into three categories that each have different requirements, depending on the quantity of waste produced and/or stored on site: Large Quantity Generators (LQGs), Small Quantity Generators (SQGs), and Conditionally-Exempt Small Quantity Generators (CESQGs) or Very-Small Quantity Generators (VESQGs). Some states play a large role in implementing RCRA regulations: the EPA has authorized some states, such as Oregon, to set more stringent standards than those set by the EPA, and implement their hazardous waste requirements by issuing permits.

Legacy contamination is primarily regulated by the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), which is discussed further in Section 3.18.1.6 below.

#### *3.18.1.2 Hazardous Waste Generation and Storage at WVS Dams*

The 13 USACE dams that comprise the WVS are each considered Conditionally Exempt Small Quantity Generators (CESQGs) as defined in Chapter 16 of Oregon's Small Quantity Hazardous Waste Generator Handbook. CESQGs produce up to 220 pounds (100 kg) of hazardous waste or hazardous waste residues (including contaminated soils) per month, or less than 2.2 pounds (1 kg) of acute hazardous waste per month. Some of the hazardous waste generated and stored at

WVS dams includes used oil from turbines and transformers, lead-based paint (LBP) debris from demolition or renovation, and universal waste such as aerosol cans and lamps. Detroit, Fall Creek, and Foster dams have dedicated hazardous waste storage buildings that are fire-rated and include secondary containment for spills. The generation of very small quantities of hazardous waste at the facilities would occur through the life of the WVS.

Management of hazardous waste within the WVS complies with all applicable Federal, State, and local requirements. Requirements include the inventorying and reporting requirements of Title III of CERCLA, also known as the Emergency Planning and Community Right to Know Act (EPCRA), and in accordance with regulations identified in 40 CFR 262, Standards Applicable to Generators of Hazardous Waste, and Oregon Administrative Rules (OAR) 340-100, Hazardous Waste Management. CESQGs may store up to 2,200 pounds (1,000 kg) of waste before the waste must be shipped to a permitted off-site treatment, disposal, or recycle facility.

#### *3.18.1.3 Transport of Hazardous Wastes*

The transport of hazardous wastes on public roadways is controlled by United States Department of Transportation (USDOT) regulations. Any transport of such wastes to or from a project site must be done in compliance with these regulations to protect public health and safety. The hazardous waste transported is that which is generated and stored as described above in Section 3.18.1.2. All hazardous waste would be transported by commercial carriers contracted by the USACE in accordance with the hazardous substances shipping requirements of CFR Title 49 and in compliance with the Federal Motor Carrier Safety Regulations of the DOT, parts 383, 390, 397, and 399.

In the event of a release or spill, the transportation company would be responsible for response and cleanup. USACE would specify that the contract carriers be licensed and inspected as required by the Oregon Department of Environmental Quality (DEQ) and Oregon Department of Transportation (DOT). The permits, licenses, and certificates are the responsibility of the carrier. CFR Title 49 requires that all shipments of hazardous substances be properly identified and placarded. Shipping documents must be accessible and include safety data sheets (SDS) that contain information describing the hazardous substance, immediate health hazards, fire and explosion risks, immediate precautions, firefighting information, procedures for handling leaks or spills, first aid measures, and emergency response telephone numbers. Hazardous wastes would be properly disposed of in accordance with RCRA regulations. Transportation of these wastes would adhere to all applicable State and Federal regulations including requirements for hazardous waste manifests with shipments, labeling or using placards, and emergency information requirements.

#### *3.18.1.4 Legacy Environmental Contamination*

Legacy environmental contamination exists within the WRB from historic mining activities and initial construction of the WVS. Contamination from historical mining primarily involves heavy metals, with mercury generally posing the greatest risk to public health and safety. Contamination from the construction of the WVS includes hazardous or toxic substances such as diesel, polychlorinated biphenyls (PCBs), and heavy metals. Specific sites and sources are detailed below.

#### *3.18.1.5 Mercury and Mine Waste Sites*

Mercury is a heavy metal and neurotoxin that can have severely negative health effects on humans and wildlife, depending on a number of factors. Exposures to inorganic mercury (Hg) are most common when liquid mercury is spilled and the vapors are inhaled. However, mercury in its methylated form ($CH_3Hg$) is more toxic to vertebrates than inorganic mercury (EPA 2021g). Mercury methylation occurs as a result of naturally occurring sulfate-reducing bacteria reacting with inorganic mercury. Methylmercury is fat soluble, allowing it to easily bioaccumulate in organisms like fish. Because of this, Oregon has a statewide consumption advisory on bass sportfish, as well as more detailed advisories based on the consumer's age, water body, and type of fish (OHA No Date-b).

Although mercury is an element that occurs naturally in geologic formations within the earth, as long as it is sequestered there its presence does not typically cause problems unless extracted by humans. One significant global source of mercury is mining (AMAP/UN Environment 2019). Oregon has a rich history of mining (DOGAMI No Date), including the mining of cinnabar (mercury ore, Hg-S). Legacy contamination exists from historic mining activities, including within the WVS (Jackson, Eagles-Smith, and Emery 2019), where hydrologic events have moved contamination onto USACE property (EPA 2018).

##### *3.18.1.5.1 Black Butte Mine*

The Black Butte Mine was a cinnabar mine within the Coast Fork Willamette River watershed, located 7.5 miles upstream of Cottage Grove Reservoir to the north. Mine waste materials, such as tailings and waste rock, contain mercury and other toxic metals. Mercury has been released into Cottage Grove Reservoir and the Coast Fork Willamette River from hydrologic events eroding and transporting mine materials (EPA 2018). Here, mercury primarily exists as inorganic mercury in rock and sediment and methylmercury in fish tissue. Due to the public health risk, the Black Butte Mine was added to the EPA's Superfund National Priorities List (NPL) in 2010, making it eligible for federal funding to provide long-term cleanup under the Comprehensive Environmental Response and Liability Act (CERCLA). In 2018, two removal actions occurred, where Furnace Creek, the primary source of mercury-contaminated soil was excavated. These actions focused on reducing material that is easily mobilized downstream or has a substantial contact risk to people. After 13,100 cubic yards of contaminated soils were removed and stored in an onsite repository, Furnace Creek's stream channel and banks were restored, stabilized, and the area was seeded with native plants. Post-construction monitoring still occurs at the site (EPA 2018).

Although two removal actions have occurred at the Black Butte Mine site, mercury-containing sediment still exists in the area. CDM Smith, the EPA's prime contractor for the Black Butte Mine removal actions, determined in a post-removal risk assessment that the total cancer risks associated with residential exposure were within the EPA's acceptable risk range but above the

ODEQ range, despite a lack of data relating mercury exposure to cancer (CDM Smith 2020; EPA 2005). The noncancer hazard for a child was still above the threshold, primarily due to exposure to mercury-contaminated sediment (CDM Smith 2020). However, it should be noted that the Black Butte Mine is still an active CERCLA site: its listing remains on the NPL and it is currently in the remedial investigation/feasibility study phase (see section 3.18.1.6 below for more information on the CERCLA process).

##### *3.18.1.5.2 Bohemia Mining District*

The Bohemia Mining District is a 9-square mile area located approximately 18 miles upstream of Dorena Reservoir to the southeast. This mining district contained multiple mines that used inorganic mercury for over 60 years to recover gold and silver as part of an amalgamation process (Hygelund, Ambers, and Ambers 2001). Limited inspections for hazardous waste and materials have occurred within the Bohemia Mining District because only part of the property is owned by the U.S. Forest Service (USFS) and the rest of the property is privately owned. While some contamination certainly exists due to the history of the area, the contamination has not warranted listing as a brownfield site or on the EPA's Superfund National Priorities List (ODEQ 2021c).

It was believed that fish in Dorena Reservoir were contaminated with mercury, but the source was unconfirmed until a 2001 study by Hygelund et al. That study analyzed the mercury content of fine-grained sediment samples from streams that do not drain the Bohemia Mining District, streams that do drain the Bohemia Mining District, mine waste piles, and Dorena Reservoir sediment (Table 3.18-1). The study strongly suggested that the source of the mercury contamination in the Dorena Reservoir Watershed is the Bohemia Mining District, but was not able to rule out the naturally high mercury content of soils and rock in the area as a source (Hygelund, Ambers, and Ambers 2001). Although Dorena Reservoir has a much lower concentration of mercury in its sediment than Cottage Grove Reservoir, a fish consumption advisory is still in effect for both reservoirs.

**Table 3.18-3.18-1. Mercury Concentrations in the Dorena Reservoir Watershed**

| Sample Area | Mercury Concentration (ppm)[1] |
|---|---|
| Sediment in streams not draining the mining district | 0.006 |
| Sediment in streams draining the mining district | 0.14 - 1.339 |
| Dorena Reservoir sediment | .025 - .095 |
| Mine Waste Rock[2] | 10 - 50 |

[1]Data from Hygelund, Ambers, and Ambers 2001., 2001; ppm = parts per million

[2]That which is removed from a mine as part of the mining process, but has no economic value.

#### ***3.18.1.6 CERCLA Sites***

The CERCLA, also known as Superfund, provides a federal fund to clean up uncontrolled or abandoned hazardous waste sites as well as accidents, spills, and other emergency releases of pollutants and contaminants into the environment. The CERCLA process has nine steps, described below.

1. Preliminary Assessment/Site Inspection: Review historic information and visit site to evaluate the potential for hazardous substance releases.
2. National Priority Listing (NPL): Rank hazards using the EPA's Hazard Ranking System, which quantifies risks and prioritizes which sites warrant further investigation. Only the most hazardous sites are listed on the NPL.
3. Remedial Investigation/Feasibility Study: Characterize the nature and extent of contamination, as well as assess threats to human health and the environment. Evaluate performance and cost of various contaminant treatment options.
4. Records of Decision: Explain which cleanup alternative will be used.
5. Remedial Design/Remedial Action: Develop and implement detailed cleanup plans.
6. Construction Completion: Complete all necessary construction outlined during the Remedial Design step.
7. Post Construction Completion: Continue to monitor site.
8. National Priorities List Deletion: Delete site from NPL once cleanup goals have been achieved.
9. Site Reuse/Redevelopment: Reuse or redevelop site in a safe manner agreeable with local plans.

The only site within the WVS that has been placed on the NPL is the Black Butte Mine, which is described above in Section 3.18.1.5.1, because its contamination source fundamentally differs from the majority of other WVS CERCLA sites. Most of the contamination at WVS CERCLA sites came from industrial waste disposal that occurred during the initial construction of the dams. Contaminants include petroleum, solvents, metals, and PCBs, amongst others, and sites are in various stages of the CERCLA process (Table 3.18-2).

**Table 3.18-3.18-2. USACE WVS CERCLA Site Summaries**

| WVS Project | Contamination Source | Contaminants | CERCLA Progress | Summary |
|---|---|---|---|---|
| Big Cliff | Project waste disposal | Petroleum, heavy metals, volatile organic compounds (VOCs; submerged[2]) | Feasibility study nearly complete | Contaminants present in sediment from improper waste disposal during the initial construction of the dam. Surface water sampling suggests no risks to downstream communities. |

| WVS Project | Contamination Source | Contaminants | CERCLA Progress | Summary |
|---|---|---|---|---|
| Blue River | Project waste disposal | Heavy metals, pesticide (submerged[2]). | Site Investigation complete. Remedial Investigation funding requested | Contaminants present in sediment near the saddle dam, although not necessarily in levels high enough to warrant a cleanup. Further investigation is recommended. |
| Cottage Grove[1] | Mercury mine | Mercury, arsenic | One time-critical and one non-time-critical removal action complete. Long-term monitoring is in progress, but ongoing investigations are occurring that may result in further removal action(s). | Contaminants present in Cottage Grove sediment from the upstream Black Butte cinnabar mine. 13,100 cubic yards of contaminated soil were removed from the mine during a removal action in 2018, but the site is still in the remedial investigation/feasibility study phase. |
| Cougar | Unclear, but likely from fuel leaks and spills during initial construction | Petroleum | Site investigation partially complete. Funding requested | Petroleum contaminated soils were discovered during O&M activities. 7,000 cubic yards of soil removed. No further action is needed as contaminants are not detected above residential preliminary remediation goals. |
| Detroit | Project waste disposal | Petroleum, heavy metals, PCBs | Site investigation complete. Remedial Investigation funding requested | Multiple contamination sites in the area. Cleanup documentation is unclear, but at least three separate contaminated soil removal actions took place in the 90s. Further investigation is recommended. |
| Dexter | Domestic and project waste disposal | PCBs, mercury | Site investigation partially complete. Funding requested | Solid waste scattered around roadside dump near powerhouse. No remediation actions have occurred but further investigation is recommended. |

| WVS Project | Contamination Source | Contaminants | CERCLA Progress | Summary |
|---|---|---|---|---|
| Dorena | Project waste disposal | VOCs, heavy metals | Site Investigation complete | Contaminants present but near background levels consistent with that reported in the area. Sampling suggests there is no significant threat to humans or the environment. |
| Fall Creek | Project O&M chemical storage | Lead, arsenic | Site Investigation complete | Contaminants present from former chemical storage area. Several cleanup operations occurred, but documentation is unclear. No further steps will be taken to list this site on the NPL. |
| Green Peter | Project waste disposal | Petroleum, solvents, heavy metals | Site Investigation complete. Remedial investigation funding requested | Contaminants present from disposal of various toxic and hazardous liquid wastes. Some level of cleanup has occurred for petroleum-contaminated soils, but documentation is unclear. A limited site inspection is recommended. |

[1]The Cottage Grove Reservoir contamination is a product of historic mining activities and not related to USACE. Cottage Grove is the only CERCLA site in this table that is not from USACE-related activities.

[2]Contaminants are generally submerged below the surface of the reservoir. Contaminants are located at historic landfills and contractor work areas that were used during the initial construction of the dams but are now covered with water for most of the year.

### 3.18.2 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on public health and safety from hazardous, toxic, and radioactive waste (HTRW). The discussion includes the methodology used to assess effects, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis of effects under each alternative.

#### *3.18.2.1 Methodology*

The potential effects to public health and safety from HTRW were assessed by examining ongoing trends in legacy contamination and the generation, storage, and presence of hazardous waste in soil, sediment, air, and water (exposure pathways) with regards to public health and safety within the WVS. These trends were analyzed with respect to how they could be affected by the action alternatives using information from USACE, scientific literature, and reports. This information was then used to qualitatively predict the severity of the threat that HTRW poses to public health and safety over the life of the project. Table 3.18-3 describes the evaluation criteria for the magnitude, duration, and extent, and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.18-3.18-3. Evaluation Criteria for Potential Effects to Public Health and Safety from Hazardous, Toxic, and Radioactive Waste**

| Term | Definition |
|---|---|
| **Magnitude** | |
| Negligible | The risk to public health from HTRW would be nondetectable or very small. |
| Minor | The risk to public health from HTRW would be measurable but below regulatory standards. |
| Moderate | The risk to public health from HTRW would be measurable and near (slightly above or below) regulatory standards. Mitigation measures would be necessary and would reduce the risk of adverse public health effects. |
| Major | The risk to public health from HTRW would be readily measurable and substantially above regulatory standards. Mitigation measures would be required to decrease the risk of adverse public health effects. |
| **Duration** | |
| Short term | Alteration lasts for the duration of small construction projects, and is continuous for less than 2 years. |
| Medium term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (i.e., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Effects would be confined to the project area. |
| Medium | Effects would be perceived throughout a single county, multiple counties, or the entire WVS. |
| Large | Effects would be perceived throughout the entire state. |

#### *3.18.2.2 Measures Analyzed for Public Health and Safety- Hazardous, Toxic, and Radioactive Waste*

The measures that could affect public health and safety from HTRW are: operation, maintenance, repair, replacement, and rehabilitation; Foster fish ladder temperature improvement (#479); provide Pacific lamprey passage and infrastructure (#52); construct water temperature control tower (#105); construct structural downstream fish passage (#392);

structural improvements to reduce total dissolved gas (#174); deeper fall reservoir drawdowns for fish passage (#40); use spillway for surface spill in summer (#721); and construct adult fish facility (#722). The following measures would have no effect on public health and safety from HTRW, and are therefore not discussed further.

- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Integrated temperature and habitat flow regime (#30a);
- Augment instream flows by using the power pool (#304);
- Gravel augmentation below dams (#384);
- Restore upstream and downstream passage at drop structures (#639);
- Pass water over spillway in spring for fish passage (#714);
- Augment instream flows by using the inactive pool (#718);
- Adapt Hatchery Program (#719);
- Spring reservoir drawdown for downstream fish passage (#720);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Maintenance of existing and new fish release sites above dams (#726); and
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9).

A summary of the effects to public health and safety from hazardous, toxic, and radioactive waste is provided in Table 3.18-4.

Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the lesser beneficial effect does not occur at that reservoir. This follows the approach to present the most conservative conclusions in this table; instead of simply omitting reservoirs where less severe or more beneficial effects would occur. Discussions of all adverse and beneficial effects are included below.

**Table 3.18-4. Summary of Effects to Public Health and Safety from Hazardous, Toxic, and Radioactive Waste**

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | **NAA** | **1** | **2a** | **2b** | **3a** | **3b** | **4** | **5** |
| | **Short-Term** | | | | | | | |
| Magnitude | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse |
| Extent | Local (basin-wide) | Local (basin-wide, FRN, GPR) | Local (basin-wide, GPR) | Local (basin-wide, GPR) | Local (basin-wide, BLU, HCR, GPR) | Local (basin-wide, BLU, HCR, GPR) | Local (basin-wide, FRN, HCR) | Local (basin-wide, GPR) |
| | **Medium-Term** | | | | | | | |
| Magnitude | Minor adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse |
| Extent | Local (basin-wide) | Local (DET, CGR, DEX, FOS, GPR, LOP) | Local (CGR, DET, FOS, GPR, LOP) | Local (CGR, DET, FOS, GPR, LOP) | Local (BLU, GPR, HCR) | Local (BLU, CGR, GPR, HCR) | Local (DET, HCR, LOP, FOS, CGR, DEX, GPR) | Local (CGR, DET, FOS, GPR, LOP) |
| | **Long-Term (Permanent, Intermittent, or Recurring)** | | | | | | | |
| Magnitude | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse | Minor to moderate adverse |
| Extent | Statewide | Statewide, local (basin-wide) | Statewide, local (basin-wide) | Statewide, local (basin-wide) | Statewide, local (basin-wide) | Statewide, local (basin-wide) | Statewide, local (basin-wide) | Statewide, local (basin-wide) |
| Duration Type | Permanent | Permanent | Permanent | Permanent | Permanent and Recurring | Permanent and Recurring | Permanent | Permanent |

### *3.18.2.3 Discussion of Effects by Measure*

This section applies the methodology described above to each measure analyzed for HTRW to determine the potential effects. The discussion is grouped by measures that would have similar effects where possible. Operation, maintenance, repair, replacement, and rehabilitation, use spillway for surface spill in summer (#721); provide Pacific lamprey passage and infrastructure (#52); Foster fish ladder temperature improvement (#479); structural improvements to reduce total dissolved gas (#174); construct adult fish facility (#722); construct water temperature control tower (#105); construct structural downstream fish passage (#392); and deeper fall reservoir drawdowns for fish passage (#40) would require construction as described above in Section 3.1.4.2. Site-specific project details for each construction measure will be determined during the preconstruction engineering and design phase. While general, qualitative effects from construction are discussed below on a programmatic level, the more detailed, site-specific analysis will be included in the tiered EA or EIS.

#### *3.18.2.3.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

The effects of operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

Routine maintenance would result in small amounts of hazardous waste being generated by the scheduled maintenance of turbines and transformers, lead-based paint (LBP) debris from demolition or renovation, and universal waste such as aerosol cans and lamps. The amount of waste generated would be less than the CESQG limit of 220 pounds (100 kg) per month. USACE would comply with RCRA regulations and follow BMPs, including but not limited to: providing workers with safety training and PPE[57], installing secondary containment for waste where applicable, and maintaining accurate waste documentation. Therefore, effects would be adverse and negligible in magnitude. Major maintenance and rehabilitation could result in small amounts of hazardous waste being generated by activities that would still be under the CESQG limit, similar to routine maintenance or, for example, the modernization of the Detroit Dam ROs.

Major maintenance and rehabilitation also result in the generation of hazardous waste that would exceed the CESQG limit during unique circumstances could. There has only been one CESQG exceedance: a 2007 electrical fire in the Detroit Dam Powerhouse that required approximately 20 cubic yards of hazardous waste to be shipped off site of during rehabilitation activities. However, this event was an anomaly and the waste generator status of dams as CESQGs would remain for the life of the project. USACE would continue to adhere to applicable BMPs and regulations, including but not limited to wearing PPE, coordinating with ODEQ and

[57] The USACE Willamette Valley Project Hazard Communication Plan is summarized below in Section 3.19.1.1, Hazardous Materials.

EPA, and restricting access when appropriate. Therefore, effects would be negligible to minor in magnitude for large construction projects. Effects for both routine and major maintenance would be local in extent because they would be confined to the project area. While routine maintenance projects would be short-term because they would take less than two years and major maintenance projects would be medium-term because they would take more than two years, the effects of both routine and major maintenance would occur for the life of the project, and therefore, also be long-term in duration.

Therefore, potential adverse effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

##### *3.18.2.3.2 Use spillway for surface spill in summer (#721) and Provide Pacific lamprey passage and infrastructure (#52)*

The effects of using the spillway for surface spill in the summer and providing Pacific lamprey passage and infrastructure would be negligible in magnitude, local in extent, adverse, and short-term in duration.

These measures would only have effects on public health and safety from HTRW during construction activities. Using the spillway for surface spill in the summer would require structural modifications with excavators and concrete in order to make the spillway useable. Providing Pacific lamprey passage and infrastructure may require modifying fish passage infrastructure with metal strips to provide areas for lamprey to attach. These measures would involve construction and could require compressed gasses for cutting, welding, and brazing, or could otherwise require hazardous material and generate hazardous waste from construction activities in general. Common components of hazardous waste streams from construction sites include lead, asbestos, paint thinners and strippers, aerosol cans, and fluorescent bulbs (Stanford Environmental Health and Safety No date). These measures would likely not require these types of materials or generate these types of wastes because they primarily involve work with construction equipment, metal, and concrete, rather than the construction or demolition of buildings.

Compressed gas cylinders could be classified as hazardous waste if they originally contained a hazardous material and have been spent (i.e., no longer serves the purpose for which it was produced). However, spent compressed gas cylinders would likely be returned to the vendor, and the EPA has determined that compressed gas cylinders that are returned by customers for re-use, refilling, and re-issue are not considered wastes (EPA 1980). If the compressed gas cylinders were to be discarded, or other forms of hazardous wastes were generated during construction, the wastes would be treated as hazardous and stored in accordance with the projects’ CESQG status until being shipped off site for disposal. Consequently, these measures could result in the generation of small amounts of hazardous waste, but the effects would be adverse and negligible in magnitude. Because the waste would be contained in cylinders, drums, or other vessels pursuant to RCRA regulations, the effects to public health and safety would be confined to the project area, and thus, be local in extent. Small amounts of waste would be generated during the construction activities that would take less than two years to complete, so the effects would be short-term in duration.

Therefore, potential adverse effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

##### *3.18.2.3.3 Foster Fish Ladder Temperature Improvement (#479) and Structural improvements to reduce total dissolved gas (#174)*

The effects of improving the Foster fish ladder and improving structures to reduce TDG would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

Improving the Foster fish ladder would involve boring a hole through the Foster Dam, attaching a prefabricated intake structure to the hole using barge-mounted cranes, and then installing mechanical and electrical systems. Improving structures to reduce TDG could involve installing rebar dowels into bedrock and placing concrete. TDG structures would be integrated within the WTC towers at Detroit, Green Peter, and Lookout Point, and therefore, there would be no separate structures built to reduce TDG at these locations. Similar to the measures described above in Section 3.18.2.3.2, these measures could potentially generate small amounts of hazardous waste from activities such as using compressed gasses for cutting, welding, and brazing, or could otherwise require hazardous material and generate small amounts of hazardous waste from construction activities in general.

Therefore, potential adverse effects would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

##### *3.18.2.3.4 Construct water temperature control tower (#105), Construct structural downstream fish passage (#392), and Construct adult fish facility (#722)*

The effects of constructing WTC towers, structural downstream fish passage, and AFFs would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

The specific design and techniques for constructing WTC towers are not available at the programmatic level. Constructing structural downstream passage would involve either FSCs or FSSs depending on the dam, and at Foster Dam, the fish weir would be modified. FSC and FSS construction would involve off-site metal fabrication of the passage structure itself, and then affixing the structure to the WTC tower. Modifying the Foster Dam fish weir would require structural, mechanical, and electrical work to be completed on the spillway gate. Constructing AFFs would involve earthwork, concrete placement, in-water-work, mechanical, and electrical work to construct trap and haul facilities similar to those built at Cougar, Minto, Foster, and Fall Creek. Like the measures described above in both Sections 3.18.2.3.2 and 3.18.2.3.3, these measures could potentially generate small amounts of hazardous waste from activities such as using compressed gasses for cutting, welding, and brazing, or could otherwise require hazardous material and generate small amounts of hazardous waste from construction activities in general. FSC and FSS construction would take more than two years, so the effects would be medium-term in duration. Modifying the Foster Dam fish weir would take less than two years, so effects would be short-term in duration.

After construction, these measures would continue to have effects from operation. WTC towers effectively serve as hydropower turbine intakes and would require hydraulic-oil-filled systems to adjust the gates that control water flows. Additionally, WTC towers, fish passage structures, and AFFs would each require the installation of an emergency diesel generator (EDG) to power equipment during power interruptions. Oil has a finite life, and due to routine equipment maintenance (i.e., oil changes), these oil-filled systems would produce small amounts of hazardous waste. However, the wastes would be treated as hazardous (as applicable) and stored in accordance with the projects' CESQG status until being shipped off site for disposal, and therefore, effects would be adverse and negligible in magnitude. Because the waste would be contained in cylinders, drums, or other vessels pursuant to RCRA regulations, the effects to public health and safety would be confined to the project area, and thus, be local in extent. The small amounts of waste generated would continue for the life of the project and would not change the waste-generator status of the projects as CESQGs, so the effects would be long-term in duration.

Therefore, the potential adverse effects would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

###### *3.18.2.3.5 Deeper fall reservoir drawdowns for fish passage (#40)*

The effects of deeper fall reservoir drawdowns for downstream fish passage would be negligible in magnitude, local in extent, and adverse in the medium and long term, and be minor in magnitude, local in extent, and adverse, and recurring in the long term.

At Cougar Dam, an intake and access tower would be constructed to use the diversion tunnel as a routine outlet for deep drawdowns. At Detroit, Green Peter, and Lookout Point, EDGs would be installed to control water gates during a power interruption, as the current cooling water intakes are located too high to be used during deep drawdowns. And at the Blue River Reservoir, deep drawdowns could expose previously inundated legacy-contaminated sediment near the saddle dam.

Like the measures described above in Section 3.18.2.3.2 constructing an intake and access tower at Cougar Dam required for the drawdown to the DT could potentially generate small amounts of hazardous waste from activities such as using compressed gasses for cutting, welding, and brazing, or could otherwise generate small amounts of hazardous waste from construction activities in general and during O&M of oil-filled systems. Additionally, the installation of EDGs at Detroit, Green Peter, and Lookout Point would generate small amounts of hazardous waste during O&M of oil-filled systems. Constructing an intake and access tower at Cougar Dam would take more than two years, so the effects would be medium-term in duration. The generation of small amounts of hazardous waste during O&M of oil-filled systems would continue for the life of the project, so effects would be long term. The wastes would be treated as hazardous (as applicable) and stored in accordance with the projects' CESQG status until being shipped off site for disposal, and therefore, effects would be adverse and negligible in magnitude. Because the waste would be contained in cylinders, drums, or other vessels pursuant to RCRA regulations, the effects to public health and safety would be confined to the project area, and thus, be local in extent.

At the Blue River Dam, deeper fall reservoir drawdowns could expose the previously inundated legacy-contaminated sediment near the saddle dam, described above in Section 3.18.1.6. This would increase the risk to public health and safety because the contamination would potentially become accessible to the public (the water that would typically make the contamination inaccessible would be drawn-down). If contaminated sediment were to dry, contaminants could also spread due to wind erosion and deposition. A previous site investigation indicated that contaminants may not exist in levels high enough to warrant a cleanup, but concluded by recommending further investigation. While the deeper drawdown would increase the risk to public health and safety, the risk could be reduced by using administrative controls, such as signage, security patrols, and fencing to restrict access to the reservoir while it is drawn-down if needed. Further, the spreading of contamination from wind erosion could be mitigated by using temporary windbreaks or wetting the area, if determined necessary. However, as stated in the Air Quality resource under Section 3.10.3.3.3, average wind speeds would not be high enough to entrain the (contaminated) sediment into the air. Therefore, the effects would be adverse and minor in magnitude. The drawdowns would occur for approximately three weeks out of the year and recur annually for the life of the project, so effects would be short term and long-term recurring. Effects to public health and safety would be confined to the project, so they would be local in extent.

Therefore, the effects of deeper fall reservoir drawdowns for downstream fish passage would be negligible in magnitude, local in extent, and adverse in the medium and long term, and be minor in magnitude, local in extent, and adverse, recurring in the long term.

#### *3.18.2.3.6 Suite of Near-term Operations*

The majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns for improved downstream fish passage at Green Peter and Lookout Point dams would require the installation of an EDG and would generate small amounts of hazardous waste during its O&M for the life of the project, so effects would be long term. The waste would be treated as hazardous (as applicable) and stored in accordance with the projects' CESQG status until being shipped off site for disposal, and therefore, effects would be adverse and negligible in magnitude. Because the waste would be contained in cylinders, drums, or other vessels pursuant to RCRA regulations, the effects to public health and safety would be confined to the project area, and thus, be local in extent. Therefore, the effects of the suite of near-term operations would be negligible in magnitude, local in extent, and adverse in the long term.

### *3.18.2.4 No Action Alternative*

Under the NAA, the existing O&M of the WVS would continue. The O&M of this system includes the generation, storage, and transportation of hazardous waste and the presence of legacy contamination. The NAA assumes that ongoing activities would continue.

Hazardous waste would continue to be generated, stored, and transported throughout the basin from the operation, maintenance, repair, replacement, and rehabilitation of the WVS, from, including but not limited to, the lubrication of hydropower turbines and insulation of electrical transformers, as well as smaller sources such as maintenance, construction, and demolition. USACE WVS dams have historically produced hazardous waste far under their allowed CESQG limit of 220 pounds per month. There has only been one CESQG exceedance: the 2007 Detroit Dam powerhouse fire described above in Section 3.18.2.3.1, which was an anomaly. The waste generator status of dams as CESQGs would remain for the life of the project and USACE would continue complying with RCRA regulations and following BMPs as described above in Section 3.18.2.3.1. Therefore, the effects from ongoing operation, maintenance, repair, replacement, and rehabilitation under the NAA would be identical to those described above: negligible to minor in magnitude, adverse, local in extent, in the short- medium- and long-term.

The presence or management of WVS legacy contamination would not change under the NAA. The legacy contamination is associated with two major sources: waste from mining, and waste from the initial construction and earlier O&M of dams. Mining contamination was determined to be a more serious risk to public health and safety due to the acute and chronic effects of mercury exposure (EPA 2021g). The Pacific Northwest was found to contain lower average mercury concentrations in fish tissue than the rest of the nation (Herger 2016); however, mercury concentrations are frequently reported to be above the Oregon Department of Environmental Quality's (ODEQ) human health water quality criteria for toxic pollutants (Table 3.18-5) (Hillwig and Farrer 2016; ODEQ 2015; ODEQ 2021c). Oregon has a state-wide consumption advisory on bass fish because of mercury contamination, as well as more detailed advisories based on the consumer's age, water body, and type of fish (Table 3.18-6) (OHA No Date-b). Therefore, effects would be state-wide in extent. Of all the contamination in the WVS, mercury is the largest threat to public health and safety, not only due to its neurotoxicity, but because it can be found in fish tissue, to which the public is more exposed than to other contaminants. Because the risk to public health and safety would range from measurable but below regulatory standards, to near regulatory standards depending on quantity, type, and origin of fish consumed, effects would be adverse and minor to moderate in magnitude.

**Table 3.18-5. Oregon Mercury Fish Tissue Concentrations Found in Bass Compared to the Health Criteria**

| | Mercury Concentration(s) |
|---|---|
| Statewide range found in Oregon bass fish[1] | 0.08 to 0.86 (mg/kg) |
| Oregon ODEQ Health Criteria[2] | .04 (mg/kg) |

[1]Data reported by the OHA from Hillwig and Farrer 2016; ODEQ 2015 and reported in mg of total mercury per kg of fish tissue.

[2]Data from ODEQ 2021d, reported in mg of methylmercury per kg of fish tissue.

**Table 3.18-6. Oregon Health Authority Fish Advisories and Consumption Guidelines[2]**

| Area | Contaminant | Affected Fish | Meals per Month | |
|---|---|---|---|---|
| | | | Vulnerable populations | Everyone Else |
| Lower Willamette River | PCB[1] | All fish | Dependent on fish type | Dependent on fish type |
| Cottage Grove Reservoir | Mercury[3] | All fish except stocked rainbow trout < 12 inches | 0 | 4 |
| Dorena Reservoir | Mercury[3] | All fish except stocked rainbow trout < 12 inches | 1 | 4 |
| Willamette River (from the Columbia River to Eugene) | Mercury[3] | All fish | 1 | 4 |

[1]PCBs are considered by OHA to be polychlorinated biphenyls, dioxins, and certain pesticides.

[2]Data from OHA No Date-b.

[3]Methylmercury

The other primary source of WVS legacy contamination is waste from the initial construction and previous O&M of dams. Contaminants such as petroleum, solvents, metals, and PCBs exist at historic disposal sites throughout several of the USACE projects, which are summarized in above in the affected environment (Table 3.18-2). All of these sites have had at least preliminary investigations completed. Their statuses range from “sampling suggests no risks to downstream communities” and “contaminants not detected above residential remediation goals” to “further investigation recommended”. Although no sites have public health risk levels high enough to warrant listing on the NPL, the mere presence of contamination poses a “non-zero” risk to public health and safety. This risk is reduced by using administrative controls such as signage, security patrols, and fencing, which would discourage and restrict access to areas where the public could come into contact with contamination.

Overall, the effects would be negligible to minor in magnitude, adverse, local in extent, in the short, medium, and long term due to ongoing operation, maintenance, repair, replacement, and rehabilitation; and effects would be minor to moderate in magnitude, adverse, and statewide in extent due to Oregon’s mercury contamination.

##### *3.18.2.4.1 Climate Change*

Climate change presents indirect risks to public health and safety from HTRW. Climate change is expected to exacerbate the frequency and severity of natural disasters such as wildland fires and floods. Increasing the severity of fires and floods could compromise contamination sites, and hazardous waste storage facilities to a lesser degree. Fires could make contaminants, especially volatile compounds like solvents and some forms of petroleum, airborne, which would increase the potential for public exposure. Fires could also potentially destroy hazardous waste management infrastructure, such as buildings and containers, and expose waste to the elements. Floods and fires could both spread and expose contamination that had previously not been a risk to the public. However, flooding is a larger concern in tidally-influenced areas, and the WVS is not tidally-influenced. Further, the WVS waste-storage facilities (at Detroit, Fall Creek, and Foster dams) are fire-rated, and BMPs are used to minimize the risk of fires spreading to the facilities, such as trimming tree limbs 30 feet from structures and six feet from the ground. Effects from climate change on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

#### ***3.18.2.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures***

Under Alternative 1, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from providing Pacific lamprey passage and infrastructure at Fern Ridge and Green Peter would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from improving the fish ladder at Foster Dam, and improving structures to reduce TDG at Cougar, Dexter, and Foster would be negligible in magnitude, local in extent, adverse, and medium-term in duration. Effects from constructing a WTC tower at Detroit, Green Peter, and Lookout Point, constructing structural downstream fish passage at Detroit, Foster, and Lookout Point, and constructing an AFF at Green Peter would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

These effects would be greater than Alternatives 2a, 2b, 3a, 3b, and 5, but less than Alternative 4 due to the number of construction measures with medium- and long-term effects.

##### *3.18.2.5.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

##### *3.18.2.5.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 1, providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Green Peter. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

##### *3.18.2.5.3 Foster Fish Ladder Temperature Improvement (#479) and Structural improvements to reduce total dissolved gas (#174)*

Under Alternative 1, improving the fish ladder would occur at Foster Dam and improving structures to reduce TDG would occur at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point (but would only have effects at Cougar, Dexter, and Foster due to the WTC towers). As discussed above in Section 3.18.2.3.3, effects would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

##### *3.18.2.5.4 Construct water temperature control tower (#105), Construct structural downstream fish passage (#392), and Construct adult fish facility (#722)*

Under Alternative 1, constructing a WTC tower would occur at Detroit, Green Peter, and Lookout Point, constructing structural downstream fish passage would occur at Detroit, Foster, Green Peter, and Lookout Point, and constructing an AFF would occur at Green Peter. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

##### *3.18.2.5.5 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 1 on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

#### ***3.18.2.6 Alternative 2a – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)***

Under Alternative 2a, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from providing Pacific lamprey passage and infrastructure at Green Peter would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from improving the fish ladder at Foster and constructing an AFF at Green Peter would be negligible in magnitude, local in extent, adverse, and medium-term in duration. Effects from constructing a WTC tower at Detroit and constructing structural downstream fish passage at Cougar, Detroit, Foster, and Lookout Point would be negligible in magnitude, local in extent, and adverse in both the medium and long term. Effects from the deeper fall reservoir drawdown at Green Peter would be negligible in magnitude, local in extent, and adverse in the long term. The effects from the suite of near-term operations at Green Peter and Lookout Point dams would be negligible in magnitude, local in extent, and adverse in the long term.

These effects would be greater than Alternatives 2b and 5, but less than Alternatives 1, 3a, 3b, and 4 due to the number of construction measures with medium- and long-term effects.

###### *3.18.2.6.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

###### *3.18.2.6.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 2a, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

###### *3.18.2.6.3 Foster Fish Ladder Temperature Improvement (#479)*

Under Alternative 2a, improving the fish ladder would occur at Foster Dam. As discussed above in Section 3.18.2.3.3, effects would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

###### *3.18.2.6.4 Construct water temperature control tower (#105), Construct structural downstream fish passage (#392), and Construct adult fish facility (#722)*

Under Alternative 2a, constructing a WTC tower would occur at Detroit, constructing structural downstream fish passage would occur at Cougar, Detroit, Foster, and Lookout Point, and constructing an AFF would occur at Green Peter. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

###### *3.18.2.6.5 Deeper fall reservoir drawdowns for fish passage (#40)*

Under Alternative 2a, deeper fall reservoir drawdowns for downstream fish passage would occur at Green Peter. As discussed above in Section 3.18.2.3.5, effects would be negligible in magnitude, local in extent, and adverse in the long term.

##### *3.18.2.6.6 Suite of Near-term Operations*

As discussed in Section 3.18.2.3.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns at Green Peter and Lookout Point dams would each require the installation of an EDG and would generate small amounts of hazardous waste; therefore, the effects would be negligible in magnitude, local in extent, and adverse in the long term.

##### *3.18.2.6.7 Climate Change*

Alternative 2a would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 2a on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

#### ***3.18.2.7 Alternative 2b – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 2b, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from providing Pacific lamprey passage and infrastructure at Green Peter would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from improving the fish ladder at Foster would be negligible in magnitude, local in extent, adverse, and medium-term in duration. Effects from constructing a WTC tower at Detroit, constructing structural downstream fish passage at Detroit, Foster, and Lookout Point, and constructing an AFF at Green Peter would be negligible in magnitude, local in extent, and adverse in both the medium and long term. Effects from the deeper fall reservoir drawdown would be negligible in magnitude, local in extent, and adverse in the long term at Green Peter, and in the medium and long term at Cougar. The effects from the suite of near-term operations at Green Peter and Lookout Point would be negligible in magnitude, local in extent, and adverse in the long term.

These effects would be the same as Alternative 5 and less than all other action alternatives due to the number of construction activities with medium- and long-term effects.

##### *3.18.2.7.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

###### *3.18.2.7.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 2b, providing Pacific lamprey passage and infrastructure would occur at Green Peter. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

###### *3.18.2.7.3 Foster Fish Ladder Temperature Improvement (#479)*

Under Alternative 2b, improving the fish ladder would occur at Foster Dam. As discussed above in Section 3.18.2.3.3, effects would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

###### *3.18.2.7.4 Construct water temperature control tower (#105), Construct structural downstream fish passage (#392), and Construct adult fish facility (#722)*

Under Alternative 2b, constructing a WTC tower would occur at Detroit, constructing structural downstream fish passage would occur at Detroit, Foster, and Lookout Point and constructing an AFF would occur at Green Peter. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

###### *3.18.2.7.5 Deeper fall reservoir drawdowns for fish passage (#40)*

Under Alternative 2b, deeper fall reservoir drawdowns for downstream fish passage would occur at Cougar and Green Peter. As discussed above in Section 3.18.2.3.5, effects would be negligible in magnitude, local in extent, and adverse in the medium and long term.

###### *3.18.2.7.6 Suite of Near-term Operations*

As discussed in Section 3.18.2.3.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns at Green Peter and Lookout Point dams would each require the installation of an EDG and would generate small amounts of hazardous waste; therefore, the effects would be negligible in magnitude, local in extent, and adverse in the long term.

###### *3.18.2.7.7 Climate Change*

Alternative 2b would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam’s DT). These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 2b on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

#### *3.18.2.8 Alternative 3a – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Under Alternative 3a, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from using the spillway for surface spill in the summer would occur at Blue River and Hills Creek, and effects from providing Pacific lamprey passage and infrastructure at Blue River, Green Peter, and Hills Creek would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from constructing AFFs at Blue River, Green Peter, and Hills Creek would be negligible in magnitude, local in extent, adverse, and medium- and long-term in duration. Effects from the deeper fall reservoir drawdowns would be negligible in magnitude, local in extent, and adverse in the long term at Detroit, Green Peter, and Lookout Point. The deeper fall drawdowns would also have minor in magnitude, local in extent, adverse, short-term and long-term recurring effects at Blue River. The effects from the suite of near-term operations at Green Peter and Lookout Point would be negligible in magnitude, local in extent, and adverse in the long term.

These effects would be greater than Alternatives 2a, 2b, and 5, but less than Alternatives 1, 3b, and 4 due to the quantity of oil-filled equipment that would need to be installed for deeper drawdowns.

##### *3.18.2.8.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

##### *3.18.2.8.2 Use spillway for surface spill in summer (#721) and Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 3a, using the spillway for surface spill in the summer would occur at Blue River, Detroit, Foster, Green Peter, Hills Creek, and Lookout Point (but would only have effects at Blue River and Hills Creek due to structural improvements), and providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

#### *3.18.2.8.3 Construct adult fish facility (#722)*

Under Alternative 3a, constructing an AFF would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, adverse, and medium- and long-term in duration.

#### *3.18.2.8.4 Deeper fall reservoir drawdowns for fish passage (#40)*

Under Alternative 3a, deeper fall reservoir drawdowns for downstream fish passage would occur at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point (but would only have effects at Detroit, Green Peter, and Lookout Point due to the installation of EDGs, and at Blue River, due to the legacy contamination). As discussed above in Section 3.18.2.3.5, effects would be negligible in magnitude, local in extent, and adverse in the long term at Detroit, Green Peter, and Lookout Point. Effects would be minor in magnitude, local in extent, and adverse in the short term and recurring in the long term at Blue River.

#### *3.18.2.8.5 Suite of Near-term Operations*

As discussed in Section 3.18.2.3.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns at Green Peter and Lookout Point dams would each require the installation of an EDG and would generate small amounts of hazardous waste; therefore, the effects would be negligible in magnitude, local in extent, and adverse in the long term.

#### *3.18.2.8.6 Climate Change*

Alternative 3a would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 3a on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

### ***3.18.2.9 Alternative 3b – Operations-Focused Fish Passage Alternative (using diversion tunnel at CGR)***

Under Alternative 3b, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from using the spillway for surface spill in the summer would occur at Blue River and Hills Creek, and effects from providing Pacific lamprey passage and infrastructure at Blue River, Green Peter, and Hills Creek would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from constructing an

AFF at Blue River, Green Peter, and Hills Creek would be negligible in magnitude, local in extent, adverse, and medium- and long-term in duration. Effects from the deeper fall reservoir drawdowns would be negligible in magnitude, local in extent, and adverse in the medium and long term at Cougar and in the long term at Detroit, Green Peter, and Lookout Point. The deeper fall drawdowns would also have minor in magnitude, local in extent, adverse, short-term and long-term recurring effects at Blue River. The effects from the suite of near-term operations at Green Peter and Lookout Point would be negligible in magnitude, local in extent, and adverse in the long term.

These effects would be greater than Alternatives 2a, 2b, 3a, and 5, but less than Alternatives 1 and 4 due to the quantity of oil-filled equipment that would need to be installed for deeper drawdowns.

##### *3.18.2.9.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

##### *3.18.2.9.2 Use spillway for surface spill in summer (#721) and Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 3b, using the spillway for surface spill in the summer would occur at Blue River, Detroit, Foster, Green Peter, Hills Creek, and Lookout Point (but would only have effects at Blue River and Hills Creek due to structural improvements), and providing Pacific lamprey passage and infrastructure would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

##### *3.18.2.9.3 Construct adult fish facility (#722)*

Under Alternative 3b, constructing an AFF would occur at Blue River, Green Peter, and Hills Creek. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, adverse, and medium- and long-term in duration.

##### *3.18.2.9.4 Deeper fall reservoir drawdowns for fish passage (#40)*

Under Alternative 3b, deeper fall reservoir drawdowns for downstream fish passage would occur at Blue River, Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point (but would only have effects at Blue River, Cougar, Detroit, Green Peter, and Lookout Point due to construction, legacy contamination and installation of EDGs). As discussed above in Section 3.18.2.3.5, effects would be negligible in magnitude, local in extent, and adverse in the medium and long term at

Cougar, and long term at Detroit, Green Peter, and Lookout Point. Effects would be minor in magnitude, local in extent, adverse in the short term and recurring in the long term at Blue River.

#### *3.18.2.9.5 Suite of Near-term Operations*

As discussed in Section 3.18.2.3.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns at Green Peter and Lookout Point dams would each require the installation of an EDG and would generate small amounts of hazardous waste; therefore, the effects would be negligible in magnitude, local in extent, and adverse in the long term.

#### *3.18.2.9.6 Climate Change*

Alternative 3b would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 3a on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

### ***3.18.2.10 Alternative 4 – Improve Fish Passage with Structures-Based Approach***

Under Alternative 4, basin-wide effects from operation, maintenance, repair, replacement, and rehabilitation would be negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation. Effects from providing Pacific lamprey passage and infrastructure at Fern Ridge and Hills Creek would be negligible in magnitude, local in extent, adverse, and short-term in duration. Effects from improving the fish ladder at Foster Dam and improving structures to reduce TDG at Cougar, Dexter, Foster, and Green Peter would be negligible in magnitude, local in extent, adverse, and medium-term in duration. Effects from constructing a WTC tower at Detroit, Hills Creek, and Lookout Point, constructing structural downstream fish passage at Cougar, Detroit, Foster, Hills Creek, and Lookout Point, and constructing an AFF at Green Peter would be negligible in magnitude, local in extent, and adverse in both the medium and long term. The effects from the suite of near-term operations at Green Peter and Lookout Point would be negligible in magnitude, local in extent, and adverse in the long term.

These effects would be greater than Alternatives 1, 2a, 2b, 3a, 3b, and 5 due to the number of construction activities with medium- and long-term effects.

###### *3.18.2.10.1 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Under all action alternatives, operation, maintenance, repair, replacement, and rehabilitation would occur basin-wide. As discussed above in Section 3.18.2.3.1, potential effects negligible in magnitude, local in extent, adverse, and short- and long-term for routine/scheduled maintenance; and be negligible to minor in magnitude depending on the activity, local in extent, adverse, and medium- and long-term in duration for major maintenance and rehabilitation.

###### *3.18.2.10.2 Provide Pacific lamprey passage and infrastructure (#52)*

Under Alternative 4, providing Pacific lamprey passage and infrastructure would occur at Fern Ridge and Hills Creek. As discussed above in Section 3.18.2.3.2, potential effects would be negligible in magnitude, local in extent, adverse, and short-term in duration.

###### *3.18.2.10.3 Foster Fish Ladder Temperature Improvement (#479) and Structural improvements to reduce total dissolved gas (#174)*

Under Alternative 4, improving the fish ladder would occur at Foster Dam and improving structures to reduce TDG would occur at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point (but would only have effects at Cougar, Dexter, Foster, and Green Peter due to the WTC towers). As discussed above in Section 3.18.2.3.3, effects would be negligible in magnitude, local in extent, adverse, and medium-term in duration.

###### *3.18.2.10.4 Construct water temperature control tower (#105), Construct structural downstream fish passage (#392), and Construct adult fish facility (#722)*

Under Alternative 4, constructing a WTC tower would occur at Detroit, Hills Creek, and Lookout Point, constructing structural downstream fish passage would occur at Cougar, Detroit, Foster, Hills Creek, and Lookout Point, and constructing an AFF would occur at Hills Creek. As discussed above in Section 3.18.2.3.4, effects would be negligible in magnitude, local in extent, and adverse in both the medium and long term.

###### *3.18.2.10.5 Suite of Near-term Operations*

As discussed in Section 3.18.2.3.6, the majority of the near-term operations involve water-management operations, and thus, would not have effects on public health and safety from HTRW. The deep drawdowns at Green Peter and Lookout Point dams would each require the installation of an EDG and would generate small amounts of hazardous waste; therefore, the effects would be negligible in magnitude, local in extent, and adverse in the long term.

###### *3.18.2.10.6 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. These measures would only have negligible adverse effects on public health and safety from HTRW. Climate change would exacerbate effects, but they would not be appreciably larger than those described under the NAA above in Section 3.18.2.4.1. Therefore, the effects from climate change and Alternative 4 on public health and safety from HTRW would be negligible to minor in magnitude, adverse, regional in extent, and long-term in duration.

#### *3.18.2.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 is similar to Alternative 2b but includes the *refined* integrated habitat and flow regime (#30b), rather than the integrated habitat and flow regime (#30a). This measure would not have adverse effects to public health and safety from HTRW. Therefore, the effects would be identical to Alternative 2b: less than all other action alternatives.

#### *3.18.2.12 Conclusion*

Severity of adverse effects on public health and safety from HTRW is primarily driven by the number of medium-term construction projects, and secondarily by the number of measures that would require the installation of oil-filled equipment and subsequently result in long-term effects. The action alternatives organized in order of least-severe to most-severe adverse effects on hazardous materials would be: 2b/5, 2a, 3a, 3b, 1, and 4. Differences between the action alternatives would not contribute to effects from climate change on public health and safety from HTRW. Therefore, all action alternatives would result in approximately equal effects from climate change with respect to public health and safety from HTRW.

## 3.19 PUBLIC HEALTH AND SAFETY – DRINKING WATER

### 3.19.1 Affected Environment

This section discusses the importance of protecting drinking water resources for public health and the federal and state regulatory requirements for drinking water. Groundwater and surface water sources that communities rely on for public drinking water are located downstream of the WVS reservoirs. The City of Monroe relies on drinking water from the Long Tom River where the Fern Ridge reservoir is located. The City of Cottage Grove receives drinking water from Row River, which is downstream of the Dorena Reservoir. The City of Sweet Home receives irrigation water from Foster Reservoir. The cities of Salem, Eugene, and Springfield all receive drinking water from downstream of the WVS reservoirs. Lastly the City of Lowell relies on drinking water directly from the Dexter Reservoir. The water sourced from downstream of the reservoirs or directly from the reservoirs is treated by a combination of filtration, aeration, and disinfection at a public water treatment facility before it is distributed.

### 3.19.2 Drinking Water Regulatory Background

The proper treatment, disinfection, and distribution of clean drinking water is vital to the prevention of public health risks in the WVS. Contamination of drinking water sources can be caused by pesticides, animal waste, improper disposal of chemicals, and naturally-occurring substances within the watershed. Drinking water that has not been treated or a distribution system that needs maintenance can also pose health risks. Federal drinking water regulations and Oregon state rules and guidelines protect drinking water sources, including lakes, rivers, springs, and groundwater wells.

The federal Safe Drinking Water Act (SDWA) was passed in 1974 to protect national public drinking water sources including groundwater and surface waters such as rivers, lakes, streams, reservoirs, springs, ponds, and wells. The SDWA authorizes the U.S. Environmental Protection Agency (EPA) to set standards for drinking water. The SDWA originally set forth standards for safe drinking water in tap water. The 1996 amendment set further protections for source water at drinking water reservoirs, as well as operator training and funding for water system projects (EPA 2004).

Water can dissolve substances from human activities or animals as it runs over land or through the ground and drains to drinking water sources. Containments that can be found in drinking water include microbial contaminants such as viruses and bacteria, inorganic contaminants such as salts and metals, pesticides and herbicides, chemicals, and radioactive contaminants which may be naturally occurring (City of Sweet Home Public Works 2021). Metals including iron and manganese are found to be in high concentrations in instream waters downstream of reservoirs as well as excessive nutrients such as nitrogen and phosphorus which can cause algal blooms (Kennedy & Gaugush 1988). Some algal blooms are harmful if people or pets come in contact with polluted water or consume tainted fish or shellfish (EPA 2022d). See Section 3.17.1 Harmful Algal Blooms.

The EPA drinking water standards regulate over 90 contaminants. These standards are grouped in two categories: the National Primary Drinking Water Regulations (NPDWR or primary standards) and the National Secondary Drinking Water Regulations (NSDWR or secondary standards). Primary drinking water standards are legally enforceable. The primary standards set mandatory water quality standards or “maximum contaminant levels” (MCLs) to protect the public against drinking water contaminants. Secondary standards are non-enforceable and provide guidelines for aesthetic considerations such as taste, color, and odor (EPA 2021h). Table 3.19-1 include a partial list of contaminants regulated by the NPDWR and Table 3.19-2 lists the NSDWR.

**Table 3.19-1. Partial list of contaminants regulated under National Primary Drinking Water Regulations (EPA 2022a)**

| Contaminant | MCLG (mg/L) | Potential Health Effects from Long-Term Exposure Above the MCL (unless specified as short-term) | Sources of Contaminant in Drinking Water |
|---|---|---|---|
| Cryptosporidium | zero | Gastrointestinal illness (such as diarrhea, vomiting, and cramps) | Human and animal fecal waste |
| *Giardia lamblia* | zero | Gastrointestinal illness (such as diarrhea, vomiting, and cramps) | Human and animal fecal waste |
| *Legionella* | zero | Legionnaire's Disease, a type of pneumonia | Found naturally in water; multiplies in heating systems |
| Total Coliforms (including fecal coliform and *E. Coli*) | zero | Not a health threat in itself; it is used to indicate whether other potentially harmful bacteria may be present | Coliforms are naturally present in the environment; as well as feces; fecal coliforms and E. coli only come from human and animal fecal waste. |
| Turbidity | na | Turbidity is a measure of the cloudiness of water. It is used to indicate water quality and filtration effectiveness (such as whether disease-causing organisms are present). Higher turbidity levels are often associated with higher levels of disease-causing microorganisms such as viruses, parasites and some bacteria. These organisms can cause symptoms such as | Soil runoff |

| Contaminant | MCLG (mg/L) | Potential Health Effects from Long-Term Exposure Above the MCL (unless specified as short-term) | Sources of Contaminant in Drinking Water |
|---|---|---|---|
| | | nausea, cramps, diarrhea, and associated headaches. | |
| Viruses (enteric) | zero | Gastrointestinal illness (such as diarrhea, vomiting, and cramps) | Human and animal fecal waste |
| Chlorite | 0.8 | Anemia; infants and young children: nervous system effects | Byproduct of drinking water disinfection |
| Chloramines (as Cl2) | MRDLG=41 | Eye/nose irritation; stomach discomfort, anemia | Water additive used to control microbes |
| Chlorine (as Cl2) | MRDLG=41 | Eye/nose irritation; stomach discomfort | Water additive used to control microbes |
| Asbestos (fiber > 10 micrometers) | 7 million fibers per liter (MFL) | Increased risk of developing benign intestinal polyps | Increased risk of developing benign intestinal polyps |
| Cyanide (as free cyanide) | 0.2 | Nerve damage or thyroid problems | Discharge from steel/metal factories; discharge from plastic and fertilizer factories |
| Lead | zero | Infants and children: Delays in physical or mental development; children could show slight deficits in attention span and learning abilities<br>Adults: Kidney problems; high blood pressure | Corrosion of household plumbing systems; erosion of natural deposits |
| Nitrate (measured as Nitrogen) | 10 | Infants below the age of six months who drink water containing nitrate in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome. | Runoff from fertilizer use; leaking from septic tanks, sewage; erosion of natural deposits |
| Nitrite (measured as Nitrogen) | 1 | Infants below the age of six months who drink water containing nitrite in excess of the MCL could become seriously ill and, if untreated, may die. Symptoms include shortness of breath and blue-baby syndrome. | Runoff from fertilizer use; leaking from septic tanks, sewage; erosion of natural deposits |

| Contaminant | MCLG (mg/L) | Potential Health Effects from Long-Term Exposure Above the MCL (unless specified as short-term) | Sources of Contaminant in Drinking Water |
|---|---|---|---|
| Glyphosate | 0.7 | Kidney problems; reproductive difficulties | Runoff from herbicide use |

[1]Maximum Residual Disinfectant Level Goal (MRDLG) - The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of the use of disinfectants to control microbial contaminants.

**Table 3.19-2. List of National Secondary Drinking Water Regulations (EPA 2022b)**

| Contaminant | Secondary Standard |
|---|---|
| Aluminum | 0.05 to 0.2 mg/L |
| Chloride | 250 mg/L |
| Color | 15 (color units) |
| Copper | 1.0 mg/L |
| Corrosivity | noncorrosive |
| Fluoride | 2.0 mg/L |
| Foaming Agents | 0.5 mg/L |
| Iron | 0.3 mg/L |
| Manganese | 0.05 mg/L |
| Odor | 3 threshold odor number* |
| pH | 6.5-8.5 |
| Silver | 0.10 mg/L |
| Sulfate | 250 mg/L |
| Total Dissolved Solids | 500 mg/L |
| Zinc | 5 mg/L |

*Threshold odor number is the number of dilutions it takes to produce odor free water.

The Surface Water Treatment Rule (SWTR) requires all utilities with a surface water supply, or a groundwater supply influenced by surface water, to provide adequate disinfection to prevent illness from pathogens (EPA 2021i) which include *Legionella*, *Giardia lamblia*, and *Cryptsosporidium*. The Ground Water Rule (GWR) provides protection for ground water sources which can be susceptible to fecal contamination. It applies to public water systems which use groundwater as a drinking water source.

The Oregon Drinking Water Quality Act enacted in 1981 ensures safe drinking water, provides a regulatory program for drinking water, and provides a means to improving inadequate drinking water systems. The rules promote coordination between the programs for supervising water systems which are conducted by the Authority and the EPA (OHA No Date-c). The Oregon Health Authority (OHA) regulates drinking water under Oregon state law and the SDWA and works with ODEQ on drinking water source protection to prevent public health risks. ODEQ works to protect drinking sources by implementing the CWA, identifying the source waters in watersheds and aquifers for surface water and groundwater for public water supply systems, and developing water assessments and guides for community public water systems (ODEQ 2021e).

### 3.19.3 Groundwater and Surface Water

Groundwater is a critical source of drinking water in the state of Oregon where almost half of the population relies on groundwater for daily consumption. Approximately 35 percent of people rely solely on groundwater for drinking water, 10 percent rely on surface water, and 55 percent rely on a combination of both (OHA 2018). This heavy reliance on groundwater is due to the decreasing availability of surface water and higher costs for treating surface water (the proportion of groundwater users in the WRB has not been quantified because it would require researching the source water information for each town or city in the WRB which is beyond the scope of a programmatic document). Groundwater wells can be contaminated by surface pollutants such as microbial contamination, fertilizers and pesticides, and arsenic. Currently, there are approximately 50 public water systems in Oregon that are exposed to groundwater contamination from active chemical cleanup sites (OHA No Date-e).

The DEQ is designated as the lead agency for implementation of the Wellhead Protection Program (WHPP). The WHPP was implemented in order to "protect wellhead areas within their jurisdiction from contaminants which may have any adverse effect on the health of persons" (OHA No Date). The program provides incentives for community participation in the program, provides a detailed guidance manual for local implementation, and promotes public awareness of the impact of land use on drinking water among other initiatives. With the 1996 amendment of the SDWA, states were required to develop Source Water Assessment Programs. As such, Oregon has been working to expand the WHPP to develop a Drinking Water Protection Program that includes surface water sources (OHA No Date-e). Private drinking water wells which serve fewer than 25 people are not regulated by the SDWA (EPA 2022c).

Source water assessments were completed in Oregon in 1999 and 2005 with updates in 2016 and 2017 (OHA 2018). Source water assessments for individual community public water systems which rely on surface water within the WVS can be found on the DEQ website. The assessments indicate the potential contaminant sources within the watershed areas of the water supply. The assessments allow communities to develop strategies to protect drinking water sources based on the land uses within the water supply area and the inventory of potential contaminants (ODEQ 2019b). Strategies for source water protection include mapping source water protection areas, inventorying known and potential contamination sources, and developing action plans to prevent contamination.

Water supply allocations for M&I and agricultural irrigation (AI) have been planned for a 30-year planning horizon to the year 2050. Table 1-6 lists the allocated storage for fish and wildlife, M&I, and AI water supply. In deficit water years, water delivery for AI uses may be ceased or curtailed; however, this would not affect M&I drinking water availability.

### 3.19.4 Monitoring

The ODEQ Laboratory conducted 45 groundwater assessments between 1980 and 2000 and determined the most commonly detected contaminants in Oregon included nitrates, pesticides, and bacteria. The groundwater studies found 35 of the 45 study areas had some impairment. In the Willamette Valley, approximately thirty-three percent of rural water wells contained at least one pesticide from historic uses (DEQ 2017). The Corps commonly uses pesticides such as triclopyr choline and glyphosate for routine maintenance (see further discussion in Section 3.16 Hazardous materials).

If drinking water is found to be contaminated, a water advisory is issued by public water system officials (CDC 2020). The OHA Drinking Water Advisories website posts current drinking water advisories in Oregon. It includes information such as the source of water (surface water or groundwater), the reason for the advisory (i.e., nitrate, *E. coli*, arsenic), and the towns or communities affected (OHA No Date-d).

### 3.19.5 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on Public Health and Safety – Drinking Water. The discussion includes the methodology, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis for each alternative.

#### *3.19.5.1 Methodology*

The methodology below is used to assess the No Action Alternative (NAA) and the action alternatives' effects on the drinking water quality and supply in the WVS. The measures for the alternatives would cause either adverse effects or be beneficial to the availability and quality of drinking water in the reservoirs. Adverse effects to drinking water as it relates to public health and safety would be caused by a decline in water quality or water supply. Beneficial effects to drinking water as it relates to public health and safety would improve water quality or water supply. The effects to the quality and availability of drinking water could last for several days or up to a year or more and can occur over a small localized area or the entire reservoir and the downstream reaches.

Table 3.19-3 describes the evaluation criteria for the effect factors (magnitude, duration, and extent), and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.19-3. Evaluation Criteria for Potential Effects to Public Health and Safety – Drinking Water**

| Effect Factors and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Public health and safety would not be affected, or changes or benefits would be either nondetectable or, if detected by monitoring or exposure to pollutants within the drinking water supply, would have slight effects. Chemical or physical changes to water quality would be within regulatory standards for water quality conditions for drinking water. No mitigation measures would be necessary. There would be little or no detectable adverse effects to the availability of drinking water affecting water supply for consumers or beneficial effects to the availability of drinking water resulting in a surplus of water supply |
| Minor | Changes to public health and safety would be measurable if detected by monitoring or exposure to pollutants within the drinking water supply, although the changes would be small. Chemical or physical changes to water quality would be detectable by monitoring or exposure to unsafe drinking water, but would be within regulatory standards for water quality conditions for drinking water. No mitigation measures would be necessary. There would be small detectable adverse effects to the availability of drinking water affecting water supply for consumers or beneficial effects to the availability of drinking water resulting in a surplus of water supply |
| Moderate | Changes to public health and safety would be measurable by monitoring and any increased or decreased exposure to pollutants within the drinking water supply would have adverse /beneficial effects (respectively) on the affected water body and any affected local downstream receiving waters for drinking water. Chemical or physical changes to water quality would be below regulatory standards for water conditions suitable for drinking water. Mitigation measures would be necessary if the affected water body and local downstream receiving waters are used for drinking water. There would be detectable adverse effects to the availability of drinking water affecting water supply for consumers or beneficial effects to the availability of drinking water resulting in a surplus of water supply. |
| Major or Significant | Changes to public health and safety would be readily apparent, either severely adverse or exceptionally beneficial, and result in substantial, noticeable effects on the affected water body and any affected local downstream receiving waters for drinking water. The |

| Effect Factors and Scale | Definition |
|---|---|
| | effects would be detectable by monitoring or exposure to pollutants within the drinking water supply. Chemical or physical changes to water quality would be well below regulatory standards for water quality conditions suitable for drinking water. Mitigation measures would not be sufficient to reduce pollutant levels to an acceptable drinking water quality. There would be detectable adverse effects to the availability of drinking water affecting water supply for consumers or beneficial effects to the availability of drinking water resulting in a surplus of water supply. |
| **Duration** | |
| Short-term | Effects last for the duration of small construction projects and are continuous for less than 2 years. |
| Medium-term | Effects are limited to the duration of large construction projects and are continuous for a period of 2-5 years. |
| Long-term | Effects are permanent or last continuously beyond operational changes or the completion of all construction projects; effects recur at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or effects occur intermittently. |
| **Extent** | |
| Small | Effects would be confined to a small area (e.g., the inflow to the dam, the area surrounding the principal inlet, along the shoreline of the reservoir, downstream of the dam, or the project area). |
| Medium | Effects occur in the entire reservoir. |
| Large | Effects occur in the entire reservoir and downstream receiving water body. |

#### *3.19.5.2 Measures Analyzed for Public Health and Safety – Drinking Water*

Measures under the action alternatives that could impact Public Health and Safety – Drinking Water include:

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9);
- Fall Creek drawdown;
- Operation, maintenance, repair, replacement, and rehabilitation;
- Foster fish ladder temperature improvement (#479);
- Construct water temperature control (WTC) towers (#105);

- Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Use spillway for surface spill in summer (#721);
- Structural improvements to reduce total dissolved gas (#174);
- Augment instream flows by using the inactive pool (#718);
- Augment instream flows by using the power pool (#304);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b)
- Restore upstream and downstream passage at drop structures (#639);
- Construct adult fish facility (AFF) (#722);
- Provide Pacific lamprey passage and infrastructure (#52);
- Construct structural downstream fish passage (#392);
- Deeper fall reservoir drawdowns for fish passage (#40);
- Spring reservoir drawdown for fish downstream fish passage (#720); and
- Pass water over spillway in spring for fish passage (#714).

The following measures would have no effect on Public Health and Safety – Drinking Water and are therefore not discussed further.

- Gravel augmentation below dams (#384);
- Adapt hatchery program (#719);
- Maintenance of existing and new fish release sites above dams (#726).
- Continued operation of existing adult fish facilities;

A summary of the Public Health and Safety – Drinking Water effects discussed in the sections below is provided in Table 3.19-4.

Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the least magnitude of beneficial effects for each alternative is listed to present the most conservative range of potential effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the least beneficial effect does not occur at that reservoir. Discussion of all adverse and beneficial effects is presented below.

**Table 3.19-4. Summary of Effects to Public Health and Safety – Drinking Water Under Each Alternative**

| Effect Factor | | Alternative | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| | **Short-Term** | | | | | | | |
| Magnitude | Minor beneficial and adverse | Minor adverse; Minor beneficial | Minor beneficial and/or adverse | Minor beneficial and/or adverse | Minor beneficial and/or adverse | Minor beneficial and/or adverse | Minor beneficial and/or adverse | Minor beneficial and/or adverse |
| Extent | Large (basin-wide, FOS, DET, FCR, CGR, DEX, BCL, LOP, HCR, GPR) | Small, large (basin-wide, BLU, CTG, DOR, FCR; CGR, DET, GPR, HCR, LOP) | Small, large (basin-wide, GRP, BLUE, FCR, CGR, DET, HCR, LOP, FOS, BCL) | Small, large (basin-wide, FCR, BLU, FCR, CGR, LOP, FCR, HCR, CGR, FOS, BCL, DET) | Small, large (basin-wide; DET, GPR, LOP, BLU, FOS, HCR, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide; DET, GPR, LOP, BLU, FOS, HCR, CTG, DOR, FCR, CGR, BCL) | Small, large (basin-wide, GPR, BLU, CTG, DOR, FCR, CGR, DET, GPR, HCR, LOP, BCL) | Small, large (basin-wide, GRP, BLU, FCR, DET, GPR, HCR, LOP, BCL, CGR, FOS, BCL) |
| | **Medium-Term** | | | | | | | |
| Magnitude | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse |
| Extent | Small (basin-wide) | Small, large (FOS, DET, FRN, GPR, CGR, DET, DEX, LOP) | Small (FOS, DET, GPR, GRP, CGR, DET, FOS, LOP, BCL, DEX) | Small (FOS, DET, GPR) | Small (BLU, GPR, HCR) | Small (BLU, GPR, HCR) | Small (FOS, HCR, CGR, DET, DEX, GPR, LOP) | Small (FOS, DET, GPR, DET; FOS, LOP, BCL, DEX) |
| | **Long-Term (Permanent, Intermittent, or Recurring)** | | | | | | | |
| Magnitude | Negligible adverse | Minor adverse; minor beneficial | Minor beneficial and/or adverse | Major, adverse; minor beneficial | Major, adverse; minor beneficial | Major, adverse; minor beneficial | Minor beneficial and/or adverse | Minor beneficial and/or adverse |
| Extent | Large (basin-wide, FOS, DET, | Small, large | Small, large (basin-wide, | Small, large, (basin-wide, | Small, large, (basin-wide; | Small, large, (basin-wide; | Small, large (basin-wide, | Small, large (basin-wide, |

| Effect Factor | | Alternative | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |

In the following subsections, effects are discussed for the NAA, for each proposed measure that could have an impact, and for each of the action alternatives.

#### *3.19.5.3 Discussion of Effects by Measure(s)*

The measures which could impact drinking water and public health and safety are analyzed by measure(s) in this section. Measures that require additional tiered analysis, near-term operations measure, and measures proposed under the action alternatives are analyzed. It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

Site-specific project details for each construction measure will be determined during the preconstruction engineering and design phase. While general, qualitative effects from construction are discussed below on a programmatic level, the more detailed, site-specific analysis will be included in a tiered EA or EIS.

##### *3.19.5.3.1 Construction and/or Modification of Structural Measures*

Construction requires the use of large equipment which could lead to erosion and sedimentation from exposed soils and cause sediment to discharge into the reservoirs in the short- or medium-term. Discharges associated with construction activities would affect drinking water quality and could affect public health and safety as sediment laden runoff could pollute reservoir waters locally. However, construction activities would be required to meet NPDES permit requirements for stormwater discharges and such adverse effects would be negligible overall as measures to prevent erosion and sedimentation would be implemented during construction.

This section discusses the potential impacts to public health and safety and drinking water from the construction and/or modification of the structural measures shown below.

- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Maintenance of existing and new fish release sites above dams (#726)
- Foster fish ladder temperature improvement
- Construct water temperature control tower (#105)
- Structural improvements to reduce TDG (#174)
- Restore upstream and downstream passage at drop structures (#639)
- Construct AFF (#722)
- Provide Pacific lamprey passage and infrastructure (#52)
- Construct structural downstream fish passage (#392)

- Operation, Maintenance, Repair, Replacement and Rehabilitation

**Maintaining revetments using nature-based engineering or altering revetments for aquatic ecosystem restoration (#9); maintenance of existing and new fish release sites above dams (#726)**

Maintaining or altering revetments (#9) and maintenance of existing and new fish release sites (#726) would occur basin wide and would affect drinking water and public health and safety from the construction work associated with the maintenance. Sediment-laden discharges from construction activities could affect drinking water quality. However, construction activities would require measures to prevent erosion and sedimentation would be implemented during construction. The short-term effects would be negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. This would include the stabilization of exposed soils using measures such erosion control blankets on slopes, temporary sediment storage basins, and silt fencing (USACE 2011).

In the long term, this maintenance work would have no effects on the public health and safety of drinking water.

**Foster fish ladder temperature improvement (#479); Construct WTC towers (#105); Structural improvements to reduce total dissolved gas (#174)**

Construction activities associated with the Foster fish ladder temperature improvement (#479), construction of WTC towers (#105), and structural improvements to reduce TDG (#174) would have negligible, adverse effects in the medium term as measures to prevent erosion and sedimentation would be implemented during construction similar to the maintenance of revetments (#9) described above.

Foster fish ladder temperature improvement (#479) would provide enhanced temperature control and normative (i.e., the standards of temperature needed for fish passage) water temperatures downstream for fish passage during regular operations. A new Forebay Warm Water Supply would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The release of warmer water at the surface would have beneficial effects on the water quality of the reservoir as it would allow mixing of the surface waters. Inadequate mixing and lack of rainfall during summer months can lead to stagnant waters and stratification of the reservoir (i.e., the formation of thermal layers). Temporal stratification has adverse effects on water quality, including the entrainment of nutrients in the water column which can lead to eutrophication (see Section 3.19.1 Affected Environment where eutrophication is discussed). Therefore, the enhanced temperature controls that reduce stratification would have a beneficial minor effect on drinking water, and public health and safety. The effects would be long term recurring during reservoir releases.

Construction of WTC towers (#105) would have beneficial effects on water quality within the reservoir and adverse effects downstream. Cooler water is released from the bottom of the reservoir to provide more normative temperatures downstream. Release of middle to lower portions of the reservoir bottom can have high concentrations of nutrients and metals from the sediment accumulated in the bottom of the reservoir (Kennedy & Gaugush 1988). The downstream waters used for drinking water would be adversely affected by deep reservoir releases due to the influx of concentrated nutrients. The effects would be adverse and beneficial minor, long term and recurring when reservoir releases occur.

Structural improvements to reduce TDG (#174) would have beneficial effects on drinking water and public health and safety in the long term. The reduction in TDG would improve water quality for drinking water as it would reduce the amount of nitrogen in downstream waters. The effects would be minor as the amount of nitrogen could be detected by monitoring. The effects would be long term and permanent in duration.

**Restore upstream and downstream passage at drop structures (#639), construct AFF (#722), provide Pacific lamprey passage and infrastructure (#52), construct structural downstream fish passage infrastructure (#392)**

These four fish infrastructure measures would have similar effects. The construction effects would be adverse and negligible as measures to prevent erosion and sedimentation would be implemented. The effects of restoring upstream and downstream passage at drop structures (#639) would be short term in duration. For the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), construction effects would be medium term in duration.

In the long term, there would be no effects to public health and safety – drinking water associated with fish collection and fish passage infrastructure.

**Operation, Maintenance, Repair, Replacement and Rehabilitation (OMRRR)**

Scheduled/routine maintenance and non-routine maintenance activities would be adverse as effects of sediment-laden discharges from construction activities could affect drinking water quality. Effects would be negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Therefore, effects are adverse and negligible in the short term. Similarly, effects of major maintenance and repairs would be adverse and negligible however the duration of major maintenance is medium and long term recurring.

#### *3.19.5.3.2 Implementation of Water Management Measures*

This section discusses the potential impacts to public health and safety and drinking water from the implementation of the following water management measures:

- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Use spillway for summer surface spill (#721)

- Pass water over spillway in spring for fish passage (#714)
- Deeper fall reservoir drawdowns for fish passage (#40)
- Spring reservoir drawdown for downstream fish passage (#720)
- Fall Creek Drawdown
- Augment instream flows by using the inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)
- Integrated temperature and habitat flow regime (#30a)
- Refined integrated temperature and habitat flow regime (#30b)
- Near-term Operations Measure

**Use regulating outlets (ROs) to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)**

Using ROs to discharge cold water (#166) would have adverse effects on downstream water quality. Discharging cold water would allow the reservoir to 'turnover' as described in Section 2.2.2.2 Water Quality Measures. However, the discharge from the ROs of the reservoir would release concentrated nutrients upward due to mixing in the water column from the lower depths of the reservoir where sediment and heavy metals accumulate in low oxygen conditions. The decreased quality of water would also be released downstream from where drinking water is sourced. The effects would be adverse and minor, short and long term recurring during reservoir releases.

**Use spillway for summer surface spill (#721); Pass water over spillway in spring for fish passage (#714)**

Using the spillway for summer surface spill (#721) would have beneficial and adverse minor effects to drinking water and public health and safety as it would promote mixing of the reservoirs' surface waters which could reduce stratification locally as described previously under Section 3.19.6.3.1 under the Foster fish ladder temperature improvement (#479). Conversely, when water flows over the spillway air dissolves into the water which causes nitrogen to increase dramatically (EPA, 1971). Increased nitrogen can be conducive to algal growth formation which could cause water quality to decline. Excess nitrogen is also harmful if ingested. The release of warmer water at the surface would be beneficial and minor, short and long term recurring during summer spillway releases.

Spring spillway fish passage (#714) would have the same effects as use of the spillway for summer surface spill (#721). The release of water from the surface spillway would have beneficial and adverse minor, short and long term recurring during spillway releases.

**Augment instream flows by using the inactive pool (#718); Augment instream flows by using the power pool (#304); Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)**

Augmenting instream flows by using the inactive pool (#718) would have adverse effects on drinking water and public health and safety. It would have minor, small, and long-term recurring effects on the availability of drinking water as the inactive pool is used only for emergencies or when the conservation pool has been emptied. This measure would have adverse effects on drinking water quality and public health and safety as well since water from the deepest layer of the reservoir would be released (see Figure 2 Reservoir storage layers in the Glossary). See the discussion under 3.19.6.3.1, construction of WTC towers (#105). The effects would be minor, short- and long-term recurring when reservoir releases occur.

Augment instream flows by using the power pool (#304) would have adverse effects on drinking water and public health and safety. Power pool storage used for hydropower generation would be separately allocated from conservation storage used for drinking water. Therefore, it would have negligible, short- and long-term recurring effects on the availability of drinking water. However, effects would also be minor because water quality would be reduced due to the release of highly concentrated nutrients from the middle of the reservoir – similar to the effects use of the inactive pool.

Reducing minimum flows to Congressionally authorized minimum flows (#723) would have beneficial effects for drinking water and public health and safety as it would allow capture of spring runoff for conservation, thereby increasing water availability. The effects on water availability are minor, short and long-term recurring when flows are reduced in the spring. Reducing minimum flows to the Congressionally authorized minimum flows requirements would allow reservoirs to capture more spring runoff rather than releasing it. These minimum flows would also maintain water quality standards. Therefore, effects would be beneficial minor, short and long term permanent when flows are reduced.

**Integrated temperature and habitat flow regime (#30a); Refined integrated temperature and habitat flow regime (#30b)**

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The adaptive fish flows would prevent stagnancy of the water, thereby maintaining water quality. Operation of the WVS follows a four-season cycle, winter flood risk management (FRM) season and summer conservation season with spring refill and fall release periods as discussed in Section 1.10. Therefore the effects would be beneficial minor, short and long term recurring.

The refined integrated temperature and habitat flow regime (#30b) would have similar beneficial effects on drinking water and public health and safety as the integrated temperature and habitat flow regime (#30a). The adaptive fish flows would prevent stagnancy of the water, thereby maintaining water quality. The effects would be beneficial minor, short and long term recurring.

**Deeper fall reservoir drawdowns for fish passage (#40); Spring reservoir drawdown for downstream fish passage (#720); Fall Creek drawdown**

The reservoir drawdowns would have adverse effects on water quality downstream. Nutrients at the bottom of the reservoir flow would be released downstream, reducing water quality and would have effects similar to the effects described under Section 3.19.6.3.1 for construction of WTC towers (#105). The WTC towers would release water from the lower depths of the reservoir similar to drawdown operations where the accumulated sediment would be released. The effects would be adverse minor, and short and long term recurring in the fall and spring.

The spring and fall drawdowns result in elevations below the minimum conservation elevation and therefore do not maintain M&I water supply storage. The spring drawdown would have a major effect on conservation pool storage because the spring drawdowns can affect the ability to refill system-wide storage. Conversely, the fall drawdowns only have a negligible to minor effect because stored water usage during this period is minimal. The effects of the drawdowns on water availability would be long term recurring when drawdowns would occur in the fall and spring.

**Near-term Operations Measure**

The Near-term Operations Measure are a suite of 16 operations described in Chapter 2. The operations measures are analyzed by grouping measures below by where water is released from the dam, either through the regulating outlets or surface spillway releases. The depth in the reservoir from where water is released would have different effects on water quality. Water released from the surface spillway would have less adverse and more beneficial effects than water released from the lower depths of the reservoir such as from the regulating outlets which is explained below.

***RO Release***

- Nighttime RO prioritization for improved downstream fish passage at Detroit Dam;
- Deep drawdown and RO prioritization for improved downstream fish passage at Cougar Dam;
- Delayed reservoir refill and RO prioritization for improved downstream fish passage at Cougar Dam;
- Nighttime RO prioritization for improved downstream fish passage (downstream fish passage) at Hills Creek Dam;
- Deep drawdown and RO prioritization for improved downstream fish passage at Lookout Point Dam;
- Extended deep drawdown and RO prioritization for improved downstream fish passage at Falls Creek Dam and delayed reservoir refill and RO prioritization for improved downstream fish passage at Falls Creek Dam

Using ROs to discharge cold water would have adverse effects on downstream waters, reducing water quality where drinking water is sourced. Discharging cold water would allow the reservoir to ‘turnover’ as described in Section 2.2.2.2. However, the discharge from the ROs of the reservoir would also release concentrated nutrients upward due to mixing in the water column from the lower depths of the reservoir where sediment and heavy metals accumulate in low oxygen conditions. The decreased quality of water would also be released downstream. Therefore, effects would be adverse and minor as changes to water quality would be small and within regulatory standards for water quality conditions for drinking water. The effects would be large in extent affecting the reservoir and downstream waters and short and long term recurring during reservoir releases. The deep drawdown, extended deep drawdown, and delayed reservoir refill and RO prioritization and would have adverse, negligible to minor, short and long-term recurring effects as the drawdown occurs in the fall and winter when stored water usage is minimal. The effects on water quality would be adverse minor, large, short and long term recurring in the fall and spring. These effects are similar to the effects of the reservoir drawdowns analyzed in the previous section above.

***Spillway release***

- Spread spill across spillways to reduce downstream TDG exceedances at Big Cliff Dam;
- Utilize spillway for improved downstream fish passage in the spring; perform spill operation until 01 May or for 30 days, whichever is longer at Green Peter Dam;
- Delay refill and utilize spillway in the spring for improved downstream fish passage; use the fish weir in the summer for improved downstream temperature management and upstream fish migration/passage at Green Peter Dam;
- Utilize the spillway for improved downstream fish passage in the fall at Foster Dam

Using the spillway for the near-term operations measure would have beneficial effects to drinking water and public health and safety as it would promote mixing of the reservoirs’ surface waters which could reduce stratification locally as described for the Foster fish ladder temperature improvement (#479) in Section 3.19.6.3.1. The release of the warmer water at the surface of the reservoir would also have beneficial and minor, short- and long-term recurring effects during summer spillway releases. Conversely, when water flows over the spillway air dissolves into the water which causes nitrogen to increase dramatically which has adverse effects to drinking water quality. Therefore effects would be beneficial and adverse, minor, short and long term recurring.

***Combined RO and Spillway release***

- Spring downstream fish passage and operational downstream temperature management at Detroit dam
- Utilize spillway for improved downstream fish passage in the spring at Lookout Point Dam; RO use in the fall for downstream temperature management at Lookout Point Dam

These measures use a combination of using both the RO and the spillway which would result in adverse and beneficial, minor, and long term recurring effects similar to the effects analyzed under the RO release and Spillway release measures above. The effects would be beneficial and adverse minor, short and long term recurring.

#### *3.19.5.4 No Action Alternative*

This analysis addresses the effects if the existing O&M of the WVS system would continue. The current operations which could have either beneficial or adverse effects on the drinking water and public health and safety. Water treatment would also minimize or eliminate the reduced quality of the drinking water. Effects of temperature control and TDG reduction measures would be beneficial and adverse minor, large, short and long term recurring. The effects of augmenting flows would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large short- and long-term recurring effects on drinking water quality. Passing water over the spillway has beneficial and adverse, minor, large, short- and long- term recurring effects. For the existing operations continued forward, the effects would be adverse, minor, large, short and long term recurring due to the Fall Creek drawdown; adverse, negligible, small, and short term recurring for routine maintenance; and adverse negligible, small, and medium- and long-term recurring effects for major maintenance.

The NAA includes water quality, flow, and upstream and downstream passage operations. Water quality operations include using the spillway to release warm surface water and manage downstream temperatures at Foster and Detroit; strategically using outlets to meet temperature targets (when possible) at Fall Creek; operating the Cougar WTC tower to manage downstream temperatures; spreading spill across the Dexter and Big Cliff spillways to reduce TDG; and discharging water through the powerhouse at power-producing dams to reduce TDG.

These water quality operations to control temperature and reduce TDG would continue to be beneficial and adverse for drinking water. The release of warmer water at the surface would have beneficial effects on the water quality of the reservoir as it would allow mixing of the surface waters and would reduce stratification of the reservoir as discussed under the Foster fish ladder temperature improvement in Section 3.19.6.3.1. Conversely, when water flows over the spillway air dissolves into the water which causes nitrogen to increase dramatically (EPA, 1971). Increased nitrogen can be conducive to algal growth formation which could cause water quality to decline. Excess nitrogen is also harmful if ingested. Therefore, effects of temperature control and TDG reduction measures would be beneficial and adverse minor, large, short and long term recurring.

Flow operations include meeting the 2008 BiOp targets basin-wide and augmenting flows using the inactive or power pool at Green Peter. Maintaining operational flow targets for fish and wildlife conservation would be adverse and negligible in the short term, medium term, and long term on the availability of water for drinking water as it would be separately allocated for municipal and industrial (M&I) water supply. The effects would be large as conservation releases would affect the entire reservoir and downstream receiving water bodies. As discussed above in Sections 3.19.6.3.2, augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large short- and long-term recurring effects on drinking water quality.

Fish passage operations include passing fish over the Foster spillway and through the lowest RO at Fall Creek (Fall Creek drawdown). Passing water over the spillway has beneficial and adverse, minor, large, short- and long- term recurring effects. The Fall Creek drawdown is discussed below under existing operations continued forward.

#### *5.19.5.4.1 Existing operations continued forward*

**Fall Creek Drawdown**

Reservoir releases or drawdowns would cause concentrated nutrients, heavy metals and sediment to be released downstream, reducing the quality of the drinking water resource. Therefore, effects would be adverse minor, large in extent affecting the entire reservoir and downstream receiving waters, short and long term recurring throughout the year as the pool volumes are adjusted. Effects on water availability would be negligible as the Fall Creek drawdown occurs in November when stored water usage during this period is minimal. Therefore, effects on water availability would be adverse negligible, large, short and long term recurring.

**Continued Operation of Existing Adult Fish Facilities**

O&M activities associated with existing AFFs would continue to have adverse negligible effects on public health and safety – drinking water. Water used for flushing of fish facilities or effluent water may be high in pollutants. However, hatcheries are required to meet water quality standards for their waste/effluent water (EPA 2021j). These discharges from fish facilities must be within the limits set forth in NPDES permit requirements. Thresholds are set for total suspended solids (TSS), settleable solids, temperature, and pH and must not be exceeded during routine monitoring. Thus, any effects would be adverse negligible, small in extent localized to the area of discharge, short and long term recurring during the regular flushing of facilities during maintenance.

**Operation, Maintenance, Repair, Replacement and Rehabilitation**

Scheduled/routine maintenance and non-routine maintenance activities would be adverse as effects of sediment-laden discharges from construction activities could affect drinking water quality. Effects would be negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Therefore, effects are adverse and negligible in the short term. Similarly, effects of major maintenance and repairs would be adverse and negligible however the duration of major maintenance is medium- and long term recurring.

#### *5.19.5.4.2 Climate Change*

The impact on public health and safety – drinking water due to environmental conditions which may change as a result of climate change is analyzed in this section. The climate change projected trend information is based on the hydrologic trends discussed in Appendix F.

Increased extreme precipitation events can cause stream flows to increase rapidly leading to increased potential for sedimentation and erosion. This can diminish the quality of water entering the reservoirs due to the sedimentation and influx of nutrients and contaminants from the watershed. These impacts would be minor, large in extent affecting the entire reservoir and downstream receiving waters, and long-term intermittent and/or permanent as extreme precipitation events occur.

Prolonged periods between rainfall events (or drought periods) could cause decreases in streamflow, leading to less water availability and the ability of the WVS to provide conservation storage and storage for M&I. Increased temperatures due to climate change could also lead to higher evapotranspiration rates thereby reducing the amount of water available for drinking water. Decreased streamflow and increasing temperatures would be adverse and have a moderate effect as the availability of drinking water could be affected. The effects would be large in extent affecting the drinking water available to users basin-wide, and long term intermittent as drought periods occur over the period of the analysis.

Warmer temperatures from climate change could also provide favorable conditions for the propagation of harmful algal blooms (HABs), which can discolor, cloud, or cover the water's surface and affect drinking water. Wildfire ash can land in reservoirs, streams, and rivers, increasing turbidity and adversely affecting the water quality of those water bodies which communities rely on for drinking water.

#### *5.19.5.4.3 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, fish passage would be improved through storage-focused measures by maximizing refill volumes of conservation pools and tapping into the power pool, augmenting flow to the congressionally authorized minimum flows. This would increase the likelihood of refilling to the maximum conservation pool levels.

Effects are the similar to the effects described under the Discussion of Effects by Measure(s). Alternative 1 effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392). In the long term, there would be no effects to public health and safety associated with fish collection, fish passage infrastructure and AFFs.

Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392) have no long-term effects. Foster fish ladder temperature improvement (#479) and construction of WTC towers (#105) would have beneficial, minor, small and long-term recurring effects.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. Reducing minimum flows to Congressionally authorized minimum flow requirements (#723) basin-wide would have beneficial minor, large and long-term recurring effects when flows are reduced in the spring on water availability. Effects on water quality would be also beneficial minor, large, and long term and recurring. Structural improvements to reduce total dissolved gas (#174) would have adverse minor, large effects in the short and long term permanent in duration.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

##### *3.19.5.4.4 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; maintenance of existing and new fish release sites above dams (#726); Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be and small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.4.5 Foster Fish Ladder Temperature Improvement (#479); Construct WTC Towers (#105) at Detroit, Green Peter and Lookout Point dams; Structural improvements to reduce total dissolved gas (#174) at Cougar, Detroit, Dexter, Foster, Green Peter, and Lookout Point dams*

Foster fish ladder temperature improvement (#479) would have beneficial effects. Construction of a new Forebay Warm Water Supply pipe would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large affecting the entire reservoir and downstream receiving waters, and long term recurring during reservoir releases.

Construction of WTC towers (#105) would have beneficial and adverse effects on water quality. The effects would be minor, large affecting the reservoir and downstream reaches, and long term and recurring when reservoir releases occur.

Structural improvements to reduce total dissolved gas (#174) would have adverse and minor, and large effects affecting the entire reservoir and the downstream receiving waters. The effects would be long term and permanent in duration.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.19.5.4.6 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove, Dorena, and Falls Creek dams; Augment instream flows by using the power pool (#304) Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point dams; Reduce minimum flows to Congressionally authorized minimum flow requirements (#723) basin-wide; Fall Creek drawdown*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large short- and long-term recurring effects on water quality.

Reducing minimum flows to Congressionally authorized minimum flow requirements (#723) would be beneficial effects on water quality and public health and safety as it would allow capture of spring runoff for conservation thereby increasing water availability. The effects on water availability are beneficial minor, large, short and long term recurring when flows are reduced in the spring. These minimum flows would also maintain water quality standards. Effects on water quality would be also beneficial minor, large, and long term and permanent.

Effects of the Fall Creek drawdown would be adverse minor, large, short and long term recurring.

###### *3.19.5.4.7 Restore upstream and downstream passage at drop structures at Fern Ridge Dam (#639); construct AFFs at Green Peter Dam (#722); provide Pacific lamprey passage and infrastructure at Fern Ridge and Green Peter dams (#52); and construct structural fish passage infrastructure (#392) at Detroit, Foster, Green Peter, Lookout Point, Big Cliff, and Dexter dams; continued operation of existing adult fish facilities*

The construction effects of restoring upstream and downstream passage at drop structures (#639) would be negligible, small, in the short term. For the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), construction effects would be negligible, small, in the medium term. In the long term, there would be no effects to public health and safety associated with fish collection, fish passage infrastructure and AFFs.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

##### *3.19.5.4.8 Climate Change*

Alternative 1 would combine storage-focused measures in order to improve fish passage. The measures in Alternative 1 would improve reservoir storage and improve water quality by reducing TDG and normalizing temperatures. Therefore, the effects of climate change on drinking water would be less severe under Alternative 1 than any other alternative, including the NAA. Climate change in combination with the measures under Alternative 1 would have adverse, minor, large, long-term intermittent and /or permanent effects to drinking water.

#### ***3.19.5.5 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative***

Under Alternative 2A, integrated temperature and habitat flow regimes would be utilized as well as using the power pool to augment flows. Structural and operational measures are proposed to address water quality as well as the Near-Term Operations Measure(s) as discussed under Section 2.2.5. The effects of the measures proposed under Alternative 2A are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392). Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392) have no long-term effects. Foster fish ladder temperature improvement (#479) would have beneficial, minor and long-term recurring effects.

The effects of using ROs to discharge cold water (#166) would be adverse minor, large, short and long term recurring on water quality. The deeper fall reservoir drawdowns for fish passage (#40) would have adverse, minor, large, short- and long-term recurring effects on water quality downstream and adverse, negligible to minor, large, short- and long-term recurring effects on water availability. Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects. Construction effects the deeper fall reservoir drawdowns for fish passage (#40) and using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. The integrated temperature and habitat flow regime (#30a) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measure would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.19.5.5.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; maintenance of existing and new fish release sites above dams (#726) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse small, negligible, and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.19.5.5.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC tower (#105)*

Foster fish ladder temperature improvement (#479) would have beneficial effects. Construction of a new Forebay Warm Water Supply pipe would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large affecting the entire reservoir and downstream receiving waters, and long term and recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse effects on water quality. The effects would be minor, large affecting the reservoir and downstream reaches, and long term and recurring when reservoir releases occur.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.5.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Deeper fall reservoir drawdowns for fish passage (#40) at Green Peter Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166) would have adverse effects on downstream water quality. The effects would be adverse and minor, large, short and long term recurring during reservoir releases.

The deep reservoir drawdowns would have adverse effects on water quality downstream. The effects would be adverse minor, large, and short and long term recurring in the fall.

The deeper fall reservoir drawdown for fish passage (#40) results in elevations below the minimum conservation elevation and therefore do not maintain M&I water supply storage. The fall drawdowns would have a negligible to minor effect because stored water usage during this period is minimal. The effects of the fall drawdowns on water availability would be large, short and long term recurring in the fall.

Construction effects of deeper fall reservoir drawdown for fish passage (#40) would be adverse negligible, small in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.5.4 Use spillway for surface spill in summer (#721) at Green Peter Dam; Pass water over spillway in spring for fish passage (#714) at Green Peter Dam*

Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, and short and long term and recurring during summer and spring spillway releases.

Construction effects of using the spillway for summer surface spill (#721) would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.5.5 Augment instream flows by using the inactive pool (#718) at Blue River and Falls Creek dams; Augment instream flows by using the power pool (#304) at Cougar, Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

##### *3.19.5.5.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The effects would be minor, small, short and long term.

##### *3.19.5.5.7 Construct adult fish facilities at Green Peter Dam (#722); Pacific lamprey passage and infrastructure at Green Peter Dam (#52); construct structural downstream fish passage (#392) at Cougar, Detroit, Foster, Lookout Point, Big Cliff, and Dexter dams; Continued operation of existing adult fish facilities*

The construction effects of the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), would be adverse, negligible, small, short or medium term in duration. In the long term, there would be no effects to public health and safety associated with fish collection and fish passage infrastructure.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

##### *3.19.5.5.8 Near-term Operations Measure*

The Near-term Operations Measure are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

##### *3.19.5.5.9 Climate Change*

Alternative 2A would integrate water management flexibility and ESA-listed fish measures (using structural downstream passage at Cougar Dam). The measures in Alternative 2A would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. In general, climate change would exacerbate effects from deep drawdowns: as temperatures increase and snowpacks decline, reservoirs may struggle to reach their conservation pool elevations over time, which would directly affect drinking water. Climate change in combination with the measures under Alternative 2A would have adverse, minor, large, long-term intermittent and /or permanent effects on drinking water.

### *3.19.5.6 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative*

Under Alternative 2B, the effects to public health and safety – drinking would be the same as those described under Alternative 2A. The difference is that the downstream passage measure at Cougar Dam is changed from a structural fish passage structure under 2A to changing of operations to a deep fall and spring drawdown with the construction of a diversion tunnel under 2B. The Near-Term Operations Measure(s) are also proposed under this alternative.

The effects of the measures proposed under Alternative 2B are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s). Effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392). Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392) have no long-term effects. Foster fish ladder temperature improvement (#479) and construction of WTC towers (#105) would have beneficial, minor and long-term recurring effects.

The effects of using ROs to discharge cold water (#166) would be adverse minor, large, short and long term recurring on water quality. The deeper fall reservoir drawdowns for fish passage (#40) would have adverse, minor, large, short- and long-term recurring effects on water quality downstream and adverse, negligible to minor, large, short- and long-term recurring effects on water availability. Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects. Construction effects the deeper fall reservoir drawdowns for fish passage (#40) and using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. The integrated temperature and habitat flow regime (#30a) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measure would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

##### *3.19.5.6.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; maintenance of existing and new fish release sites above dams (#726) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.6.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC tower (#105) at Detroit Dam*

Foster fish ladder temperature improvement (#479) would have beneficial effects. Construction of a new Forebay Warm Water Supply pipe would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large affecting the entire reservoir and downstream receiving waters, and long term and recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse effects on water quality. The effects would be minor, large affecting the reservoir and downstream reaches, and long term and recurring when reservoir releases occur.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.6.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Deeper fall reservoir drawdowns for fish passage (#40) at Cougar and Green Peter dams; spring reservoir drawdown for downstream fish passage (#720) at Cougar Dam; Fall Creek drawdown*

Using Ros to discharge cold water (#166) would have adverse effects on downstream water quality. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

The reservoir drawdowns would have adverse effects on water quality downstream. The effects are minor, large, short and long term recurring in the fall or spring.

The spring reservoir drawdown for downstream fish passage (#720) would have a major, large, and short- and long-term effects on water availability. The deeper fall reservoir drawdowns for fish passage (#40) would have a negligible to minor, large, short- and long-term recurring effects.

Effects of the Fall Creek drawdown on drinking water quality and water availability would be adverse minor, large, short and long term recurring.

Construction effects of the spring reservoir drawdown for downstream fish passage (#720) and deeper fall reservoir drawdown for fish passage (#40) would be adverse, negligible, small in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.6.4 Use spillway for surface spill in summer (#721) at Green Peter Dam; Pass water over spillway in spring for fish passage (#714) at Green Peter Dam*

Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, short and long term recurring during summer and spring spillway releases.

Construction effects of using the spillway for summer surface spill (#721) would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

##### *3.19.5.6.5 Augment instream flows by using the inactive pool (#718) at Blue River and Falls Creek dams; Augment instream flows by using the power pool (#304) at Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

###### *3.19.5.6.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The effects would be minor, small, short and long term.

###### *3.19.5.6.7 Construct adult fish facilities at Green Peter Dam (#722); Pacific lamprey passage and infrastructure at Green Peter Dam (#52); construct structural downstream fish passage (#392) at Detroit, Foster, Lookout Point, Big Cliff, and Dexter dams; continued operation of existing adult fish facilities*

The construction effects of the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), would be adverse, negligible, small, short or medium term in duration. In the long term, there would be no effects to public health and safety associated with fish collection and fish passage infrastructure.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

###### *3.19.5.6.8 Near-term Operations Measures*

The Near-term Operations Measures are a suite of operations measures in which the impacts The Near-term Operations Measures are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

###### *3.19.5.6.9 Climate Change*

Alternative 2B would integrate water management flexibility and ESA-listed fish measures (using a deep drawdown to Cougar Dam's DT). Climate change is expected to adversely affect water quantity and air and water quality. The measures in Alternative 2B would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. Due to one more deep drawdown than Alternative 2A, climate change would exacerbate the effects of Alternative 2B more than Alternatives 1 or 2A. However overall, the effects would be the same as under Alternative 2A; climate change in combination with the measures under Alternative 2B would have adverse, minor to moderate, large, long-term intermittent and/or permanent effects to drinking water.

### *3.19.5.7 Alternative 3A – Operations-Focused Fish Passage Alternative*

Under Alternative 3A, improved fish passage is proposed through the modifying of operations rather than focusing on storage (Alternative 1) or structural measures (Alternative 4). The Near-Term Operations Measure(s) are also proposed under this alternative.

Effects under Alternative 3A are the similar to the effects described under the Discussion of Effects by Measure(s). Alternative 3A effects would be similar to Alternatives 2B due to the spring drawdown. Effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722); and providing Pacific lamprey passage and infrastructure (#52. Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722) and providing Pacific lamprey passage and infrastructure (#52) have no long-term effects.

The effects of using ROs to discharge cold water (#166) would be adverse minor, large, short and long term recurring on water quality. Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects during summer and spring spillway releases. The reservoir drawdowns would have adverse, minor, large, short and long term recurring in the fall and spring. The spring reservoir drawdown for downstream fish passage (#720) would have a major, large, and short- and long-term effects on water availability. The deeper fall reservoir drawdowns for fish passage (#40) would have a negligible to minor, large, short- and long-term recurring effects. Construction effects the deeper fall reservoir drawdowns for fish passage (#40) and using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. The integrated temperature and habitat flow regime (#30a) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measure would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.19.5.7.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; maintenance of existing and new fish release sites above dams (#726) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.19.5.7.2 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Detroit; Green Peter; and Lookout Point dams; deeper fall reservoir drawdowns for fish passage (#40) at Blue River; Cougar; Detroit; Green Peter; Hills Creek; Lookout Point; spring reservoir drawdown for downstream fish passage (#720) at Cougar; Detroit; and Lookout Point dams; Fall Creek drawdown*

Using ROs to discharge cold water (#166) would have adverse effects on downstream water quality. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

The reservoir drawdowns would have adverse effects on water quality downstream. The effects are minor, large, short and long term recurring in the fall and spring.

The spring reservoir drawdown for downstream fish passage (#720) would have a major, large, and short- and long-term effects on water availability. The deeper fall reservoir drawdowns for fish passage (#40) would have a negligible to minor, large, short- and long-term recurring effects.

Construction effects of the spring reservoir drawdown for downstream fish passage (#720) and deeper fall reservoir drawdown for fish passage (#40) would be adverse, negligible, small in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.7.3 Use spillway for surface spill in summer (#721) at Blue River; Detroit; Foster; Green Peter; Hills Creek; and Lookout Point dams; Pass water over spillway in spring for fish passage (#714) at Big Cliff, Dexter, Falls Creek, Green Peter, and Hills Creek dams*

Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, short and long term recurring during summer and spring spillway releases.

Construction effects of using the spillway for summer surface spill (#721) would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.7.4 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove; Dorena; and Falls Creek dams; Augment instream flows by using the power pool (#304) at Cougar, Detroit, Green Peter; Hills Creek; and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

*3.19.5.7.5 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The effects would be minor, small, short and long term.

*3.19.5.7.6 Construct adult fish facilities (#722) at Blue River; Green Peter; and Hills Creek dams; Pacific lamprey passage and infrastructure at Blue River; Green Peter; and Hills Creek dams; continued operation of existing adult fish facilities*

The construction effects of the construction of AFFs (#722) and providing Pacific lamprey passage and infrastructure (#52) would be adverse, negligible, small, short or medium term in duration. In the long term, there would be no effects to public health and safety associated with fish collection and fish passage infrastructure.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

*3.19.5.7.7 Near-term Operations Measures*

The Near-term Operations Measures are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

##### *3.19.5.7.8 Climate Change*

Alternative 3A would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's RO). The measures in Alternative 3A would improve water quality by normalizing temperatures. It would also provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3A would include the less-deep drawdown to the Cougar RO. Due to the number of deep drawdowns, climate change would exacerbate the effects of Alternative 3A more than under Alternatives 1, 2A, 2B, 4, and 5, and less than Alternative 3B (but not appreciably). Climate change in combination with the measures under Alternative 3A would have adverse, moderate, large, long-term intermittent and/or permanent effects to drinking water.

#### ***3.19.5.8 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)***

Under Alternative 3B, the effects to public health and safety - drinking would be the same as those described under Alternative 3A. Alternative 3B proposes the slightly different combination of operations for the downstream passage. Alternative 3A proposes the drawdown to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures and 3B proposes drawdown utilizing the diversion tunnel at Cougar. The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the measures proposed under Alternative 3B are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 3B effects are similar to 2B and 3A due to the spring drawdown. Effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722); and providing Pacific lamprey passage and infrastructure (#52. Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); construction of AFFs (#722) and providing Pacific lamprey passage and infrastructure (#52) have no long-term effects.

The effects of using ROs to discharge cold water (#166) would be adverse minor, large, short and long term recurring on water quality. Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects during summer and spring spillway releases. The reservoir drawdowns would have adverse, minor, large, short and long term recurring in the fall and spring. The spring reservoir drawdown for downstream fish passage (#720) would have a major, large, and short- and long-term effects on water availability. The deeper fall reservoir drawdowns for fish passage (#40) would have a negligible to minor, large, short- and long-term recurring effects. Construction effects the deeper fall reservoir drawdowns for fish passage (#40) and using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. The integrated temperature and habitat flow regime (#30a) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

*3.19.5.8.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.8.2 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Detroit; Green Peter; and Lookout Point dams; deeper fall reservoir drawdowns for fish passage (#40) at Blue River; Cougar; Detroit; Green Peter; Hills Creek; Lookout Point and* *spring reservoir drawdown for downstream fish passage (#720) at Cougar; Detroit; and Lookout Point dams; Fall Creek drawdown*

Using ROs to discharge cold water (#166) would have adverse effects on downstream water quality. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

The reservoir drawdowns would have adverse effects on water quality downstream. The effects are minor, large, short and long term recurring in the fall and spring.

The spring reservoir drawdown for downstream fish passage (#720) would have a major, large, and short- and long-term effects on water availability. The deeper fall reservoir drawdowns for fish passage (#40) would have a negligible to minor, large, short- and long-term recurring effects.

Construction effects of the spring reservoir drawdown for downstream fish passage (#720) and deeper fall reservoir drawdown for fish passage (#40) would be adverse, negligible, small in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.8.3 Use spillway for surface spill in summer (#721) at Blue River; Detroit; Foster; Green Peter; Hills Creek; and Lookout Point dams; Pass water over spillway in spring for fish passage (#714) at Big Cliff, Detroit, Dexter, Lookout Point dams*

Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, and long term and recurring during summer and spring spillway releases.

Construction effects of this measure would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.8.4 Augment instream flows by using the inactive pool (#718) at Blue River, Cottage Grove; Dorena; and Falls Creek dams; Augment instream flows by using the power pool (#304) at Detroit, Green Peter, Hills Creek, and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

##### *3.19.5.8.5 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The effects would be minor, small, short and long term.

##### *3.19.5.8.6 Construct adult fish facilities (#722) at Blue River; Green Peter; and Hills Creek dams; Pacific lamprey passage and infrastructure (#52) at Blue River; Green Peter; and Hills Creek dams; continued operation of existing adult fish facilities*

The construction effects of the construction of AFFs (#722) and providing Pacific lamprey passage and infrastructure (#52) would be adverse, negligible, small, short or medium term in duration. In the long term, there would be no effects to public health and safety associated with fish collection and fish passage infrastructure.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

##### *3.19.5.8.7 Near-term Operations Measures*

The Near-term Operations Measures are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

##### *3.19.5.8.8 Climate Change*

Alternative 3B would improve fish passage by using operations-focused measures (using a deep drawdown to Cougars Dam's DT). The measures in Alternative 3B would improve water quality by normalizing temperatures and provide fish passage with numerous deep drawdowns. Alternatives 3A and 3B would include more than twice as many drawdowns as the other alternatives, and Alternative 3B would include the deeper drawdown to the Cougar DT. Climate change in combination with the measures under Alternative 3B would have adverse, moderate, large intermittent and/or permanent effects to drinking water in the long term.

#### *3.19.5.9 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, a structures-based approach is proposed to improve fish passage. Alternative 4 is similar to Alternative 1. The Near-Term Operations Measure(s) are also proposed under this alternative.

The effects of the measures proposed under Alternative 4 are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s). Alternative 4 effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); ; structural improvements to reduce TDG (#174); restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392). Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); restoring upstream and downstream passage at drop structures (#639); construction of AFFs (#722); providing Pacific lamprey passage and infrastructure (#52); and construction structural fish passage infrastructure (#392) have no long-term effects. Foster fish ladder temperature improvement (#479) and construction of WTC towers (#105) would have beneficial, minor and long-term recurring effects.

The effects of using ROs to discharge cold water (#166) would be adverse minor, large, short and long term recurring on water quality. Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects during summer and spring spillway releases. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. Construction effects of the using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. The integrated temperature and habitat flow regime (#30a) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measure would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

##### *3.19.5.9.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be and small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.9.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC towers (#105) at Detroit; Hills Creek; and Lookout Point dams; Structural improvements to reduce TDG (#174) at Cougar; Detroit; Dexter; Foster; Green Peter; and Lookout Point dams*

Foster fish ladder temperature improvement (#479) would have beneficial effects. Construction of a new Forebay Warm Water Supply pipe would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large affecting the entire reservoir and downstream receiving waters, and long term and recurring during reservoir releases.

Structural improvements to reduce total dissolved gas (#174) would have adverse and minor, and large effects affecting the entire reservoir and the downstream receiving waters. The effects would be long term and permanent in duration.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.9.3 Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166) at Green Peter Dam; Fall Creek drawdown*

Using ROs to discharge cold water (#166) would have adverse effects on downstream water quality. The effects would be adverse minor, large, short and long term recurring during reservoir releases.

The Fall Creek reservoir drawdown would have adverse effects on water quality downstream. The effects are minor, large, short and long term recurring.

*3.19.5.9.4 Use spillway for surface spill in summer (#721) at Green Peter Dam*

Using the spillway for summer surface spill (#721) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, and long term and recurring during summer and spring spillway releases.

Construction effects of this measure would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

#### *3.19.5.9.5 Augment instream flows by using the inactive pool (#718) at Cottage Grove; Dorena; Falls Creek; and Blue River dams; Augment instream flows by using the power pool (#304) at Cougar; Detroit; Green Peter; Hills Creek; and Lookout Point dams*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

#### *3.19.5.9.6 Integrated temperature and habitat flow regime (#30a) basin-wide*

Integrated temperature and habitat flow regime (#30a) would have beneficial effects on drinking water and public health and safety. The effects would be minor, small, short and long term.

#### *3.19.5.9.7 Restore upstream and downstream passage at drop structures (#639) at Fern Ridge Dam; construct AFF at Hills Creek Dam; provide Pacific lamprey passage and infrastructure at Fern Ridge and Hills Creek dams; and construct structural downstream fish passage Cougar; Detroit; Foster; Hills Creek; Lookout Point, Big Cliff and Dexter dams; continued operation of existing adult fish facilities*

The construction effects of restoring upstream and downstream passage at drop structures (#639) and would be negligible, small, in the short term. For the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392), construction effects would be negligible, small, short or medium term. In the long term, there would be no effects to public health and safety associated with fish collection, fish passage infrastructure and AFFs.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

#### *3.19.5.9.8 Near-term Operations Measures*

The Near-term Operations Measures are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

#### *3.19.5.9.9 Climate Change*

Alternative 4 would improve fish passage with structures-based measures. The measures in Alternative 4 would improve water quality by reducing TDG and normalizing temperatures. Alternative 4 would not improve reservoir storage like Alternative 1, but it would feature fewer drawdowns than under all other action alternatives. Therefore, climate change would exacerbate the effects of Alternative 4 more than Alternative 1, but less than Alternatives 2A, 2B, 3A, 3B, and 5. Climate change in combination with the measures under Alternative 4 would have direct, adverse, minor, large, long-term intermittent and/or permanent effects to drinking water.

#### *3.19.5.10 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 5 – the Preferred Alternative, fish passage would be improved through a combination of modified operations and structural improvements. Alternative 5 is exactly the same as Alternative 2B except the integrated temperature and habitat flow regime (Measure #30a) is replaced with refined integrated temperature and habitat flow regime (Measure #30b). The Near-Term Operations Measure(s) are also proposed under this alternative. The effects of the spillway releases, flow/temperature modifications, fish infrastructure, drawdown operations, and the near-term operations measure under Alternative 5 are analyzed in this section. Effects are the similar to the effects described under the Discussion of Effects by Measure(s).

Alternative 4 effects would be adverse negligible, small, and short term or medium term for the construction and/or modification of any structural measures which include maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726); Foster fish ladder temperature improvement (#479); construction of WTC towers (#105); construction of AFFs (#722) and construction structural fish passage infrastructure (#392). Maintenance or alteration of revetments (#9); the maintenance of existing and new fish release sites (#726; construction of AFFs (#722); (#52); and construction structural fish passage infrastructure (#392) have no long-term effects. Foster fish ladder temperature improvement (#479) and construction of WTC towers (#105) would have beneficial, minor and long-term recurring effects.

Using the spillway for summer surface spill (#721) and passing water over spillway in spring for fish passage (#714) would have beneficial and adverse minor, large, short- and long-term recurring effects during summer and spring spillway releases. Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. Construction effects of the using the spillway for summer surface spill (#721) would also be adverse and negligible in the short or medium term as measures to prevent erosion and sedimentation would be implemented during construction.

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large and long-term recurring effects on water quality. Refining the integrated temperature and habitat flow regime (#30b) would have beneficial minor, small, short- and long-term effects.

The Near-term Operations Measure would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

It should be noted that for each these measures, water treatment at the drinking water facility would mitigate some of the effects of low-quality water. Without treatment, water quality effects would be a higher magnitude, duration or extent.

###### *3.19.5.10.1 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) basin-wide; Operation, maintenance, repair, replacement and rehabilitation*

Maintenance and alteration of revetments (#9) and the maintenance of existing and new fish release sites (#726) would occur basin-wide. The effects would be adverse and negligible in magnitude as measures to prevent erosion and sedimentation would be implemented during construction. Effects would be small near the vicinity of the maintenance activities at the revetments and short term during construction. In the long term, the revetments would have no effects on drinking water and public health and safety. Operation, maintenance, repair, replacement and rehabilitation would have adverse, negligible, small, short- or medium-term and long-term recurring effects.

Construction effects of these measures would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.19.5.10.2 Foster Fish Ladder Temperature Improvement (#479); Construct WTC towers (#105) at Detroit Dam*

Foster fish ladder temperature improvement (#479) would have beneficial effects. Construction of a new Forebay Warm Water Supply pipe would allow warmer surface from the Foster forebay to be released downstream, resulting in blending with cooler surface water. The effects would be beneficial, minor, large affecting the entire reservoir and downstream receiving waters, and long term and recurring during reservoir releases.

The construction of WTC towers (#105) would have beneficial and adverse effects on water quality. The effects would be minor, large affecting the reservoir and downstream reaches, and long term and recurring when reservoir releases occur.

Construction effects of these measures would be adverse negligible, small in the medium term as measures to prevent erosion and sedimentation would be implemented during construction.

###### *3.19.5.10.3 Use spillway for surface spill in summer (#721) at Green Peter Dam*

Using the spillway for summer surface spill (#721) would have beneficial and adverse minor effects to drinking water and public health and safety. The effects would be large affecting the entire reservoir and downstream receiving waters, and long term and recurring during summer and spring spillway releases.

Construction effects of this measure would be adverse negligible, small in the short term as measures to prevent erosion and sedimentation would be implemented during construction.

*3.19.5.10.4 Augment instream flows by using the inactive pool (#718) at Blue River and Fern Creek dams; Augment instream flows by using the power pool (#304) at Detroit; Green Peter; Hills Creek; and Lookout Point dams; Fall Creek drawdown*

Augmenting instream flows by using the inactive pool (#718) and augmenting instream flows by using the power pool (#304) would have adverse negligible, small, short- and long-term recurring effects on water availability, and adverse minor, large, short- and long-term recurring effects on water quality.

The Fall Creek reservoir drawdown would have adverse effects on water quality downstream. The effects are minor, large, short and long term recurring.

*3.19.5.10.5 Refine integrated temperature and habitat flow regime (#30b) basin-wide*

Refining the integrated temperature and habitat flow regime (#30b) would have similar beneficial effects on drinking water and public health and safety as the integrated temperature and habitat flow regime (#30a). The effects would be minor and small affecting the downstream waters only, short and long term and recurring continually from February to November when base flow targets must be met, and from May to June for the temperature management flows.

*3.19.5.10.6 Construct AFF (#722) at Green Peter Dam; provide Pacific lamprey passage and infrastructure (#52) at Green Peter Dam; and construct structural downstream fish passage Detroit; Foster; Lookout Point, Big Cliff and Dexter dams; continued operation of existing adult fish facilities*

The construction effects of the construction of AFFs (#722), providing Pacific lamprey passage and infrastructure (#52), and constructing structural downstream fish passage infrastructure (#392) would be adverse, negligible, small, short or medium term in duration. In the long term, there would be no effects to public health and safety associated with fish collection and fish passage infrastructure.

The continued operation of existing adult fish facilities would be adverse, negligible, small, short and long term recurring during the regular flushing of facilities during maintenance.

*3.19.5.10.7 Near-term Operations Measures*

The Near-term Operations Measures are a suite of operations measures in which the impacts were analyzed by grouping measures which include drawdowns utilizing the ROs and/or releasing water via the spillway. These measures would result in adverse minor, large, short- and long-term recurring effects; and beneficial negligible to minor, large, short- and long-term recurring effects.

##### *3.19.5.10.8 Climate Change*

Alternative 5 is essentially the same as 2B. The measures in Alternative 5 would improve water quality by reducing TDG and normalizing temperatures. It would also provide fish passage. However, it would not improve reservoir storage like Alternative 1. Due to one more deep drawdown than Alternative 2A, climate change would exacerbate the effects of Alternative 5 more than Alternatives 1 or 2A. But overall, the effects would be the same as under Alternative 2A and 2B; climate change in combination with the measures under Alternative 5 would have direct, adverse, minor, large, long-term intermittent and/or permanent effects to drinking water.

#### ***3.19.5.11 Summary of Effects***

Alternative 1 would be the least severe because it would include only one recurring drawdown and would not include the suite of near-term operations. Alternative 1 is the only action alternative that would promote reservoir storage (i.e., from reducing minimum flows to congressionally authorized minimum flows) improving the availability of drinking water. Alternatives 2A and 2B effects are similar to one another with the exception of adverse major effects resulting from the spring drawdown. Alternative 3A and 3B have similar effects on water quality and water availability. Alternative 5 effects are less adverse than Alternative 4 because it does not include the use regulating outlets to discharge water during drawdowns and it includes structural improvements to reduce total dissolved gas which would have beneficial effects on water quality.

Overall, Alternatives 2B, 3A, and 3B would have the most adverse effects due to the spring drawdown as compared to Alternatives 1, 2A, 4, and 5. The spring drawdown would have a major effect on conservation pool storage because the spring drawdowns can affect the ability to refill system-wide storage.

## 3.20 ENVIRONMENTAL JUSTICE

The U.S. Environmental Protection Agency (EPA) defines environmental justice (EJ) as "the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies." The goal of "fair treatment" is not to shift risks among populations, but to identify potential disproportionately high and adverse impacts on minority and low-income communities and identify alternatives to mitigate any adverse impacts. The general principles for considering environmental justice under NEPA include (CEQ 1997a):

- Consideration of the affected area's composition to determine the presence of minority populations, low-income populations, or Indian Tribes that could be impacted by the proposed action and if so, whether there may be disproportionately high and adverse human health or environmental effects on these populations;
- Consideration of relevant data concerning the potential for multiple or cumulative exposure to human health or environmental hazards in the affected population and historical patterns of exposure to environmental hazards;
- Recognition of the interrelated cultural, social, occupational, historical, or economic factors that may enhance the natural and physical environmental effects of the proposed agency action;
- Development of effective public participation strategies by the agency;
- Ensuring meaningful community representation; and
- Ensuring adequate tribal representation during the process.

Executive Order 12898, Federal Actions to Address EJ in Minority Populations and Low-Income Populations, requires that federal agencies consider as a part of their action any disproportionately high and adverse human health or environmental effects to minority and low-income populations (collectively referred to as "communities with EJ concerns" or "populations with EJ concerns" throughout this section). Federal agencies are required to ensure that these potential effects are identified and addressed. For purposes of assessing EJ under NEPA, the Council on Environmental Quality (CEQ) defines a minority population as one in which the percentage of minorities exceeds 50 percent or is substantially higher than (or "meaningfully greater than") the percentage of minorities in the general population or other appropriate unit of geographic analysis (CEQ 1997a). Low-income populations are defined as households with incomes below the federal poverty level.

Potential impacts with the greatest intensity and longest duration would occur in counties comprising the Willamette Valley Basin (WVB), or where the Corps maintains and operates dams, reservoirs, fish passage facilities, fish hatcheries, or other structures that are part of the Willamette Valley System (WVS). Thus, the Region of Influence (ROI) for EJ includes the following counties:

- Benton County
- Clackamas County
- Columbia County
- Lane County
- Linn County
- Marion County
- Multnomah County
- Polk County
- Washington County
- Yamhill County

Other counties, such as Lincoln, Tillamook, and Douglas, contain only small portions of the WVB within their boundaries and do not contain structures (e.g., dams, reservoirs, fish passage facilities, hatcheries) that are operated and maintained by the Corps as part of the WVS, and are not impacted by the water resource management activities associated with the WVS. These counties are therefore not expected to be impacted by the Proposed Action and alternatives and are excluded from the ROI. For purposes of comparison, State of Oregon is defined as the region of comparison (ROC), or the "general population" as it corresponds to the CEQ definition. Note that because this Draft PEIS discusses general, qualitative effects from construction at the programmatic level, the above-listed counties and (as explained below) specific Tribes were chosen as the ROI and the State of Oregon or the respective county as the ROC. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects and conduct the EJ analysis on a smaller scale, and use census tracts or census blocks to further identify pockets of minority, low-income, and Native American communities that could be disproportionately affected by the proposed construction measures.

The CEQ EJ Guidance under NEPA recommends the identification of a geographic unit of analysis that accurately represents the occurrence and distribution of minority and low-income communities in the project area (CEQ 1997a). The Federal Interagency Working Group on EJ and NEPA Committee's Promising Practices for EJ Methodologies in NEPA Reviews notes that minority populations may reside in tightly clustered communities, or be evenly or unevenly distributed throughout the general population (FIWG on EJ & NEPA Committee 2016). Tribes that rely on the Willamette River for their subsistence needs were identified as communities with EJ concerns and were given the opportunity to be cooperating agencies for this project.

The CEQ EJ Guidance under NEPA also recommends identifying and describing human health, socioeconomic, and cultural vulnerabilities to define the affected environment (CEQ 1997a). This section considers these unique conditions of the Tribes and potential impacts from the alternatives as related to subsistence and ceremonial fishing. Section 3.12, Socioeconomic

Resources describes the socioeconomic impacts of the alternatives on the general population and Section 3.25, Cultural Resources describes impacts to cultural and historic properties and as such, this discussion will not be reiterated in this section.

U.S. Census Bureau (USCB) 2014-2019 American Community Survey (ACS) 5-year estimates are used to describe race and economic characteristics for the ROI and ROC. While 1-year ACS datasets were available for individual counties, this data was unavailable for the Tribes. To ensure that the most consistent and reliable income and demographic information is presented across populations with EJ concerns in the WVB, the ACS 5-year dataset was used.[58]

### 3.20.1 Minority Populations

The CEQ defines "minority" as including the following population groups: American Indian or Alaskan Native; Asian or Pacific Islander; Black, not of Hispanic Origin; or Hispanic (CEQ 1997a). The CEQ defines a minority population in the following ways:

- "…the minority population of the affected area exceeds 50 percent... (CEQ 1997a)." As this definition applies to the Proposed Action and alternatives, if more than 50 percent of the population in the ROI consists of minorities, this would qualify as constituting a population with EJ concerns.
- "…the minority population percentage of the affected area is meaningfully greater than the minority population percentage in the general population or other appropriate unit of geographic analysis (CEQ 1997a)." For purposes of this analysis, a discrepancy of 10 percent or more between minorities (the sum of all minority groups) in the ROI would be considered "meaningfully greater than" minorities in the State of Oregon, and would categorize the ROI as constituting a population with EJ concerns.

Table 3.20-1 shows the population broken down by race in the ROI and the ROC. The minority populations do not exceed 50 percent of the total population in any of the 10 counties included in the ROI. As such, none of the counties meet this regulatory definition of a minority population with EJ concerns.

In Benton, Clackamas, Columbia, Lane, Linn, Multnomah, Polk, and Yamhill counties, minorities represent 19.8, 18.1, 11.5, 18.2, 15.1, 30.3, 21.9, and 22.8 percent of the total population(s), respectively; in the State of Oregon, minorities represent 24.3 percent of the total population. A discrepancy of 10 percent or more between minorities (the sum of all minority groups) in these eight counties does not exist, therefore the representation of minorities in these counties is not considered "meaningfully greater than" the representation of minorities in the State of Oregon. As such, these eight counties do not meet this regulatory definition of a minority population with EJ concerns, either. However, as Table 3.20-1 indicates, Marion and Washington counties meet the regulatory definition of a minority population or minority group(s). Minorities in Marion County represent 34.5 percent of the total county population

[58] While ACS 5-year datasets are the least current, they are more reliable and use a larger sample size compared to 1-year estimates (USCB 2020a).

and minorities in Washington County represent 34.3 percent of the total county population, which is over 10 percent more than and considered “meaningfully greater than” the minority population in the state overall. By this CEQ definition of a minority population, Marion and Washington counties constitute populations with EJ concerns.

**Table 3.20-3.20-1. Summary of Minorities in the ROI and ROC in 2014 – 2019**

| Location | Total Population | Minority (%) | American Indian and Alaska Native (%) | Black or African American (%) | Asian (%) | Native Hawaiian and Other Pacific Islander (%) | Some Other Race (%) | Two or More Races (%) | Hispanic or Latino (%) |
|---|---|---|---|---|---|---|---|---|---|
| Benton County [a] | 91,107 | 19.8 | 0.5 | 1.0 | 7.1 | 0.2 | 0.2 | 3.4 | 7.4 |
| Clackamas County [a] | 410,463 | 18.1 | 0.6 | 0.9 | 4.2 | 0.2 | 0.1 | 3.3 | 8.7 |
| Columbia County [a] | 51,375 | 11.5 | 0.9 | 0.4 | 1.0 | 0.2 | 0.0 | 3.8 | 5.2 |
| Lane County[a] | 373,340 | 18.2 | 0.9 | 1.0 | 2.7 | 0.2 | 0.2 | 4.3 | 8.9 |
| Linn County [a] | 125,048 | 15.1 | 0.7 | 0.5 | 1.0 | 0.1 | 0.1 | 3.5 | 9.1 |
| Marion County [a] | 339,641 | 34.5 | 0.6 | 1.1 | 2.0 | 0.9 | 0.1 | 3.3 | 26.6 |
| Multnomah County [a] | 804,606 | 30.3 | 0.7 | 5.3 | 7.3 | 0.6 | 0.2 | 4.5 | 11.6 |
| Polk County [a] | 83,037 | 21.9 | 1.8 | 0.8 | 1.8 | 0.5 | 0.1 | 3.1 | 13.9 |
| Washington County [a] | 589,481 | 34.3 | 0.3 | 1.9 | 10.5 | 0.4 | 0.2 | 4.3 | 16.7 |
| Yamhill County [a] | 104,831 | 22.8 | 1.0 | 0.8 | 1.4 | 0.2 | 0.1 | 3.3 | 15.9 |
| State of Oregon [b] | 4,129,803 | 24.3 | 0.9 | 1.8 | 4.3 | 0.4 | 0.1 | 3.7 | 13.0 |

Note that the sum of vales for individual races and ethnicities may not add up to the total value shown in the “Minority (%)” column for some rows due to ± 0.1 percent margin of error in the dataset

### 3.20.2 Low-Income Populations

Low-income populations are defined as households with incomes below the federal poverty level. There are two slightly different versions of the federal poverty measure: poverty thresholds defined by the USCB and poverty guidelines defined by the Department of Health and Human Services (DHHS).

Poverty thresholds are defined by and updated each year by the USCB. The USCB uses a set of income thresholds that vary by family size and composition (number of children and elderly) to determine who is in poverty. If a family's total income is less than the family's threshold, then that family and every individual in it is considered in poverty. The same applies for a single individual. The official poverty thresholds do not vary geographically but are updated for inflation. The official poverty definition considers pre-tax income and does not include capital gains or non-cash benefits such as public housing, Medicaid, and food stamps (CEQ 1997a). Poverty thresholds are primarily used for statistical purposes, such as calculating poverty population figures or estimating the number of Americans in poverty each year. Poverty threshold figures are reported in the annual poverty report and provide a yardstick for progress or regress in antipoverty efforts. EJ Guidance Under NEPA recommends that USCB poverty thresholds be used to identify low-income populations (CEQ 1997a). As such, this section uses USCB poverty thresholds to identify low-income populations.

Because CEQ guidance does not specify a threshold for identifying low-income populations, the same approach used to identify EJ minority populations is applied to low-income populations. The ROI would be defined as a low-income population or population with EJ concerns if:

- More than 50 percent of the ROI consists of families or persons below the poverty threshold; or
- The percentage of low-income families or persons in the ROI is meaningfully greater than the percentage in the State of Oregon. A discrepancy of 10 percent or more between the ROI and the State of Oregon would be considered "meaningfully greater" and would categorize the ROI as constituting a low-income population with EJ concerns.

Table 3.20-2 provides income and poverty statistics for the ROI and the ROC. As Table 3.20-2 indicates, the percentage of all people and all families below the poverty threshold in the ROI is comparable to the State of Oregon's poverty levels. As such, the ROI does not have a substantially higher percentage of persons in poverty than the State of Oregon and does not qualify as a community with EJ concerns on this basis.

**Table 3.20-3.20-2. Summary of Income and Poverty Statistics in the ROI and ROC in 2014 – 2019**

| Location | People Below the Poverty Threshold (%) | Families Below the Poverty Threshold (%) |
|---|---|---|
| Benton County [a] | 19.1 | 8.3 |
| Clackamas County [a] | 8.0 | 5.2 |
| Columbia County [a] | 11.7 | 7.2 |
| Lane County [a] | 17.6 | 9.7 |
| Linn County [a] | 13.3 | 9.0 |
| Marion County [a] | 14.2 | 10.0 |
| Multnomah County [a] | 13.8 | 8.4 |
| Polk County [a] | 12.6 | 7.8 |
| Washington County [a] | 8.9 | 5.7 |
| Yamhill County [a] | 12.1 | 9.1 |
| State of Oregon [b] | 13.2 | 8.4 |

### 3.20.3 Native American Tribes

As described above, the CEQ EJ Guidance under NEPA recommends that when selecting a geographic unit of analysis for EJ, consideration should be given to the spatial distribution of minority and low-income populations, which may reside in tightly clustered communities or may be evenly or unevenly distributed throughout the general population. Per this guidance, the Corps has identified multiple federally-recognized Tribes that reside in concentrated “pockets” or reservations in and outside the WVB and that engage in unique cultural and traditional practices (subsistence and ceremonial fishing) that are directly dependent on the Willamette River, as shown in Figure 3.20-1 below. Note that while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As noted above, these tribes were given the opportunity to be cooperating agencies for this project. The demographic and income information for these tribes is provided below and is compared to the corresponding county. Note here that each tribal reservation is considered the ROI, and each corresponding county is considered the ROC. Since these Tribes exist in tightly clustered communities, a county was considered to be an appropriate unit of comparison to accurately assess the demographic and income data for the Tribes impacted by the action alternatives.

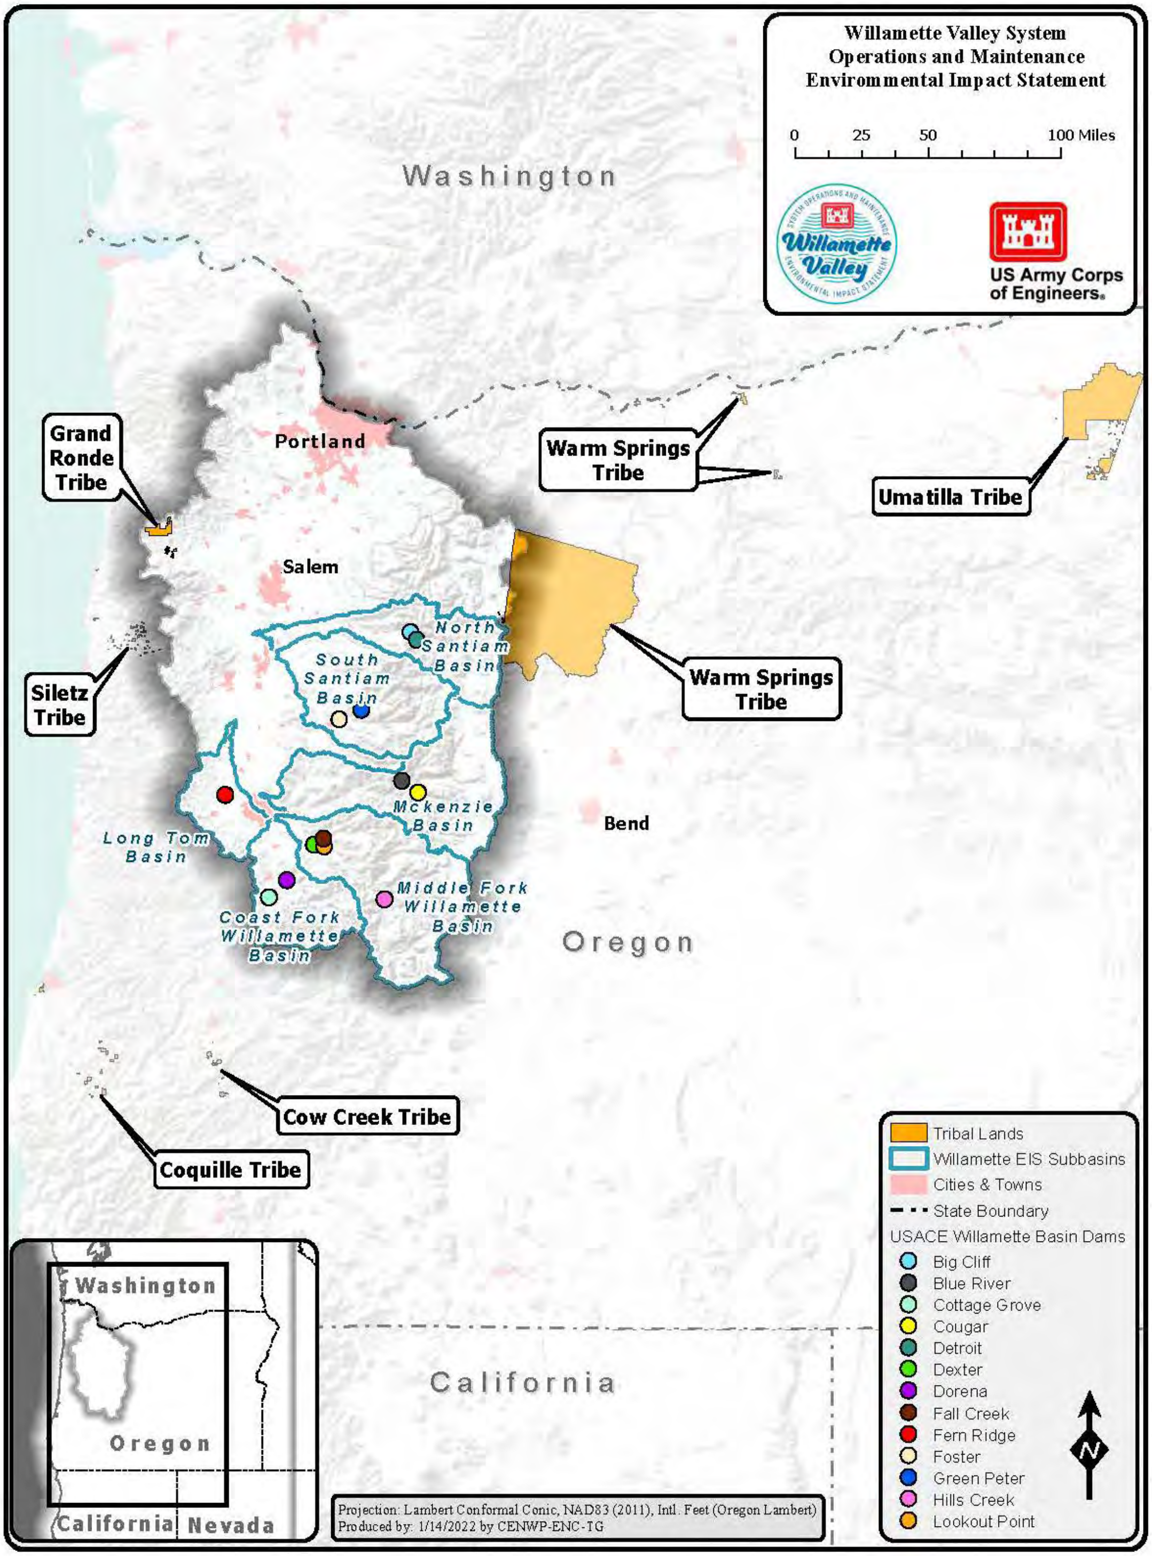

**Figure 3.20-1. Geographic Distribution of Tribal Land in and around the Willamette River Basin**

#### *3.20.3.1 Confederated Tribes of Grand Ronde Community of Oregon*

The Confederated Tribes of Grand Ronde is a community formed of more than 30 Tribes and bands from the Kalapuya, Mollala, Chasta, Umpqua, Rogue River, Chinook, and Tillamook, originating throughout western Oregon, northern California, and southwestern Washington. The entire WVS lies within the ceded lands of the 1855 treaties with the tribes and bands who were moved to the Grand Ronde reservation. Through the seven treaties listed in Chapter 7 Grand Ronde ancestors ceded all of the Willamette Valley and beyond for a significantly reduced reserve of tribal lands. The Tribal reservation extends over an area of 11,500 acres in Yamhill County, Oregon (CTGR No Date; CTGR 2014). The Tribe also owns off-reservation lands in Polk County. Members of the Confederated Tribes of Grand Ronde members live on the reservation and in off-reservation lands across the communities in and around the WVS (Grand Ronde, 2022).

Table 3.20-3 shows the population broken down by race on the Grand Ronde Community and Off-Reservation Trust Land (the ROI) and in the county where the Reservation is located (the ROC). As the table indicates, the Reservation meets the regulatory definition of a minority population because minorities represent more than 50 percent of its total population. By this CEQ definition of a minority population, the ROI constitutes a population with EJ concerns.

**Table 3.20-3.20-3. Summary of Minorities on the Grand Ronde Reservation and Trust Lands and Yamhill County in 2014 – 2019**

| Location | Total Population | Minority (%) | American Indian and Alaska Native (%) | Black or African American (%) | Asian (%) | Native Hawaiian and Other Pacific Islander (%) | Some Other Race (%) | Two or More Races (%) | Hispanic or Latino (%) |
|---|---|---|---|---|---|---|---|---|---|
| Grand Ronde Community and Off-Reservation Trust Land[a] | 586 | 88.4 | 67.1 | 0.7 | 0.5 | 0.3 | 0.1 | 10.2 | 9.6 |
| Yamhill County[b] | 104,831 | 22.8 | 1.0 | 0.8 | 1.4 | 0.2 | 0.1 | 3.3 | 15.9 |

Note that the sum of vales for individual races and ethnicities may not add up to the total value shown in the “Minority (%)” column for some rows due to ± 0.1 percent margin of error in the dataset

Table 3.20-4 shows income and poverty statistics for the Grand Ronde Community and Off-Reservation Trust Land (the ROI) and for the county where the Reservation is located (the ROC). As the table indicates, the percentage of all people and all families below the poverty threshold in the Reservation is 21.3 and 14.7 percent higher than in Yamhill County, respectively. As such, the ROI has a substantially higher percentage of all persons and all families in poverty than Yamhill County and qualifies as a community with EJ concerns on this basis.

### 3.20.3.2 *Confederated Tribes of Warm Springs*

The Warm Springs Reservation, a 640,000-acre property in north central Oregon, is home to a confederation of three Tribes: Warm Springs, Wasco, and Paiute. The Warm Springs Tribe is made up of the Upper Deschutes (Tygh), Lower Deschutes (Wyam), Tenino, and John Day (Dock-spus) bands. The Wasco Tribe comprises the Dallas (Ki-gal-twal-la) and Dog River bands (CRITFC No Date). Historically, the Paiute territories included a large area from southeastern Oregon into Nevada, Idaho, and western Utah, though they eventually settled in Warm Springs and lived in Lake, Harney, and Malheur counties in Oregon (CTWS No Date).

Table 3.20-5 shows the population broken down by race on the Warm Springs Reservation and Trust Land (the ROI) and in the counties where the Reservation is located (the ROC). As the table indicates, the Reservation meets the regulatory definition of a minority population with EJ concerns because minorities represent more than 50 percent of its total population. By this CEQ definition of a minority population, the ROI constitutes a population with EJ concerns.

**Table 3.20-3.20-5. Summary of Minorities on the Warm Springs Reservation and Trust Lands and Jefferson and Wasco Counties in 2014 – 2019**

| Location | Total Population | Minority (%) | American Indian and Alaska Native (%) | Black or African American (%) | Asian (%) | Native Hawaiian and Other Pacific Islander (%) | Some Other Race (%) | Two or More Races (%) | Hispanic or Latino (%) |
|---|---|---|---|---|---|---|---|---|---|
| Warm Springs Reservation and Off-Reservation Trust Land[a] | 4,188 | 96 | 84.1 | 0.4 | 0.1 | 0.3 | 0.1 | 2.5 | 8.5 |
| Jefferson County[b] | 23,607 | 39.6 | 15.8 | 0.8 | 0.6 | 0.1 | 0.0 | 2.4 | 20 |

Table 3.20-6 shows income and poverty statistics for the Warm Springs Reservation and Off-Reservation Trust Land (the ROI) and for the counties where the Reservation is located (ROC). As the table indicates, the percentage of all people and all families below the poverty threshold in the Reservation is 14.4 and 15.5 percent higher than in Jefferson County, respectively. Also, the percentage of all people and all families below the poverty threshold in the Reservation is 20.7 and 19.6 percent higher than in Wasco County, respectively. As such, the ROI has a substantially higher percentage of all persons and families in poverty than Jefferson and Wasco Counties and also qualifies as a community with EJ concerns on this basis.

### 3.20.3.3 *Confederated Tribes of Siletz Indians*

The Confederated Tribes of Siletz Indians is a confederation of 27 bands from western Oregon, Northern California, and Southern Washington. The Tribe owns and manages a 3,666-acre reservation along the Siletz River in Lincoln County, Oregon (NPAIHB No Date).

Table 3.20-7 shows the population broken down by race on the Siletz Reservation and off-Reservation Trust Land (the ROI) and in the county where the Reservation is located (the ROC). As the table indicates, the Reservation meets the regulatory definition of a minority population because minorities represent more than 50 percent of its total population. By this CEQ definition of a minority population, the ROI constitutes a population with EJ concerns.

**Table 3.20-3.20-7. Summary of Minorities on the Siletz Reservation and Trust Lands and Lincoln County in 2014 – 2019**

### 3.20.3.4 *Cow Creek Band of Umpqua Tribe of Indians*

The Cow Creek Band of Umpqua Tribe of Indians and its Reservation are located in Canyonville, Douglas County. Prior to 2018, the Tribe had approximately 4,471 acres of land held in trust. The Tribe uses this land to operate the Tribal government and Tribal-owned businesses (House Report 115-204 2017). In 2018, approximately 17,519 acres of timber land was reclassified from public domain lands to tribal lands and returned to the Cow Creek Tribe (Polcyn 2019; PL 115-103 HR 1306 2018). These lands are held in trust by the United States and are part of the Tribe's Reservation.

Table 3.20-9 shows the population broken down by race on the Cow Creek Reservation and Off-Reservation Trust Land (the ROI) and in Douglas County (the ROC). As the table indicates, minorities in the reservation represent 44.8 percent of its total population, which is 32.6 percent more than the minority population in Douglas County. By this CEQ definition of a minority population, the ROI constitutes a population with EJ concerns.

**Table 3.20-3.20-9. Summary of Minorities on the Cow Creek Reservation and Trust Lands and Douglas County in 2014 – 2019**

### 3.20.3.5 *Confederated Tribes of the Umatilla Indian Reservation*

The Confederated Tribes of the Umatilla Indian Reservation (CTUIR) is a union of three tribes: Cayuse, Umatilla, and Walla Walla. The Umatilla Indian Reservation is spread across approximately 172,000 acres in Umatilla County, Oregon (CTUIR No Date).

Table 3.20-11 shows the population broken down by race on the Umatilla Reservation and Off-Reservation Trust Land (the ROI) and in Umatilla County (the ROC). As the table indicates, minorities in the reservation represent 49.2 percent of its total population, which is 35 percent more than the minority population in Umatilla County. By this CEQ definition of a minority population, the ROI constitutes a population with EJ concerns.

**Table 3.20-11. Summary of Minorities on the Umatilla Reservation and Off-Reservation Trust Land and Umatilla County in 2014 – 2019**

### 3.20.4 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on communities with EJ concerns, including Native American Tribes in the WVB. The discussion includes the methodology, the measures within the alternatives that were analyzed, a detailed analysis for each alternative, and a summary of the effects.

#### *3.20.4.1 Methodology*

Consideration of the potential consequences for environmental justice requires three main components, the first of which was done in the Affected Environment.

1. A demographic assessment of the affected community to identify the presence of minority populations, low-income populations, and Native American Tribes that may be affected.
2. An assessment of all potential impacts identified to determine if any could result in adverse impacts to the affected environment.
3. An integrated assessment to determine whether any disproportionately high and adverse impacts exist for minority populations, low-income populations, and Native American Tribes present in the ROI.

As discussed in Section 3.20.1, two counties in the ROI – Marion and Washington counties – constitute populations with EJ concerns because the percentage of minorities in these counties is meaningfully greater than the percentage of minorities in the corresponding ROC. The ROI does not qualify as a community with EJ concerns on the basis of low-income populations;

therefore, low-income communities are not discussed further in this section. The potential effect on the employment or general physical health and well-being of minority populations with EJ concerns in Marion and Washington counties is assessed. In general, the types of potential impacts on communities with EJ concerns could include:

- Social and economic benefits of direct, indirect and induced jobs created;
- Health risks (especially to workers) from the proposed construction and structural improvement activities;
- Noise disturbances;
- Restricted or delayed access to schools, residential areas, public transportation, or hospital and health care facilities due to traffic and time delays;
- Results of the RECONS (Regional ECONomic System) model with the number of jobs, labor income, gross regional product, and economic output supported by capital expenditures under each alternative are presented in Section 3.11.

Additionally, impacts on the harvest of fish species by Native American Tribes for subsistence, ceremonial, and traditional uses are also assessed separately based on harvest quantities, quality of the catch, ease of fishing, and the retention/loss of cultural and traditional values. Potential impacts to these Tribes are considered disproportionate not only because subsistence fishing is important for their survival, but also because these activities help to maintain and preserve their culture and tradition, play a key role in their local economies, and foster their overall physical and mental well-being.

Table 3.20-13 describes the evaluation criteria for the effect factors (magnitude, duration, and extent), and provides a definition for the scale of each effect factor.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.20-13. Evaluation Criteria for Potential Effects to Environmental Justice**

| Effect Factor and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | No observable change to the physical or environmental health, general well-being, or socioeconomic status of minority populations in Marion and Washington counties with EJ concerns.<br>No observable change in the total annual subsistence and ceremonial catch numbers of fish species harvested by Tribes in the WVB or in the time required and the distance traveled to catch or harvest the same amount compared to current conditions. |

| Effect Factor and Scale | Definition |
|---|---|
| | Effects to both minority populations with EJ concerns in Marion and Washington counties and to Tribes would be considered disproportionately high, but would not be considered a significant. |
| Minor | Detectable change to the physical or environmental health, general well-being, or socioeconomic status of minority populations in Marion and Washington counties with EJ concerns.<br>Detectable change in the total annual subsistence and ceremonial catch numbers of fish species harvested by Tribes in the WVB or in the time required and the distance traveled to catch or harvest the same amount compared to current conditions.<br>Effects to both minority populations with EJ concerns in Marion and Washington counties and to Tribes would be considered disproportionately high, but would not be considered significant. |
| Moderate | Notable change to the physical or environmental health, general well-being, or socioeconomic status of minority populations in Marion and Washington counties with EJ concerns.<br>Notable change in the total annual subsistence and ceremonial catch numbers of fish species harvested by Tribes in the WVB or in the time required and the distance traveled to catch or harvest the same amount compared to current conditions.<br>Effects to both minority populations with EJ concerns in Marion and Washington counties and to Tribes would be considered disproportionately high, but would not be considered significant. |
| Major | Substantial change to the physical or environmental health, general well-being, or socioeconomic status of minority populations in Marion and Washington counties with EJ concerns, resulting in disproportionately high impacts to these populations. This would be considered a significant effect.<br>Substantial change in the total annual subsistence and ceremonial catch numbers of fish species harvested by Tribes in the WVB or in the time required and the distance traveled to catch or harvest the same amount compared to current conditions. Effects to Tribes would be disproportionally high and adverse. This would be considered a significant effect. |
| **Duration** | |
| Short term | Alteration lasts for the duration of small construction project, and is continuous for less than 2 years. |
| Medium term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |

| Effect Factor and Scale | Definition |
|---|---|
| Long term | Alteration is permanent or lasts continuously beyond operational changes or the completion of all construction projects; the alteration recurs at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Effects would be confined to the county where the dam/reservoir is located or to the Indian reservations and usual and accustomed places closest to the dam/reservoir. |
| Medium | Effects would occur in some counties or Indian reservations and usual and accustomed places. |
| Large | Effects would occur in all counties or Indian reservations and usual and accustomed places in the entire WRB. |

#### *3.20.4.2 Measures Analyzed for Environmental Justice*

Measures which could potentially directly or indirectly affect communities with EJ concerns if implemented under the considered alternatives include:

- Gravel augmentation below dams (#384)
- Adapt hatchery program (#719)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Maintenance of existing and new fish release sites above dams (#726)
- Foster Fish Ladder Temperature Improvement (#479)
- Construct water temperature control tower (#105)
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Structural improvements to reduce TDG (#174)
- Augment instream flows by using the inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Integrated temperature and habitat flow regime (#30a)
- Refined integrated temperature and habitat flow regime (#30b)
- Restore upstream and downstream passage at drop structures (#639)
- Construct AFF (#722)
- Provide Pacific lamprey passage and infrastructure (#52)

- Construct structural downstream fish passage (#392)
- Deeper fall reservoir drawdowns for fish passage (#40)
- Spring reservoir drawdown for downstream fish passage (#720)
- Pass water over spillway in spring for fish passage (#714)
- Fall Creek Drawdown
- Continued operation of existing AFFs
- Operation, Maintenance, Repair, Replacement and Rehabilitation

Measures that would have no effect on communities with EJ concerns (and are therefore not discussed further) include:

- Use spillway for surface spill in summer (#721)
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723)

A summary of the environmental justice effects discussed in the sections below is provided in Table 3.20-14. Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the lesser magnitude of beneficial effects for each alternative was listed in this table. For example, if there is a range of minor to moderate adverse effects, moderate adverse effects are included in the table. If beneficial effects would range from minor to moderate, the table includes minor beneficial effects. Said otherwise, the most conservative conclusions of potential effects are presented in the table below in order to avoid overstating potential beneficial effects and understating adverse effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the lesser beneficial effect does not occur at that reservoir. This follows the approach to present the most conservative conclusions in this table; instead of simply omitting reservoirs where less severe or more beneficial effects would occur. Discussion of all adverse and beneficial effects are included below.

**Table 3.20-14. Summary of Effects to Environmental Justice Under Each Alternative**

| Effect Factor | | Alternative | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| **Short-Term** | | | | | | | | |
| Magnitude | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse |
| Extent | Medium | Medium | Medium | Medium | Medium | Medium | Medium | Medium |
| **Medium-Term** | | | | | | | | |
| Magnitude | Minor adverse | Minor adverse | Minor adverse | Minor adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse |
| Extent | Large | Medium | Medium | Medium | Medium | Medium | Medium | Medium |
| **Long-Term (Permanent, Intermittent, or Recurring)** | | | | | | | | |
| Magnitude | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse | Major adverse |
| Extent | Medium | Medium | Medium | Medium | Medium | Medium | Medium | Medium |
| Duration Type | Recurring | Recurring | Recurring | Recurring | Recurring | Recurring | Recurring | Recurring |

In the following subsections, the effects are discussed for the measures analyzed in the alternatives, for the No Action Alternative, and for each of the action alternatives.

#### *3.20.4.3 Discussion of Effects by Measure(s)*

This section applies the methodology described above to each measure analyzed for environmental justice to determine the potential effect. Where possible, discussion of similar measures that would have similar effects in terms of magnitude and durations are grouped together. The effects by measure or measures are then referenced in the effects analysis by alternative that follows. This Draft PEIS discusses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Subsequent tiered NEPA documents would discuss detailed site-specific effects. And as explained above in the Affected Environment, subsequent tiered NEPA documents would use census tracts or census blocks to further identify pockets of minority, low-income, and Native American communities that could be affected by the proposed construction measures. The analysis in these tiered NEPA documents would include the effects analysis in this PEIS by reference as well as any additional, potential effects to newly identified communities with EJ concerns.

##### *3.20.4.3.1 Construction and/or Modification of Structural Measures*

This section discusses the potential impacts to communities with EJ concerns from the construction and/or modification of the structural measures shown below.

- Gravel augmentation below dams (#384)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)
- Construct water temperature control tower (#105)
- Structural improvements to reduce TDG (#174)
- Restore upstream and downstream passage at drop structures (#639)
- Construct AFF (#722)
- Provide Pacific lamprey passage and infrastructure (#52)
- Construct structural downstream fish passage (#392)
- Operation, Maintenance, Repair, Replacement and Rehabilitation

**Socioeconomic Effects**

The above listed construction and/or modification of structural measures would likely result in the creation of short- and medium-term jobs, which could be filled by minority populations. Although the majority of the construction labor would be sourced from specialized contractors located outside the ROI, these revenues would likely result in the creation of a relatively small number of construction jobs sourced from within the ROI. There would also be potential for the creation of a few full-time long-term operation and maintenance jobs to ensure the proper operation of these structures over the life of the project.

If minority populations in Marion and Washington counties are hired to work on these projects, they could experience negligible to minor health benefits through economic pathways in the short and medium term. Potential health impacts associated with increased employment overall could disproportionately benefit minority individuals hired to work on construction projects. Jobs and income are strongly associated with beneficial health outcomes such as an increase in life expectancy, improved child health status, improved mental health, and reduced rates of chronic and acute disease morbidity and mortality (HDA 2004; Cox et al. 2004).

Indirect economic impacts would also result from directly impacted industries (i.e., contractors) purchasing construction supplies and materials from other industries. Local vendors from whom construction companies would make purchases and local retail stores and establishments where the construction workers would shop would also benefit, potentially creating additional jobs. Induced impacts could also occur when employees of the directly and indirectly affected industries spend the wages they receive. The indirect and induced jobs that would be created would likely be relatively low-wage and low-skill jobs, such as restaurant workers or convenience store clerks.

The magnitude of the beneficial effects is contingent upon the level of expenditure associated with a given measure; larger expenditures will generate substantially larger direct, indirect, and induced economic impacts. Capital expenditures range from approximately $331 million to over $2 billion under the various alternatives. Therefore, the direct and indirect beneficial socioeconomic impact on communities with EJ concerns would range from negligible to minor in magnitude, and occur in the short term and medium term. However, these benefits would only persist for the duration of the construction and infrastructure improvement phases with only a small number of permanent maintenance jobs created; therefore, long-term beneficial effects would be negligible. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant.

**Noise Disturbances, Air Emissions, and Traffic**

Construction and/or structural modification projects would increase air emissions, noise levels, traffic, or visual disturbances at and near the project site in the short and medium term – less than two years or two to five years depending on the project (respectively). Thus, there may be negligible to minor adverse effects to the physical health and well-being of minority communities with EJ concerns that are hired to work at the sites for the duration of these projects. These effects would be disproportionately high and adverse, but would not be significant.

Residential development on most of the shores of most of the WVS reservoirs is minimal, including at Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point reservoirs. None of these reservoirs have towns on their shorelines.

Detroit, Dexter, Fern Ridge, and Foster reservoirs have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 192 to 10,000. The town of Detroit is in Marion County (which was identified above in Section 3.20.1 as having minority populations with EJ concerns), but the town of Detroit does not qualify as a population with EJ concerns. Following with the CEQ definition as explained in Section 3.20.1 and 3.20.2 Detroit does not qualify as having minority or low-income populations with EJ concerns by either definition. Minorities represent 2.4 percent of Detroit's population compared to 34.5 percent in Marion County; and 8.4 percent of Detroit's population lives at or below the poverty level compared to 14.2 percent in Marion County (USCB 2019e; USCB 2019f; USCB 2019w; USCB 2019x). Neither minorities nor low-income populations represent more than 50 percent of the total population in Detroit (USCB 2019w; USCB 2019x). Lowell and Veneta are in Lane County and Sweet Home is in Linn County, so discussion of disproportionately high impacts from noise disturbances, air emissions, or traffic to these towns from construction measures will be included in a tiered EA or EIS if after using census tracts or census blocks, they are identified as having populations with EJ concerns. As such, minority populations with EJ concerns in nearby residential communities are not discussed further in this PEIS.

**Subsistence Fishing and Tribal Effects**

The Corps has requested comments from the Grand Ronde, Coquille, Cow Creek, Klamath, Nez Perce, Umatilla, Warm Springs, Yakama, Confederated Tribes of the Coos, Lower Umpqua and Siuslaw (CTCLUSI), and Siletz Tribes. The CTCLUSI and Coquille Indian Tribe have deferred comments to the appropriate Tribe(s) because this Draft PEIS covers an area that is outside of their ancestral territory; none of their usual and accustomed places occur within the ROI for this Draft PEIS. The Corps is not currently aware of any subsistence fishing happening at or in the vicinity of the dams. However, in an effort to include as large a range as possible of potential effects in this Draft PEIS, a conservative approach was taken and it is assumed that Tribal subsistence fishing could occur at or in the vicinity of dams. The Final PEIS will be updated as appropriate based on information that is communicated by the Tribes.

If access to parts of the reservoir is restricted due to construction and/or modification projects where subsistence fishing occurs, there could be short and medium-term, adverse effects to Tribes. There would also be adverse impacts to Tribes that use the reservoirs for recreational purposes. If access to reservoirs is allowed when construction/structural improvement activities are taking place at those sites, Tribal communities with EJ concerns may experience short- or medium-term negligible to minor adverse impacts to their physical health and well-being from construction-related emissions, noise levels, and traffic. The magnitude would depend on the individual's proximity to the construction site. Disturbances during construction (including gravel augmentation and revetment alteration) may reduce the quantity and quality of some fish species available for harvesting due to increased turbidity from suspended sediment. Pacific lamprey is particularly sensitive to increases in turbidity and could experience respiratory distress, which may adversely impact their populations in the short or medium term and reduce their catch numbers (Lampman et al. 2021). Construction activities may also impact water quality downstream of the sites if fuel and chemical spills occur, which may contaminate the harvest and decrease its quality and quantity. As such, adverse effects to Tribal subsistence fishing and recreation could be minor in magnitude, and short-term and medium-term in duration. These effects would be disproportionately high and adverse, but would not be significant.

The implementation of measures discussed above would augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. These measures are not expected to lead to an increase in the availability of salmon, steelhead, lamprey, and other fish species for Tribal subsistence and ceremonial purposes, but would reduce the likelihood that the species would be in jeopardy of extinction. Fishing activities would not be restored at traditional sites currently abandoned by the Tribes due to dwindling fish populations. Members of the Tribes would still need to spend as much time and money as they presently do in order to travel to distant fishing sites to secure sufficient quantities of harvest. This would not help ease conflict between competing Tribes that are forced to share specific fishing sites; however, the continued existence of these fish species in the WRB would support the preservation of their cultural practices and pass on their knowledge of traditional fishing methods and customs to their youth. The implementation of these measures would not provide adequate food reserves for meetings, celebrations, and subsistence needs; Tribes would continue to rely on hatchery fish from ODFW facilities. While the implementation of the above measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, the effects would be less adverse than those currently experienced by Tribes due to dwindling fish populations in the WRB. Adverse effects would range from minor to moderate under the NAA and action alternatives in the long-term. These effects would be disproportionately high and adverse, but would not be significant.

###### *3.20.4.3.2 Implementation of Water Management Measures*

This section discusses the potential impacts to communities with EJ concerns from the implementation of the following water management measures:

- Adapt hatchery program (#719)
- Maintenance of existing and new fish release sites above dams (#726)
- Foster Fish Ladder Temperature Improvement (#479)
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Augment instream flows by using the inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Integrated temperature and habitat flow regime (#30a)
- Refined integrated temperature and habitat flow regime (#30b)
- Deeper fall reservoir drawdowns for fish passage (#40)

- Spring reservoir drawdown for downstream fish passage (#720)
- Pass water over spillway in spring for fish passage (#714)
- Fall Creek Drawdown
- Continued operation of existing AFFs

**Socioeconomic Effects**

Adverse economic effects associated with drawdowns are discussed at length throughout the socioeconomics section, beginning in Section 3.11.2.4.2 (Alteration of outflows and reservoir levels/Recreational Value), and is summarized briefly here as it applies to populations with EJ concerns. Drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. These short- and long-term recurring adverse effects would range from minor to major. The magnitude of effects under each alternative would depend on the number of drawdowns per year and the number of reservoirs at which they would occur. These effects would be adverse and disproportionate to populations with EJ concerns that are located in the county where drawdowns would occur or that are economically dependent on the reservoir where the drawdowns would occur. Disproportionately high and adverse effects that are major in magnitude would be considered a significant effect.

As described in 3.20.3, the Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are located in Yamhill, Jefferson and Wasco, Wasco, Lincoln, and Lincoln counties (respectively). Drawdowns are not proposed at any of the reservoirs located in the aforementioned counties. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns under all alternatives could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the reservoirs where drawdowns are proposed.

**Subsistence Fishing and Tribal Effects**

Reservoir drawdowns would result in high rates of sediment transport from the reservoir and high turbidity levels in areas downstream; and cause minor adverse effects to Tribal subsistence fishing activities. As described above, Pacific lamprey is particularly sensitive to increases in turbidity and could experience respiratory distress, which may adversely affect their populations in the short term and reduce their catch numbers (Lampman et al. 2021). These minor adverse effects would also be long-term and recurring because while the drawdown would only be held for three weeks, it would occur annually. These effects to Tribal subsistence fishing would be disproportionately high and adverse, but would not be significant.

As discussed at length in Section 3.14 (Recreation), it is assumed that the majority of recreationists would forgo visiting the reservoir during drawdowns; which would have a major and adverse effect on all recreationists, including Tribal recreationists. For those that continue to visit reservoirs during drawdowns, adverse effects would also be major because visually drawdowns would be very noticeable, and would substantially impact the recreational experience – including that of Tribal members. These effects would occur in the short term during the three-week drawdown and recur in the long term. These disproportionately high and major, adverse effects would be considered significant.

Similar to the construction and/or modification of structural measures, implementation of water management measures listed above – but in particular the use of water from inactive pool or power pool to increase river flows and reservoir drawdowns in spring and fall seasons – would boost fish populations downstream of the reservoirs by increasing the survival and passage rate of fish species during their downstream passage. This would have beneficial effects to Tribes engaging in subsistence fishing activities downstream of the affected reservoirs in the long term. Fishing activities would not be restored at traditional sites currently abandoned by the Tribes due to dwindling fish populations. Members of the Tribes would still need to spend as much time and money as they presently do in order to travel to distant fishing sites to secure sufficient quantities of harvest. This would not help ease conflict between competing Tribes that are forced to share specific fishing sites. However, the continued existence of these species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of their cultural practices and pass on their knowledge of traditional fishing methods and customs to their youth. The implementation of these measures would not provide adequate food reserves for meetings, celebrations, and subsistence needs; Tribes would continue to rely on hatchery fish from ODFW facilities. While the implementation of the above measures would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and long-term in duration. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.3.3 Suite of Near-term Operations*

Near-term operations that could affect environmental justice include deep drawdowns and extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Similar to the effects discussed in Section 3.20.4.3.2, extended deep drawdowns and delayed reservoir refills would also cause adverse effects to Tribal fishing activities downstream of reservoirs; and would be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Adverse effects to Tribal recreation would be major and adverse due to the reservoir drawdowns. These disproportionately high and major, adverse effects would be considered significant. These effects would still be small in extent, and short-term and long-term recurring.

The suite of near-term operations would further augment fish spawning and rearing habitat, improve instream water quality by ensuring instream temperature and TDG control, ensure adequate streamflow for biologically justified flows, and improve fish passage. While the implementation of the suite of near-term operations would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, Tribes, in general, would experience less adverse impacts than the adverse effects they presently experience due to dwindling fish populations in the WRB. These effects would be negligible in magnitude and long-term in duration. And while effects would be disproportionately high and adverse, they would not be considered significant.

### *3.20.4.4 No Action Alternative (NAA)*

Under the NAA, current actions within the WVS and the conditions that would result from continued O&M and Fall Creek drawdown would persist.

#### *3.20.4.4.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

Additional construction jobs would be created during routine and non-routine maintenance or major maintenance and rehabilitation projects, resulting in negligible beneficial effects in the short and medium term. If minority populations with EJ concerns in Marion and Washington counties are hired to work on these projects, they could experience negligible health benefits through economic pathways in the short and medium term. Potential health effects associated with increased employment overall could disproportionately benefit minority individuals hired to work on non-routine maintenance projects. As described above in Section 3.20.4.3.1, jobs and income are strongly associated with a number of beneficial health outcomes such as an increase in life expectancy, improved child health status, improved mental health, and reduced rates of chronic and acute disease morbidity and mortality (HDA 2004; Cox et al. 2004). Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. Major maintenance and rehabilitation projects would increase air emissions, noise levels, traffic, or visual disturbances at and near the project site and cause negligible to minor, medium-term adverse effects to the physical health and well-being of communities with EJ concerns hired to work at the project. The extent of effects would be small and would only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and extent of the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.4.2 Subsistence Fishing and Tribal Effects*

During major maintenance and rehabilitation projects, there would be minor adverse impacts to Tribes as subsistence fishing activities and recreation may be restricted in the medium term. If access to impacted reservoirs is allowed, Tribal communities with EJ concerns may experience medium-term negligible to minor adverse impacts to their physical health and well-being from construction-related emissions, noise levels, and traffic, depending on the individual's proximity to the construction site and the size of the project (i.e., routine maintenance versus major rehabilitation project). Disturbances during maintenance/rehabilitation projects, gravel augmentation, revetment alteration, and the Fall Creek Drawdown may reduce the quantity and quality of fish available for harvesting for some species due to increased turbidity from suspended sediment, as discussed above in Section 3.20.4.3.1. Pacific lamprey is particularly sensitive to increases in turbidity and could experience respiratory distress, which may adversely impact their populations in the short or medium term and reduce their catch numbers (Lampman et al. 2021). Construction activities may also impact water quality downstream of the sites if fuel and chemical spills occur, which may contaminate the harvest and decrease its quality and quantity at the usual and accustomed fishing areas in the vicinity of the impacted reservoirs. As such, adverse effects to Tribal subsistence fishing could be negligible to minor in magnitude, short-term and medium-term in duration, and large in extent. Effects from major maintenance and rehabilitation projects are expected to occur intermittently over the period of analysis of this Draft PEIS. These effects would be disproportionately high and adverse, but would not be significant.

The Fall Creek drawdown would also have adverse and major effects to Tribal recreationists at Fall Creek. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Fall Creek. These disproportionately high and major, adverse effects would be considered significant.

Historically, WVB supported abundant salmon returns and provided the Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Confederated Tribes and Bands of the Yakama Nation, Nez Perce Tribe, Cow Creek Band of Umpqua Tribe, and the Umatilla Tribe with a reliable, year-round source of protein. Today, fishing in the Willamette River and its tributaries continues to be an important practice providing sustenance to many Native communities and forming the foundation for many cultural and religious practices among these Tribes. However, the construction and operation of the WVS dams has led to declines in fish populations over the past few decades and has driven some species of salmon and steelhead to eminent risk of extinction, prompting federal and state agencies to set limits on the quantities of fish that can be harvested for commercial, recreational, and other purposes. For example, the Grand Ronde community can harvest up to 15 salmonids annually for ceremonial purposes at Willamette Falls (OAR 635-041-0610 No Date). Many streams in WRB no longer have harvestable populations of salmon, steelhead, and lamprey. Since traditional fishing areas are quickly disappearing, many Tribes are forced to travel greater distances and rely on fishing sites already heavily in use by several other Tribes, such as Willamette Falls, leading to competition between Tribes. The intense supplementation of hatchery fish has deteriorated the genetic integrity and viability of native fish populations. These factors have impacted the quality and quantity of fish populations available to the Tribes for subsistence and ceremonial harvesting purposes (Emery No Date; CTGR 2014).

With the decline in fish populations in WRB, the Tribes are losing a critical resource that sustains their traditions and way of life. With fewer quantities of fish available for harvest, many young Tribal members do not know how to harvest or prepare historically important subsistence foods (CTGR 2014). Earlier, celebrations surrounding First Salmon Ceremonies, events honoring the return of salmon to their freshwater habitat, would be timed with the spring arrival of salmon to the Tribal groups along the Willamette River. Now, many Tribes plan these ceremonies months in advance given uncertainties about if or when salmon might return from their migration from the ocean through the Willamette hydrosystem to the Tribal fishing sites (Emery No Date).

Under the NAA, the current operating conditions of the WVS would continue and would not adequately benefit the fish species essential to meet the subsistence and ceremonial requirements of the Tribes in the ROI. If fish populations in the WRB continue to decline, the number of traditional fishing sites could decline further, prompting Tribal members to spend more time and money to travel greater distances to suitable fishing sites. This could increase competition between Tribes, leading to fewer fish allocations by ODFW for ceremonial and subsistence purposes. Currently, certain Tribes such as the Grand Ronde Community and Siletz Indians receive up to 4,000 pounds of chinook salmon and salmon carcasses respectively for subsistence purposes from State of Oregon Fisheries (CTGR 2014; Siletz Tribal Code § 7.001 2017; CTSI No Date). The continued decline in fish populations in WRB could make the Tribes more reliant on the fish supplies from ODFW fish hatcheries, which are genetically different from the wild-caught fish species that the Tribes rely on. Overall, this could result in the loss of Tribal culture and traditions that are driven by the harvest of these fish species. As such, impacts to Tribes engaged in subsistence and ceremonial fishing in the ROI would be adverse, moderate in magnitude, long-term in duration, and large in extent. These effects would be disproportionately high and adverse, but would not be significant.

##### *3.20.4.4.3 Climate Change*

Climate change would adversely affect Tribal subsistence fishing, decreasing fish populations and therefore fish available for harvest. All of the climate change factors listed in Section

3.1.2.3 would affect water temperatures, flow regime, hydrology and ecosystem processes; increase exposure of fish to diseases and parasites; and increase the prevalence of invasive species, thereby leading to changes in population, habitat quality and quantity, and distribution of fisheries resources harvested by subsistence communities (ODFW No Date). Higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish populations).

Under the NAA, adverse effects to Tribal subsistence fishing could be minor in the short and medium term and large in extent. Climate change could exacerbate effects from maintenance/rehabilitation projects, gravel augmentation, revetment alteration, and the Fall Creek Drawdown, as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, the effects of climate change and the measures under the NAA would be minor to moderate in the short and medium term and large in extent. These effects would be disproportionately high and adverse, but would not be significant.

Under the NAA, adverse effects to Tribal recreation would be major and adverse due to the Fall Creek drawdown. Climate change would further reduce water quantity with higher air and water temperatures and if there is less water in river and reservoir systems. Overall effects from climate change and the measures under the NAA would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant.

Under the NAA, potential effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be adverse, moderate in magnitude, long-term in duration, and large in extent. All of the climate change factors listed in Section 3.1.2.3 would likely further decrease the fish species available for harvest, disrupting subsistence harvest patterns and the seasonality of harvest activities and locations of fishing areas, and inducing stress within or between communities by adversely impacting subsistence resource sharing activities. As such, the measures under the NAA in combination with climate change on subsistence, ceremonial, and traditional fishing activities of Native American Tribes reliant on fish in the WVB would be moderate to major in magnitude, large in extent, and long-term in duration. Disproportionately high and adverse effects that are major in magnitude would be considered a significant effect.

#### *3.20.4.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Alternative 1 consists of structural improvements and management measures which maximize refill volumes of conservation pools at WVS reservoirs in support of improved survival of ESA-listed fish species in addition to other authorized project purposes of the structures. Under Alternative 1, measures at and in the vicinity of dam sites/reservoirs would occur as follows:

Construction/modification of structural measures:

- Gravel augmentation below dams (#384) would occur at CGR, BLU, FOS, and BCL;
- Maintenance or alteration of revetments (#9) would occur basin wide;
- Construction of water temperature control tower (#105) would occur at LOP, GPR, and DET;
- Structural improvements to reduce TDG (#174) would occur at DEX, LOP, CGR, FOS, GPR, and DET;
- Restoration of upstream and downstream passage at drop structures (#639) would occur at FRN;
- Construction of adult fish facility (#722) would occur at GPR;
- Provision of Pacific lamprey passage and infrastructure (#52) would occur at FRN and GPR;
- Construction of structural downstream fish passage (#392) would occur at LOP, FOS, GPR, and DET; and
- Operation, Maintenance, Repair, Replacement and Rehabilitation would occur basin wide.

Operation of structural measures mentioned above and implementation of water management measures would occur as follows:

- Adaptation of Hatchery Program (#719) would occur at DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, and DET;
- Maintenance of existing and new fish release sites above dams (#726) would occur at LOP, FCR, HCR, CGR, FOS, GPR, BCL, and DET;
- Fish ladder temperature improvement (#479) would occur at FOS;
- Augmentation of instream flows by using the inactive pool (#718) would occur at CTG, DOR, FCR and BLU;
- Augmentation of instream flows by using the power pool (#304) would occur at LOP, HCR, CGR, GPR, and DET;
- Fall Creek Drawdown would occur at FCR; and
- Continued operation of existing AFFs would occur at DEX, FCR, CGR, FOS, and BCL

###### *3.20.4.5.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

The direct, indirect, and induced socioeconomic effects to communities with EJ concerns due to the creation of construction jobs, impacts to the health of workers hired from communities with EJ concerns and communities with EJ concerns residing in the vicinity of the impacted reservoirs from air emissions and increased noise levels during construction/structural improvement activities, and traffic/transportation impacts during construction are described in Section 3.20.4.3.1.

Construction expenditures associated with Alternative 1 are expected to total approximately $1.8B. As such, the direct, indirect, and induced socioeconomic impact of Alternative 1 on minority communities with EJ concerns would be beneficial, minor in magnitude, occur in the short-term and medium-term, and be medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. The adverse health effects from construction and infrastructure improvement activities on communities with EJ concerns hired to work at the project locations would be minor; and occur in the short-term and medium-term. The extent of effects would be small and would only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

Construction and infrastructure improvement activities under Alternative 1 would occur at locations spread across three counties – namely Marion, Linn, and Lane counties. It is assumed that if a project occurs in one of these three counties, many of the local workers hired to support the project would be from that county. Since Marion County constitutes an EJ minority population, the impacts to populations with EJ concerns in Marion County from activities proposed under this alternative would be markedly greater than outlying areas. Construction workers from Marion County may also be hired to work at locations in nearby Linn County. Impacts to minority communities with EJ concerns in Washington County, which is the only other county that constitutes a population with EJ concerns in the ROI, would be less pronounced since no project measures would be implemented in this county. However, construction workers from Washington County may be hired to work on projects in the nearby Marion County.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

##### *3.20.4.5.2 Subsistence Fishing and Tribal Effects*

The construction/modification of structural measures; major maintenance and rehabilitation projects; gravel augmentation and maintenance of revetments; and Fall Creek drawdown would increase turbidity and may reduce the quantity and quality of some fish species available for harvesting.

As such, adverse effects from construction and/or structural modification projects as well as the Fall Creek drawdown to Tribal subsistence fishing activities and recreation as described in Section 3.20.2.3.1 would be minor in magnitude; short-, medium-, and long-term recurring in duration; and medium in extent. Effects from major maintenance and rehabilitation projects are expected to occur intermittently over the period of analysis of this Draft PEIS. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2 and the NAA, the Fall Creek drawdown would also have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Fall Creek. These disproportionately high and major, adverse effects would be considered significant.

Impacts to Tribes that fish for subsistence purposes near the project locations or that fish recreationally at the reservoirs in the three counties mentioned above would be markedly greater than outlying areas and are described in Section 3.20.4.3. The Confederated Tribes of Warm Springs, which have reservations in counties adjacent to Marion and Linn Counties, and the Cow Creek band of Umpqua Tribe of Indians, which have reservations in the county adjacent to Lane County, would be impacted the most. Members of the Confederated Tribe of Siletz Indians would experience fewer adverse impacts since they engage in cultural fishing activities at three sites in Lincoln County (namely Euchere Creek Falls, Drift Creek, and Little Rock Creek hatchery (CTSI No Date) that are located outside of the WVS. Similarly, the Confederated Tribes of Grand Ronde Community and the Umatilla Tribe would experience minimal adverse effects due to the long distance between their reservation and presumed tribal fishing sites and the project locations.

As described in Section 3.20.4.3.2, while the implementation of the proposed measures would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.5.3 Climate Change*

As discussed in Section 3.20.4.4.3, climate change would adversely affect Tribal subsistence fishing, decreasing fish populations and therefore fish available for harvest. In particular, higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish populations).

Under Alternative 1, adverse effects to Tribal subsistence fishing from construction/structural modification projects could be minor in the short and medium term and medium in extent. Climate change could exacerbate effects from construction/modification of structural measures, maintenance/rehabilitation projects, gravel augmentation, and revetment alteration, and the Fall Creek Drawdown, as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, the adverse effects of climate change and the measures under Alternative 1 would be minor to moderate in the short and medium term; and large in extent. These effects would be disproportionately high and adverse, but would not be significant.

Under Alternative 1, adverse effects to Tribal recreation would be major and adverse due to the Fall Creek drawdown. Climate change would further reduce water quantity with higher air and water temperatures and if there is less water in river and reservoir systems. Overall effects from climate change and the measures under the Alternative 1 would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant.

Under Alternative 1, several structural and water management measures would be implemented, which would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities. However, effects would be less adverse than those that are currently experienced by Tribes; long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. All of the climate change factors listed in Section 3.1.2.3 would work against the beneficial effects from implementing structural and water management measures under this alternative. As such, the effects of climate change combined with the measures under Alternative 1 would result in overall adverse effects that are moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

### *3.20.4.6 Alternative 2A – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2A aims to improve fish passage through the WVS dams using a combination of modified operations and structural improvements, along with other measures to manage water management flexibility and meet ESA-listed fish obligations.

Construction/modification of structural measures:

- Gravel augmentation below dams (#384) would occur at CGR, BLU, FOS, and BCL;
- Maintenance or alteration of revetments (#9) would occur basin wide;
- Construction of water temperature control tower (#105) would occur at DET;
- Construction of adult fish facility (#722) would occur at GPR;
- Provision of Pacific lamprey passage and infrastructure (#52) would occur at GPR;
- Construction of structural downstream fish passage (#392) would occur at LOP, CGR, FOS, and DET; and
- Operation, Maintenance, Repair, Replacement and Rehabilitation would occur basin wide

Operation of structural measures and implementation of water management measures:

- Adaptation of Hatchery Program (#719) would occur at CGR, BLU, FOS, and BCL;
- Fish ladder temperature improvement (#479) would occur at FOS;
- Maintenance of existing and new fish release sites above dams (#726) would occur at LOP, FCR, HCR, CGR, FOS, GPR, BCL, and DET;
- Use of ROs to discharge colder water (#166) would occur at GPR;
- Augmentation of instream flows by using the inactive pool (#718) would occur at FCR and BLU;
- Augmentation of instream flows by using the power pool (#304) would occur at LOP, HCR, CGR, GPR, and DET;
- Use of integrated temperature and habitat flow regime (#30a) would occur basin wide
- Deeper fall reservoir drawdowns for fish passage (#40) would occur at GPR;
- Passage of water over spillway in spring for fish passage (#714) would occur at GPR;
- Fall Creek Drawdown would occur at FCR;
- Continued operation of existing AFFs at DEX, FCR, CGR, FOS, and BCL; and
- Near-term operations measures would occur at DET, BCL, GPR, FOS, CGR, HCR, LOP, and FCR

##### *3.20.4.6.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

The direct, indirect, and induced socioeconomic impacts to communities with EJ concerns due to the creation of construction jobs, impacts to the health of workers hired from communities with EJ concerns and communities with EJ concerns residing in the vicinity of the impacted reservoirs from air emissions and increased noise levels during construction/structural improvement activities, and traffic/transportation impacts during construction are described in Section 3.20.4.3.1.

Construction expenditures associated with Alternative 2A would total only approximately $1.1B, which is almost half of those which would occur under Alternative 1. Fewer construction and infrastructure improvement activities would be implemented compared to Alternative 1 and would impact fewer project locations. As a result, the magnitude of beneficial socioeconomic impacts to communities with EJ concerns, the adverse impacts to the health of construction workers from communities with EJ concerns and nearby residents of communities with EJ concerns due to construction-related emissions, noise generation, and traffic, and adverse impacts to tribal subsistence fishing activities and recreation under Alternative 2A would be less severe compared to Alternative 1.

As such, the direct and indirect socioeconomic impact of Alternative 2A on minority communities with EJ concerns would be beneficial, negligible to minor in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial impacts would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. The magnitude of beneficial effects from activities proposed under Alternative 2A would be most severe for populations with EJ concerns in Marion County and relatively less severe for populations with EJ concerns in Washington County. Adverse impacts of construction and infrastructure improvement activities on the health of construction workers from communities with EJ concerns would occur in the short-term and medium-term and be negligible to minor in magnitude. The extent would be small and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek and Green Peter reservoirs (respectively) are located; and where annual drawdowns are proposed. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek and Green Peter reservoirs. Given that two annual drawdowns would occur at two reservoirs, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.6.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence fishing and recreation from construction activities; gravel augmentation and maintenance of revetments; and drawdowns at Green Peter and Fall Creek would vary across Tribes and would be determined by the distance between the Tribal fishing sites and the project locations, as described in Section 3.20.4.5.2 and 3.20.4.3. Under Alternative 2A, adverse effects would be minor, short-, medium-, and long-term recurring; and medium in extent. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2, drawdowns at Fall Creek and Green Peter would also have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Fall Creek and Green Peter. These disproportionately high and major, adverse effects would be considered significant.

As described in Section 3.20.4.3.2, while the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

###### *3.20.4.6.3 Suite of Near-term Operations*

Near-term operations that could affect environmental justice include deep drawdowns and extended deep drawdowns, RO prioritization, and delayed reservoir refills for improved downstream fish passage. Similar to the effects discussed in Section 3.20.4.3.2 and 3.20.4.3.3, extended deep drawdowns and delayed reservoir refills would cause adverse effects to Tribal recreation and subsistence fishing activities downstream of reservoirs; and overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 2A, adverse effects to Tribal recreation would be major and adverse due to the Fall Creek and Green Peter drawdowns. Effects would still be major with the suite of near- term operations, small in extent, and short-term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent.

###### *3.20.4.6.4 Climate Change*

As discussed in Section 3.20.4.4.3, climate change would adversely affect Tribal subsistence fishing, decreasing fish populations and therefore fish available for harvest. In particular, higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish populations).

Under Alternative 2A, adverse effects to Tribal subsistence fishing could be minor in the short and medium term and medium in extent. Climate change could exacerbate effects from construction/modification of structural measures, maintenance/rehabilitation projects, gravel augmentation, revetment alteration, and drawdowns at Green Peter and Fall Creek, as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, the effects of climate change and the measures under Alternative 2A would be minor to moderate in the short and medium term; and large in extent. These effects would be disproportionately high and adverse, but would not be significant.

Under Alternative 2A, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Fall Creek and Green Peter. Climate change would further reduce water quantity with higher air and water temperatures and if there is less water in river and reservoir systems. Overall effects from climate change and the measures under the Alternative 2A would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant.

Under Alternative 2A, a greater number of water management measures (compared to Alternative 1) would be implemented, which would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities. However, effects would be less adverse than those that are currently experienced by Tribes; long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. All of the climate change factors listed in Section 3.1.2.3 would work against the beneficial effects from implementing several water management measures under this alternative. As such, the effects of climate change combined with the measures under Alternative 2A would result in overall adverse effects that are moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.7 Alternative 2B – Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 2B is similar to Alternative 2A but proposes a slightly different combination of measures at Cougar Dam that are $52M lower in construction expenditures than Alternative 2A. While Alternative 2A proposes constructing structural downstream fish passage at Cougar Dam, Alternative 2B includes changing operations at Cougar Dam by drafting the reservoir down so that fish can pass through the DT in the fall and spring. Under Alternative 2B, deep fall and spring drawdowns to the DT for fish passage would draft the reservoir below the power pool most of the time, making the power pool inaccessible for flow augmentation under Alternative 2B. Also, augmentation of instream flows by using the power pool (#304) would occur at four of the same locations but would not occur at Cougar Dam under Alternative 2B.

Given their overall similarity, the EJ effects of the measures under Alternative 2B are very similar to Alternative 2A and are affected by the same mechanisms discussed in Sections 3.20.4.3 and 3.20.4.6. Drawdown-related impacts would be slightly greater for Alternative 2B compared to Alternative 2A.

#### *3.20.4.7.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

The direct and indirect socioeconomic impact of Alternative 2B on minority communities with EJ concerns would be beneficial, negligible to minor in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial impacts would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. The magnitude of beneficial effects from activities proposed under Alternative 2B would be most pronounced for populations with EJ concerns in Marion County and relatively less intense for populations with EJ concerns in Washington County. Adverse impacts of construction and infrastructure improvement activities on the health of construction workers from communities with EJ concerns would occur in the short term and medium term and be negligible to minor in magnitude. Effects to minority communities with EJ concerns would be the same as those under Alternative 2A. Effects would be small in extent and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek, Green Peter, and Cougar reservoirs are located – and where annual drawdowns are proposed. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek, Green Peter, and Cougar reservoirs. Given that three annual drawdowns would occur at three reservoirs, the magnitude of effects would be moderate and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.7.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence fishing and recreation from construction activities; gravel augmentation and maintenance of revetments; and drawdowns at Green Peter, Fall Creek, and Cougar would vary across Tribes and would be determined by the distance of the Tribal fishing sites from the project locations, as described in Section 3.20.4.5.2 and 3.20.4.3. As such, these adverse effects would be minor in magnitude; short-, medium-, and long-term recurring in duration; and medium in extent. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2, drawdowns at Cougar, Fall Creek, and Green Peter would also have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Cougar, Fall Creek, and Green Peter. These disproportionately high and major, adverse effects would be considered significant.

EJ impacts of the measures under Alternative 2B are very similar to Alternative 2A and are affected by the same mechanisms discussed in Sections 3.20.4.3 and 3.20.4.6.2. While the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.7.3 Suite of Near-term Operations*

The implementation of near-term operations would also cause adverse impacts to Tribal subsistence fishing activities downstream of reservoirs; but overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 2B, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Cougar, Fall Creek, and Green Peter. Effects would still be major with the suite of near- term operations, small in extent, and short term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent.

#### *3.20.4.7.4 Climate Change*

The effects of climate change and the measures under Alternative 2B would be the same as those under Alternative 2A and are described in Section 3.20.4.6.4. The differences between alternatives 2A and 2B, like constructing a downstream fish passage at Cougar under Alternative 2A instead of a drawdown under Alternative 2B, would not change the analysis or affect the conclusions. The effects of climate change and the measures under Alternative 2A on

Tribal subsistence fishing would be minor to moderate in the short and medium term; and large in extent. These effects would be disproportionately high and adverse, but would not be significant. Overall effects from climate change and the measures under the Alternative 2A to Tribal recreation would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant. The long-term effects of climate change combined with the measures under Alternative 2A to Tribal subsistence and ceremonial fishing activities would result in overall adverse effects that are moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.8 Alternative 3A – Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)*

Alternative 3A focuses on modifying operations rather than storage or structural measures to improve the survival of ESA-listed fish species. Operational measures in Alternative 3A are intended to improve downstream fish passage, increase water management flexibility, optimize conservation season draft rates, and reduce impaired water quality below the WVS dams to benefit ESA-listed fish species.

Construction/modification of structural measures:

- Gravel augmentation below dams (#384) would occur at CGR, BLU, FOS, and DET;
- Maintenance or alteration of revetments (#9) would occur basin wide;
- Construction of adult fish facility (#722) would occur at HCR, BLU, and GPR;
- Provision of Pacific lamprey passage and infrastructure (#52) would occur at HCR, BLU, and GPR; and
- Operation, Maintenance, Repair, Replacement and Rehabilitation would occur basin wide

Operation of structural measures and implementation of water management measures:

- Adaptation of Hatchery Program (#719) would occur at DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, and DET;
- Maintenance of existing and new fish release sites above dams (#726) would occur basin-wide;
- Use of Ros to discharge colder water (#166) would occur at LOP, GPR, and DET;
- Augmentation of instream flows by using the inactive pool (#718) would occur at CTG, DOR, FCR, and BLU;
- Augmentation of instream flows by using the power pool (#304) would occur at LOP, HCR, CGR, GPR, and DET;
- Use of integrated temperature and habitat flow regime (#30a) would occur basin wide;

- Deeper fall reservoir drawdowns for fish passage (#40) would occur at LOP, HCR, CGR, BLU, GPR, and DET;
- Spring reservoir drawdown for downstream fish passage (#720) would occur at LOP, CGR, and DET;
- Passage of water over spillway in spring for fish passage (#714) would occur at DEX, FCR, HCR, BCL, and GPR;
- Fall Creek Drawdown would occur at FCR;
- Continued operation of existing AFFs at DEX, FCR, CGR, FOS, and BCL; and
- Near-term operations measures would occur at LOP, DET, BCL, GPR, FOS, CGR, HCR, and FCR

##### *3.20.4.8.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

Alternative 3A would result in the implementation of fewer construction and infrastructure improvement activities compared to all other alternatives. As a result, the beneficial socioeconomic impacts to communities with EJ concerns and the adverse impacts to the health of these communities due to construction-related emissions, noise generation, and increased traffic would be less pronounced compared to all other alternatives.

Construction expenditures associated with Alternative 3A would total only approximately $330M, which is only 34 percent of those of Alternatives 2A and 2B. As such (and as described in Section 3.20.4.3.1), the direct and indirect socioeconomic impact of Alternative 3A on minority communities with EJ concerns would be beneficial, negligible in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial impacts would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. Beneficial effects from activities proposed under Alternative 3A would be most pronounced for populations with EJ concerns in Marion County and relatively less intense for populations with EJ concerns in Washington County. Adverse effects of construction and infrastructure improvement activities on the health of construction workers hired from communities with EJ concerns to work at the project locations would occur in the short term and medium term and be negligible in magnitude. Effects would be small in extent and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. Minority populations with EJ concerns in Marion County could experience disproportionate and adverse effects associated with the fall and spring drawdowns at Detroit Reservoir. As described in 3.20.3, the Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are located in Yamhill, Jefferson and Wasco, Wasco, Lincoln, and

Lincoln counties (respectively). Drawdowns are not proposed at any of the reservoirs located in the aforementioned counties. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the seven reservoirs where drawdowns are proposed. Given that a total of ten drawdowns would occur at seven reservoirs, the magnitude of effects would be major and the extent would likely be large under this alternative, occurring in all the counties in the WVS. These disproportionately high and major, adverse effects would be considered significant.

#### *3.20.4.8.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence and recreational fishing from construction activities; gravel augmentation and maintenance of revetments; and drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit would vary across Tribes and would be determined by the distance of the Tribal fishing sites from the project locations, as described in Section 3.20.4.3.2. Effects from reservoir drawdowns would be more pronounced under Alternative 3A compared to all other alternatives since the total number of drawdowns would be higher and would occur at far more reservoirs. As such, these adverse impacts would be minor to moderate, short-, medium-, and long-term recurring; and medium in extent. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2, drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit would have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at the reservoirs themselves. These disproportionately high and major, adverse effects would be considered significant.

Alternative 3A would implement a greater number and variety of water management measures to improve fish passage. As described in Section 3.20.4.3.2, while the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Effects under Alternative 3A (and 3B) would be the least adverse compared to the other alternatives, and overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.8.3 Suite of Near-term Operations*

The implementation of near-term operations would also cause adverse impacts to Tribal subsistence fishing activities downstream of reservoirs; but overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 3A, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit. Effects would still be major with the suite of near-term operations, small in extent, and short term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and large in extent due to the greater number and variety of water management measures to improve fish passage.

#### *3.20.4.8.4 Climate Change*

As discussed in Section 3.20.4.4.3, climate change would adversely affect Tribal subsistence fishing, decreasing fish populations and therefore fish available for harvest. In particular, higher air and water temperatures, less water in river and reservoir systems, and more frequent and severe wildfires would decrease water quality from higher turbidity and increased occurrence of HABs (which would decrease dissolved oxygen (DO) concentrations and could adversely affect fish populations).

Under Alternative 3A, adverse effects to Tribal subsistence fishing could be minor to moderate in the short and medium term and medium in extent. Climate change could exacerbate effects from construction/modification of structural measures, maintenance/rehabilitation projects, gravel augmentation, revetment alteration, and drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit, as increased wildfire ash, HABs, and erosion would further increase turbidity and could further reduce the quantity and quality of some fish species available for harvest. As such, the effects of climate change and the measures under Alternative 3A would be moderate in the short and medium term and large in extent. These effects would be disproportionately high and adverse, but would not be significant.

Under Alternative 3A, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit. Climate change would further reduce water quantity with higher air and water temperatures and if there is less water in river and reservoir systems. Overall effects from climate change and the measures under the Alternative 3A would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant.

Under Alternative 3A, several water management measures would be implemented to increase the availability of fish species to subsistence communities with EJ concerns, which would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities. However, effects would be less adverse than those that are currently experienced by Tribes (3A and 3B would be the least adverse due to the number of drawdowns); long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and large in extent. All of the climate change factors listed in Section 3.1.2.3 would work against the beneficial effects from implementing several water management measures under this alternative. As such, the effects of climate change combined with the measures under Alternative 3A would result in overall adverse effects that are minor to moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)*

Alternative 3B is similar to Alternative 3A but differs primarily by their downstream passage measures. Alternative 3A proposes downstream fish passage elements at a different combination of projects and includes drawdown drafting to 10 feet over the top of the Cougar Dam RO for deep fall and spring drawdown measures. Alternative 3B, diversely, includes drawdown drafting to the DT at Cougar for both drawdown measures, a much deeper drawdown than proposed under Alternative 3A. Also, under Alternative 3B, the integrated temperature and habitat flow regime (Measure #30a as described in Section 2.3.1.1) would only be utilized at LOP, HCR, GPR, and DET, as opposed to Alternative 3A which includes all dams in the WVS. Given their overall similarity, the EJ impacts of the measures under Alternative 3B are very similar to Alternative 3A and are affected by the same mechanisms discussed in Section 3.20.2.3.

##### *3.20.4.9.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

Construction expenditures associated with Alternative 3B would total approximately $415M, or $85M in additional construction and maintenance expenditures of Alternative 3B. The direct and indirect socioeconomic impact of Alternative 3B on minority communities with EJ concerns would be beneficial, negligible in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial impacts would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. Beneficial effects from activities proposed under Alternative 3B would be most pronounced for populations with EJ concerns in Marion County and relatively less intense for populations with EJ concerns in Washington County. Adverse impacts of construction and infrastructure improvement activities on the health of communities with EJ concerns hired to work on the project would occur in the short term and medium term and be negligible in magnitude. Effects would be small in extent and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. Minority populations with EJ concerns in Marion County could experience disproportionate and adverse effects associated with the fall and spring drawdowns at Detroit Reservoir. As described in 3.20.3, the Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are located in Yamhill, Jefferson and Wasco, Wasco, Lincoln, and Lincoln counties (respectively). Drawdowns are not proposed at any of the reservoirs located in the aforementioned counties. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the seven reservoirs where drawdowns are proposed. Given that a total of ten drawdowns would occur at seven reservoirs, the magnitude of effects would be major and the extent would likely be large under this alternative, occurring in all the counties in the WVS. These disproportionately high and major, adverse effects would be considered significant.

###### *3.20.4.9.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence and recreational fishing from construction activities; gravel augmentation and maintenance of revetments; and drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit would vary across Tribes and would be determined by the distance of the Tribal fishing sites from the project locations, as described in Section 3.20.4.3.2. Similar to Alternative 3A, effects from reservoir drawdowns would be more pronounced under this alternative compared to alternatives 1, 2A, and 2B since the total number of drawdowns would be higher and would occur at far more reservoirs. As such, adverse effects would be minor to moderate-, short-, medium-, and long-term recurring and medium in extent. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2, drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit would have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at the reservoirs themselves. These disproportionately high and major, adverse effects would be considered significant.

Like Alternative 3A, Alternative 3B would implement a greater number and variety of water management measures to improve fish passage. As described in Section 3.20.4.3.2, while the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Effects under Alternative 3B (and 3A) would be the least adverse compared to the other alternatives, and overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

##### *3.20.4.9.3 Suite of Near-term Operations*

The implementation of near-term operations would also cause adverse impacts to Tribal subsistence fishing activities downstream of reservoirs; but overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 3B, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Green Peter, Fall Creek, Cougar, Lookout Point, Hills Creek, Blue River and Detroit. Effects would still be major with the suite of near-term operations, small in extent, and short-term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would be minor in magnitude and large in extent due to the greater number and variety of water management measures to improve fish passage.

##### *3.20.4.9.4 Climate Change*

The effects of climate change and the measures under Alternative 3B would be the same as those under Alternative 3A and are described in Section 3.20.4.8.4. The differences between alternatives 3A and 3B – like a much deeper drawdown at Cougar under Alternative 3B compared to 3A – would not change the analysis or affect the conclusions. The effects of climate change and the measures under Alternative 3B on Tribal subsistence fishing would be moderate in the short and medium term and large in extent. These effects would be disproportionately high and adverse, but would not be significant. Overall effects from climate change and the measures under the Alternative 3A on Tribal recreation would be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant. Effects of climate change combined with the measures under Alternative 3A to Tribal subsistence and ceremonial fishing activities would result in overall adverse effects that are minor to moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

#### ***3.20.4.10 Alternative 4 – Structures-Based Fish Passage Alternative***

Alternative 4 consists almost entirely of structural improvements which increase stream flows and enhance fish passage in support of improved survival of ESA-listed fish species.

Construction/modification of structural measures:

- Gravel augmentation below dams (#384) would occur at CGR, BLU, FOS, and BCL;

- Maintenance or alteration of revetments (#9) would occur basin wide;
- Construction of water temperature control tower (#105) would occur at LOP, HCR, and DET;
- Structural improvements to reduce TDG (#174) would occur at DEX, LOP, CGR, FOS, GPR, and DET;
- Restoration of upstream and downstream passage at drop structures (#639) would occur at FRN;
- Construction of adult fish facility (#722) would occur at HCR;
- Provision of Pacific lamprey passage and infrastructure (#52) would occur at FRN and GPR;
- Construction of structural downstream fish passage (#392) would occur at LOP, FOS, GPR, and DET; and
- Operation, Maintenance, Repair, Replacement and Rehabilitation would occur basin wide

Operation of structural measures and implementation of water management measures:

- Adaptation of Hatchery Program (#719) would occur at DEX, LOP, FCR, HCR, CGR, BLU, FOS, GPR, BCL, and DET;
- Fish ladder temperature improvement (#479) would occur at FOS;
- Maintenance of existing and new fish release sites above dams (#726) would occur at LOP, FCR, HCR, CGR, FOS, GPR, BCL, and DET;
- Use of ROs to discharge colder water (#166) would occur at GPR;
- Augmentation of instream flows by using the inactive pool (#718) would occur at FCR and BLU;
- Augmentation of instream flows by using the power pool (#304) would occur at LOP, HCR, GPR, and DET;
- Use of integrated temperature and habitat flow regime (#30a) would occur basin wide
- Deeper fall reservoir drawdowns for fish passage (#40) would occur at CGR and GPR;
- Spring reservoir drawdown for downstream fish passage (#720) would occur at CGR;
- Passage of water over spillway in spring for fish passage (#714) would occur at GPR;
- Fall Creek Drawdown would occur at FCR;
- Continued operation of existing AFFs would occur at DEX, FCR, CGR, FOS, and BCL; and
- Near-term operations measures would occur at DET, BCL, GPR, FOS, CGR, HCR, and FCR

Under Alternative 4, effects would be similar in nature to the impacts described in Section 3.20.4.3.1.

#### *3.20.4.10.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

The construction-related impacts under this alternative would be similar to the impacts expected under Alternative 1, though they may occur at different project locations compared to Alternative 1. The magnitude of such impacts would be greater compared to Alternatives 2A, 2B, 3A, and 3B.

Construction and maintenance expenditures associated with Alternative 4 would total approximately $2.0B, which is $200M greater than those of Alternative 1, and the most expensive of the alternatives. As such, the direct and indirect socioeconomic effect of Alternative 4 on minority communities with EJ concerns would be beneficial, minor in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial effects would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. Effects from activities proposed under Alternative 4 would be most pronounced for populations with EJ concerns in Marion County and relatively less intense for populations with EJ concerns in Washington County. Adverse effects of construction and infrastructure improvement activities on the health of construction workers would occur in the short term and medium term and be minor in magnitude. Effects would be small in extent and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane County, where the Fall Creek Drawdown occurs. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek Reservoir. Given that one drawdown would occur annually in one county, the magnitude of effects would be minor and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.10.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence and recreational fishing from construction activities; major maintenance and rehabilitation projects; gravel augmentation and maintenance of revetments; and reservoir drawdowns would vary across Tribes and would be determined by the distance of the Tribal fishing sites from the project locations, as described in Section 3.20.4.3. As such, these adverse impacts would be minor in magnitude, short-, medium-, and long-term recurring, and medium in extent. These effects would be disproportionately high and adverse, but would not be significant. The severity of drawdown-related impacts would be the same as Alternative 1 and the NAA and would only occur at Fall Creek.

As discussed under in Section 3.20.4.3.2 and the NAA, the Fall Creek drawdown would have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Fall Creek. These disproportionately high and major, adverse effects would be considered significant.

As described in Section 3.20.4.3.2, while the implementation of the proposed measures would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.10.3 Suite of Near-term Operations*

The implementation of near-term operations would also cause adverse impacts to Tribal subsistence fishing activities downstream of reservoirs; but overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 4, adverse effects to Tribal recreation would be major and adverse due to the Fall Creek drawdown. Effects would still be major with the suite of near- term operations, small in extent, and short term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent.

#### *3.20.4.10.4 Climate Change*

The effects of climate change and the measures under Alternative 4 would be similar to those under Alternatives 1 and 2B and are described in Section 3.20.4.5.3 and 3.20.4.7.4. Overall effects from climate change and the measures under the Alternative 4 on Tribal recreation would be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant. The effects of climate change combined with the measures under Alternative 4 on Tribal subsistence and ceremonial fishing activities would result in overall adverse effects that are moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

### *3.20.4.11 Alternative 5 – Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Alternative 5 only differs from Alternative 2B by way of the refined integrated temperature management and habitat flow regime measure (#30b), which is not a measure that would change the effects determination. Therefore, the effects of Alternative 5 would be identical to those of Alternative 2B.

#### *3.20.4.11.1 Socioeconomic Effects; Noise Disturbance, Air Emissions, and Traffic*

The direct and indirect socioeconomic effect of Alternative 5 on minority communities with EJ concerns would be beneficial, negligible to minor in magnitude, occur in the short term and medium term, and be medium in extent. Long-term beneficial impacts would be negligible in magnitude and medium in extent. Beneficial socioeconomic effects on communities with EJ concerns would be disproportionately high, but would not be significant. The magnitude of beneficial effects from activities proposed under Alternative 5 would be most pronounced for populations with EJ concerns in Marion County and relatively less intense for populations with EJ concerns in Washington County. Adverse impacts of construction and infrastructure improvement activities on the health of construction workers from communities with EJ concerns would occur in the short term and medium term and be negligible to minor in magnitude. The extent of effects would be small and only affect workers at the project location. These effects would be disproportionately high and adverse, but would not be significant.

As discussed in 3.20.4.3.2, drawdowns could result in the closure of water-based recreational businesses such as boat rental firms or guide services and ultimately reduce employment and consumer demand within the ROI. The Confederated Tribes of Grand Ronde Community of Oregon, Confederated Tribes of Warm Springs, Confederated Tribes of Siletz Indians, Cow Creek Band of Umpqua Tribe of Indians, and Confederated Tribes of the Umatilla Indian Reservation are not located in Lane and Linn counties, where the Fall Creek, Green Peter, and Cougar reservoirs are located – and where annual drawdowns are proposed. However, as noted above, while many or most Tribal members may live on, for example, the Grand Ronde Reservation, members also live across the communities in and around the WVS (Grand Ronde, 2022). As such, drawdowns could adversely and disproportionately affect tribal members throughout the WVS that are economically dependent on the Fall Creek, Green Peter, and Cougar reservoirs. Given that three annual drawdowns would occur at three reservoirs, the magnitude of effects would be moderate and the extent would likely be medium under this alternative, occurring in some of the counties in the WVS. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.11.2 Subsistence Fishing and Tribal Effects*

Impacts to subsistence and recreational fishing from construction activities; gravel augmentation and maintenance of revetments; and drawdowns at Green Peter, Fall Creek, and Cougar would vary across Tribes and would be determined by the distance of the Tribal fishing sites from the project locations, as described in Section 3.20.4.3 and 3.20.4.5.2. As such, these adverse impacts would be minor; short-, medium-, and long-term recurring; and medium in extent. These effects would be disproportionately high and adverse, but would not be significant.

As discussed under in Section 3.20.4.3.2, drawdowns at Cougar, Fall Creek, and Green Peter would also have adverse and major effects to Tribal recreationists. Some recreationists would forego visitation to the reservoir altogether during the drawdowns. Others that continue to visit the reservoir during drawdowns would be adversely affected due to visual effects on the recreational experience. Effects would occur in the short term and recur in the long term. The extent of effects would be small because they would only occur at Cougar, Fall Creek, and Green Peter. These disproportionately high and major, adverse effects would be considered significant.

EJ impacts of the measures under Alternative 5 are the same as Alternative 2B and are affected by the same mechanisms discussed in Sections 3.20.4.3 and 3.20.4.6.2. While the implementation of the proposed measures would not result in overall beneficial effects to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.11.3 Suite of Near-term Operations*

The implementation of near-term operations would also cause adverse impacts to Tribal subsistence fishing activities downstream of reservoirs; but overall effects would still be minor, short-term and long-term recurring. These effects would be disproportionately high and adverse, but would not be significant. Under Alternative 5, adverse effects to Tribal recreation would be major and adverse due to the drawdowns at Cougar, Fall Creek, and Green Peter. Effects would still be major with the suite of near-term operations, small in extent, and short-term and long-term recurring. These disproportionately high and major, adverse effects would be considered significant. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent.

#### *3.20.4.11.4 Climate Change*

The effects of climate change and the measures under Alternative 5 would be the same as those under Alternative 2B. The effects of climate change and the measures under Alternative 2B/5 on Tribal subsistence fishing would be minor to moderate in the short and medium term;

and large in extent. These effects would be disproportionately high and adverse, but would not be significant. Overall effects from climate change and the measures under the Alternative 2B/5 to Tribal recreation would still be major in the short term and recur in the long term; and be small in extent. These disproportionately high and major, adverse effects would be considered significant. The long-term effects of climate change combined with the measures under Alternative 2A to Tribal subsistence and ceremonial fishing activities would result in overall adverse effects that are moderate in magnitude, large in extent, and long-term. These effects would be disproportionately high and adverse, but would not be significant.

#### *3.20.4.12 Conclusion*

The socioeconomic and health impacts from construction and structural improvement measures on communities with EJ concerns, including Tribes, would be most severe for Alternatives 1 and 4, and least severe for alternatives 3A and 3B since the greatest number of construction/structural measures would be implemented under Alternatives 1 and 4.

Conversely, effects from the implementation of water management measures, including reservoir drawdowns, would be most severe for Alternatives 3A and 3B, followed by Alternative 2A, 2B/5, and least severe for Alternatives 1 and 4. Major and adverse effects to Tribal recreation would occur under all alternatives due to drawdowns. These disproportionately high and major, adverse effects would be considered significant under all alternatives.

While the implementation of the proposed measures under any of the alternatives would not result in overall beneficial impacts to Tribal subsistence and ceremonial fishing activities, effects would be less adverse than those that are currently experienced by Tribes due to dwindling fish populations in the WRB. Overall, long-term adverse effects to Tribes engaged in subsistence and ceremonial fishing in the ROI would range from minor to moderate in magnitude and be large in extent; and be the least adverse under Alternatives 3A and 3B. The continued existence of these fish species – or more precisely, their respective evolutionarily significant units (ESUs) and distinct population segments (DPSs) – in the WRB would support the preservation of Tribal cultural practices and the passing on of knowledge of traditional fishing methods and customs to their youth. These effects would be disproportionately high and adverse, but would not be significant.

## 3.21 CULTURAL RESOURCES

The term *cultural resources* refers to the physical manifestations that represent the heritage of a place and are associated with peoples who have historic connections to that place. For the purposes of this Draft PEIS, cultural resources include pre-contact and historical archaeological objects, features, and deposits located above or below the ground surface that are tangible evidence of prior human occupation or use in a particular area, architecture or elements of the built environment, and places or landscapes that a group of people consider culturally important because of events or practices that have occurred at the location. The last category includes places known as traditional cultural properties (TCPs) or historic properties of religious and cultural significance to Indian tribes (HPRCSITs).

Section 106 of the National Historic Preservation Act (NHPA), as amended, and the Act's implementing regulations *Protection of Historic Properties*, 36 CFR Part 800, requires the Corps to identify, evaluate for significance and potential listing in the National Register of Historic Places, and mitigate adverse effects to cultural resources that are identified as *historic properties* see Chapter 7. Historic properties are typically, but not always, at least 50 years old and retain integrity related to location, design, setting, materials, workmanship, feeling, or association. Historic properties must also be associated with significant historical events or people, represent a distinctive style of construction, retain stylistic elements representative of a master artisan, or be likely to provide important information about the past through continued study.

For the WVS 13 multipurpose dam and reservoir project areas located in Benton, Lane, Linn, and Marion counties, the Corps utilizes a program-level programmatic agreement (PA) to comply with Section 106 of the NHPA. This document modifies the Section 106 process to follow a streamlined and standardized approach to manage cultural resources that have the potential to be impacted by Corps' undertakings related to the current and future operations of the WVS. This applies to large scale operational measures as well as site-specific actions and structural measures that would be assessed through the tiered NEPA approach. The PA document was executed recently, on June 7, 2022, in partnership with several federal, state, and tribal partners and other interested parties. Per Stipulation VII (Historic Property Management Plan) of the PA, the Corps and partners are developing a companion document to the PA, known as a historic property management plan, that would allow for streamlined management and protection of historic properties that would be affected by the operations and maintenance of the WVS. For any actions that would occur as part of the PEIS, and are not covered in the PA, the Corps would utilize 36 CFR Part 800 to comply with the NHPA.

The Corps is also required to protect any archaeological resources that are at least 100 years of age from vandalism and illicit collection by complying with the Archaeological Resources Protection Act (ARPA). The Native American Graves Protection and Repatriation Act (NAGPRA) also directs the Corps to identify and protect Native American human remains, funerary objects, sacred objects, and objects of cultural patrimony of any age that are under federal management and return them to lineal descendants. Corps Engineering Regulations 1130-2-540

*Cultural Resources Management* provides guidance for how the Agency complies with ARPA, NAGPRA, and NHPA.

The area of analysis for cultural resources is confined to the WRB and is composed of three parts:

1. The individual project areas of the 13 multipurpose dams and reservoirs that comprise the WVS and cover approximately 55,000 acres of lands that are inundated by the reservoirs, have Corps infrastructure at the dams and around the reservoirs, and are uplands surrounding the dams and reservoirs,

2. The approximately 465-mile river system that is controlled by the WVS, starting at the 13 reservoirs on the Willamette River and its tributaries and ending at Willamette Falls in Oregon City, Oregon, and

3. Discrete and limited sections of the Calapooia, Clackamas, and Molalla Rivers and Mill Creek where revetments are located that could be modified in some of the alternatives, but are not downstream of the WVS and not regulated by the Corps.

The downstream area of analysis is derived to align with Section 3.2 that explains the maximum extent of the WRB waterways that are controlled by the WVS and Section 1.6.1 that summarizes the Willamette River Bank Protection Program that originally constructed existing revetments that are not downstream of the WVS but to which modifications are being considered as part of the Draft PEIS. The upstream area of analysis was derived through consideration of the potential maximum extent of impact if there were to be operational or infrastructure changes at the dams and reservoirs. The maximum extent of the upstream area of analysis includes the footprints of the 13 individual projects to cover any potential staging and work zones that may result as part of implementing any operational or infrastructure changes.

This section provides a summary of WRB history, which informs the reader of the kinds of cultural resources that may be present in the area of analysis. Between 1953 and 2021, cultural resources specialists have conducted several surveys to identify cultural resources within the footprint of 13 individual projects areas of the WVS; the results of these surveys and related resource forms are held by the Corps Portland District. These surveys allow for a quantitative component of this analysis that considers the number and type of documented cultural resources that could be impacted by the alternatives regardless of listing in federal, state, or local registers. Cultural resources are highly susceptible to unauthorized excavation and collection, and as a result, any discussion of cultural resources would be broad, and any quantitative components would be averaged and aggregated.

For the riverine settings downstream of the 13 individual projects of the WVS, these lands and waterways are not managed by the Corps and are a mix of other federal, tribal, state, municipal, county, and private ownership. These non-Corps lands have been surveyed to varying degrees, and there is no efficient way to obtain related resource data within the 465-

mile riverine setting that would allow for a quantitative analysis, with the exception of some inventory data related to revetments in the WRB. Potential impacts downstream of the dams are not anticipated to vary across the alternatives, however, because the WVS would retain the Congressionally-authorized purpose of flood risk reduction regardless of the preferred alternative. As discussed in Sections 3.2, the measures that consider operational changes would occur mostly outside of the flood season (November through February) when peak flows typically occur and are reduced by the WVS to decrease damage from flood inundation. Given that the WVS is anticipated to continue flood risk reduction, and future impacts to cultural resources downstream of the 13 individual projects that could occur in the future would not be the result of operations or infrastructure changes described in the Draft PEIS, the discussion of cultural resources downstream of the WVS would be limited to summary overview of the cultural history of the Willamette Valley.

### 3.21.1 Affected Environment

The pre-contact, ethnographic and historic sections are taken from several overview documents commissioned by the Corps to describe and understand the cultural history of the WVS area as well as its place in the greater WRB. These references include Lewis (2020), Linville and Root (2021). Provost et al. (2019), Root et al. (2020), Toepel and Beckham (1982), and Willingham (1983). The following text has been edited and in text citations removed for clarity and readability.

#### *3.21.1.1 Pre-contact Background*

The earliest archaeological evidence of human occupation in the WRB is associated with rare discoveries of projectile points associated with the Paleo-Indian Period (time range of 15,000-9,000 years B.P.), many of which were recovered in or near Corps reservoirs. Finds of Clovis points across the western United States suggest a widespread occupation where humans used a variety of landforms and resources. A square stemmed sub-type of projectile points is found in the western Cascades including at Detroit and Lookout Reservoirs that may be indicative of a similarly early occupation known as the Western Stemmed Tradition. Paleo-Indian peoples were originally thought to have been highly mobile foragers who relied primarily on large game, specifically megafauna, though this is debated in archaeological research. Megafauna generally would have been unavailable in the WVB during the period between about 10,000 - 8,000 B.P.; however, bison may have persisted in the region and other large ungulates would have supported human populations in the area. Evidence of acorn use was reported at a Willamette Valley site, dating to approximately 10,000 B.P., and hazelnuts have been found in a similarly aged hearth along the Long Tom River.

The transition from Paleo-Indian to Early Archaic archaeological cultures (time range of 9,000-6,000 years B.P.) is marked by more diverse flake stone artifact assemblages, including both formal (carefully crafted for a specific purpose) and expedient (on-the-fly and quickly made) tools. This pattern is found in the Great Basin, the Columbia Plateau, and Willamette Valley. The earliest camas ovens in the Willamette Valley date to this period, showing that people mass processed the bulbs of the camas plant by 8500 B.P. The economic system implied by an expanded flaked stone toolkit, but limited groundstone technology, is associated with the seasonal movement of Early Archaic peoples and harvesting of large and small mammals and plants across multiple ecological zones. The increased evidence of plant (specifically camas) processing in the archaeological record associated with the Early Archaic period may indicate population growth in the Willamette Valley.

The Middle Archaic period in the Willamette Valley is marked by two technologies: camas ovens and wide necked dart (atlatl) points (time range of 6,000-2,000 years B.P.). Foliate-shaped Cascade points, first used in the Early Archaic period, were still used in this period, and Willamette Valley inhabitants continued to rely on flaked stone technology much like their predecessors; however, innovations and increased use of groundstone technologies are evidenced in the archaeological record. During this period, land use patterns began to shift, and Willamette Valley occupations appear centered on camas use and exploitation of the High Cascades for summer resources and obsidian, the latter becoming an interregional commodity. The Middle Archaic can be viewed as transitional between the highly mobile lifeways of the Early Archaic and increased sedentism in the Late Archaic, during which seasonal use of stored plant food staples allowed people to return to the same locales year after year. Camas oven features, associated with charred camas bulbs, hazelnuts, and acorns have been found at several sites in the Willamette Valley. While the earliest camas ovens date to 8500 B.P., the increased scale of camas oven use in the Middle Archaic implies heavy investment in processing a seasonal resource and suggests that storage, a prerequisite for sedentism, occurred. A second indication of the intensification in plant processing was the presence of labor intensive grinding implements such as mortars and stone bowls. Stone bowl fragments were found at the Mill Creek and Long Tom sites.

The Late Archaic is the period during which traditional lifeways appear to have been similar to those documented in the ethnographic record (time range of 2,000-250 years B.P.). During this period, some archaeologists suggest that lifeways and cultural adaptations became more localized, with some patterns correlating with historically recorded ethnic and linguistic boundaries. However, there is limited ethnographic data available for the Molalla people of the Western Cascades, so archaeologists have developed lifeway models that extrapolate Willamette Valley (Kalapuyan) economic patterns into higher elevation river valleys. This tension between local differentiation and regional integration is shown in several developments in the Late Archaic. Technologically, the Late Archaic period is marked by the arrival of the bow and arrow and continued high investment in plant processing technologies including stone bowls and mortars. The Late Archaic is also marked by an increase in sedentism, expanding diets, and the development of status differences demonstrated by the attainment of long-distance trade goods. The first evidence of fish and freshwater mussels is seen in this period, indicated by midden deposits built up over repeated reuse of house or village locations.

The continuity of such exchange into the historic period is apparent in the presence of exotic items in 19$^{th}$ century ethnographic collections from Grande Ronde. Items indicating long-distance exchange include a purse containing dentalium (tooth shells or tusk shells) from Vancouver Island, a decorated horn bowl from the Wasco Tribe near The Dalles, a horn spoon from Puget Sound, and a buffalo hide parfleche from east of the Cascades. Several items in the collections have oral histories that date them to before European colonization, suggesting that exchange networks remained robust into the 19th century.

#### *3.21.1.1.1 Ethnographic Summary*

The Willamette Basin at the time of Euroamerican contact (i.e., early 19th century), represented a culturally distinct region of several groups of peoples. These Willamette Basin groups were separated from the Chinookan peoples of the Lower Columbia River by the Willamette Falls. Willamette Basin groups identified themselves and related to each other according to kin affiliations, resource use, and other factors. Ethnographers commonly refer to Willamette Basin peoples in linguistic terms of either “Kalapuya” or “Molalla”-speaking.

#### *3.21.1.1.2 Kalapuya Ethnography*

The Kalapuya lived in a region of the Willamette Valley bounded on the west by the Coast Range, the south by the Calapooya Mountain range, the north by the falls of the Willamette River, and the east by the Cascade Mountains. The Yoncalla, the southernmost of the many Kalapuya tribes, lived on the south side of the Calapooya Mountain Range along Elk and Calapooya Creeks.

In the southern portion of the Willamette Valley, there is archaeological evidence that settlement patterns were dispersed and consisted of small family groups composed of one or more base camps to pursue seasonal resources. These base camps were located in different areas, and the Kalapuya groups moved between them as resources became available, primarily gathering and processing plant foods and hunting and processing mammals and birds. A similar pattern occurred in the northern Willamette Valley. Ethnographically, the Tualatin (another major Kalapuya Tribe) are reported to have lived in as many as 15 to 20 villages in the winter, mainly on the Tualatin Plains and in the Wapato Lake area.

Kalapuya people camped on the floodplains of rivers during the summer. The Santiam Kalapuya tale of Coyote Rose Hips corroborates this claim with a description of Coyote’s house by flowing water. Shelter was not taken except during inclement weather, in which case a temporary house of grass or brush over fir boughs was erected, or temporary huts of pine branches were built under oak trees as wind breaks.

Researchers estimate that between 3,000 and 16,200 Kalapuyan people lived in the region prior to contact with Euroamericans. Kalapuya numbers had diminished substantially before ethnographic documentation began, with mortality estimates as high as 95 percent between 1770 and 1840. There are several cultural groups who reportedly identified, or were identified, as Kalapuyan, and about whom some ethnographic information has been documented in written records. These include the Tualatin, Yamhill, Luckiamute, Santiam, Yonkalla, Mary’s River, McKenzie, and Calapooia.

According to sources from 1792 to 1830, there was a complex network of marriages, shared access to resources, and trade in the Greater Lower Columbia area that linked many cultural groups living along the coast (from the Makah to the Alsea) with the Tualatin Kalapuya. The Kalapuya participated in a trade network, exchanging fur, obsidian, bone, tools, shells, dentalium, and other materials and acted as brokers in the fur trade between Vancouver and the southern interior around the early 19th century. The Kalapuya were open to many cultural influences by means of trail systems, from peoples of the Cascade Mountains, and from peoples of the rivers extending from the coast and from northern California. Trade relationships existed between not only Kalapuyan subgroups, but Columbia River tribes, Molalla, Cayuse, northern California tribes, and coastal Oregon tribes based on the exchange of slaves and resources.

###### *3.21.1.1.3 Molalla Ethnography*

The cultural practices and patterns of the Kalapuya and Molalla were similar despite linguistic, geographic, and subsistence differences. There are fewer ethnographic and historical accounts that specifically address Molalla lifeways, traditions, and customs, however, leading to some generalizations between the two groups.

While the eastern foothills of the Coastal Mountains and the lower elevations of the Willamette Valley were inhabited by the Kalapuya, the western foothills of the Cascade Mountains along the Willamette Valley, as far west as the eastern side of the confluence of the Willamette and Columbia Rivers, were inhabited by the Molalla. Molalla territory (as a cultural group rather than a linguistic one) included the Oregon City Falls, Molalla River tributaries, and southwestern tributaries of the Clackamas River. The Molalla have been typically identified as Northern Molalla, who inhabited the Santiam and Willamette River west of Mt. Hood and lands to the north along the western and high lands of the Cascade Mountains, and Southern Molalla. The history and culture of the Southern Molalla is not well documented, except for a handful of post-contact accounts of Native peoples in the valley of the Willamette River’s Middle Fork tributary.

The Molalla were mobile in the summer and sedentary in the winter. The Molalla followed a seasonal round of hunting and gathering in the Cascades. The Molalla River Valley was an excellent area to gather berries and to hunt for elk, as implied by parsing of the word “Molalla” into “moolock” (elk) and “olille” (berries). Some temporary villages were located in the mountains approximately 30 miles east of Albuqua River and were most likely summer settlements. A group of 30 intermarried Klamath and Molalla families regularly inhabited the Cascade Mountains during the summer and the Willamette Valley during the winter. In the winter, the 30-family Klamath-Molalla group inhabited the Middle Fork area of the Willamette River near Butte Disappointment, just south of Fall Creek Lake, at a placed called “Demijohn’s Tower”. Once a landmark in the area, the steep slope of Demijohn’s Tower has since been impacted by the Fall Creek Dam construction, erosion, and commercial mining.

#### *3.21.1.2 Historic Background*

European epidemics among native populations in the Pacific Northwest preceded direct Euroamerican contact and caused drastic indigenous depopulation. Consequently, changes to sociopolitical alliances and territorial boundaries occurred as surviving populations adapted. European and Asian diseases such as smallpox reportedly affected Native American populations in the Northwest as early as 1782 and again in 1797, spreading inland from contact along waterways. Despite these diseases, a Native informant (of unrecorded origin) to Lewis and Clark reported in 1806 that the “Calloh-po-e-wah nation” was very numerous.

By the second decade of the 19th century, the quest for furs led explorers into the watershed of the Willamette River. In 1805 and 1806, Meriwether Lewis, William Clark, and the Corps of Discovery had examined the lower reaches of this stream. In 1811 with the establishment of John J. Astor's fur trading post at the mouth of the Columbia, the stage was set for more intensive land-based exploration and utilization of resources. Central Kalapuya peoples, including those along the Middle Fork of the Willamette River in the vicinity of present-day Eugene and the Fall Creek Lake area, first came into contact with Euroamericans in 1812. During the early 19th century, the trapping industry began to outcompete that of the Kalapuya along the tributaries of the Willamette River, impacting a portion of the Kalapuyan trade-based economy. This had the additional effect of depleting the beaver and game animal population, which greatly reduced Kalapuyan access to these resources.

By the mid-1820s, explorers and fur seekers began passing regularly through the Upper Willamette Valley. Between 1830 and 1831, Euroamerican-introduced “fever and ague” (most likely malaria) led to major population decreases among the indigenous populations in the Columbia Basin below Celilo Falls. It was estimated that 5,000-6,000 people surrounding the Willamette River died within two years (1830-1831) due to a combination of malaria, venereal diseases, wet weather exposure, and starvation, and that the populations continued to halve every two to three years for about a decade, leaving 600 Kalapuya remaining in 1841. Census information indicates that 300 people remained of the indigenous population in the Willamette River valley in 1844, and only a small number of Kalapuya were among them.

By the 1840s, a number of factors drew Euroamerican settlers to Oregon Territory. The promise of abundant and possibly free land, an escape from debt and the depression following the Panic of 1837, the allure of a healthy climate and adventure, the promotion of publicists, and the challenge of making Oregon an American possession all beckoned to those who were willing to migrate westward. Thousands did, and by 1846 they began settling in the Upper Willamette Valley. Within a period of six years, through the Donation Land Act of 1850, mostly white families had taken up claims throughout the region. The arrival of the claimants not only dislocated many Native peoples from their lands but also led to severe depletion of the resources traditionally sustaining them by means of fire suppression, overhunting, overgrazing, and water pollution that impacted fish runs. The expansion of non-Native communities into indigenous territories ultimately led to conflict for land, resources, and the right of indigenous communities to exist in the Willamette Valley.

Multiple treaties drafted in the 1850s, by Oregon Territory and Bureau of Indian Affairs officials stated that the U.S. government would provide for reservations within the homelands of the Kalapuya and Molalla if they ceded large tracts of their territories, and that rights would be reserved to these groups for subsistence at their usual and accustomed places. However, these treaties were unratified. Eventually, treaties ratified in 1855 extinguished Kalapuya and Molalla title to their lands for a much smaller reservation of land and required them to relocate to the Grand Ronde Reservation. In 1856, the push was made for all Willamette Valley tribes to move to the Grand Ronde or Oregon Coast (or Siletz) reservations. The majority of Kalapuya and Molalla people ended up at the Grand Ronde Reservation, however, individuals, families or small groups incorporated into the Klamath or Warm Springs reservations. Some people chose to remain in their homelands, and as a result, they faced harassment from government agents who had been charged with the task of ensuring the removal of all Native peoples in order to "open up" the land for settlement. For example, the Calapooian chief "Cam-a-phee-ma" and his family refused to leave their homeland in the Yonkalla territory despite being threatened with death by a government agent.

In 1862, the Homestead Act allowed more settlers to obtain as much as 160 acres of public domain by proving up on a claim. Eugene, Springfield, and Cottage Grove emerged as the important larger towns in the 19th century. The building of the Oregon and California Railroad through the Upper Willamette Valley in the 1870s contributed to the development of additional townsites at Goshen, Creswell, Latham, and Divide. The growth of towns, as well as the increasing number of post office stations in this region, reflected the swelling non-native population which continued to push deeper into the more rugged portions of the Upper Willamette River valleys.

The United States Bureau of the Census of 1900 recorded only one Native American family in the Middle Fork region; however, many indigenous people who remained in the Willamette Valley kept a low profile by not reporting for census counts or blending into mostly white communities. Members of the Warm Springs Reservation reportedly visited the area annually (up until the second decade of the 20th century) to pick hops on lands owned by A.D. Hyland at the city of Lowell. Warm Springs Reservation members also continued to visit the area to fish for salmon, pick huckleberries, and hunt, returning to the reservation in early fall with dried and fresh fruit, clothing, and salmon. Henry Yelcus, who was reportedly the last Molalla person to continue living in the Molalla-Dickey Prairie remained until his passing in 1913.

While the Willamette River waterways became heavily populated, for years the forests had discouraged non-Native settlement or had served as obstacles to those who sought to turn these lands into agricultural areas. The availability of a transportation system in the last decades of the 19th century changed this, and within a short period sawmill operations became important sites of industry and employment. Lumber production mounted steadily in Lane County from 774,000 board feet in 1865 to 10.5 million board feet in 1895. While many small sawmills were set up along the rivers and in rural areas, by 1900 major timber companies began combined logging and lumbering enterprises. The timber business continued to grow through the first seven decades of the 20th century. From the 1920s into the 1960s, many small operators cut trees and produced lumber for the booming market along the Pacific Slope. In the 1960s and following, however, the small operators were shoved aside, and the large corporations emerged to dominate the business. Increasingly these firms were dependent upon the purchase of BLM and U.S. Forest Service logs through federal timber sales.

*3.21.1.2.1 Federal Government Actions*

From initial exploration efforts in 1841 to a series of ventures in the 1850s, the America government was important in developing information about the resources and potentials of the region. Of singular importance were the land grants to the Oregon Central Military Wagon Road and the Oregon and California Railroad. These actions of Congress in the 1860s spurred the development of key transportation routes or systems which linked the Upper Willamette to larger markets and influences.

The revestment (return of land to the government) of the Oregon and California Railroad (O&C) grant lands in 1916 and the creation of the Cascade National Forest – later the Willamette National Forest — were important actions prior to World War I that put the government into extensive land management in the watershed of the Upper Willamette River. Eventually, following World War II, the functions of the General Land Office were broadened under the new Bureau of Land Management, and specific policies of timber harvest and sales from O&C and other public lands assumed increasing importance in the region's economy. Of similar importance were the actions of USACE to work with local industry to provide for flood control in a series of reservoirs and for hydroelectric power generation throughout the Willamette Valley, built between 1940 and 1969. This was part of a national trend where the Corps oversaw hundreds of civil works projects throughout the United States.

*3.21.1.2.2 The Portland District and Willamette Valley Project*

In 1871, the Corps established the Portland District to ensure management and control of the Columbia and Willamette Rivers as navigable waterways. In the later 1800s and into the early 1900s, the Portland District focused much energy to “improve” waterways of the region. By 1876, river traffic had increased substantially along the Columbia and Willamette Rivers. By the 1880s, the Corps had also built civil works projects on the Oregon Coast. In 1896, the Corps constructed the first canal project on the Columbia (the Cascade Locks and Canal), and between 1905 and 1915, the Corps completed The Dalles-Celilo Canal. Local efforts also resulted in several private water resource projects including the building of the Willamette Falls Locks, in 1873, which the Portland General Electric Company (formerly known as the Willamette Falls Canal and Locks Company) later sold to the Corps in 1915. Many of these efforts inundated, destroyed, or cut off access to places and resources integral to the Native American economy of the Pacific Northwest including several notable points along the rivers where large gatherings had occurred for centuries and where sizeable fish runs had sustained local populations.

A prime example of this is located at the northern extent of the area of analysis. Willamette Falls, at River Mile 26.5, has been an important meeting place for generations of Native Americans throughout the Pacific Northwest. According to recent radiocarbon dating of archaeological components at the falls this legacy is at least 1400 years old, but likely extends back several millennia. The location is now fully ensconced within the city limits of Oregon City, at the southern end of the large population that surrounds the Portland Metro area. Despite this heavy industrialization of the area, it continues to be an important fishing locale for several federally recognized tribes throughout Oregon and Washington including the Confederated Tribes of Grand Ronde, the Confederated Tribes of Warm Springs, the Confederated Tribes of the Umatilla Indian Reservation, the Confederated Tribes of Siletz Indians, and the Confederated Tribes and Bands of the Yakama Nation.

This customary use of the falls continues even though Euroamericans laid claim to the area as early as 1828, starting with John McLoughlin of the Hudson Bay Company, with later capital ventures to industrialize the area (with grist, woolen, saw, and paper mills), and to facilitate navigation with the installation of the locks. As recently as 2011, the Blue Heron Paper Mill operated near the falls but was ultimately demolished in 2021. The Willamette Falls Locks was listed in the National Register of Historic Places in 1974 but has been non-operational since 2011. The complex multicomponent landscape that surrounds and includes Willamette Falls is composed of archaeological sites and built resources including urban sprawl of historic Oregon City.

By the 1920s, state and local entities attempted to initiate programs to promote the further development of navigation and flood control on the Columbia River. The Columbia Valley Association, a private organization that advocated for development in the Columbia River Basin, held meetings with business groups and other organizations to promote improvement projects. A similar group, the Willamette Valley Association, was founded in 1933. Much like the Columbia Valley Association, this organization spearheaded multiple efforts to attain federal support for improvements to the Valley's waterways. The seemingly rampant floods that struck in Oregon and across the nation in the 1920s and 1930s helped to inspire Congress to pass the Flood Control Act of 1936, a milestone in federal water resources policy. The Act was monumental in that it made flood control a priority of the Corps. In terms of the WVS, the Act became the basis for the Corps to plan, design, and ultimately construct the first dams of the Willamette Valley. As discussed in Section 1.5, the Corps constructed 13 dams and reservoirs between 1940 and 1969 through the Flood Control Act of 1938, 1948, 1950, 1954, and 1960 (Table 3.21-1).

**Table 3.21-1. Contributing Resources of the WVS Historic District**

| Project | Dates of Construction | Authorizing Flood Control Act |
|---|---|---|
| Fern Ridge | 1940-1941 | Flood Control Act of 1938 |
| Cottage Grove | 1940-1942 | Flood Control Act of 1938 |
| Dorena | 1940-1949 | Flood Control Act of 1938 |
| Big Cliff | 1949-1953 | Flood Control Act of 1948 |
| Detroit | 1948-1953 | Flood Control Act of 1938 |
| Dexter | 1953-1954 | Flood Control Act of 1950 |
| Lookout Point | 1947-1955 | Flood Control Act of 1938 |

| Project | Dates of Construction | Authorizing Flood Control Act |
|---|---|---|
| Hills Creek | 1956-1962 | Flood Control Act of 1950 |
| Cougar | 1956-1964 | Flood Control Act of 1950 |
| Fall Creek | 1961-1965 | Flood Control Act of 1950 |
| Green Peter | 1963-1967 | Flood Control Act of 1954 |
| Foster | 1964-1968 | Flood Control Act of 1960 |
| Blue River | 1963-1969 | Flood Control Act of 1950 |

*3.21.1.2.3 Documented Cultural Resources in the Area of Analysis*

The deep history of human habitation of the Willamette Valley has left tangible markers on the landscape now managed by the Corps. There are 461 documented pre-contact, historic, and multi-component archaeological resources within or intersecting with the footprint of the 13 individual WVS projects. These resources range in age from the earliest documented Paleo-Indian Period projectile points to very recent dam construction work areas of the mid-20th century, circa 1941-1972 A.D. (**Error! Reference source not found.**). Archaeological resource types include isolated artifacts and features, diagnostic task sites, non-diagnostic debris sites, one historic cemetery, residential sites, transportation/travel corridors, townsites, rock features, rockshelters, lithic scatters, etc. Portions of the WVS built environment are also eligible for National Register of Historic Places (NRHP) listing and consists of 13 historic districts with 89 contributing resources that were constructed between 1941 and 1972 (**Error! Reference source not found.**2).

**Table 3.21-2. Archaeological Resources in the WVS by Project**

| Project Name | Archaeological Resources | Contributing Resources in WVS Historic Districts |
|---|---|---|
| Big Cliff | 2 | 3 |
| Blue River | 12 | 4 |
| Cottage Grove | 24 | 6 |
| Cougar | 31 | 6 |
| Detroit | 31 | 4 |
| Dexter | 12 | 5 |
| Dorena | 14 | 6 |
| Fall Creek | 55 | 3 |
| Fern Ridge | 181 | 23* |
| Foster | 38 | 10 |
| Green Peter | 20 | 9 |
| Hills Creek | 4 | 4 |
| Lookout Point | 37 | 6 |
| Total | 461 | 89 |

*Includes the Lower Long Tom Constructed Channel

The WVS is locally significant (as the term is defined in the NHPA) and eligible for listing in the NRHP as 13 historic districts due to its impact on the development of the Willamette Valley Basin in Lane, Linn, Marion, and Benton counties between 1940 and 1972 (known as the Period of Significance, or POS). During this time, construction of the dams, reservoirs, appurtenant infrastructure, fish passage systems and hatcheries, as well as recreation sites of the WVS had major influences on the Willamette Valley through implementing a flood control mission that changed the way people settled the landscape, earned a living, accessed river resources, and recreated in the Willamette Valley. The construction of a series of large-scale infrastructure projects mobilized the local workforce, providing job opportunities and civil pride in American ingenuity and engineering feats. These projects developed recreational opportunities and related commerce throughout the Valley, instilled in the public that reservoirs and dams are places to recreate, developed and provided hydropower, and impacted native fish runs and the human response to address these impacts. It also applied innovative engineering (research and design, or R&D) to facilitate anadromous fish passage through the WVS and to boost local fish populations through hatchery programs. **Error! Reference source not found.**3 provides the types and count of contributing resources of the WVS historic districts that retain integrity, can be dated to the POS, and are directly associated with the historic themes that make the WVS historically significant to history of the Willamette River Basin.

**Table 3.21-3. Contributing Resources of the WVS Historic Districts**

| Resource Type | Contributing Resources | Notes |
|---|---|---|
| Dam | 13 | All dams are contributing |
| Powerhouse | 8 | All powerhouses, except Dexter, are contributing |
| Reservoir | 13 | All reservoirs are contributing |
| Stilling Basin | 1 | Foster |
| Ancillary Dikes/Levees | 2 | Fern Ridge |
| Saddle Dam | 1 | Blue River |
| Engineering Project Office | 3 | Cougar, Dorena, and Hills Creek |
| Caretaker's Facility | 2 | Fern Ridge and Foster |
| Garages | 2 | Fern Ridge and Foster |
| Fish Passage Facilities | 4 | Dexter, Foster, and Green Peter |
| Recreation Areas | 30 | All projects, except Big Cliff, Dexter, and Hills Creek |
| Channel/Drop Structures | 10 | Lower Long Tom Constructed Channel (part of Fern Ridge Project) |

To date, there are no identified TCPs or HPRSCITs documented in the 13 project areas. However, given that Kalapuya and Molalla peoples have inhabited the WRB for millennia, there are likely many.

As discussed in Section 1.6, the Corps has a structural footprint, with historic-age components, that extends beyond the WVS with the Willamette River Basin Bank Protection Program (WRBBPP), the Willamette Hatchery Mitigation Program, Fish Mitigation program, and the Research, Research, Monitoring, and Evaluation (RM&E) program. The WRBBPP program constructed 223 flood control structures in the WRB, of which 193 are still active and are at least 50 years of age. These resources have not been evaluated for listing in the NRHP. Associated with the remaining programs, downstream of the dams, the Corps constructed and operates five adult fish collection facilities and funds the operations and maintenance of five hatcheries that are downstream from the WVS dams, as listed in Table 3.21-4. All of the collection facilities and hatcheries have components that are at least 50 years of age, though the majority have been majorly modified or upgraded with new facilities to support fish populations in the WRB. For any actions that require modification to the built environment that support these Corps programs, an inventory and evaluation would be required to determine if the infrastructure or components are eligible for listing in the NRHP.

**Table 3.21-4. Corps-constructed Fish Hatcheries**

| Hatchery Name | Year Completed | Notes |
|---|---|---|
| Dexter Holding Ponds* | 1954 | Located at Dexter Dam; Mitigation for Dexter; now part of Willamette Hatchery |
| Leaburg Fish Hatchery | 1953 | 18.5 miles west of Cougar Dam; Mitigation for Blue River and Cougar |
| McKenzie | 1938, 1975 | Rebuilt in 1975; Mitigation for Blue River and Cougar |
| Marion Forks | 1951 | 17.5 miles southeast of Detroit Dam; Updated in 1986 and 2013; Mitigation for Detroit and Big Cliff |
| Minto Fish Facility | 1953, 2013 | 3.8 miles west of Big Cliff Dam; Rebuilt 2013; mitigation for Detroit and Big Cliff |
| Oakridge Salmon Hatchery | 1911, 1952 | 2.65 miles north of Hills Creek Dam; Rebuilt in 1952; mitigation for Hills Creek, Lookout Point, and Dexter; now part of Willamette Hatchery |
| South Santiam* | 1968 | Located at Foster Dam; Mitigation for Green Peter and Foster |
| Willamette Trout Hatchery | 1922, 1950s | 2.65 miles north of Hills Creek Dam; Rebuilt in the 1950-56; now part of Willamette Hatchery |

### 3.21.2 Environmental Consequences

This section discusses the potential effects of the alternatives on cultural resources in the WVS within the life of the project (30 years).

#### *3.21.2.1 Methodology*

The methodology used to determine potential effects to cultural resources and the nature of those effects are discussed below by resource type including archaeological sites, built resources, and traditional cultural properties. In the WVS, archaeological sites are most vulnerable to surface exposure and erosion that destroy the physical integrity of the site and expose artifacts to humans who may illicitly collect artifacts or vandalize sites, while built resources are most vulnerable to physical modifications that change aspects of contributing elements that are part of its historic fabric and make it eligible for listing in the National Register of Historic Places. The condition of traditional cultural properties are negatively affected when the people who value those places have reduced access to the location or resources or are affected by unappealing aesthetic at the location due to modification.

The cultural resources effects analysis relies heavily on qualitative discussion of how a proposed action would directly impact a resource type (e.g., erosion, exposure, modification, etc.) because the Corps does not collect quantitative data that would allow for measurable changes in cultural resources condition such as annual rates of erosion or actual days of exposure for archaeological sites or a presence-absence or wellness indicator for resources that should be present at traditional cultural properties. Once the understanding of how an action would affect a resource type is documented, however, it is possible to quantify the number of cultural resources that would be directly exposed to that action, and then compare the total number and types of resources impacted by alternatives. In the case of archaeological resources, once the count and acreage of sites that would be impacted by an action is tabulated, it is possible to use GIS and ResSim outputs to model a baseline of impact as a result of exposure (due to operations and measures in the No Action Alternative) and then compare how effects from actions that cause site exposure would vary across alternatives.

All of the alternatives propose operational measures (as opposed to structural measures) that are large in scale and would continuously and directly affect a large number of cultural resources, most notably several hundred archaeological sites, throughout an entire reservoir and across several reservoir projects throughout the duration of the proposed period of analysis (life of the project, 30 years). Impacts from operational measures to archaeological sites would be permanent, however, and therefore extend well beyond 30 years. Due to the longevity and widescale nature of these operational measures and the overarching WVS flood risk management mission, which requires actions that affect large numbers of documented archaeological sites, the evaluation criteria to assess potential effects to cultural resources is best understood on a holistic level. The criteria that would evaluate the potential impacts of each alternative address effects at the population level that are categorized as Negligible, Minor, Moderate, and Major as shown in Table 3.21-5.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.21-5. Evaluation Criteria for Potential Effects to WVS Cultural Resources**

| Effect Scale | Criteria |
|---|---|
| Negligible | Changes, whether adverse or beneficial, occur to zero or a limited number of cultural resources and is a limited proportion of all known cultural resources by reservoir project (<1%). The impact to the known cultural resources in the WVS is negligible, and the effects are not demonstrable at the local, project-specific, or system level. These impacts would be short-term and reversible or result in no change to current conditions. |
| Minor | Changes, whether adverse or beneficial, occur to a small number of cultural resources and is a small proportion of all known cultural resources by reservoir project (1.1-5%). The impact to the known cultural resources in the WVS is minor, and the effects are demonstrable only at the local or project-specific level. These impacts would be short-term, or if longer-term, easily reversible. |
| Moderate | Changes, whether adverse or beneficial, occur to many cultural resources and is a greater proportion of all known cultural resources by reservoir project (5.1-10%). The impact to the known cultural resources in the WVS is moderate, and the effects are demonstrable at the local, project-specific, and system level. These impacts would be long-term but potentially reversible. |
| Major | Changes, whether adverse or beneficial, occur to a high proportion of all known cultural resources by reservoir project (>10%). The impact to the known cultural resources in the WVS is major, and the effects are demonstrable at the local, project-specific, and system level. If adverse, these impacts would be permanent and irreversible. In the case of built resources, the changes would be long-term but could be reversible, but would require much effort to revert to prior conditions. If beneficial, the change would result in rehabilitation to original conditions or stabilization that stops future degradation to the resource. |

#### *3.21.2.1.1 Archaeological Sites*

The range of alternatives have the potential to effect archaeological sites through actions that cause erosion and exposure. Erosion is directly caused by measures that result in reservoir elevation change, most notably reservoir draft and fill cycles that are routine in flood risk management systems. During draft and fill cycles, archaeological sites that are located within three feet of the drawdown elevation (either above or below the elevation line) are exposed to wind and resulting wave action that cut into soils and disturb archaeological materials contained in the soils. Reservoir soils are routinely desaturated and then inundated, and as a result do not have much if any stabilizing vegetation cover. These unprotected soils are susceptible to splash erosion (when raindrops impact bare soil, soil surface sealing develops and water does not infiltrate the soil, and soil particles break off from soil aggregate and are displaced) and sheet erosion (water runoff removes thin layers of fine particle soil) from rainfall and water runoff. Exposed reservoir beds, particularly on slopes or where there is uneven and linear down sloping topography, are susceptible to rill erosion (when water runoff forms small channels as it moves downslope) and gully erosion (water runoff forms deep channels through soil). When exposed, tributaries that flow into the main river channel would also downcut soils along the water path further increasing unstable and deeply furrowed channels. Mass wasting events (e.g., landslides, rockfalls, soil creep) or the process of bank or terrace erosion also occur along the shores of reservoirs or within the reservoir where other forms of erosion have made landforms vulnerable to undercutting and slumpage. All types of erosion in reservoirs are related to continual exposure of non-vegetated soils to wind and water movement as well as repeated changes to overall environment, through draft and fill cycles. When drafting is accelerated over the threshold of 3 ft/day, through a deep drawdown, the reservoir beds remain saturated and do not have time to fully drain and stabilize resulting in episodic slope failure throughout the reservoir.

Routine changes in reservoir elevation result in sediment movement, particle sorting, and removal of fine grade sediments that slowly deflate archaeological sites and expose archaeological materials to the surface of the reservoir beds. This action not only erodes and further damages the physical integrity of archaeological sites, but it also exposes resources that are typically covered by water and the sites become vulnerable to human-induced effects. These include unauthorized artifact collection, knowingly or unknowingly digging into and damaging the physical integrity of archaeological sites, and side effects of unauthorized recreation (e.g., driving vehicles, rockhounding, or metal detecting in the reservoirs).

Cyclical, continual, and frequent erosion and exposure have lasting and irreversible effects to archaeological sites that cannot be fixed or rehabilitated. The best case scenario for archaeological resources is to reduce or stop actions that actively degrade physical integrity to either slow the pace of effects or stabilize the site in its current condition. The draft and fill cycle that occurs each water year has annual effects to archaeological sites, but also build off of several decades of incremental site degradation resulting in major loss to site integrity. The Corps has not actively studied rates of site erosion or exposure in the WVS, but recent subsurface evaluations of archaeological resources and a steady program of site condition assessments, in 2020-2021, have identified noticeable degradation of archaeological resource due to active erosion and human-induced impacts (mostly unauthorized surface collection of archaeological artifacts). With this in mind, discussion of erosion and exposure levels is weighted toward qualitative assessment of the potential effects the alternatives may have on cultural resources though quantitative assessments are used when possible.

The proposed measures that would affect archaeological sites are categorized by whether they result in a reservoir elevation change that would cause erosion and exposure and if they would result in a deep drawdown that would greatly increase the rate of erosion by quickly exposing soils that are not adequately desaturated at the threshold drafting rate of 3 ft/day (see Table 3.21-6).

**Table 3.21-6. Measures that Would Cause Adverse Effects to Archaeological Sites**

| Measure Number | Measure Description | Reservoir Elevation Change? | Deep Drawdown? | Notes |
|---|---|---|---|---|
| 721 | Use spillway for surface spill in summer | Yes | No | Assumes water levels higher than spillway crest to implement |
| 30a | Integrated temperature and habitat flow regime | Yes | No | Flows (and elevations) are based on fullness of reservoir on June 01. |
| 30b | Refined Integrated temperature and habitat flow regime | Yes | No | |
| 304 | Augment instream flows by using the power pool | Yes | No | Can draft to minimum power pool |
| 718 | Augment instream flows by using the inactive pool | Yes | No | Can draft to 10 feet above regulating outlets |
| 723 | Reduce minimum flows to Congressionally authorized minimum flow requirements | See Notes | No | Reduction in flows would support ability to maintain the rule curve, more stable elevation changes |
| 40 | Deeper fall reservoir drawdowns for fish passage | Yes | Yes | Target elevation 25 feet above regulating outlets |
| 714 | Pass water over spillway in spring for fish passage | Yes | No | All flows to go over the spillway when greater than 25 feet over the spillway |
| 720 | Spring reservoir drawdown to regulating outlet (to Diversion Tunnel at Cougar in Alts 2B and 3B) | Yes | Yes | Target elevation 25 feet above regulating outlets |

Deeper fall reservoir drawdowns (#40) and spring reservoir drawdowns (#720) for downstream fish passage drive noticeable increases in erosion and exposure, by drafting deeply and quickly to lower regulating outlets, extending the length of reservoir bed exposure outside of storage season, accelerated erosion due to oversaturated unstable topography, and increasing the number of draft and fill cycles that occur in one water year. Other operational measures that focus on water quality and flow, including using the spillway for summer surface spill (#721), the integrated temperature and habitat flow regime (#30a), augmenting instream flows by using the power pool (#304), augmenting instream flows by using the inactive pool (#718), and reducing minimum flows to Congressionally authorized minimum flows (#723); and operational measures that focus on downstream fish passage, including spring spillway fish passage (#714), do result in elevation changes, but these are much less drastic.

To understand the magnitude of potential effects to archaeological resources, the amount and frequency of erosion or exposure that occur in a water year should be modeled if they cannot be analyzed through direct observation. For the PEIS, it was possible to model the extent of exposure of inundated archaeological resources to compare effects of different alternatives. The analysis required two variables. First is the time period of exposure, or the number of days that a portion of the reservoir would be exposed. Second is the area of the archaeological resources. Archaeological resources can vary in size greatly, from isolated features covering just a few feet to large linear features that stretch for miles.

One way to combine these two variables (time and area) for comparison purposes is to multiply the acreage of archaeological resources in a reservoir by the number days that those acres would be exposed – in other words, an “acre-day” over the course of one water year. A single “acre-day” is the amount of exposure created when an archaeological site covering 1 acre is exposed for 1 day. In the same way, a half-acre site exposed for 2 days would also be 1 acre-day of exposure. Ten acres of archaeological site exposed for 10 days would be 100 acre-days, and so on. Archaeological resources defined as isolates or isolated finds, which are represented by point data and do not have a calculated acreage (because they cover such a small area), were not used in the analysis.

The data used to support this analysis comes from two sources. First, the information about the amount of time that particular areas would be exposed come from the reservoir operations modeling described in Section 3.2 of this EIS. See Section 3.2, Hydrologic Processes, for more details. The second part of this analysis comes from archaeological research in the reservoirs. Archaeologists have completed some inventory of the archaeological resources around and within the reservoirs. The boundaries of the archaeological resources have been recorded and converted into polygons using GIS, and these features have calculated acreage (with the exception of isolates/isolated finds). This data, combined with bathymetric information from the reservoirs, allows one to determine which sites are going to be exposed when a reservoir reaches a particular elevation. It also allows for determination of how many acres of archaeological resources are going to be exposed at a given elevation. For this analysis, the polygon site data was changed from differentially-sized vector data that did not have corresponding elevation data to equally-spaced raster point site data, each measuring 0.0032 acres in size and then paired with reservoir bathymetry from digital elevation models (DEMs) to associate each site point with a given elevation. This effort resulted in the ability to conduct fine scale tabulation of <1 acre of site by elevation and fully use the varying elevation within the area of the original polygon. This reduced overcounting or undercounting that would have occurred in the area of the original polygons if it was not partitioned and had to have an averaged elevation.

The site raster point data allowed for a summation of <1 acres of archaeological resources at a given elevation at each reservoir. Then a Microsoft Excel function was used to count all points below a given elevation, in 1-foot increments, between the maximum conservation elevation and the minimum operating elevation for each reservoir. These counts were normalized to capture site data that ranged within these maximum and minimum elevation parameters. Once counts within the appropriate range were derived, they were applied to the median daily elevations known for the EIS period of record. These outputs from ResSim include reservoir elevations spanning October 1, 1935, to September 30, 2019, and provide a timeseries with a length of a single year of exposed acres on each individual day. This information regarding acreage within each elevation interval was multiplied by the number of days that each interval would be exposed to compile acre-day measurements for each of the reservoirs. The acre-day was then calculated for each alternative at each reservoir. The difference between each action alternative and the no action alternative was also calculated at each reservoir (shown in percentage).

The analysis is only as reliable as the information that is available regarding archaeological resource locations, elevations, and boundaries. Archaeological inventory of the 13 reservoirs is incomplete, and there is differential coverage of each reservoir. The irregular coverage is largely because archaeological inventory was not completed prior to reservoir filling, and the deeper parts of the reservoirs are exposed only rarely. Project parameters also guide where archaeological surveys occur. The GIS data used here is the best available record of archaeological resources present in the WVS reservoirs. Examination of the area of recorded archaeological resources by elevational interval at each of the analyzed reservoirs shows that a greater area of archaeological sites has been recorded in littoral zone (shoreline) of the reservoirs. This pattern does not reflect precontact or historical settlement practices—it reflects the areas of the reservoirs that are easiest to access and where projects typically occur (e.g. recreation sites or operational zones).

A related concern is reliability and consistency of the bathymetric data, which came from two sources: the Corps and State of Oregon's Department of Geology and Mineral Industries (DOGAMI) Lidar dataset. Some Corps bathymetry data is more than 50 years old and based on original land surveys conducted as part of mapping each project area for eventual reservoir construction and infill. Other Corps bathymetry data is derived from aerial imagery (drone flights and fixed-wing planes, each capable of carrying different types of sensors, which in turn have varying sensitivities to collect elevation data) or hydrographic surveys that collect elevation data from multi-beam sonar soundings. DOGAMI's data was derived from aerial imagery, and many times flown while the reservoirs were at high pool, which captures water surface elevation rather than reservoir contours. Data derived from multiple sources can have varying contour ranges as well as different accuracy as to how the elevation for a given location was derived. For this analysis, the DEMs were patched together to create a mosaic that covers the 13 WVS project areas. As much as possible, elevations were checked against expected elevations of the maximum and minimum reservoir pools and anticipated elevations of documented archaeological sites.

Climate change that results in increased global temperatures and winter rains would exacerbate adverse effects to archaeological sites located in the reservoirs. The resources that are within the rule curve would continue to experience cycles of draft and fill that would inhibit landform stabilization. In the summer and fall months, hotter temperatures and less water would result in lower pool elevations that would increase the exposure of higher elevation sites for longer periods of time. These resources would also be impacted by another erosional drafting event. In the winter, when reservoir elevations are at their lowest, increased rains would continue to erode the bare reservoir surfaces until reservoir fill occurs in the following water year. The amount of time that archaeological sites are exposed to human-induced impacts would also increase. In general, climate change within the flood risk management system would exacerbate erosion and exposure processes that adversely affect archaeological site integrity.

Any measures that require construction or modification of infrastructure have the potential to cause direct effects to archaeological sites through ground disturbance and staging of equipment or short-term reservoir elevation changes that would cause erosion and exposure, however, the Draft PEIS will discuss general qualitative effects from construction at the programmatic level. Site specific effects would need to be considered during any tiered NEPA analysis and resultant design planning (see Built resources discussion below). Measure 384, which includes gravel augmentation, would require screening prior to implementing the action to ensure that gravels are not being taken from or depositing on archaeological sites present in the WVS.

Some measures would not cause effects to archaeological sites (Table 3.21-7).

**Table 3.21-7. Measures that Would Have No/Negligible Effect to Archaeological Sites**

| Measure Number | Measure Description |
|---|---|
| 166 | Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams |
| 174 | Structural improvements to reduce total dissolved gas |
| 479 | Foster fish ladder temperature improvement |
| 719 | Adapt hatchery program |

##### *3.21.2.1.2 Built Resources*

Several structural measures are proposed that have the potential to affect the built environment of the 13 historic districts in the WVS. These include small and large modifications to existing infrastructure to constructing new buildings and facilities to support upstream and downstream fish passage. When assessing potential effects to built resources, the permanence of the action must be considered as well as if the changes would occur to resources contributing to historic districts and overall effect to the historic fabric of the district itself. For the purposes of this analysis, impacts to the built environment are organized as to how localized and reversible the change would be. Negligible or minor effects would occur to a resource type (e.g., dam, reservoir, recreation areas, drop structures), but the changes would be limited to small or internal components or aspects of the contributing resource that can be hidden or are generally not noticeable when viewing the resource types listed in Table 3.21-2. The effects would also be easily reversed or changed and not result in a noticeable permanent modification to the historic district (e.g., changing the trajectory of a pipe or replacing a mechanism within a panel). A moderate effect would include impacts to a contributing resource type that are noticeable upon visual inspection of it or the historic district. These changes, however, would maintain the overall aesthetic and integrity of the historic district and not introduce incongruous components. These effects would be reversable but may be present for some or all of the period of analysis. A major effect would result in a substantial addition of infrastructure to a historic district or an action that results in changes to a resource type that causes it to lose integrity by removing or changing characteristics that make it a contributing resource type to the WVS historic districts. These changes would be long-term (throughout the period of analysis), difficult to reverse, or permanent.

With the implementation of any structural measures, it is known that the actions would have an effect on the built environment, but to what level this would occur would not be fully understood until an alternative is selected, and the design phase begins. Site-specific project details for each construction measure will be determined during the preconstruction engineering and design phase. While general, qualitative effects from construction are discussed below on a programmatic level, the more detailed, site-specific analysis will be included in the tiered EA or EIS. Table 3.21-8 lists proposed measures that would have an effect on the built environment and a range of proposed levels of effect given what is currently known about the measures. A revetment measure is included in this list, but there is a high level of uncertainty as to what level of effect may occur because the revetments have not been inventoried as part of a cultural resources survey.

**Table 3.21-8. Measures that Would Result in Changes to Built Resources and Potential Level of Adverse Effect***

| Measure Number | Measure Description | Anticipated Changes to the Built Environment | Level of Adverse Effect |
|---|---|---|---|
| 105 | Construct water temperature control tower | Effects to resource type, effects to aesthetic of a historic district | Moderate to Major |
| 174 | Structural improvements to reduce TDG | Effects to internal or minor components/aspects | Negligible to Minor |
| 479 | Foster fish ladder improvement | Effects to internal or minor components/aspects | Negligible to Minor; Moderate to Major |
| 392 | Construct structural downstream fish passage | Effects to resource type, effects to aesthetic of a historic district | Moderate to Major |
| 52 | Provide Pacific lamprey passage and infrastructure | Effects to resource type, effects to aesthetic of a historic district | Moderate to Major |

| Measure Number | Measure Description | Anticipated Changes to the Built Environment | Level of Adverse Effect |
|---|---|---|---|
| 639 | Restore upstream and downstream passage at drop structures | Effects to resource type, effects to aesthetic of a historic district | Moderate to Major |
| 722 | Construct adult fish facility | Effects to resource type, effects to aesthetic of a historic district | Moderate to Major |
| 726 | Maintenance of existing and new fish release sites above dams | Effects to resource type, effects to aesthetic of a historic district | Minor to Moderate |
| 9 | Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration | Outside of the 13 historic districts, but historic in age, requires inventory and evaluation | Unknown |

*Some alternatives consider modification of Cougar Diversion Tunnel, which is a contributing resources type to the Cougar Project Historic District.

Several measures are operational in nature and would not have an effect on built resources (Table 3.21-9).

**Table 3.21-9. Measures that Would Have No Effect to Built Resources**

| Measure | Measure Name |
|---|---|
| 166 | Use regulating outlets to discharge cold water during drawdown operations in fall and winter to reduce water temperatures below dams |
| 721 | Use spillway for surface spill in summer |
| 30a | Integrated temperature and habitat flow regime |
| 30b | Refined integrated temperature and habitat flow regime |
| 304 | Augment instream flows by using the power pool |
| 718 | Augment instream flows by using inactive pool |
| 723 | Reduce minimum flows to Congressionally authorized minimum flow targets |
| 40 | Deeper fall reservoir drawdowns for fish passage |
| 714 | Pass water over spillway in spring for fish passage |
| 719 | Adapt hatchery program |

#### *3.21.2.2.3 Traditional Cultural Properties*

TCPs or HPRCSITs are not well documented in the WVS. The USACE has not undertaken adequate surveys to identify specific locations and currently there are no TCPs or HPRCSITs recorded within the WVS. Given the long history of Kalapuya and Molalla people inhabiting the WRB it is anticipated that there are many places in the WVS that are culturally important to local tribes. The tribes have diverse and substantial interests in the health and wellbeing of the WVS and maintain strong connections to the landscape and resources currently managed by the Corps. This includes all facets of natural and cultural resources. For physical locations, where animals, plants, water, and cultural resources are present, it is reasonable to assume that actions that improve habitat and water quality are beneficial to TCPs and HPRSCITs. Those same actions may erode or expose archaeological resources resulting in an adverse effect to this particular characteristic of a TCP and HPRSCIT. Due to these major data gaps, it is beyond the scope of this analysis to consider the tradeoffs that impact this category of resource and to assess effects.

#### *3.21.2.2 Effects to Cultural Resources Across Alternatives*

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

##### *3.21.2.2.1 Archaeological Sites*

All of the alternatives would have major adverse effects to cultural resources. This is mainly due to the high number of archaeological resources present in or adjacent to the reservoirs that would be exposed to the annual draft and fill cycle that occurs at the WVS. This draft and fill cycle has occurred for much of the 50 to 80-year existence of the dams and reservoirs, and the effects of the annual cycle of draft and fill has resulted in smaller seasonal impacts that have incrementally built upon the damage of prior years and irreversibly impacted the integrity of archaeological sites that are present in the reservoir. Of the 461 documented archaeological resources, 369 (80%) would be impacted by this draft and fill cycle. This adverse, long-term, and irreversible effect to archaeological resources is considered the baseline and would occur with the NAA and is common to all of the alternatives.

In Table 3.21-10 greatly increased and major adverse impacts related to erosion and exposure of archaeological sites, that would occur as a result of Measures 40 (deeper fall drawdown to regulating outlets) and Measure 720 (spring reservoir drawdown), are noted by project and alternative. These measures drive noticeable increases in erosion and exposure, by drafting deeply and quickly to lower regulating outlets, extending the length of reservoir bed exposure outside of storage season, accelerated erosion due to oversaturated unstable topography, and increasing the number of draft and fill cycles that occur in one water year. Alternatives 3A and 3B would be the most detrimental to archaeological resources due to the high number of projects that would use these deep drawdown measures (n=7 and 54% of the reservoirs). Alternative 2B and Alternative 5 would be less impactful with the proposed use of these measures at three reservoirs (23% of reservoirs impacted), followed by Alternative 2A, which proposes the use of such actions at two projects (15% of reservoirs impacted). The NAA, Alternative 1, and Alternative 4 would have the least increase in impact to archaeological sites, because the drawdown measures would occur only at one reservoir, Fall Creek (8% of reservoirs impacted).

**Table 3.21-10. Major Adverse Effects to Archaeological Sites by Reservoir beyond Draft and Fill Annual Cycle under All Alternatives**

| Project | NAA | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|
| Fern Ridge | No | No | No | No | No | No | No | No |
| Cottage Grove | No | No | No | No | No | No | No | No |
| Dorena | No | No | No | No | No | No | No | No |
| Dexter | No | No | No | No | No | No | No | No |
| Lookout Point | No | No | No | No | Yes | Yes | No | No |
| Fall Creek | Yes | Yes | Yes | Yes | Yes | Yes | Yes | Yes |
| Hills Creek | No | No | No | No | Yes | Yes | No | No |
| Cougar | No | No | No | Yes | Yes | Yes | No | Yes |
| Blue River | No | No | No | No | Yes | Yes | No | No |
| Foster | No | No | No | No | No | No | No | No |
| Green Peter | No | No | Yes | Yes | Yes | Yes | No | Yes |
| Big Cliff | No | No | No | No | No | No | No | No |
| Detroit | No | No | No | No | Yes | Yes | No | No |
| Total WVS Reservoirs | 1 (8%) | 1 (8%) | 2 (15%) | 3 (23%) | 7 (54%) | 7 (54%) | 1 (8%) | 3 (23%) |

Because these actions occur on such a large scale (per reservoir), these measures cause at least one additional event in a given water year that would have major adverse impact to 80% of archaeological resources. While these effects are not directly measurable (e.g. by observed rate of erosion), it is useful to understand the increased adverse impacts on an order of magnitude. For the alternatives that have two or three reservoirs that would experience spring and/or fall deep drawdowns, this is a 100%-200% increase from the NAA in the number of reservoirs where this measure that would have major adverse effects to archaeological resources (Alternatives 2A, 2B, and 5). For Alternatives 3A and 3B, the use of the deep drawdown measures, would increase the number of reservoirs where major adverse effects would occur to archaeological sites to 600% greater than the NAA, Alternative 1, and Alternative 4.

Through use of GIS and ResSim outputs, one aspect of potential impact to archaeological sites, extent of archaeological site exposure, expressed in acre-days, was modeled for all of the alternatives. Table 3.21-11 shows the results over the course of one water year for the eleven reservoirs that would have reservoir elevation changes (Big Cliff and Dexter are reregulating dams and maintain year round high water elevations), whereas Table 3.21-12 shows the percent change by project and then WVS across the alternatives. In each alternative, all of the eleven reservoirs follow a rule curve that results in one major cycle of draft and fill per water year and several of the measures result in reservoir elevation change. Exposure, as a result of any reservoir elevation change, would impact the 369 (80%) archaeological sites that are adjacent to or within the WVS reservoirs.

The NAA results in 164,109 acre-days of exposure, and only Alternative 1 results in a lower acre-day exposure amount (158,734 acre-days, a 3% decrease in exposure) (Table 3.21-11 and 3.21-12). Most of the alternatives would result in 3%-4% higher exposures rates including Alternatives 2A, Alternative 2B, Alternative 4, and Alternative 5. As noted with prior discussion, Alternative 3A and 3B would be highly detrimental to archaeological resources, and for this particular analysis, would result in markedly higher rates of site exposure (31%-44%).

**Table 3.21-11. Effects to Archaeological Resources through Exposure by Reservoir and Alternative (expressed as acre-day)**

| Reservoir | NAA | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|
| Detroit | 25,768 | 24,267 | 27,272 | 27,271 | 48,013 | 29,059 | 27,298 | 27,292 |

##### 3.21.2.2.2 Built Resources

In Table 3.21-13, moderate to major adverse effects to built resources are noted by project and alternative. Effects to built resources are high in all of the alternatives (54-31%) with the exception of the NAA, which does not propose any structural measures. Given that the NAA does not propose any structural modifications, and all other alternatives do, any of the proposed structural modifications results in a 100% increase in modification to built resources (any increase from zero results in a 100% increase regardless of the amount). However, the amount of proposed modification varies across alternatives. Alternative 1 proposes the most structural measure that would have moderate to major effects to built resources, followed by Alternative 2A, Alternative 2B, and Alternative 4. Alterative 3A and Alternative 3B have the least structural measures that would have moderate to major effects to the historic WVS. Alternatives that propose structural measures to address upstream and downstream fish passage tend to have less negative effects to archaeological resources in the reservoirs, as opposed to alternatives that propose operations measures to accomplish the same goals.

**Table 3.21-13. Moderate to Major Adverse Effects to Built Resources under All Alternatives**

| Project | NAA | Alt 1 | Alt 2A | Alt 2B | Alt 3A | Alt 3B | Alt 4 | Alt 5 |
|---|---|---|---|---|---|---|---|---|
| Fern Ridge | No | Yes | No | No | No | No | No | No |
| Cottage Grove | No | No | No | No | No | No | No | No |

**Mitigating Adverse Effects to Cultural Resources**

The annual draft and fill cycle of the WVS that is common across all alternatives has cyclical and incremental permanent major adverse effects to 80% of documented archaeological sites that are present in the WVS. The spring and/or fall deep drawdowns are another set of activities that are adverse to archaeological resources in reservoirs and accelerates the erosion and exposure caused by the annual draft and fill cycle. Across all alternatives, a deep drawdown would occur at one or more reservoirs, though the locations and timing varies. For built resources, moderate to major long term adverse effects would occur to between 31% and 54% of WVS historic districts across all alternatives with the exception of the NAA. The NAA does not include any structural measures that would modify the WVS historic districts.

In general, the scale of long term and permanent adverse impacts to archaeological sites and built resources, is major and requires thoughtful consideration as to how the Corps can manage and mitigate these reservoir-wide and system-wide effects with regard to site protection against erosion and exposure, looting prevention programs, promoting tribal access to these locations, maintaining the important attributes of the WVS historic districts, and educating the public about the importance of cultural resources, local history, tribal sovereignty, and the impacts of looting. The Corps intends to continue to work with federal, state, and tribal partners and other interested parties to identify appropriate management and mitigation strategies that would occur through the proposed action like monitoring of these sites.

As discussed in the introduction of Section 3.21, one avenue currently exists with the development of the historic properties management plan that will act as a companion document to the WVS operations and maintenance NHPA Section 106 programmatic agreement. The Corps will work with Cooperators and tribal partners to identify other opportunities to collaborate on the management of WVS cultural resources.

### *3.21.2.3 No Action Alternative*

The No Action Alternative (NAA) maintains a rule curve that begins drafting in fall to low water levels through the winter, with fill beginning in late winter through the spring, with the highest reservoir level to be reached by the start of summer. This level is maintained through early fall when drafting begins again. This annual draft and fill cycle is a major erosion event for archaeological sites that exist in all of the reservoirs except Big Cliff and Dexter. Both are drawn reregulating dams that maintain high reservoir elevations (though they have been infrequently drawn down in the past and have been subject to increased erosion and exposure during these events). The WVS archaeological resources have been experiencing this cyclical inundation and exposure for five to eight decades depending on the reservoir. This has resulted in noticeable erosion and exposure damage to all resources that are known to be present in the reservoirs. Of the 461 archaeological sites documented at the WVS, 369 (80%) are located in or adjacent to reservoir environments. In the NAA, deep fall drawdowns, which accelerate erosion to landforms and archaeological sites, occur at Fall Creek or 8% of the WVS projects. The NAA would result in 164,109 acre-days of archaeological site exposure across all 11 reservoirs that would experience elevation change.

The public consistently recreates at the reservoirs when water levels are low, and it is a common pastime to collect artifacts at the WVS. The cycle of erosion and exposure is well known, and law enforcement officers increase patrols of reservoirs after a heavy rainfall specifically because the rains would have washed away more soils and exposed artifacts. Unauthorized collection has been documented at all of the 13 projects of the WVS. This is an adverse effect to cultural resources.

No new construction or modification to the 13 historic districts is considered under the NAA, and therefore is not anticipated to have adverse effects to the historic WVS.

The overall effect from the No Action Alternative to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

##### *3.21.2.3.1 Climate Change*

Climate change would continue to increase impacts to cultural resources under the NAA due to more winter rainfall that erodes exposed reservoir beds and exposes archaeological materials for the public to illicitly collect artifacts. The warmer weather in the summer and limited water would also expose sites higher in the elevation pools that would allow people to access and illicitly collect from those sites. However, active erosion would not be occurring in the summer months, so it would limit the public's ability to disturb archaeological materials without active digging and vandalism of archaeological sites.

It is anticipated that archaeological resources would continue to steadily degrade if existing draft and fill operations continue. Within 30 years, it is probable that the majority of the sites that are present in the reservoir would be mostly or completely eroded and picked over from unauthorized collection. The limited test excavations recently conducted at archaeological sites at five of the reservoirs indicate that there are little to no intact subsurface components where there are surface expressions of artifacts (at least with this sample). Recent site condition assessments that now span more than one year and one cycle of draft and fill provide further evidence that sites are being actively eroded and looted each water year. Effects to built resources as a result of climate change are not anticipated.

#### ***3.21.2.4 Alternative 1 – Project Storage Alternative***

Like the NAA, Alterative 1 follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 1 would reduce minimum flows to Congressionally authorized minimum flow requirements (#723) at all of the reservoirs except Dexter, Foster, and Big Cliff. This measure would likely have minor short-term benefits to archaeological resources on a system wide level since it would allow for more water storage and a higher likelihood of following the rule curve in a consistent pattern. This is supported by the systemwide 3% decrease in acre-days of site exposure between the NAA (164,109 acre-days) and Alternative 1 (158,734 acre-days). Alternative 1 is the only alternative that posits the use of Measure 723, and it is the only

Alternative that shows minor beneficial changes at the system-level to cultural resources. Several of the reservoirs would have decreased site exposure including Detroit (-6%), Green Peter (-15%), Blue River (-3%), Cougar (-6%), Hills Creek (-12%), Dorena (-1%), and Cottage Grove (-1%). Site exposure at Fall Creek, Fern Ridge, and Foster would not change from the NAA (0% change) whereas Lookout Point would see an 8% increase in exposure days with Alternative 1.

Like the NAA, deep fall drawdowns at Fall Creek would accelerate erosion to landforms and archaeological sites when compared to other reservoirs where deep drawdowns do not occur. As with the NAA, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of the archaeological sites present, though to a lesser extent when considering site exposure.

Alternative 1 has the potential to cause moderate to major adverse long-term effects to six of the 13 historic districts (46%) because several of the measures propose substantial modifications to the infrastructure of the historic districts. See Table 3.21-14 for corresponding structural measures and the level of effect to built resources that support water quality, downstream and upstream fish passage. Any measures that require construction or modification of infrastructure have the potential to cause effects to archaeological sites through ground disturbance and staging of equipment or short-term reservoir elevation changes that will cause erosion and exposure.

**Table 3.21-14. Level of Adverse Effect to Built Resources under Alternative 1**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | Yes (Measure 52, 639) |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | Yes (Measure 174) | N/A | Yes (Measure 392, 722) |
| Lookout Point | Yes (Measure 174) | N/A | Yes (Measure 105, 392) |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | N/A |
| Cougar | Yes (Measure 174) | N/A | N/A |
| Blue River | N/A | N/A | N/A |
| Foster | Yes (Measure 174, 479) | N/A | Yes (Measure 392) |
| Green Peter | Yes (Measure 174) | N/A | Yes (Measure 52, 105, 392, 722) |
| Big Cliff | Yes (Measure 174) | N/A | N/A |
| Detroit | Yes (Measure 174) | N/A | Yes (Measure 105, 392) |

The overall effect from Alternative 1 to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide

##### *3.21.2.4.1 Climate Change*

Climate Change impacts are assumed to be similar to those described for the NAA, with the exception that the use of Measure 723 as opposed to the 2008 BiOp target flows that are currently in use would result in retaining more water at the reservoirs and potentially reduce shifts in reservoir elevations that can affect archaeological resources. This beneficial effect is negligible/minor due to the inability to fully measure it, but the 3% decrease in site exposure that is estimated for Alternative 1 may indicate continued slight benefits if the system is maintained this way through continued climate change. Effects to built resources as a result of climate change are not anticipated.

#### ***3.21.2.5 Alternative 2A – Hybrid Alternative***

Like the NAA and Alterative 1, Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 2A proposes a deeper fall reservoir drawdown (#40) at Green Peter (780 feet) and Fall Creek as opposed to just Fall Creek (with the NAA and Alternative 1). A deep fall drawdown would increase erosion at Green Peter and Fall Creek reservoirs, but the adverse effect to documented archaeological sites is not fully measurable. On a qualitative level, it is known that deep drawdowns increase erosion because soils are not allowed to properly drain before they are exposed, and this increases the vulnerability of present sites. The number of reservoirs impacted on a project level doubles in this Alternative and results in a higher number of documented archaeological sites that would be subject to this increased erosion. In all three alternatives, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of documented archaeological sites.

Alternative 2A proposes implementing an integrated temperature and habitat flow regime (#30a) rather that adhering to either the 2008 BiOp target flows or the minimum flows to Congressionally authorized minimum flow. This flow regime may minimally affect reservoir elevations, and therefore, would result in a negligible/minor adverse effect to archaeological sites. This is supported by a minor systemwide increase in acre-days of site exposure from the NAA (3%). By project, however, several of the reservoirs would see decreased acre-days of site exposure including Foster (-1%), Blue River (-4%), Cougar (-3%), Fall Creek (-1%), and Cottage Grove (-1%). Dorena and Fern Ridge would not have any changes from the NAA (0%). Major adverse effects and increased site exposure at the local level would occur at Detroit (6%), Green Peter (16%) and Lookout Point (3%) while major beneficial reduction of exposure would occur at Hills Creek (-12%).

Alternative 2A has the potential to cause moderate to major effects to six of the 13 historic districts (46%). See Table 3.21-15 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-15. Level of Adverse Effect to Built Resources under Alternative 2A**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | N/A | N/A | Yes (Measure 52, 722) |
| Lookout Point | N/A | N/A | Yes (Measure 392) |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | N/A |
| Cougar* | N/A | N/A | Yes (Measure 392, 52) |
| Blue River | N/A | N/A | N/A |
| Foster | Yes (Measure 479) | N/A | Yes (Measure 392) |
| Green Peter | N/A | N/A | Yes (Measure 52, 722) |
| Big Cliff | N/A | N/A | N/A |
| Detroit | N/A | N/A | Yes (Measure 105, 392) |

*2A proposes construction of a downstream passage structure to support downstream fish passage at Cougar, whereas 2B uses deep drawdowns in fall and spring.

The overall effect from the Alternative 2A to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

#### *3.21.2.5.1 Near-term operations Measures*

The discussion of the near-term operations measures can be found in Chapter 2. The following considers the impacts of the near-term operations measures on cultural resources.

Operations that focus on deep drawdowns, earlier drawdown, and delayed refills for downstream fish passage would greatly increase the erosion and exposure of archaeological sites at the reservoir level and would have moderate to major adverse effects. Drafting deeply and quickly to the lower regulating outlets would accelerate landform and archaeological site erosion due to oversaturated unstable topography throughout the reservoir, and the delayed fills and early drawdowns would extend the length that most of the reservoir bed is exposed outside of the storage season (see Table 3.21-16). Other operational measures that focus on spring spills for downstream fish passage do result in elevation changes, but to a lesser extent. The elevation changes for spill operations would occur during planned fill, when reservoir levels are already increasing, and low elevation sites are already inundated. These planned fills would be controlled and would be kept at steady elevations as much as possible, resulting in infrequent or short-lived fluctuations in water elevation (which could increase site erosion within a narrow elevation range). As a result, less of the reservoir and fewer sites would be adversely affected than when the deep drawdowns and delayed refills occurred.

Operations that have the reservoir-level and more localized adverse effects would occur at four, or 31%, of the WVS reservoirs including Green Peter, Foster, Cougar, and Lookout Point. The adverse effects of these measures are major, permanent, and irreversible. It is anticipated that archaeological resources would continue to steadily degrade with the routine draft and fill operations, and the adverse effects would be accelerated by the deep drawdowns, early drawdowns, and delayed refills at Green Peter, Foster, Cougar, and Lookout Point. Within 15 years, it is probable that the majority of the sites that are present in the four reservoirs would be mostly or completely eroded and picked over from unauthorized collection.

**Table 3.21-16. Operations that Would Cause Adverse Effects to Archaeological Sites**

| Project | Operation | Reservoir Elevation Change? | Deep Drawdown? |
|---|---|---|---|
| Green Peter | Utilize spillway for improved downstream fish passage in the spring; perform spill operation until 01 May or for 30 days, whichever is longer | Yes | No |
| Green Peter | Deep drawdown and RO prioritization for improved downstream fish passage | Yes | Yes |
| Foster | Earlier fall drawdown, reach 620-625 feet by Oct. 1 | Yes | No |
| Foster | Delay refill and utilize spillway in the spring for improved downstream fish passage | Yes | No |
| Cougar | Deep drawdown and RO prioritization for improved downstream fish passage | Yes | Yes |
| Cougar | Delayed reservoir refill and RO prioritization for improved downstream fish passage | Yes | No |
| Lookout Point | Deep drawdown and RO prioritization for improved downstream fish passage | Yes | Yes |
| Lookout Point | Utilize spillway for improved downstream fish passage in the spring | Yes | No |

*Some aspects of this operation would not have adverse effects to archaeological sites.

In Table 3.21-17, the operations that would cause negligible adverse effects to archaeological sites are listed. While these actions in themselves won't increase erosion and exposure of archaeological sites, these operations are coupled with other aspects that do have moderate to major adverse effects including deep drawdown, delayed refill, early refill, and spring spill at three of the reservoirs including Green Peter, Foster, and Lookout Point. The measures at Hills Creek and Detroit would not be paired with adverse actions.

**Table 3.21-17. Operations that Would Cause No/Negligible Effects to Archaeological Sites**

| Project | Operation |
|---|---|
| Hills Creek | Nighttime RO prioritization for improved downstream fish passage (downstream fish passage) |
| Detroit | Spring downstream fish passage and operational downstream temperature management |
| Detroit | Nighttime RO prioritization for improved downstream fish passage |
| Detroit | Spread spill across spillbays to reduce downstream TDG exceedances |
| Green Peter | Outplanting plan for the reintroduction of adult Chinook salmon above Green Peter Dam |
| Foster | After Oct 1, utilize the spillway for improved downstream fish passage in the fall |
| Foster | Use the fish weir in the summer for improved downstream temperature management and upstream fish migration/passage |
| Lookout Point | RO use in the fall for downstream temperature management |

*Some aspects of this measure would have adverse effects to archaeological sites.

None of the near-term operations are structural, and therefore, would have no effect to the built resources of the WVS.

##### *3.21.2.5.2 Climate Change*

Climate change impacts are not anticipated to be substantially different than those discussed for the NAA and Alternative 1. With integrated temperature and habitat flow regimes, it is anticipated that reservoir elevations may fluctuate to meet these flow targets with increasingly hotter and drier summers.

Over the life of the project (30 years), archaeological resources would be impacted to a similar degree as that described in the NAA and Alternative 1. Effects to built resources as a result of climate change are not anticipated.

#### *3.21.2.6 Alternative 2B -- Hybrid Alternative*

Alterative 2B as well as the NAA, Alternative 1, and Alternative 2A follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 2B diverges from the other alternatives by proposing a deep spring reservoir drawdown (#720) and deeper fall reservoir drawdowns (#40) at Cougar (1330 feet), but like Alternative 2A proposes a fall deep drawdown at Green Peter (780 feet) and, like the NAA, Alternative 1, and Alternative 2A, at Fall Creek. Alternative 2B proposes structural measures at Lookout Point, Foster, and Detroit to facilitate downstream fish passage. This differs from Alternative 2A, which includes structural measures at Lookout Point, Foster, Detroit, and Cougar.

Like the other reservoirs where deep drawdowns would occur, portions of Cougar Reservoir is very steeply sloped and experiences several forms of sheet erosion and mass wasting events during routine drafting. It is anticipated that a deep drawdown in the fall and spring would have major impacts to reservoir slope stability and the archaeological sites present. Again, this is not a measurable impact, but a qualitative assessment of increased vulnerability of archaeological sites that would occur during multiple deep drawdowns. It is measurable, however, that Cougar Reservoir would experience two cycles of draft and fill in one water year, doubling impacts from this already negatively impactful action.

Alternative 2B would increase the number of reservoirs that experience deep drawdowns (up to three, from one or two with the NAA, Alternative 1 and Alternative 2A). Alternative 2B would also majorly lengthen the amount of time that sites at Cougar (22%) and Green Peter (16%) would be exposed to human-induced impacts. Both reservoirs experiences high volumes of recreationalists when the roads are passable and not snowed it, and it is anticipated that unauthorized artifact collection would increase during peak recreation season. In all three alternatives, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of documented archaeological sites, but adverse effects specifically to archaeological sites at Cougar and Green Peter are increased. Lookout Point and Detroit would also see moderate adverse effects with increase site exposure from the NAA (6%).

Overall, the WVS would see a 4% system-wide increase in site exposure with Alternative 2B. The remaining reservoirs would see decreased or no change to site exposure including Foster (-1%), Blue River (-3%), Fall Creek (0%), Hills Creek (-9%), Dorena (0%), Cottage Grove (-1%), and Fern Ridge (0%).

Alternative 2B has the potential to cause moderate to major effects to six of the 13 historic districts (46%). See Table 3.21-18 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-18. Level of Adverse Effect to Built Resources under Alternative 2B**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | N/A | N/A | Yes (Measure 52, 722) |
| Lookout Point | N/A | N/A | Yes (Measure 392) |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | N/A |
| Cougar* | N/A | N/A | Yes (Measure 52) |
| Blue River | N/A | N/A | N/A |

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Foster | Yes (Measure 479) | N/A | Yes (Measure 392) |
| Green Peter | N/A | N/A | Yes (Measure 52, 722) |
| Big Cliff | N/A | N/A | N/A |
| Detroit | N/A | N/A | Yes (Measure 105, 392) |

*2B uses deep drawdowns in fall and spring to support downstream fish passage at Cougar, whereas 2A proposes construction of a downstream passage structure.

The overall effect from Alternative 2B to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide

#### *3.21.2.6.1 Climate Change*

Climate Change impacts anticipated with Alternative 2B continue to be similar to the NAA, Alternative 1, and Alternative 2A. Over the life of the project (30 years), archaeological sites in the reservoirs would continue to degrade, though resources at Fall Creek, Cougar, and Green Peter would likely degrade from erosion and exposure at an accelerated rate. Cougar would have even more erosion as it experiences two draft and fill cycles within a given water year. Effects to built resources as a result of climate change are not anticipated.

#### *3.21.2.6.2 Near-Term Operations Measures*

See Section 3.21.3.3.1.

### ***3.21.2.7 Alternative 3A – Operations-Focused Fish Passage Alternative***

Alterative 3A deviates strongly from the NAA as well as Alternative 1, Alternative 2A, and Alternative 2B in regard to the increase in potential adverse impacts to archaeological resources. Deeper fall reservoir drawdowns (#40) are proposed for seven reservoirs including Fall Creek, Blue River (1165 feet), Hills Creek (1446 feet), Green Peter (780 feet), Detroit (1375 feet), Lookout Point (761 feet), and Cougar (1517 feet). Spring reservoir drawdowns (#720) are proposed at three of those reservoirs including Detroit, Lookout Point, and Cougar (to the same elevations).

At all of these reservoirs, accelerated erosion would impact slope stability and the archaeological sites present, but at a much larger scale. Over 50% of reservoirs and associated archaeological sites would be vulnerable to increased erosion from the fall deep drawdowns, and nearly 25% of reservoirs would experience additional erosion by doubling the cycle of draft and fill that occur in one water year. Alternative 3A would result in a 600% increase in this majorly adverse action when compared to the NAA.

Alternative 3A would also greatly lengthen the amount of time that sites at Detroit, Lookout Point, Cougar, Green Peter, and Hills Creek reservoirs would be exposed to human-induced impacts. All of these reservoirs have high volumes of recreation and known looting issues. It is anticipated that unauthorized artifact collection would increase in the spring and fall due to the 86% increase in site exposure at Detroit, 170% increase at Lookout Point, 22% increase at Cougar, 16% increase at Green Peter, and 13% increase at Hills Creek. Blue River (3% increase) and Fall Creek (0% increase) would still be subject to high levels of erosion and site exposure during the proposed fall drawdowns though the change in site exposure between the NAA and Alternative 3A is minor to negligible at these reservoirs. Like all of the preceding alternatives, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of documented archaeological sites. Unique to Alternative 3A, the WVS would experience a 44% increase in site exposure from the NAA. Adverse effects specifically to archaeological sites at seven reservoirs would be substantially high.

Alternative 3A has the potential to cause moderate to major effects to four of the 13 historic districts (31%). See Table 3.21-19 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-19. Level of Adverse Effect to Built Resources under Alternative 3A**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | N/A | N/A | N/A |
| Lookout Point | N/A | N/A | N/A |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | Yes (Measure 52, 722) |
| Cougar | N/A | N/A | Yes (Measure 52) |
| Blue River | N/A | N/A | Yes (Measure 52, 722) |
| Foster | Yes (Measure 479) | N/A | N/A |
| Green Peter | N/A | N/A | Yes (Measure 52, 722) |
| Big Cliff | N/A | N/A | N/A |
| Detroit | N/A | N/A | N/A |

The overall effect from Alternative 3A to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

##### *3.21.2.7.1 Climate Change*

Climate Change would further exacerbate adverse effects to archaeological resources under Alternative 3A, specifically at the seven reservoirs that would experience spring and/or fall deep drawdown. Low reservoir elevations in the spring, would likely continue into summer resulting in exposed and accessible reservoir beds. If target summer elevations can be met, deep fall drawdowns would impact vulnerable slopes and give way to heavy winter rains that continue to erode and degrade reservoir landforms and archaeological sites.

Over the life of the project (30 years), it is anticipated that archaeological sites may be entirely eroded from the seven reservoirs that experience deep drawdowns. At the three that would have spring and fall deep drawdowns, and would have double the draft and fill cycle, archaeological resources may be fully eroded within 10-15 years. Effects to built resources as a result of climate change are not anticipated.

##### *3.21.2.7.2 Near-Term Operations Measures*

See Section 3.21.3.3.1.

#### ***3.21.2.8 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)***

Alterative 3B shares similarities with 3A, but is quite different from the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Deeper fall reservoir drawdowns (#40) are proposed for the same seven reservoirs including Fall Creek, Blue River (1165 feet), Hills Creek (1446 feet), Green Peter (780 feet), Detroit (1375 feet), Lookout Point (761 feet), and Cougar (1517 feet). Spring reservoir drawdowns (#720), however, are proposed at Hills Creek, Cougar, and Green Peter. In both of these alternatives, Cougar would have a spring and fall deep drawdown. In Alternative 3B, the fall deep drawdown at Cougar would pass through the diversion tunnel.

Like with Alternative 3A, accelerated erosion would impact slope stability and the archaeological sites present in the reservoirs, at a similar scale, but with slightly different locations. Again, more than 50% of reservoirs and associated archaeological sites would be vulnerable to increased erosion from the fall deep drawdowns, and nearly 25% of reservoirs would experience additional erosion by doubling the cycle of draft and fill that occur in one water year. This alternative would result in a 600% increase in this adverse effect.

Alternative 3B would also greatly lengthen the amount of time of site exposure at Detroit (13%), Foster (38%), Hills Creek (80%), Cougar (22%), Lookout Point (170%), and Green Peter (100%) and ultimately exposure to human-induced impacts. All of these reservoirs have high volumes of recreation and known looting issues. It is anticipated that unauthorized artifact collection would increase in the spring and fall. Fall Creek does and would continue to experience illicit collection during the deep fall drawdown (though site exposure would remain unchanged from the NAA), and Blue River would see a minor increase in site exposure days (3%). Cottage Grove and Fern Ridge would not see an increase in site exposure days with

Alternative 3B. As with all alternatives, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of documented archaeological sites. Unique to Alternative 3B, the WVS would experience a 31% higher site exposure rate than the NAA. Adverse effects specifically to archaeological sites at seven of the reservoirs are substantially high.

Alternative 3B has the potential to cause moderate to major effects to four of the 13 historic districts (31%). See Table 3.21-20 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-20. Level of Adverse Effect to Built Resources under Alternative 3B**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | N/A | N/A | N/A |
| Lookout Point | N/A | N/A | N/A |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | Yes (Measure 52, 722) |
| Cougar | N/A | N/A | Yes* |
| Blue River | N/A | N/A | Yes (Measure 52, 722) |
| Foster | Yes (Measure 479) | N/A | N/A |
| Green Peter | N/A | N/A | Yes (Measure 52, 722) |
| Big Cliff | N/A | N/A | N/A |
| Detroit | N/A | N/A | N/A |

*This would result in modification to the existing diversion tunnel that is a contributing element of the Cougar Historic District.

The overall effect from Alternative 3B to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

### *3.21.2.8.1 Climate Change*

As with Alternative 3A, climate change would further exacerbate adverse effects to archaeological resources, specifically at the reservoirs that would experience spring and/or fall deep drawdown. Low reservoir elevations in the spring, would likely continue into summer resulting in exposed and accessible reservoir beds. If target summer elevations are met, deep fall drawdowns would impact vulnerable slopes and give way to heavy winter rains that continue to erode and degrade reservoir landforms and archaeological sites.

Over the life of the project (30 years), it is anticipated that archaeological sites may be entirely eroded from the seven reservoirs that experience deep drawdowns. At the three that would have spring and fall deep drawdowns, and would have double the draft and fill cycle, archaeological resources may be fully eroded within 10-15 years. Effects to built resources as a result of climate change are not anticipated.

##### *3.21.2.8.2 Near-Term Operations Measures*

See Section 3.21.3.3.1.

#### ***3.21.2.9 Alternative 4 – Structures-Based Fish Passage Alternative***

Alterative 4 follows a rule curve that results in one major cycle of draft and fill per water year and is similar to Alternative 1 in regard to impacts to archaeological resources. The impacts are also similar to the NAA. Alternative 4, however, does not propose any additional deep drawdowns beyond those at Fall Creek nor does the alternative propose spring spills over the spillway. Rather this alternative focuses heavily on structure-based measures to accomplish downstream fish passage. As with the NAA, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of the archaeological sites present.

Like Alternative 1, Alternative 4 would result in a minor increase in system-wide site exposure (3% increase from NAA). The most impacted reservoirs include Detroit (6%) and Green Peter (17%). The remaining reservoirs would either see negligible or minor adverse or beneficial changes in site exposure from the NAA: Lookout Point (3%), Foster (0%), Blue River (-4%), Cougar (-3%), Fall Creek (-1%), Dorena (0%), Cottage Grove (-1%), and Fern Ridge (0%). Hills Creek would see a major beneficial decrease in site exposure (-12%).

Alternative 4 has the potential to cause moderate to major effects to seven of the 13 historic districts (54%). See Table 3.21-21 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-21. Level of Adverse Effect to Built Resources under Alternative 4**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | Yes (Measure 174) | N/A | Yes (Measure 392, 722) |
| Lookout Point | Yes (Measure 174) | N/A | Yes (Measure 105, 392) |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | Yes (Measure 105, 392, 722) |
| Cougar | Yes (Measure 174) | N/A | Yes (Measure 392) |

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Blue River | N/A | N/A | N/A |
| Foster | Yes (Measure 174, 479) | N/A | Yes (Measure 392) |
| Green Peter | Yes (Measure 174) | N/A | N/A |
| Big Cliff | Yes (Measure 174) | N/A | Yes (Measure 392) |
| Detroit | Yes (Measure 174) | N/A | Yes (Measure 105, 392) |

The overall effect from Alternative 4 to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

#### *3.21.2.9.1 Climate Change*

Climate change impacts are assumed to be similar to those described for the NAA and Alternative 1, though flow regimes differ.

Over the life of the project (30 years), it is anticipated that archaeological resources would be impacted to a similar degree as that described in the NAA. Effects to built resources as a result of climate change are not anticipated.

#### *3.21.2.9.2 Near-term operations measures*

See Section 3.21.3.3.1.

### ***3.21.2.10 Alternative 5 – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Alternative 5 is nearly identical to Alternative 2B except that the integrated temperature and habitat flow regime (Measure 30a) has been replaced by the refined integrated temperature and habitat flow regime (Measure 30b).

Alterative 5 as well as the NAA, Alternative 1, Alternative 2A, Alternative 2B, Alternative 3A, Alternative 3B, and Alternative 4 follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 2B and Alternative 5 diverge from the other alternatives by proposing a spring reservoir drawdown (#720) and a deeper fall reservoir drawdown (#40) at Cougar (1330 feet), but like Alternative 2A proposes a deep fall drawdown at Fall Creek and Green Peter (780 feet). Alternative 2B and Alternative 5 propose constructing structural downstream fish passage (#392) at Lookout Point, Foster, and Detroit. This differs from Alternative 2A, which includes structural downstream fish passage at Lookout Point, Foster, Detroit, and Cougar.

Like the Green Peter and Fall Creek reservoirs, where deep drawdowns would occur, portions of Cougar Reservoir are very steeply sloped and experiences several forms of sheet erosion and mass wasting events during routine drafting. It is anticipated that a deep drawdown in the fall and spring at Cougar may have major impacts to reservoir slope stability and the archaeological sites present. Again, this is not a measurable impact, but a qualitative assessment of increased vulnerability of archaeological sites that would occur during multiple deep drawdowns. It is measurable, however, that Cougar Reservoir would experience two cycles of draft and fill in one water year, doubling impacts from this already negatively impactful action.

Alternative 2B and Alternative 5 would increase the number of reservoirs that experience deep drawdowns (up to three, from one or two with the NAA, Alternative 1, and Alternative 2B). Alternative 2B and Alternative 5 would also greatly lengthen the amount of time that sites at Detroit (6%), Green Peter (16%), Cougar Reservoir (22%) and Lookout Point (6%) would be exposed to human-induced impacts. These reservoirs experience high volumes of recreationalists when the roads are passable, and it is anticipated that unauthorized artifact collection would increase during peak recreation season. In all alternatives, the WVS cycle of draft and fill would continue to adversely affect 369 (80%) of documented archaeological sites. Adverse effects specifically to archaeological sites at Cougar, Fall Creek, and Green Peter, however, are substantially high.

Alternative 2B and Alternative 5 have the potential to cause moderate to major effects to six of the 13 historic districts (46%). See Table 3.21-22 for corresponding measures that support water quality, downstream and upstream fish passage.

**Table 3.21-22. Level of Adverse Effect to Built Resources under Alternative 5**

| Project | Negligible to Minor Adverse Effects | Minor to Moderate Adverse Effects | Moderate to Major Adverse Effects |
|---|---|---|---|
| Fern Ridge | N/A | N/A | N/A |
| Cottage Grove | N/A | N/A | N/A |
| Dorena | N/A | N/A | N/A |
| Dexter | N/A | N/A | Yes (Measure 52, 722) |
| Lookout Point | N/A | N/A | Yes (Measure 392) |
| Fall Creek | N/A | N/A | N/A |
| Hills Creek | N/A | N/A | N/A |
| Cougar* | N/A | N/A | Yes (Measure 52) |
| Blue River | N/A | N/A | N/A |
| Foster | Yes (Measure 479) | N/A | Yes (Measure 392) |
| Green Peter | N/A | N/A | Yes (Measure 52, 722) |
| Big Cliff | N/A | N/A | N/A |
| Detroit | N/A | N/A | Yes (Measure 105, 392) |

*2B and 5 use deep drawdowns in fall and spring to support downstream fish passage at Cougar, whereas 2A proposes construction of a downstream passage structure.

The overall effect from Alternative 5 to Cultural Resources would impact more than 10% of all known cultural resources and would be irreversible, adverse, and major within the WVS. Given that the effects are irreversible, the duration is permanent, and the extent of these impacts is system-wide.

###### *3.21.2.10.1 Climate Change*

Climate Change impacts anticipated with Alternative 5 continue to be similar to the NAA, Alternative 1, Alternative 2A, and Alternative 2B. Over the life of the project (30 years), archaeological sites in the reservoirs would continue to degrade, though resources at Fall Creek, Cougar, and Green Peter would likely degrade from erosion and exposure at an accelerated rate. Cougar would have even more erosion as it would experience two draft and fill cycles within a given water year. Effects to built resources as a result of climate change are not anticipated.

###### *3.21.2.10.2 Near- Term Operations Measures*

See Section 2.21.3.3.2.

## 3.22 VISUAL RESOURCES

Visual resources consist of all the features that give a landscape its visually aesthetic qualities. This includes landforms, vegetation, water surfaces, and cultural modifications, or physical changes made by human activities. Landscape features provide viewers with an overall impression of an area; this overall impression can be referred to as the area's "visual character." Visual resources are assessed to determine if a given project would appear to be visually compatible with the established landscape features of an area, or if they would appreciably contrast (Headley 2011). The focus of this section is to assess the visual resources located at the 13 dams and reservoirs within the Willamette Valley System (WVS).

### 3.22.1 Methodology

The Bureau of Land Management (BLM) Visual Resource Management (VRM) system provides a framework for managing visual resources for BLM-administered lands. While the VRM system was developed for application on the public lands managed by BLM, it is a useful tool to assess impacts on other lands as well. The system includes a mechanism for identifying visual resource values, minimizing the impacts of surface-disturbing activities on visual resources, and maintaining the scenic value of tracts of land for the future. The VRM process includes preparing an inventory of scenic values of a landscape (visual resource inventory or VRI), which will be included in this Affected Environment section; and analyzing the inventory (visual resource contrast rating), which will evaluate potential impacts from the Proposed Action and alternatives in the Environmental Effects section (BLM No Date-a).

VRI consists of assessing and rating the intrinsic scenic quality of a particular tract of land through the Scenic Quality Rating process; measuring public concern for the scenic quality of the tract through the Sensitivity Level Analysis; and classifying the distance by which tracts of land are visible from travel routes or observation points. The Scenic Quality Rating is a measure of the visual appeal of a tract of land using key factors. These key factors include physiographic characteristics, such as landforms, vegetation, and water; similar visual patterns, such as texture, color, and light; or areas of similar impact from human-made modifications, such as cultural modifications and scarcity. Each key factor has its own rating criteria based on its qualities and features (e.g., clean and clear water present at a tract of land has a higher rating compared to no water present). The total score translates into the land's scenic quality rating of A, B, or C (most to least scenic). The Sensitivity Level Analysis is a measure of public concern for scenic quality. The landscape being inventoried is assigned high, moderate, or low sensitivity levels by analyzing the various factors of public concern, such as types of users, amount of use, public interest, etc. Lastly, visual resources are categorized based on how visible that tract of land is from travel routes or observation points. The three distance zones include foreground-middleground (visible from highways, rivers, or other viewing locations less than 3 to 5 miles), background (less than 15 miles away), and seldom seen (hidden from view). Based on the results of the VRI, visual resources are assigned one of four classes, with Class I resources having the greatest relative visual values and Class IV resources having the lowest. Each class has established management objectives:

- Class I Objective – Preserve the existing character of the landscape. The level of change to the characteristic landscape should be very low and must not attract attention.
- Class II Objective – Retain the existing character of the landscape. The level of change to the characteristic landscape should be low.
- Class III Objective – Partially retain the existing character of the landscape. The level of change to the characteristic landscape should be moderate.
- Class IV Objective – Provide for management activities which require major modification of the existing character of the landscape. The level of change to the characteristic landscape can be high.

The analysis of the inventory stage of the VRM process, or the visual resources contrast rating, involves comparing features of the Proposed Action and alternatives with major features in the existing landscape to determine whether or not the potential visual impacts would meet the management objectives established for the area, or if design adjustments would be required (BLM No Date-a). This analysis will be included in the Environmental Effects section.

The VRI was developed for those dams and reservoirs whose visual resources could be impacted substantially from the Proposed Action and alternatives, such as new construction or substantial changes to water levels. This includes Lookout Point, Detroit, Green Peter, Hills Creek, Dexter, Cougar, Blue River, Foster, and Fall Creek. The overall results of the VRI (including the Scenic Quality Rating process, Sensitivity Level Analysis, and categorization of distance zones) are presented in 3.22.3 and summarized below for these dams and reservoirs. The more detailed results of the VRI are included in Appendix T. It should be noted that the VRI process is subjective and can vary based on the analyst and the resources available. Careful consideration must be given for every assessment and rating in order to conclude the most accurate inventory of each dam and reservoir. Dams and reservoirs whose visual resources are not expected to be impacted by the Proposed Action and alternatives – including Big Cliff, Dorena, Cottage Grove, and Fern Ridge – are not discussed in this section.

### 3.22.2 Willamette Valley Basin

The Willamette Valley is bound by the Cascade Range to the east, the Coast Range on the west, and the Calapooya Mountains to the south. The river valley extends approximately 187 miles to the north where it flows into the Columbia River (USACE 2019a). The valley consists of nearly level to gently sloping broad alluvial floodplains, scattered low hills, and adjacent mountain foothills (Morlan et al. 2010). While forested land covers approximately 70 percent of the watershed, agricultural land accounts for approximately 22 percent of the basin. Urban land covers approximately 6 percent of the basin and is mostly congregated in the valley along the mainstem of the Willamette River (EPA 2013b).

Since the 1850s, the Willamette Valley has been dramatically altered by agricultural, hydropower, and urban development, which has significantly affected oak woodland, grassland, and wetland habitats (OPRD 2017). Dams, diversions, levees, and similar alterations have largely disconnected the Willamette River and reduced its associated original wetland area by approximately 57 percent (Morlan et al. 2010). Some aesthetic value has been reestablished in the WVS through the creation of parks, recreational reservoirs and beaches, trails, and other scenic viewpoints accessible to the public. In FY 2019, almost two million visitors were recorded within the Willamette Valley Basin, also referred to as the Willamette watershed (USACE 2019u).

As noted above, the VRI was developed for those dams and reservoirs whose visual resources could be impacted substantially from the Proposed Action and alternatives, such as new construction or substantial changes to water levels. As shown below in Figure 3.22-1, these include Lookout Point, Detroit, Green Peter, Hills Creek, Dexter, Cougar, Blue River, Foster, and Fall Creek.

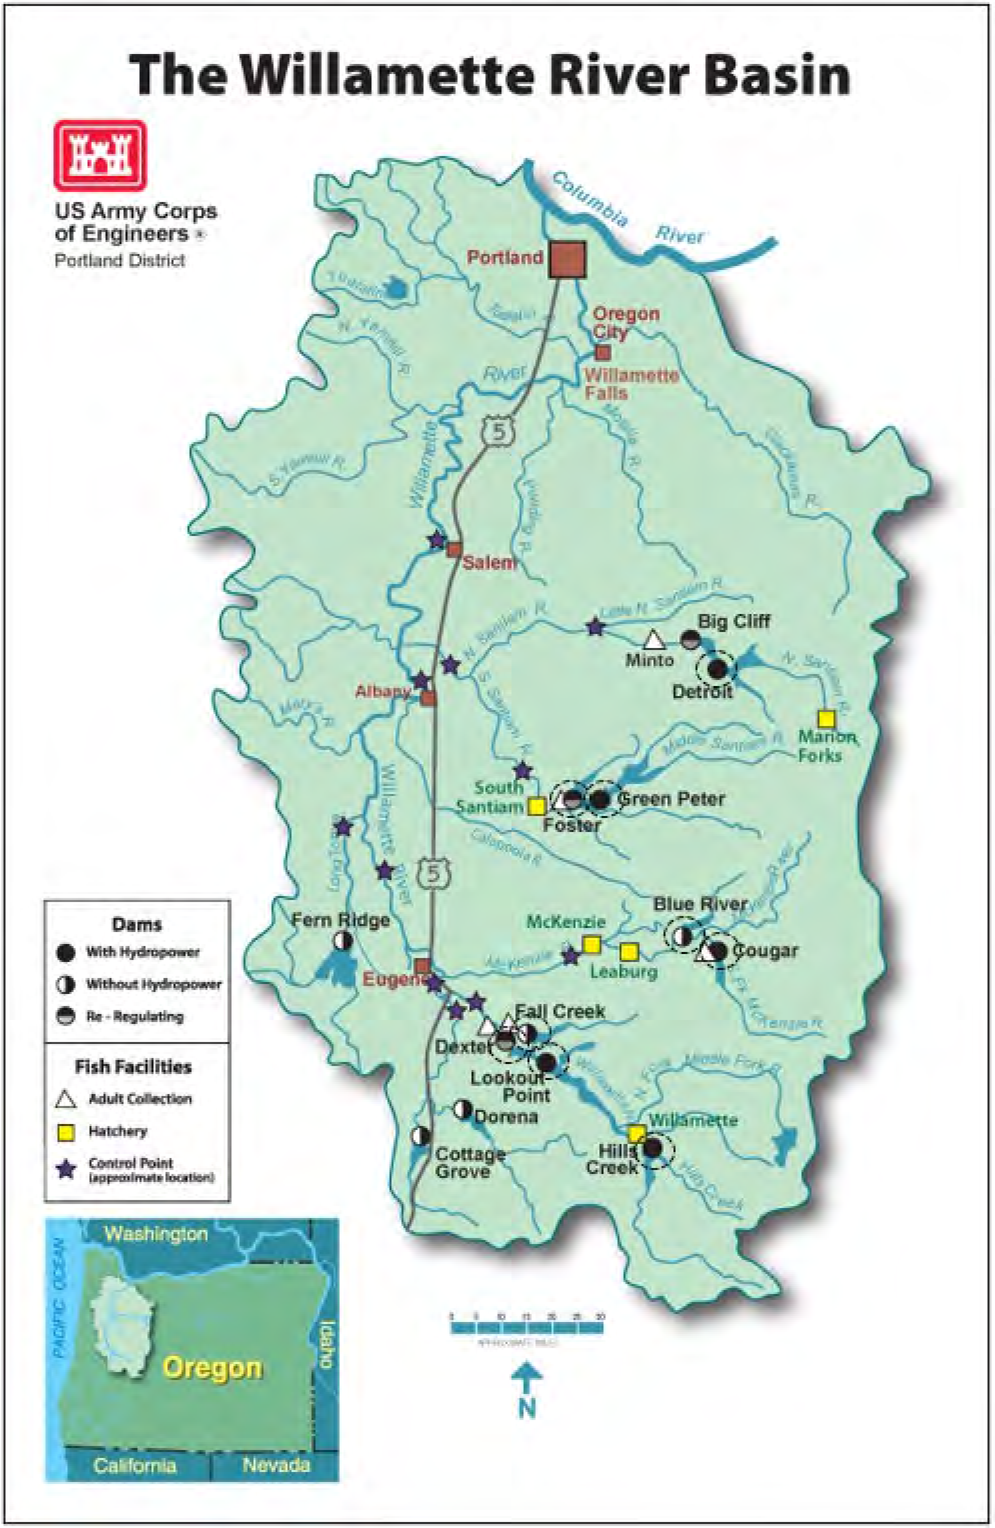

**Figure 3.22-1. Visual Resource Inventory of Dams and Reservoirs in the Willamette River Basin**

### 3.22.3 Visual Resource Inventory of Select Dams and Reservoirs

This section provides the results of the VRI for the nine dams and reservoirs that could be impacted substantially from the Proposed Action and alternatives, including the management class assigned to each dam and reservoir. A more detailed description of how each dam and reservoir was rated in the Scenic Quality Inventory, Sensitivity Level Analysis, and Distance Zones is included in Appendix T. The nine dams include Lookout Point (LOP), Detroit (DET), Green Peter (GRP), Hills Creek (HCR), Dexter (DEX), Cougar (CGR), Blue River (BLU), Foster (FOS), and Fall Creek (FCR). The results of the dams and reservoirs that were assessed for their VRI are briefly discussed in the sections below.

Table 3.22-1 shows the results of the Scenic Quality Inventory, where each dam received a Scenic Quality Rating based on the overall score from the key factors. All nine dams and reservoirs received a 'B' rating.

**Table 3.22-1. VRM Scenic Quality Inventory and Rating Chart for Select Dams and Reservoirs**

| Key Factors | Scores[1] by Dam/Reservoir | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | **LOP** | **DET** | **GRP** | **HCR** | **DEX** | **CGR** | **BLU** | **FOS** | **FCR** |
| Landform | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| Vegetation | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 |
| Water | 5 | 5 | 5 | 5 | 5 | 5 | 5 | 5 | 5 |
| Color | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 |
| Influence of Adjacent Scenery | 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| Scarcity | 3 | 1 | 3 | 1 | 3 | 3 | 1 | 3 | 1 |
| Cultural Modifications | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| **Overall Score** | **18** | **13** | **15** | **13** | **15** | **15** | **13** | **15** | **13** |
| **Scenic Quality Rating[2]** | **B** | **B** | **B** | **B** | **B** | **B** | **B** | **B** | **B** |

[1] Numerical scores were adapted from BLM VRI Manual (BLM 1986b)

[2] A = 19 or more, B = 12-18, C = 11 or less.

Table 3.22-2 shows the Sensitivity Level Analysis Factors and Ratings, which includes indicators of public concern such as the amount of use and the public interest. Each dam's sensitivity level was rated in Table 3.22-3 based on the amount of use in visits per year and amount of visitor spending in dollars per year (USACE 2019h, USACE 2019j, USACE 2019k, USACE 2019l, USACE 2019n, USACE 2019p, USACE 2019q, USACE 2019r, USACE 2019s). The number of visits and visitor spending at each dam and reservoir is for Fiscal Year (FY) 2019. The metrics for low, moderate, and high for number of visits and visitor spending were adapted from the BLM VRI Manual (BLM 1986b) and established subjectively to best cover the data range. For example, the amount of visitors in FY 2019 among the dams ranged from tens of thousands to hundreds of thousands. Therefore, a metric was established to best capture what a low, moderate, and high value would be within that data range. Less than 50,000 visitors was given a 'Low' rating, between 50,000 and 75,000 visitors was given a 'Moderate' rating, and greater than 75,000 visitors was given a 'High' rating. This process was repeated for visitor spending; visitors spending in FY 2019 among the dams ranged from hundreds of thousands of dollars to over a million dollars. Therefore, a metric was established to best capture what a low, moderate, and high value would be within that data range. Less than $1,000,000 in visitor spending was given a "Low" rating, $1,000,000 to $5,000,000 in visitor spending was given a "Moderate" rating, and greater than $5,000,000 in visitor spending was given a "High" rating.

**Table 3.22-2. VRM Sensitivity Level Analysis Factors and Ratings**

| Factors of Public Concern | Rating[1] | | |
|---|---|---|---|
| | High | Moderate | Low |
| Amount of Use | Greater than 75,000 visits, FY 2019 | 50,000 – 75,00 visits, FY 2019 | Less than 50,000 visits, FY 2019 |
| Public Interest (Economic: Visitor Spending) | Greater than $5,000,000, FY 2019 | $1,000,000 - $5,000,000, FY 2019 | Less than $1,000,000, FY 2019 |

[1] Ratings were adapted from the BLM VRI Manual (BLM 1986b)

**Table 3.22-3. VRM Sensitivity Level Analysis for Select Dams and Reservoirs**

| Factors of Public Concern | Sensitivity Level Rating by Dam/Reservoir[1] | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | LOP | DET | GRP | HCR | DEX | CGR | BLU | FOS | FCR |
| Amount of Use | Low | Moderate | High | Low | High | Low | Low | High | High |
| Public Interest | Moderate | Moderate | Moderate | Moderate | High | Low | Low | High | Moderate |
| **Overall Rating** | Low – Moderate | Moderate | High – Moderate | Low – Moderate | High | Low | Low | High | High – Moderate |

[1] USACE 2019h, USACE 2019j, USACE 2019k, USACE 2019l, USACE 2019n, USACE 2019p, USACE 2019q, USACE 2019r, USACE 2019s

Table 3.22-4 displays which distance zone each dam fell into based upon their visibility from travel routes or observation points. All nine dams fell in the foreground-middleground distance zones due to visibility from points of less than 3 to 5 miles away.

**Table 3.22-4. VRM Distance Zones for Select Dams and Reservoirs**

| Distance Zones | Dam/Reservoir | | | | | | | | |
|---|---|---|---|---|---|---|---|---|---|
| | LOP | DET | GRP | HCR | DEX | CGR | BLU | FOS | FCR |
| Foreground-middleground | X | X | X | X | X | X | X | X | X |
| Background | | | | | | | | | |
| Seldom Seen | | | | | | | | | |

The scores from the Scenic Quality Inventory, Sensitivity Level Analysis, and distance zones were organized into a matrix included in Table 3.22-5. Based on their aggregate scores, each dam and reservoir was assigned a class which is displayed in Table 3.22-6.

**Table 3.22-5. Visual Resource Inventory Class Matrix[1] and Results**

| Visual Sensitivity Levels | | High | | Moderate | | Low |
|---|---|---|---|---|---|---|
| Special Areas | | I | | I | | I |
| Scenic Quality | A | II | | II | | II |
| | B | II | III* | III | IV* | IV |
| | C | III | IV* | IV | | IV |
| Distance Zones | | Foreground – middleground zone | | | | |

[1] VRI Class Matrix adapted from BLM VRI Manual (BLM 1986b)

* If a sensitivity level was rated between two levels, the lower-level Class was assigned.

**Table 3.22-6. Visual Resource Inventory Class Results by Dam**

| LOP | DET | GRP | HCR | DEX | CGR | BLU | FOS | FCR |
|---|---|---|---|---|---|---|---|---|
| IV | III | III | IV | II | IV | IV | II | III |

### *3.22.3.1 Detroit Dam and Reservoir*

The concrete Detroit Dam is a massive structure that is 463 feet (ft) high and 1,523 ft wide, and includes gated spillways and two hydropower generating units. Detroit Reservoir is 9 miles long and encompasses an area of 3,500 acres when the reservoir is full (USACE No Date-e). Detroit Dam is commonly used as a scenic viewpoint for the dam itself and is a designated stop along the Mt. Jefferson section of the Oregon Cascades Birding Trail. Viewers can also observe Big Cliff Reservoir below the dam and Detroit Reservoir above the dam. It has 30 miles of shoreline with campgrounds, marinas, Detroit Lake State Park, and other natural features (USACE No Date-e). Figure 3.22-2 shows the scenic view of Detroit Reservoir from the dam; and as shown in Figure 3.22-3, visitors can observe rockfaces and trees along North Santiam Highway (Google Earth No Date).

**Figure 3.22-2. View of Detroit Reservoir from the Dam (Google Earth No Date)**

**Figure 3.22-3. Heading East on North Santiam Highway, Detroit Reservoir (Google Earth No Date)**

A VRI was completed for Detroit Dam due to potential impacts from the Proposed Action and alternatives: Alternatives 1, 2A, 2B, and 4 propose the construction of a water temperature control tower and downstream passage structure; Alternative 3A proposes a deep fall reservoir drawdown and a deep spring reservoir drawdown; and Alternative 3B propose a deep fall reservoir drawdown. The Scenic Quality Evaluation resulted in an overall score of 13 and a 'B' Rating, as the presence of water increased the score. Sensitivity Level was moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Detroit Dam and Reservoir was rated as a Class III area, which is of moderate visual value.

### *3.22.3.2 Foster Dam and Reservoir*

Foster Dam is a rock-filled structure that includes a concrete gated spillway. The dam is 126 ft high and 4,565 ft wide and paved to enable drivers to cross over. Foster Reservoir is 3.5 miles long and encompasses an area of 1,220 acres when the reservoir is full (USACE No Date-j). As shown in Figure 3.22-4, visitors who cross the dam can view Foster's Reservoir above the dam. Visitors can also see the South Santiam River, marinas, parks, and the South Santiam Fish Hatchery below the dam (Google Earth No Date). It has parks, boat ramps, marinas, and observation points to allow scenic views of the water, trees, shrubs and rare wildlife such as the northern spotted owl, western pond turtle, and several amphibians (USACE No Date-j).

A VRI was completed for Foster Dam due to potential impacts from the Proposed Action and alternatives: Alternatives 1, 2A, 2B, and 4 propose the construction of a downstream passage structure. The Scenic Quality Evaluation resulted in an overall score of 15 and a 'B' Rating, as the presence of water and rare wildlife within this landscape increased the score. Sensitivity Level was high due to the high amount of use and public interest, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Foster Dam and Reservoir was rated as a Class II area, which is of higher moderate visual value.

**Figure-3.22-4. Foster Dam Road and Foster Reservoir (Google Earth No Date)**

### *3.22.3.3 Green Peter Dam and Reservoir*

Green Peter Dam is located 11 miles northeast of Sweet Home, OR. The concrete dam is 327 ft high and 1,500 ft wide and includes a gated spillway and two hydropower generating units. Green Peter Reservoir is 10 miles long and encompasses an area of 3,720 acres when the reservoir is full (USACE No Date-k). North River Road is lined with trees on the dam side and rocky cliffs on the opposite side, obstructing motorists' view of the dam itself (Google Earth No Date). The overlook at the dam provides scenic views of the dam's structure, while other boat ramps and parks along the reservoir's 10-mile shoreline offer scenic views of water, vegetation, and rolling hills topped with various tree species. Osprey are also known to nest along the shorelines of the reservoir and may enhance aesthetic views of the area.

A VRI was completed for Green Peter Dam due to potential impacts from the Proposed Action and alternatives: Alternative 1 proposes the construction of a water temperature control tower, adult fish facility, and downstream passage structure; Alternative 2A and 2B proposes the construction of an adult fish facility and a deep fall reservoir drawdown; Alternative 3A proposes the construction of an adult fish facility, a deep fall reservoir drawdown, and a deep spring reservoir drawdown; and Alternative 3B proposes the construction of an adult fish facility, and a deep fall reservoir drawdown. The Scenic Quality Evaluation resulted in an overall score of 15 and a ‘B’ Rating, as the presence of water and the potential to see osprey nests along the shorelines increased the score. Sensitivity Level was high to moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. The Green Peter Dam and Reservoir was rated as a Class III area, which is of moderate visual value.

#### *3.22.3.4 Cougar Dam and Reservoir*

Cougar Dam is located on the South Fork McKenzie River about 42 miles east of Eugene, Oregon. The rockfilled structure is 452 ft high and 1,600 ft wide and contains a gated concrete spillway, powerhouse, fish ladder, and temperature control tower that includes a portable floating fish collector. Cougar Reservoir is 6 miles long and encompasses an area of 1,280 acres when the reservoir is full. (USACE No Date-d). The Cougar Dam Overlook located on the northeast side of the dam allows viewers to look below the massive dam to the South Fork McKenzie River, and above the dam at Cougar Reservoir as seen in Figure 3.22-5, which is surrounded by forests and steep rocky cliffs (Google Earth No Date). The area contains many parks, campgrounds, and creeks; the reservoir itself is a designated stop along the Three Sisters section of the Oregon Cascades Birding Trail, where American peregrine falcons have been observed around the cliffs of the reservoir (USACE No Date-d).

**Figure 3.22-5. View of the Cougar Reservoir from the Cougar Dam Overlook (Google Earth No Date)**

A VRI was completed for Cougar Dam due to potential impacts from the Proposed Action and alternatives: Alternative 2A and 4 propose the construction of downstream passage structures; Alternative 2B and 3A propose a deep fall reservoir drawdown and a deep spring reservoir drawdown; and Alternative 3B proposes a deep fall reservoir drawdown. The Scenic Quality Evaluation resulted in an overall score of 15 and a 'B' Rating, as the presence of water and the Three Sisters section of the Oregon Cascades Birding Trail increased the score. Sensitivity Level was low, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Cougar Dam and Reservoir was rated as a Class IV area, which is of least visual value.

#### *3.22.3.5 Blue River Dam and Reservoir*

Blue River Dam is located 38 miles east of Eugene, Oregon. The rockfilled structure is 270 ft high and 1,265 ft wide, and includes a gated concrete spillway. Blue River Reservoir is nearly 6 and a half miles long and encompasses an area of 1,009 acres when the reservoir is full (USACE No Date-b). A viewpoint located on the northeast end of the dam provides observers with a scenic view of the dam's massive structure, along with views of Blue River below the dam and the reservoir above the dam (Google Earth No Date) that includes western pond turtles and ospreys that have been known to roost (rest or sleep) in large trees and snags (USACE No Date-b). Forest and steep, rocky cliffs encompass most of the reservoir, while boat ramps and campgrounds provide access to the scenic views of the reservoir and surrounding forests (USACE No Date-b).

A VRI was completed for Blue River Dam due to potential impacts from the Proposed Action and alternatives: Alternative 3A and Alternative 3B propose the construction of an adult fish facility and a deep fall reservoir drawdown. The Scenic Quality Evaluation resulted in an overall score of 13 and a ‘B’ Rating, as the presence of water increased the score. Sensitivity Level was low, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Blue River Dam and Reservoir was rated as a Class IV area, which is of least visual value.

#### *3.22.3.6 Lookout Point (Meridian) Dam and Reservoir*

Lookout Point Dam is located on the Middle Fork Willamette River about 22 miles southeast of Eugene, OR. It is an earth and gravel-filled dam that is 276 ft high and 3,381 ft wide with a concrete gated spillway, powerhouse, and the Dexter Service Building, a USACE Office. Lookout Point Reservoir is over 14 miles long and encompasses an area of 4,360 acres when the reservoir is full (USACE No Date-m). As shown below in Figure 3.22-6, visitors to the dam can stop at Meridian Park and observe the expansive reservoir surrounded by rocky cliffs and rolling hills topped with various tree species. The area surrounding the reservoir includes several parks, boat ramps, and creeks that provide scenic views of the water, vegetation, and rolling forested hills. The reservoir and rolling hills to the northeast are visible from Willamette Highway through breaks in the treeline (Google Earth No Date). Visitors may also spot rare species, including the northern spotted owl and western pond turtles. Bald eagles are known to winter and regularly nest at Lookout Point (USACE No Date-m). Lowell Covered Bridge is located west of the dam and provides views of the dam, surrounding water bodies, forests, and rolling hills (Google Earth No Date).

**Figure 3.22-6. View of Lookout Point Reservoir from Dam (Google Earth No Date)**

A VRI was completed for Lookout Point Dam due to potential impacts from the Proposed Action and alternatives: Alternative 1 and Alternative 4 propose the construction of a water temperature control tower and a downstream passage structure; Alternative 2A and 2B propose the construction of a downstream passage structure; Alternative 3A propose a deep fall reservoir drawdown and a deep spring reservoir drawdown; and Alternative 3B propose a deep fall reservoir drawdown. The Scenic Quality Evaluation resulted in an overall score of 18 and a ‘B’ Rating, as the presence of water, the rare wildlife, and views of the dam from Lowell Covered Bridge increased the score. Sensitivity Level was low to moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Lookout Point Dam and Reservoir was rated as a Class IV area, which is of least visual value.

#### *3.22.3.7 Hills Creek Dam and Reservoir*

Hill Creek Dam is located 4 miles southwest of Oakridge, Oregon. It is an earthfilled dam that rises 304 ft high and 2,235 ft wide and includes a gated concrete spillway, two hydropower generating units, a powerhouse, an outlet to regulate reservoir levels, and a hatchery and ranger station located west of the dam. Hills Creek Reservoir is nearly 8 miles long and encompasses an area of 2,735 acres when the reservoir is full. The area around the reservoir contains picnic areas, campgrounds, creeks, and multiple viewpoints of the dam itself. From scenic viewpoints in this area, visitors can observe the massive earthen structure, the reservoir, forested hills, and wildlife such as birds that stop along the Three Sisters section of the Oregon Cascades Birding Trail (USACE No Date-l).

A VRI was completed for Hills Creek Dam due to potential impacts from the Proposed Action and alternatives: Alternative 3A proposes the construction of an adult fish facility and a deep fall reservoir drawdown; Alterative 3B proposes the construction of an adult fish facility, a deep fall reservoir drawdown, and a deep spring reservoir drawdown; and Alternative 4 proposes the construction of a water temperature control tower, an adult fish facility, and a downstream passage structure. The Scenic Quality Evaluation resulted in an overall score of 13 and a 'B' Rating; the presence of water increased the score. Sensitivity Level was low to moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Hills Creek Dam and Reservoir was rated as a Class IV area, which is of least visual value.

#### *3.22.3.8 Dexter Dam and Reservoir*

Dexter Dam is located about 22 miles southeast of Eugene, Oregon. It is an earth and gravel-filled embankment dam that is 93 ft high and 2,739 ft wide with concrete gated spillways, a powerhouse, and a fish facility. Dexter Reservoir is almost 3 miles long and encompasses an area of 1,024 acres when the reservoir is full (USACE No Date-f). Willamette Highway runs along the southern edge of Dexter Reservoir and provides scenic views of the water, trees, and hills, while Shore Line Drive runs northeast of the dam into the City of Lowell, where it crosses the reservoir as Lowell Covered Bridge (Google Earth No Date). Figure 3.22-7 below shows where Shore Line Drive crosses Dexter Reservoir at Lowell Covered Bridge. This mixture of natural landscape along with urban structures such as the dam, bridge, and the City of Lowell on the northern embankment provide a diverse assortment of landscape features for visitors to observe.

**Figure 3.22-7. Lowell Covered Bridge, Dexter Reservoir (Google Earth No Date)**

A VRI was completed for Dexter Dam due to potential impacts from the Proposed Action and alternatives: Alternative 1 and Alternative 4 propose the construction of an adult fish facility. The Scenic Quality Evaluation resulted in an overall score of 15 and a 'B' Rating, as the presence of water and views of Lowell Covered Bridge, the City of Lowell, and other urbanized features that mix with the natural landscape increased the score. Sensitivity Level was moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Deter Dam and Reservoir was rated as a Class II area, which is of higher moderate visual value.

#### *3.22.3.9 Fall Creek Dam and Reservoir*

Fall Creek Dam is located on Fall Creek, a major tributary to the Middle Fork Willamette River, one mile upstream of Unity, Oregon and 25 miles upstream of Eugene and Springfield, Oregon. It is a rock filled, earth dam that is 205 ft high and 5,050 ft wide with a concrete spillway, two spillway gates, and a regulating outlet (USACE No Date-h). North Shore Park and Winberry State Recreation Site are located on the north and south sides of the dam, respectively. Big Fall Creek Road stretches along the north side of the reservoir while Peninsula Road traverses the southern shore. These roads provide scenic views of the forested landscape, with breaks in the tree line opening up to views of the reservoir. Moving away from the dam to the northeast corner of the reservoir lies Fall Creek State Recreation Area and Cascara Campground which provides a dense and rustic forested space along the narrowing stretches of Fall Creek reservoir.

A VRI was completed for Fall Creek Dam due to potential impacts from No Action alternative: ongoing reservoir drawdown annually during late fall to its lowest outlet. The Scenic Quality Evaluation resulted in an overall score of 13 and a ‘B’ Rating, as the presence of water increased the score. Sensitivity Level was high – moderate, and the dam was categorized within the foreground-middleground distance zone due to its visibility from highways and observation points of less than 3 to 5 miles away. Fall Creek Dam and Reservoir was rated as a Class III area, which is of moderate visual value.

### 3.22.4 Environmental Effects

This section discusses the potential effects of the Proposed Action and alternatives on visual resources. The discussion includes the methodology, the measures within the action alternatives that were analyzed, a summary of the effects, and a detailed analysis for each alternative.

#### *3.22.4.1 Methodology*

This analysis uses a three-step process to determine potential visual effects at each dam, which are discussed in detail in 3.22.4.1.1 (Visual Resource Contrast Rating), 3.22.4.1.2 (Evaluation Criteria), and 3.22.4.1.3 (VRM Class Management Objectives).

1. Visual Resource Contrast Rating – The visual resource contrast rating of each dam is determined by comparing the proposed project measures with the major features in the existing landscape using the basic design elements of form, line, color, and texture.
2. Evaluation Criteria – For purposes of this NEPA analysis, the visual resources contrast ratings correspond with the magnitude (how much or severity) of potential effects. The evaluation criteria (shown in Table 3.22-7 below) also include duration (how long) and extent (how far or sphere of influence).
3. VRM Class Management Objectives – The visual contrast rating is compared to the VRM Class management objectives for each dam (as established in the Affected Environment) to ensure that level of change is allowed at each dam. If a dam’s level of change is not within its Class management objectives, design adjustments or mitigations could be required. This is a subjective process due to the varying degrees of change allowed per Class rating.

##### *3.22.4.1.1 Visual Resource Contrast Rating*

The first part of the BLM Visual Resource Management (VRM) process, the BLM Visual Resource Inventory (VRI), is described for select dams in the Affected Environment (Section 3.22.3). A more detailed description of how each dam and reservoir was rated in the Scenic Quality Inventory, Sensitivity Level Analysis, and Distance Zones is included in Appendix T. The second part in the BLM VRM process is the visual resources analysis, or the visual resource contrast rating. The contrast rating determines the degree of contrast that an effect would have on the landscape, and can range from “none” or no visible contrast, to “strong” or a contrast that dominates the landscape.

Basic design elements, such as form, line, color, and texture, are used to make this comparison and to describe the visual contrast created by the measures. Form is defined by the changes in the shape or mass of landforms or structures; the degree of change depends on how dissimilar the introduced forms are to those continuing to exist in the landscape. Line is defined by the changes in edge types and interruption or introduction of edges, bands, and silhouette lines; new lines may differ in their sub elements (boldness, complexity, and orientation) from existing lines. Color is defined by the changes in value and hue that create the greatest contrast; other factors such as chroma, reflectivity, and color temperature may also increase the contrast. Texture is defined by the changes in grain, density, and internal contrast; other factors such as irregularity and directional patterns of texture may affect the rating (BLM 1986a).

Therefore, potential alterations to the form, line, color, and texture of the landscape from proposed measures are evaluated to determine the contrast rating (i.e., none, weak, moderate, and strong). For example, the contrast rating would be "none" if the alteration would not visible and would not attract attention, or more specifically, if the proposed measure would not:

1. Alter the shape and mass of the landscape (form);
2. Alter edge types, bands, and silhouette lines of the landscape (line);
3. Alter the hue and coloration of the landscape (color); and
4. Alter the grain, density, and internal contrast of the landscape (texture).

The degree of the rating increases based on the level of contrast determined for each basic design element. These basic design elements are subjective to the analyst, and therefore the interpretation of the effect can vary.

#### *3.22.4.1.2 Evaluation Criteria*

For purposes of this analysis, the VRM's contrast rating system has been adapted into the evaluation or significance criteria. Contrast ratings (i.e., none, weak, moderate, and strong) correspond to the magnitude of effects (i.e., negligible, minor, moderate, and major or significant) on visual resources. Effects range from negligible (a contrast that is not visible and does not attract attention) to major (a contrast that demands attention, cannot be overlooked, and dominates the landscape). In the event that no modification or contrast change would occur, the magnitude of effects would be none and are not analyzed further.

Table 3.22-7 describes the evaluation criteria for magnitude, duration, and extent, and provides a definition for the scale of each effect factor. Extent was derived from the amount of use recorded at each location, as this metric was used for the Sensitivity Level Analysis for the VRI in the Affected Environment. Note that the definitions for short term, medium term, and long term are the same for all resources.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.22-7. Evaluation Criteria for Potential Effects to Visual Resources**

| Term | Definition |
|---|---|
| **Magnitude** | |
| Negligible | A modification cannot be seen and does not attract attention. |
| Minor | A modification can be seen, but does not attract attention. |
| Moderate | A modification begins to attract attention and begins to dominate the characteristic landscape. |
| Major | A modification demands attention, cannot be overlooked, and dominates in the landscape. |
| **Duration** | |
| Short term | Alteration lasts for the duration of small construction project, and is continuous for less than 2 years. |
| Medium term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (i.e., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Visual quality is altered for less than 50,000 visitors. |
| Medium | Visual quality is altered for 50,000 to 75,000 visitors. |
| Large | Visual quality is altered for more than 75,000 visitors. |

Source: BLM 1986a

#### *3.22.4.1.3 VRM Class Management Objectives*

Table 3.22-8 provides the VRM Management Objectives based on Class. Higher Classes (I and II) are most valued and management activities aim to preserve the existing character of the landscape. Lower Classes (III and IV) represent lower value landscapes and may provide more allowance for management activities to alter its appearance. Class ratings (i.e., I, II, III, IV) roughly correspond with the degrees of contrast or change (i.e., none, weak, moderate, and strong), although these can vary based on the nature of the management activity or measure. A measure that results in a high level of change in a higher Class may be subject to mitigation measures.

**Table 3.22-8. VRM Class Management Objectives**

| Class | Management Objective | Degree of Contrast | Dam/ Reservoir |
|---|---|---|---|
| Class I | The objective of this Class is to preserve the existing character of the landscape. It provides for natural ecological changes, and does not preclude very limited management activity. Any change to the landscape must not attract attention. | None (or Negligible) | N/A |
| Class II | The objective of this Class is to retain the existing character of the landscape. Management activities may be seen, but should not attract the attention of the casual observer. Any changes must repeat the basic elements of form, line, color, and texture found in the predominant natural features of the characteristic landscape. | Weak (or Minor) | Dexter (DEX), Foster (FOS) |
| Class III | The objective of this Class is to partially retain the existing character of the landscape. Management activities may attract attention but should not dominate the view of the casual observer. Changes should repeat the basic elements found in the predominant natural features of the characteristic landscape. | Moderate | Detroit (DET), Green Peter (GRP), Fall Creek (FCR) |
| Class IV | The objective of this Class is to provide for management activities which require major modification of the existing character of the landscape. Management activities may dominate the view and be the major focus of viewer attention. However, every attempt should be made to minimize the effect of these activities through careful location, minimal disturbance, and repeating the basic elements. | Strong (or Major) | Lookout Point (LOP), Hills Creek (HCR), Cougar (CGR), Blue River (BLU) |

Source: BLM 1986a

As described above, VRM Class Management Objectives are compared to the level of change or contrast rating the proposed project measure would create to determine if the effect would be within each dam's management objective. If a dam's level of change is not within its Class management objectives, design adjustments or mitigations could be required.

### *3.22.4.2 Measures Analyzed for Visual Resources*

Measures under the action alternatives that could have an effect on visual resources include construction of water temperature control (WTC) towers (#105), construction of adult fish facilities (AFF) (#722), construction of structural downstream fish passage (#392), deeper fall reservoir drawdowns for fish passage (#40), and spring reservoir drawdowns for downstream fish passage (#720).

The following measures would have no effect on visual resources, and are therefore not discussed further.

- Gravel augmentation below dams (#384);
- Adapt hatchery program (#719);
- Maintenance of existing and new fish release sites above dams (#9);
- Continued operation of existing adult fish facilities;
- Operation, maintenance, repair, replacement, and rehabilitation;
- Foster fish ladder temperature improvement (#479);
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166);
- Use spillway for surface spill in summer (#721);
- Structural improvements to reduce total dissolved gas (#174);
- Augment instream flows by using the inactive pool (#718);
- Augment instream flows by using the power pool (#304);
- Reduce minimum flows to Congressionally authorized minimum flow requirements (#723);
- Integrated temperature and habitat flow regime (#30a);
- Refined integrated temperature and habitat flow regime (#30b);
- Restore upstream and downstream passage at drop structures (#639);
- Provide Pacific lamprey passage and infrastructure (#52); and
- Pass water over spillway in spring for fish passage (#714).

A summary of the effects to visual resources discussed in the following sections is provided in Table 3.22-9. Note that where a range of potential effects would occur, the most severe magnitude of adverse effects and the least magnitude of beneficial effects for each alternative is listed to present the most conservative range of potential effects. Also, the extent of effects includes all reservoirs where potential effects would occur, even if the most severe adverse effect or the least beneficial effect does not occur at that reservoir. Discussion of all adverse and beneficial effects is presented below.

**Table 3.22-9. Summary of Effects to Visual Resources Under Each Alternative***

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | **NAA** | **1** | **2A** | **2B** | **3A** | **3B** | **4** | **5** |

| Effect Factor | Alternative | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | **NAA** | **1** | **2A** | **2B** | **3A** | **3B** | **4** | **5** |
| Duration Type | Recurring | Permanent and/or Recurring | Permanent and/or Recurring | Permanent and/or Recurring | Permanent and/or Recurring | Permanent and/or Recurring | Permanent and/or Recurring | Permanent and/or Recurring |

*This summary table does not include the effects from near-term operations due to the uncertainty of the implementation and duration of these operations.

In the following subsections, the effects are discussed for the measures analyzed in the alternatives, for the No Action Alternative, and for each of the action alternatives.

### *3.22.4.3 Discussion of Effects by Measure*

This section applies the methodology described above for each measure analyzed for visual resources to determine the potential effect. Where possible, the discussion of the magnitude and duration of effects is grouped by measures that would have similar effects, such as the construction of WTC towers and structural downstream fish passages. These effects by measure will then be referenced in the action alternatives analysis that follows. Potential effects that occur at one or many dam(s) are grouped by VRM class as appropriate, and this discussion is included under the appropriate alternative. The extent of effects is discussed by dam/reservoir under the appropriate alternative.

This Draft PEIS discusses general, qualitative effects from construction at the programmatic level. Site-specific project details for each construction measure will be determined during the implementation phase. Structural measures with a construction phase that will affect visual resources include construction of WTC towers, AFFs, and structural downstream fish passage, and deeper fall and spring reservoir drawdowns. Subsequent tiered NEPA documents would discuss detailed site-specific effects of construction.

#### *3.22.4.3.1 Construct water temperature control (WTC) towers (#105), Construct structural downstream fish passages (#392), and Construct adult fish facilities (AFFs) (#722)*

The contrast rating or the magnitude of effects from the construction of WTC towers (#105), structural downstream fish passages (#392), and/or AFFs (#722) would be minor in the short, medium, and long term at all of the dams. These potential effects are determined below and referred to in the action alternative analysis.

In general, the WTC towers, structural downstream fish passages, and AFFs would be located next to the dam. Construction activities and equipment associated with these measures, including work vehicles, machinery, and building materials, would likely be visible during the duration of the construction phase. Construction activities would blend into the already existing landscape of the dams by generally matching in color, texture, line, and form. Construction vehicles and equipment would generally match the coloration of the dams, contain a similar rectangular form that is comparable to the dams, have straight lines comparable to the dams, and have similar grain, density, and overall textured contrast similar to the dams. Because these vehicles and equipment would not drastically alter any of the basic design elements in the landscapes, the contrast rating and magnitude of adverse effects would be minor, as the vehicles and equipment would be seen but would not attract attention and would not dominate the landscapes. There would be a short-term effect to the landscape at Foster because the modification to the existing spill (fish) weir would take less than a year to be completed. There would be a medium-term effect to the landscape from the WTC towers, structural downstream fish passages, and AFFs because the construction activities from these measures would take between two and five years to be completed.

Once construction is complete, the WTC towers, structural downstream fish passages, and AFFs would blend into the already existing landscape of the dams by generally matching in color, texture, line, and form. These structures would likely use similar building materials to the dams, match the gray coloration of the dams, contain a similar rectangular form that is comparable to the dams, have straight lines comparable to the dams, and have similar grain, density, and overall textured contrast similar to the dams. It would also likely add to the visual interest that the dams already provide, which could be viewed as a beneficial effect based on the perspective of the observer. Because these structures would not drastically alter any of the basic design elements in the landscapes, the contrast rating and magnitude of adverse and beneficial effects would be minor, as these structures would be seen but do not attract attention and do not dominate the landscapes. There would be a long-term effect to the landscapes because these structures would be permanent.

Therefore, potential adverse effects from the construction of the WTC towers, structural downstream fish passages, and AFFs would be minor in magnitude, and short and medium term in duration. In the long term, potential adverse and beneficial effects from these structures would also be minor in magnitude.

###### *3.22.4.3.2 Fall Creek drawdown, Deeper fall reservoir drawdowns for fish passage (#40), and Spring reservoir drawdowns for downstream fish passage (#720)*

The contrast rating or the magnitude of effects from the Fall Creek Drawdown, deeper fall reservoir drawdowns (#40), and spring reservoir drawdowns (#720) would be moderate in the short term and major in the long term at all the reservoirs, regardless of the exact drawdown level. These potential effects are determined below and referred back to under all alternatives.

Shoreline erosion is not expected to occur, given that the drawdowns would only last for three weeks. However, suspended solids would mobilize as the deep drawdowns occur. This would lead to sediments, organic materials, and other debris being washed downstream and affecting water color and clarity (USACE No Date-p). This would also have a noticeable effect on the basic design elements of color, texture, and form. Color would change slightly to a darker color with the introduction of darker clays, silts, and sediments; texture would change slightly with the introduction of grainy sediment particles and other larger suspended particulate materials; and form would change slightly with the introduction of a variety of irregular shapes, sizes, and masses from the suspended solids. Because sediment transport would noticeably alter the basic design elements in the landscapes, the contrast rating and magnitude of adverse effects at all the dams and reservoirs would be moderate, as sediment transport downstream would begin to attract attention and begin to dominate the landscapes. There would be a short-term effect to the landscapes for the 3-week drawdown period; water clarity and coloration would return to baseline conditions in the days to weeks that follow.

Reservoir drawdowns could reveal mudflats, substrate, tree stumps, and other submerged littoral zone attributes (submerged vegetation, roots, sediments, rocks, snails, shells, etc.), and would have an effect on the basic design elements of color, texture, line, and form. Color would change substantially with the loss of surface water and the exposure of previously submerged littoral zone attributes containing darker colors; texture would change substantially from the water's smooth surface to rough, more grainy surfaces with the exposure of mudflats or other submerged substrate; line would change substantially from the solid, smooth, and curved lines of the water's surface and edge to jagged, irregularly shaped lines with the introduction of submerged littoral zone attributes; and form would change substantially from the uniform and ubiquitous shape and mass of the reservoirs to a variety of irregular shapes, sizes, and masses with the exposure of submerged littoral zone attributes. An example of this difference can be seen in Section 3.22.4.4. It should be noted that the typical vegetation cover around the reservoir is unlikely to change, meaning trees, grasses, and other plants are not expected to expand into the reservoirs. Because the drawdowns would substantially alter the basic design elements in the landscapes, the contrast rating and magnitude of adverse effects at all the dams and reservoirs would be major, as the reservoir drawdowns would demand attention, cannot be overlooked, and dominate the landscapes. There would be a long-term, recurring effect to the landscapes because while this elevation would only be held for three weeks, it would occur annually. Mitigation measures may be recommended for some project locations where reservoir drawdowns would not be consistent with their Class Management Objectives. Mitigation measures could include limiting drawdowns elevations, monitoring turbidity downstream, or installing temporary signage to inform visitors of the dates and times of reservoir drawdowns so that these viewsheds can be avoided.

##### *3.22.4.3.3 Near-Term Operations*

The contrast rating or the magnitude of effects from near-term operations would be major in the short term or medium term at all the dams. These potential effects are determined below and referred back to under Alternatives 2A, 2B, 3A, 3B, 4, and 5.

Near-term operations that would potentially affect visual resources include:

- Deep drawdown and RO prioritization for improved downstream fish passage at Green Peter, Cougar, and Lookout Point dams;
- Delayed reservoir refill and RO prioritization for improved downstream fish passage at Cougar and Fall Creek dams;
- Extended deep drawdown and RO prioritization for improved downstream fish passage at Fall Creek; and
- Delay reservoir refill and utilize spillway in the spring for improved downstream fish passage at Foster dam.

As discussed above in Section 3.22.4.3.2 (Reservoir Drawdowns), potential adverse effects from revealed mudflats, substrate, tree stumps, and other submerged littoral zone attributes would be major in magnitude. It should be noted that the duration and recurrence of near-term operations ultimately would depend on when other operations or structures proposed at a location in the action alternatives can be implemented; therefore, duration of effects would be short term and/or medium term depending on the implementation process of measures in the action alternatives. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs because these dams recorded greater than 75,000 visitors in FY 2019; and small at Lookout Point and Cougar because these dams recorded less than 50,000 visits in FY 2019. These measures would generally be consistent with the Class IV management activities for Cougar and Lookout Point. However, long-term effects from reservoir drawdowns and delayed refills would not be consistent with Class II or III management activities at Foster, and Green Peter and Fall Creek Dams and Reservoirs, respectively. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

#### *3.22.4.4 No Action Alternative*

Under the NAA, revetments would be maintained using nature-based engineering or altered for aquatic ecosystem restoration (#9). Revetments are located along the Willamette River and its tributaries and not along reservoir shorelines. As such, they were not considered key elements to visual resources as they do not occur at the 13 USACE dams and reservoirs and the locations of revetments cannot be seen from project locations. Since revetments were not subjected to the VRM process, maintaining or altering revetments would have no effect on visual resources.

Under the NAA, Fall Creek reservoir would continue to be drawn down annually to its lowest outlet for a few weeks in November, potentially lasting into December. As discussed in Section 3.22.4.3.2, the drawdowns would substantially alter the basic design elements in the landscape. An example of these drawdowns can be seen below. Figure 3.22-8 shows Fall Creek Dam and Reservoir at full capacity, and Figure 3.22-9 shows the reservoir at a drawdown elevation of 10 feet above the ROs and near the historical streambed.

As discussed above in Section 3.22.4.3.2, potential adverse short-term effects from sediment transport during drawdowns would be moderate in magnitude. Potential adverse long-term, recurring effects would be major in magnitude. Effects would be large in extent because Fall Creek recorded greater than 75,000 visitors in FY 2019. Fall Creek is listed as a Class III area, meaning its objectives are to partially retain the existing character of the landscape. Short-term potential adverse effects from sediment transport during drawdowns would be consistent with the Class III Management Objectives. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities.

**Figure 3.22-8. View of Fall Creek Dam and Reservoir at full capacity (USACE No Date-h)**

**Figure 3.22-9. View of Fall Creek Dam and Reservoir during a deep reservoir drawdown to 10 ft above the ROs (USACE No Date-o)**

### *3.22.4.4.1 Climate Change*

Climate change would adversely affect visual resources within the WVS. Ambient air temperature changes, low summer flows, and reservoir evaporation could potentially affect visual resources at project locations by lowering the reservoir level and altering basic design elements from surface water landscapes to terrestrial landscapes. Long-lasting droughts and warm spells could compromise earth dams as a result of soil cracking due to drying, and would potentially erode or alter landscape characteristics (See Appendix F1); this could be of particular concern at earth and gravel-filled dams such as Lookout Point and Dexter Dams, and earth-filled dams such as Hills Creek Dam. Warmer temperatures from climate change could also provide favorable conditions for the propagation of harmful algal blooms (HABs), which can discolor, cloud, or cover the water's surface and affect visual resources. Wildfire intensity and frequency associated with climate change would drastically alter the basic design elements of a forested, natural landscape by substantially changing the color, form, and texture due to the burnt, darkened, and decimated landscapes that follow wildfires. Wildfire ash can also land in reservoirs, streams, and rivers, increasing turbidity and affecting the visual resources of those water bodies.

Effects from the Fall Creek Drawdown would be moderate in the short term and major in the long term. Climate change could exacerbate short-term effects from sediment transport during drawdowns, as increased wildfire ash, HABs, and erosion would further increase turbidity and noticeably alter the basic design elements in the landscapes. As such, the effects of climate change and the Fall Creek Drawdown would be moderate to major in the short term.

Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity, affecting water color and clarity. This would have a noticeable effect on the basic design elements of color, texture, and form. Color would change slightly to a darker color with the introduction of darker clays, silts, and sediments; texture would change slightly with the introduction of grainy sediment particles and other larger suspended particulate materials; and form would change slightly with the introduction of a variety of irregular shapes, sizes, and masses from the suspended solids. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. All above-mentioned effects would be large in extent.

#### *3.22.4.5 Alternative 1. Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, adverse effects from the construction of the WTC towers, structural downstream fish passages, and AFFs would be minor in magnitude in the medium and long term. The extent of effects would be large at Green Peter; medium at Detroit; and small at Lookout Point. Potential beneficial effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in the long term. The extent of effects would be large at Foster in the short term and long term due to the construction of a structural downstream fish passage in the form of a modification to the existing spill (fish) weir. The measures under this alternative would be consistent with the Class II, III, and IV management activities for Foster, Detroit and Green Peter, and Lookout Point, respectively.

Furthermore, as discussed in Section 3.22.4.3.2 (Fall Creek Drawdown, Deeper Fall Reservoir Drawdowns for Fish Passage, and Spring Reservoir Drawdowns for Downstream Fish Passage) and in Section 3.22.4.4 (NAA), reservoir drawdowns at Fall Creek would continue to have moderate short-term effects and major long-term, recurring effects. Short-term effects would be consistent with Class III management objectives, but long-term effects would not, and mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

In general, all of the major effects to visual resources would occur because of the drawdown(s). One drawdown – the Fall Creek drawdown – would occur under the NAA, Alternative 1, and Alternative 4; and the magnitude of effects would be major under these alternatives. Under Alternatives 3A and 3B, the alternatives with the most drawdowns, 10 drawdowns would occur across seven reservoirs (including the drawdown at Fall Creek). While the severity of effects would still be major, effects under Alternatives 3A and 3B would be more severe or more adverse than under Alternative 1 (and the NAA and Alternative 4). As such, Alternative 1 would have the same effect as Alternative 4, and would be less severe compared to Alternative 2A, 2B, 3A, 3B, and 5.

#### *3.22.4.5.1 Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs*

Under Alternative 1, the construction of large concrete WTC towers and of structural downstream fish passages in the forms of Floating Screen Structures (FSSs) consisting of large screen barges that float up or down with reservoir stage would occur at Detroit Dam, Green Peter Dam, and Lookout Point Dam. The construction of a structural downstream fish passage in the form of a modification to the existing spill (fish) weir would occur at Foster Dam. The construction of an AFF would occur at Green Peter Dam.

**Foster Dam and Reservoir (Class II)**

At Foster, the structural downstream fish passage would be a modification to the existing spill (fish) weir, located on the dam. As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse short- and long-term permanent effects from the structural downstream fish passages would be minor in magnitude. Effects would be large in extent because Foster recorded greater than 75,000 visits in FY 2019. Foster is listed as a Class II area, meaning its objective is to retain the existing character of the landscape. Construction of the structural downstream fish passage would be consistent with Class II management activities.

**Detroit and Green Peter Dams and Reservoirs (Class III)**

At Detroit and Green Peter, the WTC towers, structural downstream fish passages, and AFF would be located next to the existing dams. As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in magnitude. Effects would be medium in extent because Detroit recorded between 50,000 and 75,000 visits in FY 2019; and large in extent because Green Peter recorded more than 75,000 visits in FY 2019. Detroit and Green Peter are both Class III areas, meaning its objective is to partially retain the existing character of the landscape. The construction of WTC towers, structural downstream fish passages, and AFFs would be consistent with Class III management activities.

**Lookout Point Dam and Reservoir (Class IV)**

At Lookout Point, the WTC tower and structural downstream fish passage would be located next to the existing dam. As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of WTC tower and structural downstream fish passage would be minor in magnitude. Effects to the landscape would be small in extent because Lookout Point recorded less than 50,000 visits in FY 2019.

Lookout Point is a Class IV area, meaning its objective is to allow major modification of the existing character of the landscape. Construction of the WTC tower and the structural downstream fish passage would be consistent with Class IV management activities.

*3.22.4.5.2 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

Under Alternative 1, alterations to the visual landscape from the construction of WTC towers, structural downstream fish passage structures, and AFFs would have minor effects in the medium and long term. Climate change would not exacerbate medium-term visual effects from the presence of construction vehicles or the long-term permanent effects from the erection of these structures. The effects of climate change and the construction measures under Alternative 1 would still be minor in the medium and long term.

Effects from the Fall Creek Drawdown would be moderate in the short term and major in the long term. As described under the NAA, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity, affecting water color and clarity. Measures in Alternative 1 would actually improve reservoir storage and generally increase the quantity of water in reservoirs. Therefore, the effects of climate change from low summer flows and long-lasting droughts on visual resources would be less severe under Alternative 1 than any other alternative, including the NAA. That said, the effects of climate change and the Fall Creek Drawdown would still be major in the long term. All above-mentioned effects would be large in extent.

### *3.22.4.6 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Passage at Cougar Dam)*

Under Alternative 2A, adverse effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in the short, medium, and long term. Potential beneficial effects from the construction of WTC towers and AFF would be minor in the long term. Drawdowns would have moderate short-term effects and major long-term, recurring effects. The extent of effects would depend on the specific dam and would be small at Lookout Point and Cougar; medium at Detroit; and large at Foster and Green Peter. The measures under this alternative would generally be consistent with the Class II, III, and IV management activities for Foster; Detroit, Fall Creek, and Green Peter; and Cougar and Lookout Point, respectively. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities at Fall Creek and Green Peter Dam and Reservoirs. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

As discussed in 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. Therefore, long-term, recurring effects would be major under all alternatives. Two drawdowns would occur under Alternative 2A; effects under this alternative would therefore be less severe compared to alternatives 2B, 5, 3A, and 3B; and would be more severe compared to Alternatives 1 and 4.

#### *3.22.4.6.1 Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs*

Under Alternative 2A, the construction of a large concrete WTC tower would occur at Detroit Dam. Construction of structural downstream fish passages in the forms of a FSS and a Floating Surface Collector (FSC) would occur at Detroit Dam and Cougar Dam, and Lookout Point Dam, respectively. The construction of a structural downstream fish passage in the form of a modification to the existing spill (fish) weir would occur at Foster Dam. The construction of an AFF would occur at Green Peter Dam.

**<u>Foster Dam and Reservoir (Class II)</u>**

As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse short- and long-term permanent effects would occur from the construction of the structural downstream fish passage in the form of a modification to the existing spill (fish) weir and would be minor in magnitude. As discussed under Alternative 1, effects would be large in extent because Foster recorded greater than 75,000 visits in FY 2019. Foster is a Class II area, meaning its objective is to retain the existing character of the landscape. Construction of the structural downstream fish passage would be consistent with Class II management activities.

**<u>Detroit and Green Peter Dams and Reservoirs (Class III)</u>**

As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in magnitude. As discussed under Alternative 1, effects would be medium in extent because Detroit recorded between 50,000 and 75,000 visits in FY 2019; and large in extent because Green Peter recorded more than 75,000 visits in FY 2019. Detroit and Green Peter are Class III areas, meaning its objective is to partially retain the existing character of the landscape. Construction of WTC towers, structural downstream fish passages, and AFFs would be consistent with Class III management activities.

**<u>Lookout Point and Cougar Dams and Reservoirs (Class IV)</u>**

As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of structural downstream fish passages would be minor in magnitude. As discussed under Alternative 1, effects would be small in extent because Lookout Point and Cougar both recorded less than 50,000 visits in FY 2019. Lookout Point and Cougar are Class IV areas, meaning their objective is to allow major modification of the existing character of the landscape. Construction of the structural downstream fish passages would be consistent with Class IV management activities.

*3.22.4.6.2 Reservoir Drawdowns*

Under Alternative 2A, deeper fall reservoir drawdowns to 25 feet over the ROs would occur at Green Peter Dam. The Fall Creek Drawdown would continue to recur under this alternative (and under all alternatives) and is discussed in Section 3.22.4.3.2 and 3.22.4.4.

**<u>Green Peter Dam and Reservoir (Class III)</u>**

As discussed above in Section 3.22.4.3.2, potential adverse short-term effects from sediment transport during drawdowns would be moderate in magnitude. Potential adverse long-term, recurring effects from revealed mudflats, substrate, tree stumps, and other submerged littoral zone attributes would be major in magnitude. Effects would be large in extent because Green Peter Dam and Reservoir recorded greater than 75,000 visitors in FY 2019. Green Peter is listed as a Class III area, meaning its objectives are to partially retain the existing character of the landscape. Short-term potential adverse effects from sediment transport during drawdowns would be consistent with the Class III Management Objectives. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

##### *3.22.4.6.3 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point) management objectives, they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) management objectives, and mitigation measures would be recommended.

##### *3.22.4.6.4 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under Alternative 1, effects to the visual landscape due to the presence of construction vehicles and the erection of these new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

Effects from the drawdowns at Fall Creek and Green Peter would be moderate in the short term and major in the long term. As described under the NAA, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. All above-mentioned effects would be large in extent.

#### ***3.22.4.7 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 2B, the effects to visual resources would be nearly the same as those described under Alternative 2A. The following occur under both alternatives 2A and 2B and are already discussed in Sections 3.22.4.6.1 and 3.22.4.6.2: The construction of a WTC tower at Detroit Dam; the construction of structural downstream fish passages at Detroit, Lookout Point, and Foster; construction of an AFF at Green Peter; and reservoir drawdowns at Fall Creek and Green Peter. The difference between Alternative 2B and 2A would be that the structural downstream fish passage would not be constructed at Cougar under Alternative 2B; and deeper fall reservoir drawdowns and spring reservoir drawdowns would also occur at Cougar under Alternative 2B. Potential adverse effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in the short, medium, and long term. Potential beneficial effects from the construction of WTC towers and AFF would be minor in the long-term and permanent. Drawdowns at Fall Creek, Green Peter, and Cougar would have moderate short-term effects and major long-term, recurring effects. The extent of effects would depend on the specific dam and would be small at Lookout Point and Cougar; medium at Detroit; and large at Foster and Green Peter. The measures under this alternative would generally be consistent with the Class II, III, and IV management activities for Foster, Detroit and Green Peter, and Cougar and Lookout Point, respectively. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities at Fall Creek and Green Peter. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

As discussed in Section 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. Therefore, long-term, recurring effects would be major under all alternatives. Four drawdowns would occur under Alternative 2B (and Alternative 5), compared to the one drawdown under the NAA and alternatives 1 and 4, two drawdowns under Alternative 2A; and 10 drawdowns under alternatives 3A and 3B. As such, Alternative 2B would have the same effect as Alternative 5; would be less severe compared to alternatives 3A and 3B; and would be more severe compared to alternatives 1, 2A, and 4.

#### *3.22.4.7.1 Reservoir Drawdowns*

Under Alternative 2B (and under all alternatives), the Fall Creek Drawdown would continue to recur and is discussed in Section 3.22.4.3.2 and 3.22.4.4. Deeper fall reservoir drawdowns would also occur at Green Peter Dam, and are described in Section 3.22.4.6.2. Alternative 2B would also include deeper fall reservoir drawdowns and spring reservoir drawdowns to 25 feet over the top of the diversion tunnel at Cougar Dam.

**Cougar Dam and Reservoir (Class IV)**

As discussed above in Section 3.22.4.3.2, potential adverse short-term effects from sediment transport during drawdowns would be moderate in magnitude. Potential adverse long-term, recurring effects would be major in magnitude. Effects would be small in extent because Cougar Dam and Reservoir recorded less than 50,000 visitors in FY 2019. It should be noted that drawdowns to the diversion tunnel at Cougar Dam would require dam modifications, consisting of gate structures, a tower, and a bridge that connects the tower to the edge of the reservoir. These additional modifications would drastically alter the basic design elements of the landscape, but would contribute to the overall major effect that reservoir drawdowns would already have at Cougar. Cougar is listed as a Class IV area, meaning its objectives are to allow major modification of the existing character of the landscape. Reservoir drawdowns would be consistent with Class IV management activities.

#### *3.22.4.7.2 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point), they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) and mitigation measures would be recommended.

#### *3.22.4.7.3 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under alternatives 1 and 2A, effects to the visual landscape due to the presence of construction vehicles and the erection of new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

Effects from the drawdowns at Fall Creek, Green Peter, and Cougar would be moderate in the short term and major in the long term. As described under the NAA and alternatives 1 and 2A, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. Effects would be large in extent at Green Peter and Fall Creek and small at Cougar.

### ***3.22.4.8 Alternative 3A. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Regulating Outlet)***

Under Alternative 3A, adverse effects from the construction of AFFs would be **minor** in magnitude in the medium and long term. Potential beneficial effects from the construction of AFFs would be minor in the long term. Drawdowns would have moderate short-term and major long-term, recurring effects. The extent of effects would depend on the specific dam and would be small at Blue River, Hills Creek, Lookout Point, and Cougar Dams; medium at Detroit; and large at Fall Creek and Green Peter. The measures under this alternative would generally be consistent with the Class III and IV management activities for Detroit and Green Peter, and

Cougar, Lookout Point, Blue River, and Hills Creek, respectively. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities at Fall Creek, Detroit and Green Peter Dams and Reservoirs. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

As discussed in Sections 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. Therefore, long-term, recurring effects would be major under all alternatives. Ten drawdowns would occur across seven reservoirs per year under Alternative 3A (and Alternative 3B) and be a main component of these alternatives, compared to the one drawdown under the NAA, Alternative 1, and Alternative 4; two drawdowns under Alternative 2A; and four drawdowns under alternatives 2B and 5. As such, Alternative 3A (and 3B, discussed below) would have the most severe adverse effects to visual resources compared to other alternatives.

#### *3.22.4.8.1 Construction of AFFs*

Under Alternative 3A, the construction of AFFs would occur at Hills Creek Dam, Blue River Dam, and Green Peter Dam.

**Green Peter Dam and Reservoir (Class III)**

As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of a new AFF would be minor in magnitude. As discussed under Alternatives 1 and 2, effects would be large in extent because Green Peter recorded greater than 75,000 visits in FY 2019. Green Peter is listed as a Class III area, meaning its objectives are to partially retain the existing character of the landscape. Construction of the AFF would be consistent with the Class III management activities.

**Blue River and Hills Creek Dams and Reservoirs (Class IV)**

At Blue River and Hills Creek Dams, the AFFs would be located next to the existing dams. As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of AFFs would be minor in magnitude. Effects would be small in extent because Blue River and Hills Creek recorded less than 50,000 visits in FY 2019. Blue River and Hills Creek are listed as Class IV areas, meaning its objectives are to allow major modification of the existing character of the landscape. Construction of the AFFs would be consistent with the Class IV management activities.

#### *3.22.4.8.2 Reservoir Drawdowns*

Under Alternative 3A, deeper fall reservoir drawdowns to 10 feet over the ROs would occur at Lookout Point Dam, Hills Creek Dam, Cougar Dam, Blue River Dam, Green Peter Dam, and

Detroit Dam. Spring reservoir drawdowns to 10 feet over the ROs would occur at Lookout Point Dam, Cougar Dam, and Detroit Dam. The Fall Creek Drawdown would continue to recur under this alternative (and under all alternatives) and is discussed in Section 3.22.4.3.2 and 3.22.4.4.

**Detroit and Green Peter Dams and Reservoirs (Class III)**

As discussed above in Section 3.22.4.3.2, potential adverse short-term effects from sediment transport during drawdowns would have moderate effects on visual resources. Potential adverse long-term, recurring effects from revealed mudflats, substrate, tree stumps, and other submerged littoral zone attributes would be major in magnitude. Effects would be large in extent because Green Peter Dam and Reservoir recorded greater than 75,000 visitors in FY 2019; and medium in extent because Detroit Dam and Reservoir recorded between 50,000 and 75,000 visitors in FY 2019. As discussed under Alternative 2A, Green Peter and Detroit are Class III areas. As such, short-term adverse effects would be consistent with the Class III Management Objectives; but long-term effects would not be. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

**Blue River, Hills Creek, Lookout Point, and Cougar Dams and Reservoirs (Class IV)**

As discussed above in Section 3.22.4.3.2, potential adverse short-term effects from sediment transport during drawdowns would be moderate in magnitude. Potential adverse long-term, recurring effects would be major in magnitude. Effects would be small in extent because Blue River, Hills Creek, Lookout Point, and Cougar Dams and Reservoirs recorded less than 50,000 visitors in FY 2019. Blue River, Hills Creek, Lookout Point, and Cougar are listed as Class IV areas, meaning its objectives are to allow major modification of the existing character of the landscape. Reservoir drawdowns would be consistent with Class IV management activities.

#### *3.22.4.8.3 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point), they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) and mitigation measures would be recommended.

#### *3.22.4.8.4 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under alternatives 1, 2A, and 2B, effects to the visual landscape due to the presence of construction vehicles and the erection of new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

Effects from the drawdowns at Fall Creek, Green Peter, Detroit, Blue River, Hills Creek, Lookout Point, and Cougar would be moderate in the short term and major in the long term. As described under the NAA and alternatives 1, 2A, and 2B, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. The extent of effects would be small at Blue River, Hills Creek, Lookout Point, and Cougar Dams; medium at Detroit; and large at Green Peter and Fall Creek.

#### *3.22.4.9 Alternative 3B. Improve Fish Passage Through Operations-Focused Measures (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 3B, the effects to visual resources would be nearly the same as those described under Alternative 3A. The following occur under both alternatives 3A and 3B and are already discussed in Sections 3.22.4.8.1 and 3.22.4.8.2: The construction of AFFs at Hills Creek, Blue River, and Green Peter; fall reservoir drawdowns at Fall Creek, Lookout Point, Hills Creek, Cougar, Blue River, Green Peter, and Detroit; and spring reservoir drawdowns at Cougar. The difference between Alternative 3B and 3A is that spring reservoir drawdowns would occur at Green Peter, similar to Alternative 2A, and Hills Creek under Alternative 3B instead of Detroit and Lookout Point under Alternative 3A. In addition, Cougar would be drafted down to 25 feet over the top of the diversion tunnel, similar to Alternative 2B. Potential adverse effects from the construction of AFFs would be minor in the medium- and long-term and permanent. Potential beneficial effects from the construction of AFFs would be minor in the long term. Drawdowns would have moderate short-term and major long-term, recurring effects. The extent of effects would depend on the specific dam and would be small at Blue River, Hills Creek, Lookout Point, and Cougar Dams; medium at Detroit; and large at Fall Creek and Green Peter. The measures under this alternative would generally be consistent with the respective Class management activities as they were under Alternative 3A; though again reservoir drawdowns would be inconsistent with Class III management activities at Fall Creek, Detroit and Green Peter. Alternative 3B (and 3A, discussed above) would have the most severe adverse effects to visual resources compared to other alternatives.

As discussed in Section 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. Therefore, long-term, recurring effects would be major under all alternatives. Ten drawdowns would occur across seven reservoirs per year under Alternative 3B (and Alternative 3A) and be a main component of these alternatives, compared to the one drawdown under the NAA, Alternative 1, and Alternative 4; two drawdowns under Alternative 2A; and four drawdowns under alternatives 2B and 5. As such, Alternative 3B (and 3A, discussed above) would have the most severe adverse effects to visual resources compared to other alternatives.

#### *3.22.4.9.1 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point), they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) and mitigation measures would be recommended.

#### *3.22.4.9.2 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under alternatives 1, 2A, 2B, and 3A, effects to the visual landscape due to the presence of construction vehicles and the erection of new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

Effects from the drawdowns at Fall Creek, Green Peter, Detroit, Blue River, Hills Creek, Lookout Point, and Cougar would be moderate in the short term and major in the long term. As described under the NAA and alternatives 1, 2A, 2B, and 3A, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. The extent of effects would be small at Blue River, Hills Creek, Lookout Point, and Cougar Dams; medium at Detroit; and large at Green Peter and Fall Creek.

### *3.22.4.10 Alternative 4. Improve Fish Passage with Structures-Based Approach*

Under Alternative 4, the effects to visual resources would be nearly the same as those described under Alternative 1. The following occur under both alternatives 1 and 4 and are already discussed in Section 3.22.4.5.1: The construction of WTC towers at Detroit and Lookout Point and the construction of structural downstream fish passages at Detroit, Lookout Point, and Foster. The difference between Alternative 4 and 1 is that a WTC tower and AFF would be constructed at Hills Creek under Alternative 4 instead of Green Peter under Alternative 1; and structural downstream fish passages would be constructed at Cougar, similar to Alternative 2A, and Hills Creek under Alternative 4 instead of Green Peter under Alternative 1. Potential adverse effects from the construction of WTC towers, AFFs, and structural downstream fish passages would be minor in magnitude in the short, medium, and long term. Potential beneficial effects from the construction of WTC towers and AFFs would be minor in the long term. The extent of effects would be large at Foster; medium at Detroit; and small at Lookout Point, Hills Creek, and Cougar Dams. The measures under this alternative would be consistent with the respective Class management activities as they were under Alternative 1.

Furthermore, as discussed in Section 3.22.4.3.2 (Fall Creek Drawdown, Deeper Fall Reservoir Drawdowns for Fish Passage, and Spring Reservoir Drawdowns for Downstream Fish Passage) and in Section 3.22.4.4 (NAA), reservoir drawdowns at Fall Creek would also continue to have moderate short-term effects and major long-term, recurring effects. Short-term effects would be consistent with Class III management objectives, but long-term effects would not, and mitigation measures would be recommended to reduce the effect these measures would have to visual resources.

As discussed in Section 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. One drawdown would occur under the NAA, Alternative 1, and Alternative 4; and the magnitude of effects would be major under these alternatives. However, the major effects under Alternative 4 (and the NAA and Alternative 1), with the fewest number of drawdowns, would be less severe than the major effects under alternatives 3A and 3B that have the most drawdowns. Alternative 4 would have the same effect as Alternative 1, and would be less severe compared to alternatives 2A, 2B, 3A, 3B, and 5.

#### *3.22.4.10.1 Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs*

Under Alternative 4, the construction of a large concrete WTC tower, structural downstream fish passage in the form of a FFS, and an AFF would occur at Hills Creek Dam.

**Hills Creek Dam and Reservoir (Class IV)**

At Hills Creek Dam, the WTC tower, structural downstream fish passage, and AFF would be located next to the existing dam. As discussed above in Section 3.22.4.3.1 (Construction of WTC Towers, Structural Downstream Fish Passages, and AFFs), potential adverse medium- and long-term permanent effects from the construction of WTC tower and structural downstream fish passage at Hills Creek Dam would be minor in magnitude. Effects would be small in extent because Hills Creek Dam and Reservoir recorded less than 50,000 visits in FY 2019. Hills Creek is a Class IV area, meaning its objective is to allow major modification of the existing character of the landscape. Construction of the WTC tower, structural downstream fish passage, and AFF would be consistent with Class IV management activities.

##### *3.22.4.10.2 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point), they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) and mitigation measures would be recommended.

##### *3.22.4.10.3 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under Alternative 1, effects to the visual landscape due to the presence of construction vehicles and the erection of new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

As described under the NAA and Alternative 1, effects from the Fall Creek Drawdown would be moderate in the short term and major in the long term. Climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. Effects would be large in extent at Fall Creek.

#### ***3.22.4.11 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 5, the effects to visual resources would be the same as those described under Alternative 2B. The following are the same in alternatives 2B and 5 and are already discussed in Sections 3.22.4.6.1, 3.22.4.6.2, and 3.22.4.7.1: The construction of a WTC tower at

Detroit; the construction of structural downstream fish passages at Detroit, Lookout Point, and Foster; the construction of an AFF at Green Peter; fall reservoir drawdowns at Fall Creek, Cougar and Green Peter; and spring reservoir drawdowns at Cougar. Potential adverse effects from the construction of WTC towers, structural downstream fish passages, and AFFs would be minor in the short, medium, and long term. Potential beneficial effects from the construction of WTC towers and AFF would be minor in the long-term and permanent. Drawdowns would have moderate short-term effects and major long-term, recurring effects. The extent of effects would depend on the specific dam and would be small at Lookout Point and Cougar; medium at Detroit; and large at Fall Creek, Foster and Green Peter. The measures under this alternative would generally be consistent with the Class II, III, and IV management activities for Foster, Detroit and Green Peter, and Cougar and Lookout Point, respectively. However, long-term effects from reservoir drawdowns would not be consistent with Class III management activities at Fall Creek and Green Peter Dams and Reservoirs. Mitigation measures would be recommended to reduce the effect these measures would have to visual resources. Alternative 5 would have the same effect as alternatives 2A and 2B; would be less severe compared to alternatives 3A and 3B; and would be more severe compared to alternatives 1 and 4.

As discussed in Section 3.22.4.5, all of the major effects to visual resources would occur because of the drawdown(s), and at least one drawdown (the Fall Creek Drawdown) occurs under each alternative. Therefore, long-term, recurring effects would be major under all alternatives. Four drawdowns would occur under Alternative 5 (and Alternative 2B), compared to the one drawdown under the NAA and alternatives 1 and 4, two drawdowns under Alternative 2A; and 10 drawdowns under alternatives 3A and 3B. As such, Alternative 5 would have the same effect as Alternative 2B; would be less severe compared to alternatives 3A and 3B; and would be more severe compared to alternatives 1, 2A, and 4.

##### *3.22.4.11.1 Near-Term Operations*

As discussed above in Section 3.22.4.3.3, potential adverse short- or medium-term effects from near-term operations from reservoir drawdowns and delayed reservoir refills would be major in magnitude. Effects would be large in extent at Green Peter, Foster, and Fall Creek Dams and Reservoirs; and small at Lookout Point and Cougar Dams and Reservoirs. While these measures would generally be consistent with Class IV dams (Cougar and Lookout Point), they would be inconsistent with Class II dams (Foster) and Class III dams (Green Peter and Fall Creek) and mitigation measures would be recommended.

##### *3.22.4.11.2 Climate Change*

As discussed in Section 3.22.4.4.1, climate change would adversely affect visual resources within the WVS, including more intense wildfires, low summer flows, long-lasting droughts, earthen dams cracking and drying, and HABs which would alter the basic design elements of the characteristic landscape.

As described under Alternative 2B, effects to the visual landscape due to the presence of construction vehicles and the erection of new structures would not be exacerbated by climate change. The effects of climate change and the construction measures/the new structures would still be minor in the medium and long term.

Effects from the drawdowns at Fall Creek, Green Peter, and Cougar would be moderate in the short term and major in the long term. As described under Alternative 2B, climate change could exacerbate short-term effects from sediment transport during drawdowns; the effects of climate change and the drawdowns would be moderate to major in the short term. Climate change could also exacerbate long-term, recurring effects from drawdowns and further change the basic design elements of color, texture, and form. If reservoir levels are already lower due to low summer flows and long-lasting droughts, shoreline erosion could occur and cause sedimentation and increase turbidity; affecting water color and clarity. As such, climate change and the drawdowns would further exacerbate the already major and long-term, recurring effects. Effects would be large in extent at Green Peter and Fall Creek and small at Cougar.

#### *3.22.4.12 Conclusion*

Alternatives 2A, 2B, 3A, 3B, and 5 would include adverse moderate short-term effects, adverse minor medium-term effects, and adverse major long-term, recurring effects. Alternatives 1 and 4 would include adverse minor effects in the short, medium, and long term (permanent). All alternatives would include beneficial minor effects in the long term (permanent).

Alternatives 3A and 3B would cause the most severe adverse effects to visual resources, followed by alternatives 2A, 2B, and 5. The NAA and Alternatives 1 and 4 would cause the least severe adverse effects to visual resources. This conclusion is mostly due to the severe effect reservoir drawdowns would have on the basic elements in the characteristic landscape. Reservoir drawdowns would be a main component of alternatives 3A and 3B, with a total of 10 drawdowns across seven reservoirs per year. In contrast, alternatives 1 and 4 would consist largely of structural measures that would mostly blend into the already existing landscape of the dams and other structures and potentially provide a beneficial and visually intriguing effect to the viewshed.

## 3.23 NOISE

This section describes the existing noise environment and the potential effects of the proposed action on and from noise. Noise is considered a resource because, like physical, biological, or human resources, the noise environment can ultimately be beneficial or adverse to the welfare of humans or other desirable features of the environment, such as wildlife. An introduction to noise and noise levels is provided below. This is followed by a description of the area of analysis that would be affected by the activities described in Chapter 2. The relevant laws or regulations that govern noise are then described. The section concludes with a discussion of the sources of noise in the WVS.

### 3.23.1 Affected Environment

Noise is unwanted sound that disrupts normal activities or diminishes the quality of the environment for humans and other receptors (e.g., wildlife). Depending on the intensity and level of exposure, excessive noise could lead to a range of effects: disrupted sleep, difficulty communicating, changes in behavior, increased stress levels, and physical injury (USACE et. al., 2020). At sound levels below those that cause physiological effects, noise can reduce the aesthetic quality of the environment, especially in natural settings enjoyed by recreationists, and may affect resource integrity for tribal members engaging in cultural activities or practices (USACE et. al. 2020).

Noise traveling through air is usually expressed in decibels on the A-weighted scale (dBA), which is weighted to correspond to how humans hear sound. Table 3.23-1 provides typical noise levels in dBA from common sources that can serve as a basis for comparison of noise emissions associated with activities described in Chapter 2.

**Table 3.23-1. Common Noise Levels**

| Noise Source | Sound Level (dBA) |
|---|---|
| Night club with music | 110 |
| Pile driver | 95–101 |
| Concrete saw | 90 |
| Urban area, adjacent to freeway | 88 |
| Construction equipment, pneumatic tools | 80–85 |
| High-density urban areas | 78 |
| Urban areas | 60–65 |
| Normal conversation indoors | 60 |
| Suburban/residential areas | 45–50 |
| Rural areas | 35–40 |

Source: USACE et. al. 2020

Noise exposure depends on the amount of time an individual spends near the source and their distance from the source. To account for fluctuating sound levels, statistical descriptors have been developed for environmental noise. Exceedance levels (L levels) refer to the A-weighted sound level that is exceeded for a specified percentage of the time during a specified period. Thus, $L_{10}$ refers to a particular sound level that is exceeded 10 percent of the time (USACE et. al. 2020).

#### *3.23.1.1 Area of Analysis*

The area of analysis for the noise environment is the same as the overall area of analysis or geographic scope for this project, which is the WVS; that is, the 13 dams and reservoirs on the Willamette River and its tributaries (See Figure 1.1-2), fish hatcheries, and communities and populations within the WVS.

#### *3.23.1.2 Relevant Laws and Regulations*

The Noise Control Act of 1972 (42 USC § 4901 et seq.), as amended, has a broad goal of protecting all people from noise that jeopardizes their health or welfare. The Act further states that federal agencies are authorized and directed to further this policy to the fullest extent consistent with their authority (USACE et. al. 2020).

The Oregon Administrative Rules (OAR 340-035) specify noise limits according to the type of property where the noise would be heard (the “receiving property”). For example, hydroelectric dams are classified as industrial sources for purposes of establishing allowable noise levels at the receiving property. For such facilities, Oregon allows an $L_{50}$ noise level of 55 dBA in daytime and 50 dBA at night and $L_{10}$ of 60/55 dBA day/night (OAR 340-035). Under the Oregon regulations, construction noises are usually exempt during the day (USACE et. al. 2020).

Occupational noise is monitored and regulated in accordance with 29 CFR 1910.95, Occupational Noise Exposure. These requirements are administered by the Occupational Safety and Health Administration (OSHA) and are broadly intended to protect workers from harmful noise exposures, both in real-time and long-term.

#### *3.23.1.3 Willamette Valley System-wide Noise Environment*

Noise that is generated from the activities described in Chapter 2 occurs throughout the WVS in generally the same manner and with similar effects regardless of specific locations where the activities occur. These activities will be categorized and discussed as WVS-wide noise-generating events in the following sections that discuss heavy equipment noise, truck transport noise, light construction noise, operational noise of system facilities and equipment, and occupational noise.

For sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. This means that noise levels listed in Table 3.23-2 are reduced by 30 decibels within 1,600 feet. In many cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects. Noise emissions information that is relevant to construction activities discussed in this section, including truck transport, is presented below in Table 3.23-2.

**Table 3.23-2. Construction Equipment Noise Levels**

| Equipment | Typical Noise Level (dBA) 50 ft from Source | Distance to Reduce Noise Level to 50dBA-55dBA (feet) |
|---|---|---|
| Air Compressor | 81 | 1,600 |
| Backhoe | 80 | 1,600 |
| Ballast Equalizer | 82 | 1,600 |
| Ballast Tamper | 83 | 1,600 |
| Compactor | 82 | 1,600 |
| Concrete Mixer | 85 | 1,600 |
| Concrete Pump | 82 | 1,600 |
| Concrete Vibrator | 76 | 800 |
| Crane Mobile | 83 | 1,600 |
| Dozer | 85 | 1,600 |
| Generator | 81 | 1,600 |
| Grader | 85 | 1,600 |
| Impact Wrench | 85 | 1,600 |
| Jack Hammer | 88 | 2,400 |
| Loader | 85 | 1,600 |
| Paver | 89 | 2,600 |
| Pile Driver (Impact) | 101 | 10,600 |
| Pile Driver (Sonic) | 96 | 5,900 |
| Pneumatic Tool | 85 | 1,600 |
| Pump | 76 | 800 |
| Rail Saw | 90 | 3,000 |
| Rock Drill | 98 | 7,500 |
| Saw | 76 | 800 |
| Scraper | 89 | 2,600 |
| Shovel | 82 | 1,600 |
| Truck | 88 | 2,400 |

Source: FHWA 2021

##### *3.23.1.3.1 Heavy Equipment Noise*

Heavy equipment noise is typically characterized as noise emitted from large construction vehicles and equipment. For this analysis, and as a basis for comparison, heavy equipment noise is considered to be noise exceeding 85 dBA at 50 feet from the noise sources, and similar types of equipment, shown in Table 3.23-2 above. Operations and maintenance activities in the WVS that could generate heavy equipment noise include construction activities at dams, spillways, and fish collection facilities and modifications to the streambeds below dams or revetments.

##### *3.23.1.3.2 Truck Transport Noise*

Truck transport noise is generated by the operation of large trucks. Truck transport noise is approximately 88 dBA at 50 feet from the noise source as shown in Table 3.23-2 above. Operations and maintenance activities in the WVS that could generate truck transport noise include construction activities at dams, spillways, and fish collection facilities, fish relocation sites and transport routes, and modifications to the streambeds below dams or to revetments.

##### *3.23.1.3.3 Light Construction Equipment Noise*

The sources of light construction equipment noise are noise emissions from small/medium construction vehicles and equipment such as utility and pickup trucks, automobiles, small power tools, and hand tools. For this analysis, and as a basis for comparison, noise from light construction equipment sources is considered to be noise which does not exceed 85 dBA at 50 feet from these noise sources and similar types of smaller construction equipment to that shown in Table 3.23-2 above. Operations and maintenance activities in the WVS that could generate light construction equipment noise include minor construction activities at dams, spillways, and fish ladders and collection facilities, and modifications to the streambeds below dams or to revetments.

##### *3.23.1.3.4 Operational Noise of System Facilities and Equipment*

Operational noise associated with WVS facilities and equipment includes noise emitted from hydroelectric equipment such as turbines and generators within powerhouses. Turbine and generator noise can reach levels in excess of 100 dBA within some areas of the power house. Operations and maintenance activities in the WVS that could generate operational noise of system facilities and equipment include facility operations activities at dams, fish collection facilities, and adjacent to waterways.

##### *3.23.1.3.5 Occupational Noise*

Occupational noise can be characterized as proximate noise emissions from any of the equipment listed above that expose workers using the equipment and others close by to noise above ambient levels. This type of noise is regulated by OSHA and is most often managed through the use of worker safety and health plans or programs and/or safety manuals that accompany the specific equipment generating the noise. Operations and maintenance activities in the WVS that could generate occupational noise include both construction and operations activities at dams, spillways, and fish collection facilities, fish relocation sites and transport routes, and modifications to the streambeds below dams or to revetments.

### 3.23.2 Environmental Consequences

This section analyzes the environmental effects for the No Action Alternative and each of the action alternatives, all of which are described in Chapter 2 of this EIS. The environmental effects include both direct and indirect effects as determined by the application of the methodology described in the following section. The results of applying the methodology are presented for each alternative and are used to make an informed judgement of whether the alternative produces significant effects.

#### *3.23.2.1 Methodology*

An evaluation of environmental effects must be systematically applied to the relevant factors that apply to the resource. This analysis of the noise effects of the proposed action and alternatives began with the development of uniform evaluation criteria that could be used to present an unbiased assessment of each alternative considered. The evaluation criteria included determinations of the thresholds for magnitude, duration, and extent of the effects, which are outlined in Table 3.23-3 and summarized in the analysis section for each specific alternative.

**All comparisons of effects for each action alternative are in comparison to the NAA unless stated otherwise.**

**Table 3.23-3. Evaluation Criteria for Potential Effects from Noise**

| Effect Factors and Scale | Definition |
|---|---|
| **Magnitude** | |
| Negligible | Changes or benefits would be either nondetectable, or if detected, effects would be well below regulatory standards, as applicable. |
| Minor | Changes to the resource would be measurable, but adverse effects or benefits would be within or below regulatory standards, as applicable and would not create any incompatible land use. |
| Moderate | Changes to the resource would be measurable. Effects would be within or below regulatory standards, but historical conditions would be altered and some amount of incompatible land use may occur in undeveloped, agricultural, or low-density residential areas. Mitigation measures would be necessary and would reduce potential adverse effects. |
| Major | Changes would be readily measurable and would have substantial effects. Effects would exceed regulatory standards and a substantial |

| Effect Factors and Scale | Definition |
|---|---|
| | amount of noise exposure to incompatible land uses may occur in high density residential areas and in close proximity to noise sensitive receptors such as schools, hospitals, libraries, and other care facilities. |
| **Duration** | |
| Short-term | Alteration lasts for the duration of small construction project, and is continuous for less than 2 years. |
| Medium-term | Alteration is limited to the duration of large construction projects, and is continuous for a period of 2-5 years. |
| Long-term | Alteration is permanent or lasts continuously beyond operation changes or the completion of all construction projects; the alteration recurs at regular intervals (e.g., deep drawdowns that occur for a 3-week period in the fall and/or spring); or the alteration occurs intermittently. |
| **Extent** | |
| Small | Measurable effects confined primarily to within the site boundary |
| Medium | Measurable effects localized to areas surrounding the site |
| Large | Regional level effects – noise would be audible for several miles |

In the absence of actual measurement of sound levels for the proposed measures, the magnitude of the effects used throughout Section 3.23.2, Environmental Consequences is determined by performing a comparison with typical noise exposure levels for noise sources described in Section 3.23.1 Affected Environment.

#### *3.23.2.2 Measures Analyzed for Noise*

Measures under the action alternatives that could have an effect for noise include:

- Construct water temperature control (WTC) towers (#105)
- Construct Adult Fish Facility (#722)
- Construct Structural Downstream Fish Passage (#392)
- Gravel augmentation below dams (#384)
- Operation, maintenance, repair, replacement, and rehabilitation;
- Adapt hatchery program (#719)
- Maintenance of existing and new fish release sites above dams (#726)
- Structural Improvements to Reduce Total Dissolved Gas (#174)
- Foster Fish Ladder Temperature Improvement (#479)

- Restore Upstream and Downstream Passage at Drop Structures (#639)
- Provide Pacific Lamprey Passage and Infrastructure (#52)
- Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)

The following proposed measures would have no effect for noise, and are therefore not discussed further.

- Integrated temperature and habitat flow regime (#30a)
- Refined Integrated temperature and habitat flow regime (#30b)
- Use regulating outlets to discharge colder water during drawdown operations in fall and winter to reduce water temperatures below dams (#166)
- Use spillway for surface spill in summer (#721)
- Augment instream flows by using inactive pool (#718)
- Augment instream flows by using the power pool (#304)
- Reduce Minimum Flows to Congressionally Authorized Minimum Flow Requirements (#723)
- Deeper Fall Reservoir Drawdowns for Fish Passage (#40)
- Spring Reservoir Drawdown for Downstream Fish Passage (#720)
- Pass Water Over Spillway in Spring for Fish Passage (#714)
- Fall Creek Drawdown
- Suite of Near-term Operations Measure
- Existing Operations Continued Forward

A summary of the effects for noise discussed in the following sections is provided in Table 3.23-4. Note that the most severe magnitude of adverse effects for each alternative was listed in this table. Discussion of all adverse effects, including those that are less severe than those listing in this table, are included in the discussion below.

**Table 3.23-4. Summary of Effects for Noise Under Each Alternative**

| Effect Factor | Alternatives | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | NAA | 1 | 2A | 2B | 3A | 3B | 4 | 5 |
| **Short-term** | | | | | | | | |
| Magnitude | Moderate adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse | Negligible adverse |
| Extent | Small | Medium | Medium | Medium | Medium | Medium | Medium | Medium |
| **Medium-term** | | | | | | | | |
| Magnitude | None | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse | Moderate adverse |
| Extent | None | Medium | Medium | Medium | Medium | Medium | Medium | Medium |
| **Long-term (Permanent, Intermittent, or Recurring)** | | | | | | | | |
| Magnitude | Negligible adverse | None | None | None | None | None | None | None |
| Extent | Small | None | None | None | None | None | None | None |

In the following subsections, the effects are discussed for the No Action Alternative, for the measures analyzed in the action alternatives, and for each of the action alternatives.

### ***3.23.2.3 Discussion of Effects by Measure***

This section applies the methodology described above for each measure analyzed for noise to determine the potential effect. These effects by measure will then be referenced in the action alternatives analysis that follows.

#### *3.23.2.3.1 Construct water temperature control (WTC) towers (#105); Construct adult fish facilities (AFF) (#722); Construct structural downstream fish passage (#392); Structural Improvements to reduce total dissolved gas (#174); Foster Fish Ladder Temperature Improvement (#479); Restore upstream and downstream passage at drop structures (#639); Provide Pacific lamprey passage and infrastructure (#52)*

The construction of WTC towers (#105), construction of AFFs (#722), construction of structural downstream fish passage infrastructure (#392), structural improvements for TDG (#174), the Foster Fish Ladder Temperature Improvement (#479), restoring upstream and downstream passage at drop structures (#639), and provide Pacific lamprey passage and infrastructure (#52) would involve light to heavy construction using light-duty, dump, and cement-mixing trucks; power tools; pneumatic tools; welders; and construction equipment that could possibly include dozers, backhoes, loaders, scrapers, and cranes.

Therefore, potential adverse effects from the construction of WTC towers (#105), the construction of AFFs (#722), the construction of structural downstream fish passage infrastructure (#392), structural improvements for TDG (#174), the Foster Fish Ladder Temperature Improvement (#479), restoring upstream and downstream passage at drop structures (#639), provide Pacific lamprey passage and infrastructure (#52) would be of moderate magnitude for a medium-term duration and medium extent, limited to areas immediately surrounding the construction site. There would be no long-term effects.

#### *3.23.2.3.2 Gravel augmentation below dams (#384)*

Gravel augmentation below dams (#384) would involve light construction using light-duty and dump trucks and construction equipment that could possibly include draglines, dozers, and loaders.

Therefore, potential adverse effects from gravel augmentation below dams (#384) would be of minor magnitude for a short-term duration and small extent, limited to areas immediately surrounding the augmentation site. There would be no long-term effects.

###### *3.23.2.3.3 Adapt Hatchery Program (#719) and Maintenance of Existing and New Fish Release Sites (#726)*

Noise-related effects resulting from adapting the hatchery program (#719) and maintenance of existing and new fish release sites (#726) arise from the use of tank trucks to transport adult fish from hatcheries to placement sites.

Therefore, potential adverse effects from adapting hatchery program (#719) and maintenance of existing and new fish release sites (#726) would be negligible for a short-term duration and a medium extent limited to the area of fish transport from hatcheries to placement sites. There would be no long-term effects.

###### *3.23.2.3.4 Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)*

Actions to maintain or alter revetments (#9) would involve light construction using light-duty and dump trucks and construction equipment that could possibly include draglines, dozers, and loaders.

Therefore, potential adverse effects from the actions to maintain or alter revetments (#9) would be of minor magnitude for a short-term duration and small extent, limited to areas immediately surrounding the construction site. There would be no long-term effects.

###### *3.23.2.3.5 Continued Operation of Existing Adult Fish Facilities*

The magnitude of effects for continued operation of AFFs would be minor for a medium-term duration and medium extent, limited to areas immediately surrounding the construction site.

Actions for continued operation of AFFs would involve year-round routine O&M activities of the adult fish collection facilities.

Therefore, potential adverse effects for continued operation of AFFs would be of minor magnitude for a medium-term duration and medium extent, limited to areas immediately surrounding the construction site. There would be no long-term effects.

###### *3.23.2.3.6 Operation, Maintenance, Repair, Replacement and Rehabilitation*

Actions for operation, maintenance, repair, replacement and rehabilitation would involve light to heavy construction for update and repair of existing measures using trucks and construction equipment such as front-end loaders and dozers.

Therefore, potential adverse effects from the actions for operation, maintenance, repair, replacement and rehabilitation would be of minor magnitude for a medium-term duration and medium extent, limited to areas immediately surrounding the construction site. There would be no long-term effects.

#### 3.23.2.4 *No Action* Alternative

Section 2.3.1 describes current actions within the WVS and the conditions that would result from continued O&M and configuration of the WVS under existing management with no change. All ongoing, scheduled, and routine maintenance actions for the federal infrastructure and all federal structural features, including those recently constructed or that are reasonably foreseeable, are included within the NAA. Categories of actions are described in Sections 2.3.1.1 to 2.3.1.13 and they establish a baseline for ongoing effects that action alternatives will build from. These categories include flood risk management and water control, hydropower generation, electric power transmission, water quality, fish and wildlife conservation, streamflow, hatchery program, water supply, recreation, navigation, maintenance operations, coordination, and revetments and levees.

The baseline effects resulting from NAA activities have not been specifically measured and documented, but may be estimated based in part upon common noise exposure levels. Noise from activities associated with electric power transmission; water quality; fish and wildlife conservation; streamflow; water supply; and coordination would have negligible effects in the long-term and be small in extent; and would not have any short- or medium-term effects. Noise from activities associated with FRM and water control; hydropower generation; recreation would have adverse and minor effects in the long term and would be small in extent; and would not have any short- or medium-term effects. Noise from activities associated with the hatchery program; maintenance operations; and revetments and levees would have moderate and short-term effects that are small in extent; and would not have short- or medium-term effects. The analysis showed very little variation in noise effects from category-to-category and from location-to-location. Following analysis, the effects for the No Action Alternative are determined to be of negligible to moderate magnitude, short-term or long-term duration, and small or large extent. An analysis of the effects is are summarized below in Table 3.23-5.

**Table 3.23-5. Summary of Noise Effects for No Action Alternative Activities**

| No Action Alternative Categories | Noise Sources | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Flood Risk Management and Water Control | Water flow through dam and/or spillway | Negligible/Long-term/Small |
| Electric Power Transmission | Transmission line noise, repair work | |
| Water Quality | Water flow through temperature control/TDG features | |
| Fish and Wildlife Conservation | Water flow for fish and wildlife management | |
| Streamflow | Water flow to manage streamflow levels | |
| Water Supply | Water flow for water supply management | |

| No Action Alternative Categories | Noise Sources | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Recreation | Operate and maintain recreation facilities | |
| Navigation | Water flow to maintain navigation depths | |
| Gravel Augmentation Below Dams | Light construction using light-duty and dump trucks and construction equipment that could possibly include draglines, dozers, and loaders | Minor, Short-term, Small |
| Operation, maintenance, repair, replacement, and rehabilitation | Light to heavy construction for update and repair of existing measures using trucks and construction equipment such as front-end loaders and dozers | Minor, Medium-term, Medium |
| Hydropower Generation | Water flow through penstocks, turbines | Moderate/Long-term/Small[1] |
| Hatchery Program | Construction of hatchery production facilities | Moderate/Short-term/ Small |
| Maintenance Operations | Routine and unscheduled maintenance of facilities and structures | |
| Revetments and Levees | Clear, slope, and revet river banks<br>Construction of pile and timber bulkheads and drift barriers<br>Implement minor channel improvements and maintenance of existing works | |

[1]Noise from penstocks and turbines is attenuated by powerplant structure before reaching exterior receptors

Summarizing the data outlined in Table 3.23-5, the effects are determined to be of negligible to moderate magnitude, short-term or long-term duration, and small or large extent.

### *3.23.2.5 Alternative 1 – Improve Fish Passage Through Storage-Focused Measures*

Under Alternative 1, adverse effects for noise result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include WTC construction (#105), dissolved gas reduction (#174), upstream and downstream passage restoration (#639), AFF construction (#722), Pacific lamprey passage construction (#52), and structural downstream fish passage construction (#392) that would be moderate in magnitude in the medium term, with a medium extent of effects. Alternative 1 would have approximately the same effect as Alternative 4, primarily because each has the same number of proposed measures (13). There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-6 below show little variation from location-to-location and they are of a magnitude that, while detectable, is generally not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development (e.g., residential areas), so the listed noise levels would quickly dissipate and diminish before reaching most potential noise sensitive receptors. Action locations would typically feature nearby lookout points, parks, and recreation areas, but these areas would generally be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas. Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are unacceptable to them. See Section 3.14 for the discussion of effects to recreation.

**Table 3.23-6. Alternative 1 Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Adapt Hatchery Program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct water temperature control (WTC) towers (#105) | Detroit; Green Peter; Lookout Point | |

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Structural improvements for TDG (#174) | Foster; Cougar; Detroit; Dexter; Green Peter; Lookout Point | Moderate/ Medium/ Medium |
| Foster Fish Ladder Temperature Improvement (#479) | Foster | |
| Construct structural downstream fish passage (#392) | Dexter, Lookout Point, Foster, Green Peter, Big Cliff, Detroit | |
| Restore upstream and downstream passage at drop structures (#639) | Fern Ridge | |
| Construct adult fish facility (#722) | Green Peter | |
| Provide Pacific lamprey passage and infrastructure (#52) | Fern Ridge, Green Peter | |

Summarizing the data outlined in Table 3.23-6, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

#### *3.23.2.5.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs. Future analyses that are tiered from this document should specifically consider the distance to the sensitive noise receptor so that it can be compared to the distance for meeting regulatory noise thresholds.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.

- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

Wildlife species generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

#### *3.23.2.5.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

#### *3.23.2.6 Alternative 2A. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Structural Downstream Fish Passage at Cougar Dam)*

Under Alternative 2A, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include WTC construction (#105), AFF construction (#722), Pacific lamprey passage construction (#52), and structural downstream fish passage construction (#392) that would be moderate in magnitude in the medium term, with a medium extent of effects. There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-7 below show little variation from location-to-location and they are of a magnitude that, while detectable, is generally not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby lookout points, parks and recreation areas, but these areas would generally be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate and diminish before reaching recreationists using these areas, Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-7. Alternative 2A Noise Effects Summary**

<table>
<tr><th>Measure</th><th>Project Location</th><th>Effects Magnitude/ Duration/Extent</th></tr>
<tr><td>Adapt Hatchery Program (#719)</td><td>North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins</td><td rowspan="2">Negligible/ Short/ Medium</td></tr>
<tr><td>Maintenance of existing and new fish release sites above dams (#726)</td><td>North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins</td></tr>
<tr><td>Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9)</td><td>Basin-Wide</td><td>Minor/ Short/ Small</td></tr>
<tr><td>Gravel augmentation below dams (#384)</td><td>North Santiam, South Santiam, and McKenzie River Basins below Big</td><td></td></tr>
</table>

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| | Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct water temperature control tower (#105) | Detroit | Moderate/ Medium/ Medium |
| Construct Adult Fish Facility (#722) | Green Peter | |
| Provide Pacific lamprey passage and infrastructure (#52) | Green Peter | |
| Construct structural downstream fish passage (#392) | Cougar; Detroit; Foster; Lookout Point | |
| Foster Fish Ladder Temperature Improvement (#479) | Foster | |

Summarizing the data outlined in Table 3.23-7, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

*3.23.2.6.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.

- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

#### *3.23.2.6.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

#### *3.23.2.7 Alternative 2B. Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)*

Under Alternative 2B, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include WTC construction (#105), AFF construction (#722), Pacific lamprey passage construction (#52), and structural downstream fish passage construction (#392) that would be moderate in magnitude in the medium term, with a medium extent of effects. There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-8 below show little variation from location-to-location and they are of a magnitude that, while detectable, is not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby viewpoints, parks, and recreation areas, but these areas would generally be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas. Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-8. Alternative 2B Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Adapt Hatchery Program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct water temperature control tower (#105) | Detroit | Moderate/ Medium/ Medium |
| Construct adult fish facility (#722) | Green Peter | |
| Provide Pacific lamprey passage and infrastructure (#52) | Green Peter | |
| Construct structural downstream fish passage (#392) | Detroit; Foster; Lookout Point | |
| Foster Fish Ladder Temperature Improvement (#479) | Foster | |

Summarizing the data outlined in Table 3.23-8, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

### *3.23.2.7.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.
- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

##### *3.23.2.7.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

#### *3.23.2.8 Alternative 3A – Operations-Focused Fish Passage Alternative*

Under Alternative 3A, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include AFF construction (#722) and Pacific lamprey passage construction (#52) that would be moderate in magnitude in the medium term, with a medium extent of effects. There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-9 below show little variation from location-to-location and they are of a magnitude that, while detectable, is not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby lookout points, parks and recreation areas, but these areas would typically be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas. Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-9. Alternative 3A Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/ Extent |
|---|---|---|
| Adapt hatchery program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct adult fish facility (#722) | Blue River; Green Peter; Hills Creek | Moderate/ Medium/ Medium |
| Provide Pacific lamprey passage and infrastructure (#52) | Blue River; Green Peter; Hills Creek | |

Summarizing the data outlined in Table 3.23-9, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

*3.23.2.8.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.
- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

##### *3.23.2.8.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

#### *3.23.2.9 Alternative 3B – Operations-Focused Fish Passage Alternative (using diversion tunnel at COU)*

Under Alternative 3B, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include AFF construction (#722) and Pacific lamprey passage construction (#52) that would be moderate in magnitude in the medium term, with a medium extent of effects. There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-10 below show little variation from location-to-location and they are of a magnitude that, while detectable, is not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby viewpoints, parks, and recreation areas, but these areas would typically be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas. Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-10. Alternative 3B Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/ Extent |
|---|---|---|
| Adapt Hatchery Program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct adult fish facility (#722) | Blue River; Green Peter; Hills Creek | Moderate/ Medium/ Medium |
| Provide Pacific lamprey passage and infrastructure (#52) | Blue River; Green Peter; Hills Creek | |

Summarizing the data outlined in Table 3.23-10, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

*3.23.2.9.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.
- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

#### *3.23.2.9.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

### *3.23.2.10 Alternative 4 – Structures-Based Fish Passage Alternative*

Under Alternative 4, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include WTC tower construction (#105), total dissolved gas reduction (#174), upstream and downstream passage restoration (#639), AFF construction (#722), structural downstream fish passage construction (#392), and Pacific lamprey passage construction (#52) that would be moderate in magnitude in the medium term, with a medium extent of effects. Alternative 1 would have approximately the same, most adverse effect as Alternative 4 primarily because each has the same, greatest number of proposed measures (13). There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-11 below show little variation from location-to-location and they are of a magnitude that, while detectable, is not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby lookout points, parks and recreation areas, but these areas would typically be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas. Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-11. Alternative 4 Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/ Extent |
|---|---|---|
| Adapt Hatchery Program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct water temperature control tower (#105) | Detroit; Hills Creek; Lookout Point | Moderate/ Medium/ Medium |
| Structural improvements to reduce TDG (#174) | Cougar; Detroit; Dexter; Foster; Green Peter; Lookout Point | |
| Foster Fish Ladder Temperature Improvement (#479) | Foster | |
| Restore upstream and downstream passage at drop structures (#639) | Fern Ridge | |
| Construct adult fish facility (#722) | Hills Creek | |
| Provide Pacific lamprey passage and infrastructure (#52) | Fern Ridge; Hills Creek | |
| Construct structural downstream fish passage (#392) | Cougar; Detroit; Foster; Hills Creek; Lookout Point | |

Summarizing the data outlined in Table 3.23-11, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

#### *3.23.2.10.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.
- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

#### *3.23.2.10.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

To the extent that these changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the likelihood that these land cover changes occur in close proximity to proposed projects is slight. It is also true that there are no proposed measures that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

### ***3.23.2.11 Alternative 5. Preferred Alternative – Refined Integrated Water Management Flexibility and ESA-Listed Fish Alternative (Includes Operational Downstream Passage at Cougar – Drawdown to Diversion Tunnel)***

Under Alternative 5, adverse effects result from measures that range from Adapt hatchery program (#719) and Maintenance of existing and new fish release sites (#726), with effects that would be negligible in magnitude in the short term with a medium extent of effects, to adverse effects from measures that include WTC construction (#105), AFF construction (#722), Pacific lamprey passage construction (#52), and structural downstream fish passage construction (#392) that would be moderate in magnitude in the medium term, with a medium extent of effects. Alternative 1 would have approximately the same effect as Alternative 4 primarily because each has the same number of proposed measures (13). There would be fewer measures for Alternatives 2A (11), 2B (11), 3A (9), and 3B (9), and 5 (11) and the noise effects would be comparatively less even though the level of each individual effect is relatively the same.

The noise effects presented in Table 3.23-12 below show little variation from location-to-location and they are of a magnitude that, while detectable, is not disruptive and unexpected within their surroundings. Therefore, the listed noise effects for measures implemented for multiple project locations would be uniformly applicable at each project location.

Project locations are typically removed from medium to high density land use development, so the listed noise levels would quickly dissipate before reaching most potential noise sensitive receptors. Project locations would typically feature nearby lookout points, parks and recreation areas, but these areas would typically be located at a distance such that noise levels, although of minor to moderate magnitude at a 50-foot distance, would quickly dissipate before reaching recreationists using these areas, Recreational opportunities are typically abundant near the project locations, and recreationists would have nearby alternatives available to them if the noise levels near the project locations are not acceptable to them.

**Table 3.23-12. Alternative 5 Noise Effects Summary**

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Adapt Hatchery Program (#719) | North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins | Negligible/ Short/ Medium |
| Maintenance of existing and new fish release sites above dams (#726) | North Santiam, South Santiam, South Fork McKenzie, and Middle Fork Willamette sub-basins | |
| Maintain revetments using nature-based engineering or alter revetments for aquatic ecosystem restoration (#9) | Basin-Wide | Minor/ Short/ Small |
| Gravel augmentation below dams (#384) | North Santiam, South Santiam, and McKenzie River Basins below Big Cliff, Foster, Cougar, and Blue River dams | |
| Continued Operation of Existing Adult Fish Facilities | Foster, Fall Creek, Minto (downstream of Big Cliff), and Cougar | Minor/ Medium/ Medium |
| Operation, Maintenance, Repair, Replacement and Rehabilitation | Basin-Wide | |
| Construct water temperature control tower (#105) | Detroit | Moderate/ Medium/ Medium |
| Construct adult fish facility (#722) | Green Peter | |
| Provide Pacific lamprey passage and infrastructure (#52) | Green Peter | |

| Measure | Project Location | Effects Magnitude/ Duration/Extent |
|---|---|---|
| Construct structural downstream fish passage (#392) | Detroit; Foster; Lookout Point | |
| Foster Fish Ladder Temperature Improvement (#479) | Foster | |

Summarizing the data outlined in Table 3.23-12, the effects are determined to be of negligible to moderate magnitude, short-term or medium-term duration, and small or medium extent.

*3.23.2.11.1 Potential Sensitive Noise Receptors*

Amongst the thirteen WVS reservoirs, nine are less developed than the others. These include Big Cliff, Blue River, Cottage Grove, Cougar, Dorena, Fall Creek, Green Peter, Hills Creek, and Lookout Point. While there are no cities directly on their shores, many have shorelines with at least some residential development. As a general observation, it would be unlikely to see sensitive noise receptors such as schools, hospitals, libraries, and medical facilities within a distance that would be impacted by project noise at these reservoirs.

The other four reservoirs of Detroit, Dexter, Fern Ridge, and Foster have the towns of Detroit, Lowell, Veneta, and Sweet Home on their shores, respectively, which range from populations of 80 to 10,000. These reservoirs would continue to be slowly developed. The potential for noise exposure exists for sensitive noise receptors in these towns, as well as Lookout Point, and are noted as follows:

- Foster: this dam is located right in Sweet Home, so there would be some proximity to schools, day care facilities, and a retirement home. For example, the distance to the Foster Elementary School from the dam spillway is 0.3 miles. If a representative project noise level is assumed to be 80-85 dBA at this distance, then the noise level would be reduced to approximately 50-55 dBA within 0.3 miles, or the level of suburban/residential noise, per Table 3.23-1.
- Dexter and Lookout Point: the City of Lowell is located in between each dam and has schools and day care. There is a medical office (not a hospital) and library just south of Dexter Dam in the town of Dexter.
- Fern Ridge: there is a pre-school just east of the dam.

For those sensitive noise receptors with potential exposure to noise from projects, the likelihood of a substantial impact is greatly reduced by the inverse square law, which provides that a doubling of the distance from a noise source reduces the sound pressure level by 6 decibels. In a practical sense, this means that noise levels at fifty feet listed in Table 3.23-2 are reduced by 30 decibels within 800 feet. In most cases, this would be sufficient to reduce noise to an acceptable level for noise sensitive receptors, but future projects that may arise within this distance should calculate and consider the noise effects.

Wildlife generally experience a different response to noise than humans, but as a general consideration, wildlife nearer to the project sites would experience higher sound levels and could exhibit short-term behavioral responses; depending on the season, some wildlife may avoid foraging or nesting near a project while structural measures are implemented (USACE et. al. 2020). As an example, project noise associated with construction activities adjacent to the Oregon Cascades Birding Trail at specific dams may have this effect. Black bears are also common in the area and denning bears in particular, may be sensitive to noise.

#### *3.23.2.11.2 Climate Change Effects*

As discussed in Appendix F, climate change is expected to result in wetter winters, drier summers, lower summer flows, increased reservoir evaporation, and increased wildfire intensity and frequency in the WRB, independent of the WVS O&M, over the next 30 years. As discussed in the land use section, these factors would contribute to changes in basin-wide land cover; however, they are less likely to result in changes to land use.

Wetter winters and drier summers would be expected to lead to changes in vegetation community composition and distribution over time, as drought tolerant species become predominant and invasive plants potentially take-over communities of native species, as discussed in Section 3.06, Vegetation. Adverse effects to land cover would occur as droughts become more frequent and severe and average summer river flows and reservoir water levels decrease. Some areas of vegetative cover could eventually transition to less desirable types of coverage (e.g., and become barren), due to the decreasing availability of water and increasing air and water temperatures. Adverse effects from droughts would become more severe over time. More severe and noticeable effects to land cover from climate change would occur as the intensity and frequency of wildfires increase. Wildfires would turn forest coverage into barren or shrub/scrub coverages immediately after a fire, and post-wildfire land cover may last for years because it could take areas decades to fully recover from wildfires, depending on the size of the fire.

The transmission of noise between a source and receptor is reduced by absorption or deflection of sound waves by solid intervening barriers, with the amount of reduction determined by the density of the intervening barrier. Some barriers such as walls beside highways are constructed of dense materials for the purpose of noise reduction. Natural vegetation may also reduce noise transmission, although the density of such a barrier would be less than walls beside highways. To the extent that climate-induced changes in land cover result in vegetation that is sparser or barren in the case of wildfire areas, the capability to absorb noise transmission is reduced. However, the degree to which these land cover changes occur near proposed projects is indeterminate. It is also true that there are no specific proposed measures having effects that are dependent upon vegetation density to mitigate for substantial noise impacts. Therefore, the effects of climate change on noise would be adverse and negligible in magnitude, small in extent, and long-term.

## 3.24 TRIBAL RESOURCES

The definition of tribal resources is multifaceted and dependent on the circumstance that requires the characterization. For the purposes of this EIS, tribal resources include lands and resources defined as Indian Trust Assets (ITAs), treaty and reserved rights that occur on and off Indian trust lands, and the lands and resources that are in the ancestral territories and usual and accustomed places of tribes but are now owned by the federal government.

Due to the unique relationship between federally recognized Indian tribes and the U.S. federal government, which is based on nearly 250 years of treaties, case law, federal statute, and executive orders, the federal government has a legal “trust responsibility” to ensure that it supports tribal self-governance, economic prosperity, access to treaty resources, and rights of access and use of natural and cultural resources on ancestral lands. This trust doctrine is part and parcel to the treaties that serve as the foundation for tribal legal standing as domestic sovereign nations. Indian tribes ceded millions of acres of tribal lands to the federal government, between 1798 and 1871, in return for much smaller land reservations and the federal government guaranteed rights, assets, and support to ensure the well-being and continuance of Indian tribes. The reserved lands were located in undesirable or less desirable locations like the outer edges or outside of the Willamette Valley.

During the reservation era, lawmakers developed a system to place these tribal lands and resources in the care of the federal government. The federal government came to hold these tribal resources “in trust” for Indian tribes. These assets that belong to tribes but are held in trust by the federal government are Indian Trust Assets (ITAs). In this legal relationship, the federal government acts as a trustee of assets for the tribe, or beneficiary. There is a fiduciary responsibility on behalf of the federal government to ensure that those assets are managed for the benefit of Indian tribes or individuals.

ITAs can include reserved tribal lands, minerals on trust lands, and hunting, fishing, and gathering rights typically on trust lands, and water rights that can be on or off tribal lands (U.S. DOI n.d.a, n.d.b; U.S. DHHS n.d.; Tsosie 2003). Treaty and reserved rights are another component of tribal resources. During the treaty-signing era, Indian tribes granted lands and rights to the federal government while explicitly retaining certain rights (as written in the treaties), but they also retained or reserved those rights not expressly granted to the federal government.

In November 2021, the Advisory Council on Historic Preservation, the Department of Defense (which oversees the Corps), the Department of the Interior, the White House Council on Environmental Quality, and 12 other departments and independent agencies executed the *Memorandum of Understanding regarding Interagency Coordination and Collaboration for the Protection of Tribal Treaty Rights and Reserved Rights* (ACHP et al., 2021). Through this document, the signatory agencies stated:

> Treaty-protected rights to use of and access to natural and cultural resources are an intrinsic part of tribal life and are of deep cultural, economic, and subsistence

> importance to tribes. Many treaties protect not only the right to access natural resources, such as fisheries, but also protect the resource itself from significant degradation. Under the U.S. Constitution, treaties are part of the supreme law of the land, with the same legal force and effect as federal statutes. Pursuant to this principle, and its trust relationship with federally recognized tribes, the United States has an obligation to honor the rights reserved through treaties, including rights to both on and, where applicable, off-reservation resources, and to ensure that its actions are consistent with those rights and their attendant protections. Accordingly, the Parties recognize the need to consider and account for the effects of their actions on the habitats that support treaty-protected rights.
>
> The Supreme Court has explained that Indian treaties are to be interpreted liberally in favor of tribes, giving effect to the treaty terms as tribes would have understood them, with ambiguous provisions interpreted for their benefit… This means that federal agencies must give effect to treaty language and ensure that federal agency actions do not conflict with tribal treaty and reserved rights.
>
> Integrating consideration of tribal treaty and reserved rights into agency decision-making and regulatory processes is consistent with the federal government's trust responsibility to federally recognized tribes and to fundamental principles of good government. Treaties themselves are the source of legal authority to ensure that agency processes account for reserved treaty rights.

The governance of ITAs is explicit because the resources in questions are only to provide benefit to Indian tribes and individuals, whereas the full expression of treaty and reserved rights off tribal trust lands can be unclear especially when these rights conflict with “public trust” and federal lands (Tsosie, 2003). The federal government owns and manages approximately 640 million acres of land (CRS, 2021; NALC, n.d.; U.S. GAO, n.d.). This is approximately 28% of the 2.7 billion acres that is the United States. Four land managing agencies oversee the majority of public lands (606.5 million acres or 95%) including the Forest Service, Fish and Wildlife Service, National Park Service, and Bureau of Land Management. The Corps also manages nearly nine million acres. Each of these agencies have a different mission statement, but the concept of public trust is that all federal agencies employ ethical management and stewardship of public lands and resources for the continued benefit of the American public. This is a major tenet of the four land-managing agencies.

Americans recreate on, have access to natural and cultural resources, and enjoy public lands per this public trust, which can directly impact how tribes can access and use treaty and reserved rights. An example of this management conflict is when recreational activities are incongruous with the management of tribal sacred sites (Tsosie, 2003).

More generally, treaty and reserved rights that are off Indian trust lands occur on public lands and are within the ancestral territories or usual and accustomed areas of tribes. For this EIS, traditional tribal lands are the third facet of tribal resources. These places are where indigenous communities lived, traveled, traded, etc. for millennia before European and Asian colonizers, explorers, and immigrants came to what is now known as the State of Oregon, in the late 16th century, and to the Willamette Valley, in the early 19th century. By their reckoning, Willamette Valley tribes have lived here since "time immemorial", and it is a historical fact that the tribes were unwillingly divested of their homelands through deceit and force. The tribes may have ceded the lands of the Willamette Valley and the majority of the State of Oregon to the federal government, but this did not sever their connection to or use of the area. It is notable that all of the major treaties signed by tribes of the Willamette Valley occurred prior to Oregon statehood of 1859 (between 1853 and 1855). The descendants of the original Willamette River Basin peoples are now represented by several federally recognized tribes, and the management of natural and cultural resources on trust lands, ancestral territories, and usual and accustomed areas are of primary concern to these tribes.

Inherent in this effects analysis is that all resources considered in the EIS are tribal resources. The health and viability of the economy, environment, and society of the Willamette Valley and connected areas are important to the individual American citizens who also belong to sovereign nations of federally recognized tribes. Federally recognized tribes with a vested interest in and deep historical connection to the Willamette Valley have reiterated this through the consultative process with the Corps on a government-to-government basis and through project-specific consultation that has and continues to occur.

Federal Indian policy of the last 50 years has moved towards supporting self-determination and prosperity for Indian tribes. In this vein, the Corps as a federal agency adheres to the following tenets:

- Tribal governments are sovereign nations, and the Corps recognizes the right of tribes to self-government;
- The Agency will work to meet trust obligations, protect trust resources, and obtain tribal views of trust and treaty responsibilities;
- The Corps leaders will meet with the leaders of tribal governments on a government to government level. The Agency recognizes that tribes have a right to be treated in accordance with the principles of self-determination;
- The Corps will collaboratively involve tribes, before and throughout the decision-making process, to ensure a timely exchange of information, to take into account disparate viewpoints, and use a fair and impartial dispute resolution process;
- The Corps will search for ways to involve tribes in programs, projects, and other activities that build the economic capacity and manage tribal resources while preserving cultural identities;
- The Corps will act to fulfill its obligations to preserve and protect trust resources and to consider the potential effects of Corps programs on natural and cultural resources (USACE, n.d.c.).

The U.S. Constitution, more than a century of case law, the following Executive Orders, and guidance documents guide Corps Tribal Policy Principles:

- Executive Order (EO) 13175, dated November 6, 2000, Consultation and Coordination with Indian Tribal Governments,
- Presidential Memorandum (PM), dated April 29, 1994, Government-to-Government Relations with Native American Tribal Governments,
- PM, dated November 5, 2009, Tribal Consultation,
- and the Office of the Secretary of Defense's Trust Responsibility and Consultation Matrix.

The Corps also complies with numerous environmental and cultural resources protection laws that require early and meaningful consultation and collaboration with tribes to identify, manage, and assess and mitigate effects to resources and lands that are important to the tribes (e.g. USACE, n.d.a, n.d.b.). Major laws include the National Environmental Policy Act of 1969, the National Historic Preservation Act of 1966, and the Native American Graves Protection and Repatriation Act, of 1990.

### 3.24.1 Methodology

The area of analysis for the tribal resources is defined broadly as the geographic boundaries of the Willamette River Basin (WRB). As noted in Chapter 1, the Willamette River is located entirely within the state of Oregon, beginning south of the community of Cottage Grove, and extending approximately 187 miles to the north where it flows into the Columbia River.

The area of analysis is derived by casting a wide net to include all of the resources considered in the EIS, and mirrors the extent used for the analysis of Fish, Aquatic Invertebrates, and Habitat (Section 3.8), which is the most expansive area of analysis for a resource. Given the importance of fish and aquatic invertebrates to tribes consulted for this EIS and for the Columbia River System Operations EIS (USACE, BOR, & BPA 2020), this is extent is reasonable. The northernmost boundary of the area of analysis for the other resources analyzed in this EIS stops at Willamette Falls in Oregon City, Oregon. This is based on the hydrological modeling which indicates that this is the most downstream point that is controlled by the WVS. Willamette Falls is a historically significant place that continues to be used by several of the WRB and Columbia River tribes that were consulted for this EIS.

The effects analysis for tribal resources has two components: 1) the assessment of the agency preparing the EIS, and 2) the views of the tribes who have a vested interest in the WRB and the potential impacts of the operations and maintenance of the WVS. The first component can be found in Chapter 3, Affected Environment and Environmental Consequences, and more specifically in the following sections Hydrological Processes (Section 3.2), River Mechanics and Geomorphology (Section 3.3), Geology (Section 3.4), Water Quality (Section 3.5), Vegetation (Section 3.6), Wetlands (Section 3.7) Fish, Aquatic Invertebrates (Section 3.8), Wildlife, Birds, and Terrestrial Habitat (Section 3.9), Air Quality (Section 3.10), Socioeconomic Resources

(Section 3.11), Power Generation and Transmission (Section 3.12), Water Supply (Section 3.13), Recreation (Section 3.14), Land Use (Section 3.15), Hazardous Materials (Section 3.16), Public Health and Safety (Sections 3.17-3.19), Environmental Justice (Section 3.20), Cultural Resources (Section 3.21), Visual Resources (Section 3.22), and Noise (Section 3.23).

Defining and documenting the second component is ongoing and will require more outreach and engagement with tribes. As will be discussed below, three tribes are participating in the EIS as cooperating agencies and have provided some comments through this process. Other tribes have provided comment on the EIS through the scoping process. The Corps has also requested a point of contact for potentially affected tribes, as well as asking them to provide written perspectives on tribal resources and the potential impacts of the operations and maintenance of the WVS on them. The tribal resources section will be updated as this consultation continues, but it is anticipated that any narratives provided by the tribes on how their interests will be impacted will be included verbatim in Appendix O, Tribal Coordination and Perspectives, and referenced, where applicable, throughout the body of the EIS.

The Corps, Bureau of Reclamation, and Bonneville Power Association recently completed the Columbia River System Operations Final Environmental Impact Analysis and issued a Record of Decision, in July and September of 2020. Those efforts included outreach to 19 federally recognized tribes including several that have interests in WRB and the WVS (USACE, BOR, & BPA 2020a, 2020b). The three agencies asked the tribes to provide information on ITAs, tribal perspectives on the impacts of the Columbia River System operations, and qualitative statements regarding tribal interests. The received responses are applicable to this EIS. Specifically, five tribes with whom the Corps is currently consulting for this EIS provided responses. The waters of the WVB feed into the Columbia River, and the WVS affects resources that also occur in the Columbia River, at least in the case of fish, aquatic invertebrates, and habitat. For other resources, the northern extent of the area of analysis terminates at Willamette Falls, an extremely significant location for several federally recognized tribes of the WRB and Columbia Plateau.

### 3.24.2 Affected Environment

The Corps has initiated consultation with ten federally recognized Indian tribes including:

- Confederated Tribes and Bands of the Yakama Nation (Yakama)
- Confederated Tribes of Coos, Lower Umpqua, and Siuslaw Indians (CTCLUSI)
- Confederated Tribes of Grand Ronde Community of Oregon (Grand Ronde),
- Confederated Tribes of Siletz Indians (Siletz),
- Confederated Tribes of the Umatilla Indian Reservation (Umatilla)
- Confederated Tribes of Warm Springs (Warm Springs)
- Coquille Indian Tribe (Coquille)

- Cow Creek Band of Umpqua Tribe of Indians (Cow Creek)
- Klamath Tribes (Klamath)
- Nez Perce Tribe (Nez Perce)

In response to Corps' letters dated September 30, 2021, representatives from the CTCLUSI, Coquille, and Klamath tribes declined to consult on the EIS and deferred to other tribes. For a list of major correspondence between the Corps and tribes, see Appendix O, Tribal Coordination and Perspectives.

The Corps routinely consults with the Cow Creek, Grand Ronde, Siletz, and Warm Springs tribes for WVS actions that require NEPA review and undertakings that require National Historic Preservation Act compliance. These actions typically occur within the footprint of the 13 multipurpose dam and reservoir project areas. The Grand Ronde tribe is actively participating as a Cooperating Agency in the development of this EIS and the Corps and tribe have an MOU executed on February 28, 2020. The Siletz and Warm Springs have also participated in cooperator meetings, but have not signed an MOU with the Corps.

The Corps, in partnership with the Cow Creek, Grand Ronde, Siletz, and Warm Springs tribes, as well as several federal and state partners and other interested parties, recently executed a program-level programmatic agreement that modifies the Section 106 process to follow a streamlined and standardized approach to manage historic properties that have the potential to be impacted by Corps' undertakings related to the current and future operations of the WVS. The Corps continues to work with these partners to meet the requirements of the programmatic agreement, part of which includes drafting a historic properties management plan.

The Corps has also included four Columbia River tribes who are members of the Columbia River Inter-Tribal Fish Commission (CRITFC) and were consulted for the Columbia River System Operations EIS. These tribes include the Yakama, Umatilla, Warm Springs, and Nez Perce. CRITFC was established, in 1977, to protect fishery resources and reserved treaty rights, and "to ensure that salmon are provided the respect accorded by tribal cultural beliefs and required under law" (CRITFC, 2021a). CRITFC employs legal experts, policy analysts, law enforcement officers, technical specialists, public information specialists, etc. to act as a "champion of tribal rights and resources protection and an authoritative entity working on behalf of native fish and native people in the Columbia River Basin" (CRITFC, 2021a). The commission espouses four major goals: 1) put fish back in the rivers and protect watersheds where fish live, 2) protect tribal treaty fishing rights, 3) share salmon culture, and 4) provide fisher services (CRITFC, 2021b). Given the area of analysis for the Fish, Aquatic Invertebrates, and Habitat terminates where the Willamette River meets the Columbia River, it follows that the member tribes of CRITFC have a valid interest in the development of the WVS EIS. The Grand Ronde tribe was also consulted as part of the Columbia River System Operation EIS.

Table 3.24.1 provides a list of treaties that serve as the legal foundations that connect the seven federally recognized tribes with the Willamette Valley. The tribes have distinct but sometimes overlapping interests. Of note, for this EIS, the Grand Ronde, Siletz, and Cow Creek tend to have interests that are centered within the Willamette Valley (though interests definitely expand beyond the Willamette Valley), while the Yakama, Umatilla, and Nez Perce are centered in the Columbia Plateau. The Warm Springs have interests that extend to both the Columbia River and Willamette Valley.

**Table 3.24-1. Affected Indian Tribes and WRB-Relevant Treaties**

| Federally-Recognized Tribe(s) | Treaties |
|---|---|
| Confederated Tribes of Grand Ronde Community of Oregon | Rogue River Treaty, September 10, 1853<br><br>Treaty with Cow Creek Band of Umpqua, September 19, 1853<br><br>Rogue River Treaty, November 15, 1854<br><br>Treaty with the Chasta, Scoton, and Umpqua, November 18, 1854<br><br>Treaty with the Umpqua and Kalapuya, November 29, 1854<br><br>Willamette Valley Treaty, January 22, 1855<br><br>Treaty with the Molalla, December 21, 1855 |
| Cow Creek Band of Umpqua Tribe of Indians | Cow Creek Band of Umpqua Treaty, September 19, 1853 |
| Confederated Tribes and Bands of the Yakama Nation | Yakama Treaty, June 9, 1855 |
| Nez Perce Tribe | Nez Perce Treaty, June 11, 1855 |
| Confederated Tribes of the Umatilla Indian Reservation | Walla Walla Treaty, June 9, 1855 |
| Confederated Tribes of Warm Springs | Treaty of 1855 (also Treaty with the Tribes of Middle Oregon, June 25, 1855) |
| Confederated Tribes of Siletz Indians | Rogue River Treaty, September 10, 1853 |

One area of noticeable overlap is the historic and continued use of Willamette Falls. All of the tribes with the exception of the Cow Creek tribe, claim the falls as ceded lands or ancestral territory and continue to procure salmon and lamprey there today (CTGR, 2022B; CTUIR, 2021; CTWS, 2021b; Karson Engum, 2020; WFT, n.d.).

According to the Bureau of Indian Affairs, Division of Land Titles and Records, only the Grand Ronde and Warm Springs tribes have ITA holdings in the outer reaches of the WRB (BIA, n.d.). In the western extent of Yamhill sub-basin, the Grand Ronde tribe has a 11,500-acre reservation (CTGR, 2022A). This amount is significantly reduced from the original size of the Grand Ronde Reservation established by Executive Order, on June 30, 1857 (61,000 acres), but increased from 9,811 acres that the tribe got back through the Grand Ronde Restoration Act of November

22, 1983 (CTGR, 2022A). Through the seven treaties listed in Table 3.24-1, Grand Ronde ancestors ceded all of the Willamette Valley and beyond for a significantly reduced reserve of tribal lands. On the opposite end of the WRB, a small portion of the western boundary the Warm Springs reservation overlaps with the eastern tips of the Clackamas and North Santiam sub-basins. The reservation currently totals 644,000 acres, which is a small fraction of the 10 million acres ceded in 1855. The original treaty incorrectly provided for 464,000 acres, but this was rectified to include another 180,000 acres, in 1972, after the resolution of a longstanding boundary dispute. In each of these instances the ITA holdings are located outside of the WVS (Clackamas and Yamhill) or in the upper reaches above the WVS (North Santiam).

The concept of tribal resources, when viewed through a federal legal framework, is different than tribal understanding of tribal resources. As detailed in the Columbia River System Operations EIS, tribes who chose to provide tribal input and perspective found that federal agencies failed to understand the holistic connections between natural resources, cultural resources, and the everyday practice of tribal lifeways. This was reflected, they contended, in the agencies' adoption of a definition of "cultural resources" that focused on properties, as suggested by the National Historic Preservation Act, versus a more holistic definition of cultural resources that sees a much broader range of phenomena as cultural resources. For example, several tribes claimed that fish, which are a key part of many Native American ceremonies in the Pacific Northwest, are just as much of a cultural resource as an archaeological site or a historic building. This reliance on a property-based definition of cultural resources is just one example of how the perspective adopted by the agencies is fundamentally at odds with most indigenous peoples' learning systems (USACE, BOR, & BPA, 2020:3-1456).

For the WVS EIS, the Grand Ronde, Yakama, and CRITFC (representing the member tribes Yakama, Umatilla, Warm Springs, and Nez Perce) provided comments in the same vein as those provided for the Columbia River Operations System EIS, but CRITFC also provided comments specific to operating and maintaining the WVS that show a deep interest in fish and wildlife habitat, water quality, water allocation, and cultural resources.

In a letter dated June 2, 2020, Grand Ronde provided comments to the Corps acting in their capacity as a Cooperating Agency. The comments were specific to the alternatives and measure for the WVS EIS. The Grand Ronde requested to be involved in the development of the measures and shared concerns about the alternative development. They noted that overall we tribal staff feel that we are being given opportunities to weigh in verbally on the WVS-EIS alternatives and measures. However, much of what is presented to the Cooperating Agencies is often too vague or general to provide full and informed comments on.

Grand Ronde preferred alternatives that did not create a dichotomy of structure-focused versus operations-focused but requested that needs and feasibility be considered based on the location. The tribe further indicated that monitoring, evaluating, and adaptive management would be requirements and there should be room for interim measures rather than a long-term or no-term measure.

Grand Ronde recommended that the Corps analyze whether measures in the Coast Fork and Long Tom watersheds would benefit salmon and lamprey and noted that there are few measures that deal directly with those watersheds. One consideration should be removal or modification of the structures in the lower Long Tom (below Fern Ridge Reservoir). Grande Ronde noted that historically the Coast Fork had salmonid runs and the Long Tom had Pacific lamprey runs. The Tribe recommended fish passage measures at Dorena and Cottage Grove, and supported annual drawdowns, similar to those occurring at Fall Creek, to occur where feasible. Overall, the tribe requested that Pacific lamprey passage be considered at all of the projects. Grand Ronde also asked that structures at Detroit and Cougar be considered with the EIS rather than as standalone NEPA actions. Finally, the tribe also requested to be involved in any future water quality discussions.

In a letter dated June 28, 2019, CRITFC provide scoping comments for the operations and maintenance of the WVS on behalf of the four Columbia Plateau tribes asserting that they possess rights they reserved by treaties with the federal government to take a fair share of the fish destined to pass their usual and accustomed fishing places in the interior Columbia River basin and its tributaries. Inherent in the right to take fish is the conservation and protection of the fishery resource. These reserved rights are not geographically limited to lands ceded to the United States…federal agencies must use their authorities in a manner that will protect and enhance – not degrade – the fish species that underlie treaty fishing right. The *U.S. v. Oregon* and *U.S. v. Washington* cases also affirmed that Northwest tribes, by virtue of their treaties with the U.S. government, have co-management status on fisheries resources. In reserving the right to fish at all usual and accustomed places, tribes retained their authority to regulate the tribal fishery. State and federal government co-managers are therefore required to have meaningful consultation on actions that affect the treaty-protected fisheries resources. These actions include non-tribal fisheries, hatchery production, protection of natural spawning environment, and protection of downstream and upstream migration through the river.

CRITFC offered several recommendations to avoid and minimize impacts on the tribal fishery resources or providing concerns specific to the operations and maintenance of the WVS. These include

- CRITFC stated that “the Willamette Basin is one of the most prominent habitats for lamprey, with Willamette Falls as a significant historical fishing site…the largest proportion of lamprey in the Willamette Basin inhabit the Santiam River, a tributary that will be affected by this project. Diminished in the Columbia River, the Willamette is one of the last few basins for lamprey to thrive.” CRITFC recommends that the Corp improve issues with known adult lamprey passage, develop alternative forms of passage, and implement a research, monitoring, and evaluation plan for larval and juvenile lamprey. CRITFC also noted that upstream tributaries where larval lamprey have been observed need to be maintained for habitat and water quality.
- CRITFC is concerned that water quality impacts may result from changes in the WVS operations and how this will hurt juvenile lamprey, steelhead, and chinook salmon.

- Climate change must be considered to develop an accurate WVS EIS. CRITFC noted that changes may result in reduced water in the reservoirs, affect local flows that will make it difficult to meet BiOp targets, water temperatures may impact lamprey, steelhead, and chinook salmon.
- CRITFC "greatest concern" is the lack of live flows to meet fish and wildlife year-round BiOp requirements and Corps' ability to maintain consistent flows.
- CRITFC notes that tribal cultural resources are more than archaeological sites and that the National Historic Preservation Act and Archaeological Resources Protection Act account for historic properties of religious and cultural significance to tribes or traditional cultural properties. CRITFC identifies these as places where tribal members gather First Foods, hunt, and fish, other cultural sites where tribal members visit or use for various purposes, and salmon and lamprey and their ecosystem. CRITFC noted that the cultural resources analysis will need to involve the Yakama, Umatilla, Warm Springs, and Nez Perce.
- CRITFC recommends using spill/flow programs, seasonal/permanent drawdown, summer spill/flow operations, and altered operations for low and mid-range water years to support salmon habitat and survival. These recommendations are defined as hydro system operational changes.
- Recommended hydro system structural modifications to improve fish passage and survival through the WVS include the installation of temperature structures, surface passage structures/collectors, improvement of existing ladders for adult passage or trap and haul facilities and evaluating smolt transport options.
- CRITFC notes that a "suite of tributary and estuary mitigation actions" (off site mitigation) will support complying with the Northwest Power Act.
- CRITFC recommends that the EIS consider the effects of the WVS on reservoir ecology and how these changes would affect fish and wildlife resources.
- CRITFC asks that the EIS include metrics and data related to fish project survival, reach survival, and delayed mortality and to consider at a minimum reach, project, and SAR survival metrics and some of the modeling should not rely on the COMPASS model.

Independently of the CRITFC scoping letter, the Yakama tribe provided scoping comments in a letter, dated April 17, 2019, to state that the tribe had concerns that development for the WVS EIS could interfere with treaty reserved rights in the Yakama tribe's usual and accustomed areas. The letter further requested "meaningful technical level engagement with USACE during the NEPA process and the development of the EIS."

Table 3.24-2 provides a summary list of concerns or issues provided by the tribes through comment on the WVS EIS. It also provides WRB-specific topics and issues that the tribes describe for their own natural and cultural resources programs on tribal websites.

**Table 3.24-2. Issues that Tribes Have Identified for the WVS EIS and WRB**

| Federally-Recognized Tribe or Tribal Representative | Issues and Concerns |
|---|---|
| Confederated Tribes of Grand Ronde Community of Oregon | The Grand Ronde provided comments in 6/2/2020 noting the following:<br>The tribe wishes to be involved in measure and alternative development<br>Balance project needs to include operations and structure based measures, as needed<br>Monitoring, evaluation, and adaptive management programs<br>Consider interim measures as well as long-term and no-term in analysis<br>Analyze measures for the Coast Fork and Long Tom watersheds to salmon and lamprey<br>Long Tom structure removal/modification<br>Fish passage measures at Dorena and Cottage Grove<br>Use annual drawdowns at all or most projects, where feasible<br>Pacific lamprey passage be considered at all projects<br>Consider structures at Cougar and Detroit as part of the EIS<br>Include the tribe in water quality discussions<br>Baseline analysis should be pre-system for all resources that existed before the WVS<br><br>Cultural resources are also important to the Grand Ronde:<br>The Grand Ronde have been in consultation with the Corps in the development of the Willamette Valley Project program-level National Historic Preservation Action Section 106 programmatic agreement to manage cultural resources. |

| Federally-Recognized Tribe or Tribal Representative | Issues and Concerns |
|---|---|
| CRITFC, while not a tribe, submitted comments on behalf of representing Yakama, Umatilla, Warm Springs, and Nez Perce tribes | CRITFC provided comments on 6/28/2019 and noted interest and concern with:<br>Tribal fishery of Columbia River and tributaries<br>Non-tribal fishery of Columbia River and tributaries<br>Hatchery production<br>Protection of natural spawning environment<br>Protection of downstream and upstream migration through the river<br>Pacific Lamprey<br>Fish and Wildlife<br>Cumulative Impact Requirement for the Willamette Basin Water Reallocation Project and WVS EIS<br>Water Quality<br>Climate Change<br>Adequate Flows for Fish and Wildlife<br>Tribal Cultural Resources<br>Hydro System Operations<br>Hydro System Structural Modifications<br>Off-site Mitigation<br>Reservoir Ecology<br>Data and Metrics used in EIS Analysis |
| Confederated Tribes of Siletz Indians | The Siletz have been invited to consult with the Corps in the development of the Willamette Valley Project program-level National Historic Preservation Action Section 106 programmatic agreement to manage cultural resources. |
| Cow Creek Band of Umpqua Tribe of Indians | The Cow Creek have been invited to consult with the Corps in the development of the Willamette Valley Project program-level National Historic Preservation Action Section 106 programmatic agreement to manage cultural resources. |

| **Federally-Recognized Tribe or Tribal Representative** | **Issues and Concerns** |
|---|---|
| Confederated Tribes and Bands of the Yakama Nation | A letter from Yakama Tribe stated there are concerns that development for the WVS EIS could interfere with treaty reserved rights in the Yakama tribe's usual and accustomed areas<br>Yakama tribe also requested meaningful technical level engagement with USACE during the NEPA process and the development of the EIS<br>CRITFC also provided comments on behalf of the Columbia River tribes (6/28/2019) |
| Nez Perce Tribe | CRITFC provided comments on behalf of the Columbia River tribes (6/28/2019) |
| Confederated Tribes of the Umatilla Indian Reservation | CRITFC provided comments on behalf of the Columbia River tribes (6/28/2019) |
| Confederated Tribes of Warm Springs | CRITFC provided comments on behalf of the Columbia River tribes (6/28/2019)<br>The Warm Springs tribe has been in consultation with the Corps in the development of the Willamette Valley Project program-level National Historic Preservation Action Section 106 programmatic agreement to manage cultural resources.<br><br>The Warm Springs tribe (CTWS, 2021a) has identified following topics and issues in their usual and accustomed areas:<br>*Fisheries Program*<br>Upland, riparian, and aquatic habitats for fish<br>Natural production of anadromous and resident fish populations<br>Enhancing and supplementing Chinook salmon and steelhead trout populations<br>Providing support and expertise to agencies that manage fisheries programs |

| Federally-Recognized Tribe or Tribal Representative | Issues and Concerns |
|---|---|
| | *Conservation Lands Program and the Willamette Wildlife Mitigation Program (ODFW, n.d.).*<br>Little Sweden is 183.17acres of privately-owned tribal lands on the North Santiam River, directly downstream from Big Cliff Reservoir (1 mile west of the dam). The tribe manages it for members to hunt, fish, gather forest products, and recreate. It is managed to fish and wildlife habitat. This is not an ITA.<br>Austin Hot Springs is a 151.7-acre privately-owned tribal property in the Clackamas River drainage. It is not located on the WVS. This is not an ITA.<br>Red Hills is a privately-owned tribal property of 278.5 acres of fish and wildlife habitat. Tribal members can hunt, fish, gather forest products, and recreate. This is not an ITA. |

Tallying treaty rights and reserved rights, ancestral territories and usual and accustomed areas, and the resources held within to attempt to quantify tribal resources would be difficult (if not impossible), but it is accurate to state that the entirety of the WRB landscape and resources are important to the tribes being consulted as part of this EIS. The WBR as a whole can be considered a tribal resource when taking the views and beliefs of the tribes into consideration.

### 3.24.3 Environmental Consequences

This section briefly summarizes results from the environmental consequences sections for Water Quality (Section 3.5), Fish, Aquatic Invertebrates, and Habitat (Section 3.8), Wildlife, Birds, and Terrestrial Habitat (Section 3.9), and Cultural Resources (Section 3.21). These sections were selected to reflect the primary concerns outlined by the tribes as discussed in the affected environment (3.24.2). Refer to the resource sections in Chapter 3 for full consideration of impacts including climate change.

#### *3.24.3.1 No Action Alternative*

The NAA would represent the current management direction of the WVS. Specific measures included in the NAA are described in Section 2.4.1.

The NAA is predicted to have MAJOR adverse impacts on UWR Chinook salmon and winter steelhead. Life cycle models predict high extinction risk in all sub-basins for both species. Adverse impacts on bull trout are predicted to be MINOR. Bull trout above Cougar have been stable for several years and have been increasing above Hills Creek. Habitat scores for bull trout are reasonable, with one hundred percent of the spawning habitat available, and 70% of the rearing/foraging habitat available. The WVS passage conditions at dams limit bull trout access to below dam rearing/foraging habitat. Climate change is predicted to further degrade habitat for bull trout particularly below dams and will reduce the ability to meet operational fish passage, minimum flows, and water temperature objectives below dams for UWR spring Chinook salmon and UWR steelhead.

No fish passage improvements would be proposed as part of the NAA. This would continue to limit foraging opportunities for piscivorous wildlife species such as river otters, muskrats, and eagles within stream reaches upstream of the WVS dams where passage has not been provided for native migratory fish, including salmonids and Pacific lamprey (Lampetra tridentata). This would result in a long-term, minor, adverse effect to piscivorous wildlife species and overall habitat function in the North Santiam, South Santiam, McKenzie, and Middle Fork Willamette sub-basins.

The No Action Alternative (NAA) maintains existing operations and maintenance activities including a rule curve that begins drafting in fall to low water levels through the winter, with fill beginning in late winter through the spring, with the highest reservoir level to be reached by the start of summer. This level is maintained through early fall when drafting begins again. This annual draft and fill cycle is a major erosion event for archaeological sites that exist in all of the reservoirs except Big Cliff and Dexter (reregulating dams that maintain high reservoir elevations). These resources have been experiencing this cyclical inundation and exposure for five to eight decades depending on the reservoir. Of the 461 archaeological sites documented at the WVS, 369 (80%) are located in or adjacent to reservoir environments. No new construction or modification to the 13 historic districts is proposed under the NAA. The overall effect from the NAA to Cultural Resources would be irreversible, adverse, and major within the WVS.

This alternative does not consider lamprey passage or habitat improvement, and has minor, long-term adverse effects to wildlife and habitat. The NAA would have major adverse impacts to cultural resources and fish. The NAA does not benefit tribal resources.

#### *3.24.3.2 Alternative 1 – Project Storage Alternative*

Alternative 1 proposes to improve fish passage through storage-focused measures. Specific measures included in the Alternative 1 are described in Section 2.4.3.

Compared to the NAA, Alternative 1 would result in minor to major beneficial water temperature effects in the Middle Fork Willamette, South Santiam, and North Santiam basins due to the proposed temperature control structures at Lookout Point, Green Peter, Detroit Dams. Minor to Major beneficial TDG effects are expected in the North Santiam and South Fork

McKenzie basins based on the reduced number of spill days and proposed TDG abatement structures in Alternative 1.

Large floating fish passage structures would be implemented compatible with water storage needs in the North, South Santiam, and the Middle Fork. A fall deep drawdown at Fall Creek will continue. Minimum below-dam flow values support capturing water in reservoirs during spring. Alternative 1 implementation is predicted to have MAJOR impacts on UWR spring Chinook salmon and MINOR adverse impacts on UWR steelhead in the North and South Santiam as compared to the NAA. Lifecycle models predict low extinction risk for Chinook in the North and South Santiam, and high risk of extinction in the McKenzie and Middle Fork. The downstream passage structure at Lookout Point is dependent on the dam operations and predicted to perform poorly likely due to the storage theme of Alternative 1. Both life cycle models predict low extinction risk in Santiam UWR steelhead populations, although one model predicted low recruits per spawning for the South Santiam. Scores and risks for bull trout would be ranked similar to the NAA, with MINOR effects predicted. Habitat scoring for bull trout is only marginally better than in the NAA with rearing/forage habitat increases for North Santiam bull trout below Detroit. Structural improvements for fish passage and water temperature provide resilience to climate change by increasing operational flexibility in the North Santiam, South Santiam, McKenzie and Middle Fork sub-basins.

Alternative 1 will provide lamprey passage at Dexter dam (Measure 52); fish passage at the Long Tom River drop structures downstream of Fern Ridge (Measure 639); and downstream fish passage at Detroit (operation not a structure), Foster, Green Peter, Lookout Point, and Detroit dams (Measure 392). This would improve lamprey populations in the Middle Willamette subbasin and salmonid populations in the North Santiam, South Santiam, Long Tom, and Middle Willamette subbasins as compared to the NAA. Improving fish populations will provide long-term minor benefits in terms of increased foraging opportunities for piscivorous wildlife species. In addition, improving anadromous salmonid populations in the North Santiam, South Santiam, Long Tom, and Middle Willamette subbasins will have minor long-term benefits compared to the NAA for habitat functions related to nutrient cycling as a result of fish decaying in these sub-basins after spawning.

Like the NAA, Alterative 1 follows a rule curve that results in one major cycle of draft and fill per water year. Alternative 1 would reduce minimum flows to Congressionally authorized minimum flow requirements (#723) at all of the reservoirs except Dexter, Foster, and Big Cliff. This measure would likely have minor short-term benefits to archaeological resources on a system wide level since it would allow for more water storage and a higher likelihood of following the rule curve in a consistent pattern as compared to the NAA. This is supported by the systemwide 3% decrease in acre-days of site exposure between the NAA (164,109 acre-days) and Alternative 1 (158,734 acre-days). Alternative 1 is the only alternative that includes Measure 723, and it is the only Alternative that shows minor beneficial changes at the system-level to cultural resources. As with the NAA, the WVS cycle of draft and fill will continue to adversely affect 369 (80%) of the archaeological sites present. Alternative 1 has the potential to cause moderate to major effects to six of the 13 historic districts with proposed structural measures that support water quality, downstream and upstream fish passage. The overall effect from Alternative 1 to Cultural Resources would be irreversible, adverse, and major within the WVS when compared to the NAA.

Alternative 1 includes lamprey passage measures and there are some reduced adverse impacts to UWR spring Chinook salmon and UWR steelhead, though increased adverse impacts to Bull Trout as compared to the NAA. Water quality with regard to temperature and TDG measures in Alternative 1, have moderate to major beneficial effects for ESA-listed species. Alternative 1 has major adverse impacts to cultural resources, though slightly improved when compared with the NAA through reduced days of site exposure. This alternative benefits some tribal resources and reduces adverse effects to other tribal resources when compared to the NAA.

#### *3.24.3.3 Alternative 2A – hybrid alternative*

Alternative 2A includes structural and operational measures to provide flexible water management. It also includes a structural downstream passage measure at Cougar Dam. Specific measures included in the Alternative 2A are described in Section 2.4.4.
